Given the strong evidence that chronic illness (of self or parent) places children and adolescents at risk of developmental problems, recent research appropriately focuses on the processes and mechanisms that account for these relationships. This is a highly complex issue because there are multiple pathways by which illness affects development. For children who are chronically ill, characteristics of the illness, its *sequellae*, and the nature and efficacy of medical management all play a role in helping to protect against or, alternatively, increasing the risk of developmental problems. As noted above, some illnesses have direct effects on developmental outcomes (e.g., when diseases cause cognitive problems or constrict the child's ability to form bonds with peers). Illness severity has an impact on development beyond the symptoms and impairments generated by the disease. For example, the greater the level of absence from school as a result of illness, the more severe the developmental problems (McCubbin 1988). Medical treatments also play a role in developmental outcomes. Some medications have side effects that place the child at risk of developmental obstacles (e.g., inability to concentrate); other treatments (e.g., chemotherapy) can impair functioning in multiple domains. Finally, the stigma associated with chronic illness (Hermann et al. 1989) can lead to rejection from peers and discomfort in public places (e.g., diabetic children require special diets and cannot participate in many 'normal' childhood activities).

Beyond the constraints of the illness and its treatment, the family plays a strong role in increasing or lessening the ill child's risk of developmental problems. Quality of parenting and the parents' methods of coping with a chronically ill child are especially important (McCubbin 1988). The entire dynamic of family life is changed by the presence of a chronically ill child. Parenting requires more time, special skills, and maintaining a delicate balance between 'normalizing' the child's life as much as possible, while also providing high levels of supervision and medical management. Demands change over time as the illness waxes or wanes and as the child ages. Providing care to a chronically ill child over long periods of time is draining and affects all areas of parent's lives (e.g., the marital relationship, relationships with other children, labor force participation, financial security) (Avison et al. 1991).

Family dynamics also appear to explain the conditions under which children experience developmental problems when a parent is chronically ill. Two processes seem to be especially important in this regard. First, if parental illness is accompanied by high levels of marital discord, the likelihood of developmental problems in the children is greatly increased (e.g., Mann and MacKenzie 1996). Second, the risk of developmental problems increases exponentially if the parent's illness is associated with being 'emotionally unavailable' to the child (e.g., Wootton et al. 1997). Indeed, developmental delays can be observed by the age of 2 when the parent is emotionally estranged or distant from the child (Radke-Yarrow et al. 1985).

3. *The Effects of Development on Health*

There also is impressive evidence that developmental outcomes during childhood and adolescence have strong effects on health in middle and late life. There are three primary pathways by which early developmental outcomes exert persisting effects on health: socioeconomic achievements, social integration, and social support.

Of all the social factors related to health, socioeconomic status (SES) is the most consistent and powerful (House et al. 1994, Link and Phelan 1995). SES typically is operationalized as a combination of income and education, and sometimes occupation as well. All three SES components are related to health and longevity, although they seem to operate in somewhat different ways. The relationship between income and health is multifaceted, for example, income is related to access to and quality of healthcare, and to goods and services that promote health (e.g., safe housing, adequate nutrition). Occupation is, of course, a primary determinant of income, but also affects health via prestige and greater autonomy and control in occupational settings (e.g., Link et al. 1993). Education typically exhibits the strongest relationships with health outcomes, in part via its effects on occupation and income, and more directly via better health habits and increased knowledge and use of

information about health and healthcare (Ross and Wu 1995). SES during adulthood is strongly related to early development. As noted earlier, school performance and educational attainment are major developmental outcomes during early life.

Social integration refers to the attachments individuals sustain with the larger society and are typically measured in terms of occupational, organizational, and community roles. A broad body of research, beginning with Durkheim's classic work on suicide, has documented strong links between social integration and health and longevity (House et al. 1988). Again, early developmental outcomes are linked directly to social integration during adulthood. Sustaining social integration requires social competence, reasonable intelligence, and the self-discipline required for adequate role performance—all of which are developmental outcomes that are established, in large part, during early life.

There is impressive evidence that health is related robustly to social relationships. The effects of social ties on health operate in a variety of ways. First, high-quality relationships with family and friends are directly related to better health and longevity (e.g., House et al. 1988). Second, close relationships are the foundation from which social support emerges during times of stress. Social support takes a variety of forms ranging from consolation and reassurance to the provision of information and tangible assistance. High levels of social support help to protect against the onset or exacerbation of illness and facilitate recovery from illness (de Leon et al. 1999, George et al. 1989). The ability to form appropriate attachments and the social skills needed to sustain social bonds are established early in life.

Thus, early development sets the stage for subsequent health in a variety of ways. Moreover, the benefits of successful development tend to increase over time, whereas the disadvantages that result from unsuccessful development also spiral over time. This pattern, known as cumulative advantage/disadvantage (Ross and Wu 1996), results in diverging levels of health across adulthood, until very late life when biological factors may act as 'levelers,' narrowing the differences between the advantaged and disadvantaged.

Health in middle and late life is affected by both proximal and distal factors. Unquestionably, proximal and contemporaneous factors are typically more powerful predictors of morbidity and mortality than are distal patterns. Nonetheless, life course research has added to the knowledge base in two ways. First, sometimes, early events and experiences have persisting demonstrable effects on health and longevity, even when more proximal factors are taken into account. Second, the indirect effects of early events and experiences often help to elucidate the selection processes that result in more proximal antecedents of morbidity and mortality.

4. *Methodological Challenges*

A variety of methodological issues complicate efforts to better understand the links between development and health; two especially important ones are considered here. First, adequate depiction of the complex and time-dependent relationships between development and health requires longitudinal data collected over a significant portion of the life span. Such studies are especially important for identifying the effects of development on health because it is not until middle age that a significant proportion of the population exhibits health problems. Few studies to date assess developmental and health outcomes over the appropriate age range (i.e., from childhood/adolescence until at least late middle age). Such studies are very expensive in both time and money, making a substantial increase in the future unlikely.

Selective mortality also poses a serious threat to our understanding of the links between development and health, both of which are related strongly to mortality. Extant research is based on survivors, which has two important implications. First, it is likely that research findings *underestimate* the effects of developmental outcomes on subsequent health because the most unhealthy are likely to have died. Second, selective mortality may account for some of the observed patterns among survivors. For example, the narrowing of SES differences in health during late life may be due to earlier mortality among low SES persons rather than a 'biological leveling' at the end of life (Bartley and Plewis 1997). There is no way to overcome this problem. However, given longitudinal data covering large segments of the life course, the effects of selective survival can be estimated. The possible effects of selective survival should be considered in the interpretation of all empirical findings.

5. *Future Directions*

Future research on the links between health and human development is likely to focus on two major topics. First, efforts will continue to trace the specific pathways and mechanisms by which development and health affect each other. Although extant research has made important contributions to this issue, substantial components of these processes remain unknown and replication of findings to date is especially important because of reliance on cross-sectional and short-term longitudinal research designs. Second, future research will address the extent to which and ways in which developmental and health problems in early life can be compensated for or reversed. Some contributions to this issue will result from naturalistic research that identifies compensatory factors that permit early disadvantage, in either development or health, to be overcome or minimized. Other contributions will result from research in which interventions designed to

prevent developmental or health problems or to compensate for them are evaluated in terms of feasibility, cost, and effectiveness. Given the complex web of factors associated with early developmental and health problems, the challenges of arresting or reversing trajectories of disadvantage will be great, but the benefits will be great as well.

Human Development, Bioecological Theory of

The bioecological model, together with its corresponding research designs, is an evolving theoretical system for the scientific study of human development

over time. Within the bioecological theory, development is defined as 'the phenomenon of continuity and change in the biopsychological characteristics of human beings, both as individuals and as groups. The phenomenon extends over the life course, across successive generations, and through historical time, both past and future.' The term 'future' raises a question: How is it possible to investigate scientifically phenomena that have not yet taken place? The question, of course, is hardly new; indeed it pervades every field of scientific endeavor. However, we are the only species that has, over historical time, developed the capacity to engage successfully in scientific inquiry, and thereby, in many respects, has been able to change the nature of the world in which we live. As a result, within certain limits, we humans have altered the nature and course of our own development as a species (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998).

To place the bioecological theory of human development into a larger context, it is important to recognize that many of the general perspectives advanced and elaborated in this theory, are also parts of other related lines of theoretical and empirical inquiry into human development. Examples are lifespan psychology (Baltes et al. 1999), cultural psychology (Cole 1995), Magnusson's developmental theory of contextual-interactive holism (Magnusson and Stattin 1998), and, especially, the work of Robert Cairns, who through communications and publications extending over three decades, has played a major role in the evolution of the four defining properties of bioecological model: process-person-context-time. Cairns is of course best known as the founder and principal protagonist of developmental science. Examples of his books and articles that have been most relevant to the evolution of the ecological model are cited in the bibliography (Bergman et al. 2000, Cairns 1970, Cairns and Cairns 1994). The specific profile of the theory of Bronfenbrenner and his colleagues is its comprehensive interdisciplinary and integrative focus on the age periods of childhood and adolescence and its explicit interest in applications to policies and programs pertinent to enhancing youth and family development.

1. *Defining Properties of the Bioecological Model*

The term 'evolving' highlights the fact that the model, along with its corresponding research designs, has itself undergone a process of development over its own 'life course.' Another defining property of the bioecological model specifies that it deals with two closely-related but nevertheless fundamentally different developmental processes, each taking place over time. The first defines the phenomenon under investigation: namely, that of continuity and change in the biopsychological characteristics of human beings. The second focuses on the development of the scientific tools—the theoretical models and corresponding research designs required for assessing the continuity and change.

These two tasks cannot be carried out independently, for they are the joint product of emerging and converging ideas, based on both theoretical and empirical grounds—a process called 'developmental science in the discovery mode' (Bronfenbrenner and Evans 2000, pp. 999–1000). In the more familiar 'verification mode' the aim is to replicate previous findings in other settings to make sure that the findings still apply. By contrast, in the discovery mode, the aim is to fulfill two broader but interrelated objectives:

(a) Devising new alternative hypotheses and corresponding research designs that not only call existing results into question, but also stand a chance of yielding new, more differentiated, more precise, replicable research findings and, thereby, producing more valid scientific knowledge.

(b) Providing scientific bases for the design of effective social policies and programs that can counteract newly emerging developmentally disruptive influences. This has been an explicit objective of the bioecological model from its earliest beginnings.

A major challenge to today's bioecological model is to discover how such new working hypotheses and corresponding research designs can be developed for the future. One answer lies in the possibility that, despite historical change, some elements of the model, and their inter-relationships, may remain constant across both time and space. From this perspective, today's model has several distinctive defining properties that become the foundation for the rest. Some are of relatively recent origin; others date back to the model's earliest formal beginnings (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998, for reviews). Each is expressed here in the form of a Proposition.

1.1 *Proposition I*

An early critical element in the definition of the ecological model is experience. The term is used to indicate that the scientifically relevant features of any environment for human development include not only its objective properties but also the way in which these properties are subjectively experienced by the persons living in that environment. This equal emphasis on an 'experiential' as well as an 'objective' view springs neither from any antipathy to behaviorist concepts, nor from a predilection for existential philosophical foundations. It is dictated simply by a hard fact. Very few of the external influences significantly affecting human behavior and development can be described solely in terms of objective physical conditions and

events (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998).

A critical term in the foregoing formulation is the word 'solely.' In the bioecological model, both objective and subjective elements are posited as driving the course of human development; neither alone is presumed sufficient. Moreover, these elements do not always operate in the same direction. It is therefore important to understand the nature of each of these two dynamic forces, beginning on the phenomenological or experiential side. Both of the underlined terms are relevant because, while related to each other, they are typically applied to somewhat different spheres. The former is more often used in relation to cognitive development and pertains mainly to changes in how the environment is perceived at successive stages of the life course, beginning in early infancy and proceeding through childhood, adolescence, adulthood, and, ultimately, old age.

By contrast, 'experience' pertains more to the realm of feelings; for example, anticipations, forebodings, hopes, doubts, or personal beliefs. These too, emerge in early childhood, continue through life, and are characterized by both stability and change. They can relate to self or to others, and especially to family, friends, and other close associates. They can also apply to the activities in which one engages; for example, those that one most or least likes to do. But the most distinctive feature of such experiential qualities is that they are 'emotionally- and motivationally-loaded', encompassing both love and hate, joy and sorrow, curiosity and boredom, desire and revulsion, often with both polarities existing at the same time but usually in differing degrees. A significant body of research evidence indicates that such positive and negative subjective forces, evolving in the past, can also contribute in powerful ways to shaping the course of development in the future (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998).

But these are not the only powerful forces at work. There are others that are more objective in nature. This does not mean, however, that they are necessarily either more or less influential, mainly because the two sets of forces are interdependent and affect each other. Like their subjective counterparts, these more objective factors also rely for their assessment on corresponding theoretical models and associated research designs that have evolved over time. These more objective relationships are documented below in the form of two propositions (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998). The first specifies the theoretical model, and provides concrete examples; the second foreshadows the corresponding research designs for their assessment.

1.2 Proposition II

Over the life course, human development takes place through processes of progressively more complex reciprocal interaction between an active, evolving biopsychological human organism and the persons, objects, and symbols in its immediate external environment. To be effective, the interaction must occur on a fairly regular basis over extended periods of time. Such enduring forms of interaction in the immediate environment are referred to as proximal processes. Examples of such processes include feeding or comforting a baby; playing with a young child; child-child activities; group or solitary play; reading, learning new skills; athletic activities; problem solving; caring for others; making plans; performing complex tasks; and acquiring new knowledge and know-how.

For the younger generation, participation in such interactive processes over time generates the ability, motivation, knowledge, and skill to engage in such activities both with others and on one's own. For example, through progressively more complex interaction with their parents, children increasingly become agents of their own development, to be sure only in part.

In sum, proximal processes are posited as the primary engines of development. The next defining property speaks to the corresponding research designs.

1.3 Proposition III

The form, power, content, and direction of the proximal processes producing development vary systematically as a joint function of the characteristics of the developing person (including genetic inheritance); the environment—both immediate and more remote—in which the processes are taking place; the nature of the developmental outcomes under consideration; and the continuities and changes occurring in the environment over time, through the life course, and during the historical period in which the person has lived.

Propositions II and III are theoretically interdependent and subject to empirical test. An operational research design that permits their simultaneous investigation is referred to as a Process-Person-Context-Time model (PPCT).

In the corresponding research designs for the bioecological model, the element of time has special importance. To show that development has actually occurred, the research design must demonstrate, or at least make plausible, that the elements in the design, and their dynamic relationships to each other, have influenced the 'biopsychological characteristics of the developing person over an extended period of time.'

For example, a rich data archive generously made available by Small and Luster (1990) from their statewide studies of youth at risk in Wisconsin has made possible some reanalyses of working hypotheses derived from the newly-emerging formulations.

Figure 1 depicts the results from a reanalysis of the effects of parental monitoring on the academic

Figure 1
Parental monitoring and high school grades by gender: mothers with more than a high school education

achievement of high school students living in one of the three most common family structures found in the total sample of over 2500 cases. The students were between 14 and 16 years of age. The participants were also differentiated by gender, and stratified by two levels of mother's education, with completion of high school as the dividing line. The figure shows the results only for the high school graduates.

Parental monitoring was defined as 'the effort by parents to keep informed about and set limits on their children's activities outside the home.' Levels of parental monitoring, ranging from 0 to 12, are shown on the horizontal axis, and grade point average (GPA) appears on the vertical scale. The markers to the right of each curve record the average GPA for each of the six groups.

The data were fitted to a curve with a declining slope, rather than simply with a straight line, based on the following considerations derived from the bioecological model: Higher levels of academic performance require mastery of progressively more complex tasks, and hence are more difficult to achieve. As can be seen in Fig. 1, the relation between parental monitoring and school grades does indeed show a declining curvilinear trend. This effect, however, is far stronger for girls than for boys, particularly in the most advantaged ecological niche—families with two biological parents in which the mother had some education beyond high school.

Both of these results are consistent with two working hypotheses derived from the bioecological model. The first stipulates that proximal processes (in this instance, parental monitoring) are likely to have greater impact in two-parent families than in those in which the mother is a single-parent or the father is a stepparent. The second hypothesis posits a stronger and longer-lasting influence of the family on the development of females than of males.

In addition, a distinctive feature of the pattern for girls is a marked flattening of the curve at higher levels of monitoring, and, in the case of daughters of single-parent mothers, even becomes a turnaround. This finding suggests that under such circumstances, the demands on the girls may become so great that the existing proximal processes are not equal to the task, and as a result, bring fewer educational returns. Finally, an analysis (not shown) of data on students whose mothers had no more than a high-school education revealed a similar pattern, but the constructive influence of monitoring was appreciably weaker, and its greater benefit to girls was reduced. Nevertheless, daughters of mothers with less than a high-school education both in single parent and in stepfather families still had higher GPA scores than did sons. Moreover, within each level of mothers' education statistically significant differences by family structure were found in school achievement, with students growing up in two-parent families receiving the highest grades and those from single-parent families the lowest.

To turn to a related issue: although proximal processes function as the engines of development, the energy that drives them comes from deeper sources that take us back to the experiential world of Proposition I (Bronfenbrenner and Evans 2000, Bronfenbrenner et al. 1996, Bronfenbrenner and Morris 1998). Both the subjective and the objective forces exert an especially strong influence on development during the formative years (from early infancy to young adulthood). A substantial body of research over the past century indicates that, two or three decades ago, these forces lay mainly within the family, with parents acting as the principal caregivers and sources of emotional support for their children, and with other adult family members living in the home being next in line. To a lesser extent, other relatives, family friends, and neighbors also functioned in this role.

However, there has been a marked change in this pattern over the past three decades. Parents, and other adult family members as well, have been spending increasing amounts of time commuting to and working at full-time jobs (in which overtime is increasingly often required or expected).

The nature of this trend and its relevance for human development are conveyed in the Propositions that follow. (For brevity's sake, the term 'child' is used below to encompass the entire period from infancy through young adulthood.)

1.4 Proposition IV

In order to develop—intellectually, emotionally, socially, and morally—a child requires, for all of these, the same thing: participation in progressively more complex activities, on a regular basis over an extended period of time in the child's life, with one or more persons with whom the child develops a strong, mutual emotional attachment, and who are committed to the child's well-being and development, preferably for life (Bronfenbrenner and Evans 2000, Bronfenbrenner and Morris 1998). The prerequisites stipulated in Proposition IV then lead to the developmental consequences described in the next Proposition.

1.5 Proposition V

The establishment of a strong mutual emotional attachment leads to internalization of the parent's activities and expressed feelings of affection. Such mutual ties, in turn, motivate the child's interest and engagement in related activities in the immediate physical, social, and—in due course—symbolic environment that invite exploration, manipulation, elaboration, and imagination. The next Proposition broadens the family circle.

1.6 Proposition VI

The establishment and maintenance of patterns of progressively more complex interaction and emotional attachment between parent and child depend to a substantial degree, on the availability and involvement of another adult, a third party, who assists, encourages, spells off, gives status to, and expresses admiration and affection for the person caring for and engaging in joint activity with the child. It also helps, but is not absolutely essential, that the third party be of the opposite sex from that of the other person caring for the child, because this is likely to expose and involve the child in a greater variety of developmentally-instigative activities and experiences (Bronfenbrenner et al. 1996). Where this is an attachment to two or more parent figures, each can serve as a third party to the other.

The research evidence for this Proposition came mainly by default. It was produced by demographic data documenting a rapid rise in the proportion of single-parent households. The trend began in the 1980s, and then continued at an even faster rate through most of the 1990s. The overwhelming majority of such homes were those in which the father was absent and the mother bore primary responsibility for the upbringing of the children.

A large number of investigations of developmental processes and outcomes in families of this kind have since been conducted across a range of cultural and social class groups. In general, the findings lead to two complementary conclusions:

(a) Even in families living in favorable socioeconomic circumstances, children of single-parent mothers, or of fathers, for whom no other person is

acting reliably in a 'third party' role are at greater risk for experiencing one or more of the following developmental problems such as: hyperactivity or withdrawal; lack of attentiveness; difficulty in deferring gratification; poor academic achievement; school misbehavior; and frequent absenteeism.

(b) At a more serious level, there is the so-called 'teenage syndrome' of behaviors that tend to be associated together: dropping out of school; involvement in socially-alienated or destructive peer groups; smoking, drinking, frequent sexual experience, adolescent pregnancy, a cynical attitude toward work, and—in the more extreme cases—drugs, suicide, vandalism, violence, and criminal acts. Most of these effects are more pronounced for boys than for girls (Bronfenbrenner et al. 1996).

Not all single-parent families, however, exhibited these disturbed relationships and their disruptive effects on children's development. Systematic studies of the exceptions have identified what may be described as a general 'immunizing' factor. For example, children of single parents were less likely to experience developmental problems especially in families in which the mother (or father) received strong support from other adults living in the home. Also helpful were nearby relatives, friends, neighbors, members of religious groups, and, when available, staff members of family support and child care programs. What mattered most was not only the attention given to the child—important as this was—but also the assistance provided to the single parent or by others serving in the supportive roles cited in Proposition VI. It would seem that, in the family dance, 'it takes three to tango.'

But dancing is not the whole story. By the 1980s, theory and research in the ecology of human development had documented an accelerating trend toward greater permissiveness in styles of child rearing in American families. At the same time, successive scientific investigations had revealed progressively greater developmental advantage for strategies that placed increased emphasis on parental discipline and demand. The interpretation that emerged from analyses of the available data suggested that widespread application of these research findings would serve as an effective response to the developmentally disruptive changes taking place in contemporary society.

At this point, it is important to mention two other bodies of research that contributed significantly to the development of bioecological theory and its corresponding research designs. The first is now of long standing. In 1974 the sociologist Glen H. Elder, Jr., in his classic volume Children of the Great Depression (1974, 1999), extended the concept of development beyond the formative years to encompass the entire life course.

The second addition has yet to be fully exploited. Bronfenbrenner and Ceci (1994), taking the bioecological model as their point of departure, suggested an empirically testable alternative for the established scientific paradigm used in behavior genetics. The proposed alternative model: (a) allows for nonadditive synergistic effects; (b) employs direct measures of the environment; and (c) proposes proximal processes as mechanisms of person–environment interaction through which genotypes for developmental competence are transformed into phenotypes. The model predicts that: (a) estimates of heritability (h^2) for developmental competence increase markedly with the magnitude of proximal processes; (b) heritability measures the proportion of variation in individual differences that are attributable only to 'actualized' genetic potential, with the degree of 'unactualized' potential remaining unknown; (c) actualized genetic potential (h^2) will vary with the quality of the environment, and will increase as that quality is improved (for example, through providing job opportunities, health services, and intervention programs in low-income neighborhoods).

The authors also suggested that high levels of such patterns of parental behavior as 'neglect, abuse, or domination' could serve as powerful mechanisms for actualizing genetic potentials for developmentally maladaptive behaviors that both disrupt proximal processes and produce developmental disarray.

1.6.1 The bioecological model in the discovery mode: future perspectives. This section is based on Propositions and working hypotheses derived from the bioecological model for which, as yet, there are few empirical data. The section begins with future prospects for addressing the second stated goal of the bioecological model: that of 'providing needed scientific bases for the design of effective social policies and programs that can counteract newly-emerging developmentally-disruptive influences.'

In accord with the latter objective, the section begins with an unorthodox proposal. By and large, thus far, theory and research on human development have been concerned with the influence of the older generation on the development of the younger. In the Proposition that follows, the direction is reversed. (It should be noted that the basic idea underlying this Proposition is not new, and is foreshadowed both in the theory of Vygotsky (1978), and in the contemporary 'action' theory of Brandtstädter (1998, 1999).)

1.7 Proposition VII

The psychological development of parents is powerfully influenced by the behavior and development of their children. This phenomenon occurs through the life course; is more evident during the formative years when most children are living at home in the care of their parents; and often becomes especially pronounced during adolescence, when the young begin to

strive for independence both as individuals and as members of peer-groups. Such behavior is particularly likely to occur amongst those adolescents or youth who have comparatively little contact with their parents or other caring adults earlier in life. Although many studies have focused on the development of such alienated young people, the impact of the latter's behavior on the subsequent development of their parents has yet to receive the systematic investigation hat it deserves. The converse of the foregoing Proposition—the influence of the successful transition of children through adolescence and young adulthood on the constructive development of their parents—has regrettably received even less scientific attention.

1.8 Proposition VIII

Over the life course, the process of attachment exhibits a turnaround. In the beginning, it is the children who are the beneficiaries of the parents' irrational commitment, whereas toward the end the roles are reversed. Then it is the elderly parents who receive the love and care of their now middle-aged children. If, however, there was no attachment at the beginning, there may be no attachment at the end.

In this regard, developmental science has yet to address a curious omission both with respect to theory and research design. Resort to search engines in psychology and related fields has thus far failed to identify any investigations of the influence of parent-child attachment on the future development of the parent in contrast to that of the child.

This is not quite the case, however, for the next proposition in the discovery mode. The theoretical model, the corresponding research design, as well as half of the necessary empirical data are already available. The only problem is to find or conduct a study that meets the requirements of this model.

1.9 Proposition IX

If an investigation conducted in the past meets the requirements of the bioecological model, including assessment of developmental outcomes 'over an extended period of time,' then replication of the study at a later point in time would reveal whether the processes under investigation were still valid or had been nullified or superseded by subsequent historical changes. When the latter occurs, the investigator is confronted with the challenge of proposing alternative working formulations for explaining the observed phenomena.

At the conclusion of this article, we move from the domain of theory and research design to the world of reality and action. In the bioecological model, these two worlds have never been far apart. Especially from 1970 to 2000, these two worlds have become ever closer to each other. At a more general level, the findings from both domains reveal what has been referred to as 'growing chaos' in the lives of children, youth, families, schools, the world of work, and the ever-greater commuting in between (Bronfenbrenner and Evans 2000, p. 1022). The most recent report of this phenomenon appears in an article by Bronfenbrenner and Evans (2000). It contains the following summary about the nature of 'chaos' and its developmental consequences.

'Chaos integrates the various elements involved, and foreshadows the role [of chaos] in the bioecological model in terms of what is called 'chaotic systems.' Such systems are characterized by frenetic activity, lack of structure, unpredictability in everyday activities, and high levels of ambient stimulation. Background stimulation is high, and there is a general lack of routinization and structure in daily life. The environment is also a major source of interruption of proximal processes in the form of residential noise, crowding, and classroom design' (p. 121).

At the turn of the century, we are left with a troubling question: From the perspective of the bioecological model, what is the prospect for the future development of our species? The answer to that question lies with the willingness of the USA and other economically developed countries to heed the emerging lessons of developmental science. At the moment, it is difficult to know what the answer will be. The future could go either way.

Given this alternative, then surely it becomes the responsibility of developmental science to communicate such knowledge as we possess, and to do so in words that can still find an echo. Here is a first draft.

In the USA it is now possible for a youth, female as well as male, to graduate from high school, or university, without ever caring for a baby; without ever looking after someone who was ill, old, or lonely; or without comforting or assisting another human being who really needed help. The developmental consequences of such a deprivation of human experience have not as yet been scientifically researched. But the possible social implications are obvious, for—sooner or later, and usually sooner—all of us suffer illness, loneliness, and the need for help, comfort, and companionship. No society can long sustain itself unless its members have learned the sensitivities, motivations, and skills involved in assisting and caring for other human beings.

Human Development, Successful: Psychological Conceptions

From its outset human development is dependent on the presence of essential and beneficial conditions in the physical and social environment. Some of these conditions are fundamental and the same for all human beings (oxygen, water, food), while others are more complex and necessary to varying degrees (e.g., support of caregivers, language education, culturally specific competencies). Human beings also differ from one another in their psychological and physical needs: congenital and acquired vulnerability and deficiencies need special support and encouragement, some of them may even require specialist intervention or preventive treatment (e.g., specialized diets in the case of inherited metabolic disturbances such as phenylketonuria). At any event, there needs to be a minimum degree of fit between the individual and his or her environment before development can actually take place. Within these bounds, however, a very wide range of human development can unfold: An individual's predispositions and qualities encounter an immeasurably vast range of diverse environmental influences (socialization, critical and non-normative life events, historical influences, etc.). These influential factors operate throughout an individual's ontogenesis (Baltes et al. 1998). Human development never reaches completion, is multidirectional and seldom irreversible, while at the same time features a high degree of interindividual variability and intraindividual plasticity (Baltes 1987, Baltes and Baltes 1990). Moreover, there is now a broad consensus that human development does not take place uniformly in an irreversible sequence of different stages and phases, but is a process that individuals themselves actively influence in substantial ways (Brandtstädter 1998).

In view of this broad range of possibilities, the question of how and under what circumstances human development can succeed proves to be complex in several respects. The purpose of this chapter is to deal with two questions. The more important, of course, is the question of what makes development successful: which are the prerequisites of an 'art of life' (Staudinger 1999)? To answer this question, however, the term 'successful' needs to be clarified.

1. *What is 'Successful' Development? The Problem of Criteria*

Since the work of David Hume (1978), many have argued that while empirical sciences like psychology may, for reasons of principle, apply criteria which are value judgments, they cannot justify or legitimize the use of such criteria. According to this view, no matter how good science may be, it can only describe and explain the world, but it cannot judge it. Is the question of 'successful' development hence unanswerable from the start, at least from the viewpoint of an empirical science?

Actually, the relationship between empirical description and explanation on the one hand and value judgments or normative standards on the other is in fact more complex than that. Even if empirical facts do not constitute sufficient conditions for making evaluations, as a rule they are nevertheless necessary ones (Brandtstädter and Schneewind 1977). Any decision or action is predicated not only upon preferences and value judgments but also upon expectations which take account of empirical facts. For instance, the demand for a juvenile who commit crimes to be 'educated' by a punishment assumes that punishment actually serves to influence his future actions. This is an assumption that can, and indeed must, be empirically tested. In this respect science plays a key role in answering the question of successful development, even if the criterion for measuring 'success' has had to be determined on a prescientific basis.

Yet it is open to question whether assessments of human action and biographies really are as completely arbitrary as is suggested by a Humean perspective. Without wishing to become involved in the finer points of the philosophical debates surrounding the 'deducibility' of normative statements from descriptive ones, it can nevertheless be said that all positions purporting to offer proof of the inherent distinction between 'is' and 'ought' in fact tend to presuppose this 'gap' of principle rather than to prove its existence (Mavrodes 1968). In search for firm foundations for value judgments as well as for empirical descriptions, the last line of defense is the practice of simply not calling certain statements into question because the grounds for doubting them appear more dubious than the statements themselves.

So although we can forget any prospect of finding 'the' best biography *per se* in the foreseeable future, indisputably negative examples can easily be identified within the variations realized. For instance, there is no doubt that a person who persistently and repeatedly violates others for no reason, leads a less 'productive' life than one who shows reasonable consideration for others' interests and needs when taking his or her actions and decisions. Likewise, one can hardly describe an old age marred by illness and loneliness, causing distress particularly to the aged person but also to his or her relatives and friends, as 'successful' without arousing the suspicion that this is an artificial, academic discussion or simply cynicism. The details of examples such as these will be controversial, and here too particular constellations will lead to changes in our assessments. Nevertheless, such examples show that in many cases value judgments ('better'–'worse') are scarcely more doubtful than the 'brute' facts.

However, the search for universal criteria of successful development which can be applied to all people irrespective of their individual, cultural and historical circumstances, is likely to be fruitless, because it follows from the actional perspective of human development that people's 'success' depends to no small degree on what they themselves consider to be successful. Within the development-regulating normative rules and developmental tasks of a culture, which incidentally are themselves subject to cultural development processes, the individual organizes ways of shaping his or her own life, looking for and construing orientations which give meaning to his or her personal development (Brandtstädter 1998).

These considerations point toward a solution to the question of criteria. Beyond the fulfillment of the fundamental conditions essential for life, the prerequisites for successful development are clearly those meta-competencies and meta-resources which ensure that individuals can make use of opportunities and encouragement, can compensate for deficiencies and vulnerabilities, can choose and realize their own developmental goals, and thus can actively shape their development within the framework defined by immediate and potential possibilities (Brandtstädter and Schneewind 1977). This metaperspective implies a multicriteria approach on the one hand, and the integration of subjective and objective criteria of 'success' on the other (Baltes and Baltes 1990).

2. *What Makes Development Successful?*

If human development is basically the product of culture and, at the same time, the result of individual action, an essential prerequisite for successful development is the capacity to act, i.e., to choose developmental goals, to make decisions, to form intentions and to put them into practice, and also to overcome resistance and to revise strategies where necessary. Acting successfully entails first the precise competencies needed to carry out a particular action in practice. Additionally, an adequate representation of these competencies and potentials in the person's self-concept is a prerequisite for an appropriate and autonomous choice to be made from among the possible developmental options. Thus, processes of self-regulation perform an integrating, 'orchestrating' function for human development (Staudinger et al. 1995).

Self-regulating processes can essentially be classified into two modes (Brandtstädter and Greve 1994). In the assimilative mode, goals are maintained even

against resistance, and strategies are pursued tenaciously until they are achieved. Obviously, development can only succeed if people are sufficiently willing and capable; anyone who always gives up immediately will achieve neither essential tasks nor those of his or her choosing. In the accommodative mode, when faced with goals that are truly or are perceived to be unachievable, or with irreversible losses and deterioration, preferences and orientations are adapted in a way that avoids meaninglessness and depressive tendencies, and preserves subjective well-being, but at the same time brings new, achievable goals into view, which revive the capacity and motivation to act. These aspects are illustrated with examples from the research fields of juvenile delinquency and successful aging.

2.1 Autonomy and Social Integration: The Sample Case of Juvenile Delinquency

Although difficulties of coping with developmental tasks occur throughout the lifecourse, juvenile delinquency serves as a good example with which to illustrate such difficulties. Challenges such as physical changes and sexual maturation, the need to develop interpersonal skills (e.g., for relationships with the opposite sex), acquiring education and, in particular, forming a personal and social identity are not just the storms to be weathered during adolescence; these challenges are vitally bound up with laying the groundwork for successfully solving the tasks and meeting the demands of adult life (Crockett and Crouter 1995). In particular, social developmental tasks play a particularly prominent role during the years of youth (Petersen and Leffert 1995). Especially at a juvenile age, the dualism involved in social integration is patently evident: at one and the same time, social integration is an aim in itself and a prerequisite for successfully fulfilling the developmental task of preparing adulthood. However, both the necessity and the opportunity to change and challenge social contexts are characteristic features of adolescence too. Since the dividing line between creatively transgressing the social rules and a deviant or pathological disregard for social limits can be a fuzzy one, these dilemmas of individuation vs. integration and of autonomy vs. adaptation may serve as a background for the explanation of juvenile delinquency (Coie and Dodge 1998). Delinquent juveniles, in particular those whose deviance is 'adolescence-limited' (Moffitt 1993), have evidently not managed to cope successfully with these tasks (Petersen and Leffert 1995). Thus, personal resources of coping with discrepancies between the social demands on the one hand and the personal goals, desires and competencies on the other gain a key function in explaining juvenile delinquency and, as a consequence, successful juvenile development. In particular, the goodness of fit between the individual and his or her social environment thus becomes an important precondition and, at the same time, a central criterion for developmental success of adolescence.

2.2 Resources of Resilience: The Sample Case of Successful Aging

Going yet another step further, human development in general can be regarded as a hierarchical, interactive sequence of micro- and macroscopic coping processes. While current coping processes and resources are shaped by developmental conditions, coping reactions can also act as forces in creating future development. That leads on to the investigation of developmental constellations of individual and social resources that make an individual either resilient against or vulnerable to new strains as they arise. The discussion of the conditions under which people cope successfully with aging illuminates this aspect very well. Numerous studies have shown that people's ability to function and their sense of well-being are not greatly impaired as they grow old, if at all. Indicators of overall psychological status such as self-esteem, general sense of well-being, or being convinced of having control over one's own life are variables which, taken together, do not show any substantial covariance with age (e.g., Brandtstädter et al. 1993, Staudinger et al. 1995). As a consequence, the stereotype of aging being a process strongly characterized by deficiencies and loss has gradually gone out of favor as being too one-sided and incomplete, to be superseded by a more multifaceted view of 'productive' and 'successful' aging (Baltes and Baltes 1990). These findings are most surprising when set against the well-documented fact that, whether in terms of cognitive development, changing sensory functions or morbidity, aging does entail a real increase in the losses and impairment people suffer (Bond et al. 1995).

This apparent contradiction between the growing strains and losses on the one hand and the stability of the self and well-being on the other is resolved once the personal constellations of 'resilience' (Rutter 1990) are made the focus of the theoretical perspective (Baltes and Baltes 1990, Brandtstädter 1998, Staudinger et al. 1995). In addition to the model of developmental self-regulation already mentioned (Brandstädter et al. 1993), the main model providing important insights that help to explain resilience in old age is that of 'selective optimization with compensation' (Baltes and Baltes 1990). As losses occur, they can be partly cushioned or alleviated by way of selective improvement (training, expertise), and compensated for as people reorient their lives or change their strategies. Against the background of the actional conception of development, it is important to point out that resilience is not just a reactive quality, but is often brought to bear proactively, before the troubling event

actually occurs or the degenerative tendency sets in. For instance, the fact that people have less chance of becoming crime victims as they grow older is partially explained by an increasing tendency to behave more cautiously (Greve 1998).

3. *Conclusion: Courses and Conditions of Successful Development*

In terms of cognitive functions, social integration, and self-regulation, human development features a considerable amount of plasticity (Baltes et al. 1998), which not only makes up the core prerequisite for the dynamics of resilience and the coping processes discussed here, but indeed is also a general precondition for the very possibility of lifespan development. Self-regulation processes are both a central criterion for adaptation processes on the one hand and they substantially control them on the other.

Personal well-being and psychological health, and social integration can only be maintained and improved if the individual can be protected against unfavorable conditions by resilient resource constellations, if personal and social coping resources can help to cushion and compensate for the crises and losses that will inevitably occur, and if the individual capacity to act is largely maintained, whether by stabilizing the required conditions or by finding a new orientation toward achievable objectives. Actually, all of these aspects can be seen both as the products and the producers of successful development.

Development essentially consists in upholding and implementing the individual's capacity to adapt to the discrepancies in new situations and developmental tasks as he or she seeks (via assimilation or accommodation) to attain a solution to, or dissolution of, the discrepancies that are generating a crisis or creating a burden, if these are unavoidable in the long run. Thus, successful development implies a progressive adaptation which simultaneously maintains or indeed expands this plasticity and adaptivity. As far as we know today, this is possible—and usual—at least up to the latest years of very old age (Baltes 1997). That leads to the somewhat tautological-sounding statement that successful development essentially means ensuring that development, i.e., progressive adaptation, will always be possible and really will occur.

The emerging perspective of adaptivity and activity as the roots of successful human development suggests essential new research perspectives focusing on sources of resiliency and vulnerability at any stage of human development. Moreover, even if the preconditions and processes are known which provide successful development, the ways to improve the individual's capacity to acquire or to use them are still to be investigated. Thus, studies in applied developmental science are needed in order to discover techniques and strategies of individual and social improvement of both of these core conditions, with respect to special interventions, e.g., in the case of juvenile delinquency, as well as with respect to primary prevention of developmental crises, e.g., in the case of successful aging in very old age.

Human Ecology

Human ecology addresses the relationships of humans to their environments. This demarcation concept unites an array of otherwise unconnected scholarly traditions. The traditions are distinguished by their different interpretations of ecology itself, by the different theory frames they employ for the study of human ecology, and by their respective objects of explanation or problematics. This article begins with the different interpretations as a preview for sorting and examining the different theory frames and their problematics.

1. *Interpretations of Ecology*

Interpretations of the concept and substance of ecology differ according to the unique vantage points provided by independent scholarly traditions.

1.1 *The Biological Interpretation*

Ecology was originally given a biological interpretation in 1866 when Ernst Haeckel defined the science in accord with the work of Darwin, who had attempted to explain evolution in terms of the adaptations of organisms to the biotic and abiotic features of their environments. A generation later another foundation concept appeared: since evolutionary studies indicated there was an ecology of living organisms before humans evolved, and humans themselves are living organisms, there must therefore be a human ecology. On the biological interpretation, humans are part and parcel of the natural world, and are subject to the same biophysical dynamics that govern the organization of other living communities. For most of the twentieth century, however, although gradually shifting in the last couple of decades, biologists took only a passing interest in the scientific study of the ecology of humans *per se*.

1.2 *The Metaphorical Interpretation*

Social scientists, by contrast, were quick to seize on the idea of a human ecology with independent investigations begun in the 1920s, in India, by Radhakamal Mukerjee, who followed the biological interpretation, and in the USA by Robert Park, whose students did not. Aware of theories of community succession that their biological colleagues were then developing for natural communities, in which society was used as a metaphor to understand natural organization, some early US sociologists came to use nature as a metaphor to understand social organization. Setting aside the rhetorical uses of 'ecology' as a synonym for 'contextual' or 'environmental,' two variants of metaphorical interpretation can now be found in social science. The first applies bioecological concepts to the study of human communities *per se*, reasoning by analogy. Here, institutional or organizational settings are taken as contexts or environments for humans within their groups, populations, or societies, which are supposed to be organized parallel to natural communities. This variant generally overlooks the fact that natural communities contain multiple species and humans are a single species, preferring to finesse this by elaborating biological species and evolutionary analogies for societal divisions of labor. The second variant, discussed in Sect. 2.3, treats ecological knowledge as a social construct. Left unaccounted for in the metaphorical interpretation are biological connections between human societies and other natural systems. The metaphorical interpretation is a blueprint for the study of the internal workings of society through the adaptations of its populations or groups by means of their social organizations and shared cultural knowledge (see *Biology's Influence on Sociology: Human Sociobiology*).

1.3 *The Ideological Interpretation*

With the reawakening of the modern environmental movement worldwide and its growth in the last decades of the twentieth century, an ideological interpretation of ecology has appeared. In this, the biological and metaphorical interpretations of ecology are freely interwoven and supplemented with value judgments gauged against standards supposedly congruent with ecological science. Some versions of the ideological interpretation use nature as an ideal to evaluate and reform social and political organization, economic practice, and personal conduct, while others try to frame environmental ethics so as to integrate ecological science with politics, economics, philosophy, education and various religions and cultures. The ideological interpretation is neither monolithic nor uniform, but its advocates generally fall to the left of ideological spectra. The common thread is that ecology is more than science or metaphor: It is a world view with ethical implications for personal, cultural,

International Encyclopedia of the Social & Behavioral Sciences ISBN: 0-08-043076-7

and institutional change (see, for example, Evernden 1992, Oelshlaeger 1994, Orr 1992).

2. Theory Frames for Human Ecology

The multifarious research traditions of human ecology may be understood in terms of the different theory frames they have employed, which reflect their respective interpretations of ecology. Different theory frames address different problematics.

2.1 The Evolutionary Theory Frame

The evolutionary theory frame assumes that ecological forces act on genetic and cultural variation among individuals and populations so as to effect a selective survival and reproduction. Using this assumption, neo-Darwinian principles of natural selection are applied to understand how individuals adapt to their natural environments, how different social species reflect common principles of social organization in response to ecological contingencies, and how populations and cultures are affected by pathogenic disease.

Individual behavior and social organization are classic problematics in social science. The application of evolutionary theory attempts to provide a fuller explanation of these. One strand of theory develops a human evolutionary ecology patterned on the behavioral and evolutionary ecology of the biological sciences. In this, an adaptive design is assumed to be the product of the elemental behavior of individuals, such as foraging, territorial defense, time allocation and mate selection, all of which are presumed to satisfy economic cost–benefit principles (Smith and Winterhalder 1992). It has yet to be demonstrated whether neo-Darwinian evolutionary–economic models have application beyond the case of hunter-gatherers. Because organic traits (such as brain size, bipedalism, and vocal chords) underlie cultural capabilities, and culture is understood as a human adaptation, some evolutionary models assume the coevolution of biological and cultural traits in ecological context (Boyd and Richerson 1985, Durham 1991). Another strand of theory focuses on problematics of social organization among different species, with a view to discovering common principles but without presuming that the properties of social organization can be reduced to the summed behavior of individuals. In addition to comparisons with social primates, a research tradition of long standing, Machalek's (1999) transpecific sociology enables the comparison with humans of the demographic constraints, division of labor, and homeostatic mechanisms that appear in colonies of social insects, and of common strategies of environmental exploitation across social species (see *Cultural Evolution: Overview*; *Human Ecology*).

Problematics of epidemiology, ancient, and contemporary, fall within an evolutionary theory frame inasmuch as most scholars consider pathogens to be the principle agents of natural selection operating on humans since sedentary lifestyles were adopted 10,000–12,000 years ago. The most startling and horrible example of the human ecology of disease is the cultural and demographic extirpation of untold millions of native Americans in times of post-Columbian exploration, due to epidemic pathogens imported by Europeans and their African slaves, and from which the tribes had no inherited or acquired immunities. In modern times, medical authorities are again sounding alarms about the development and spread of epidemic pathogens, old and new, because normal genetic mutations eventually produce drug-resistant variants of old as well as new, and now dangerous, variants of formerly benign organisms. Since microbic pathogens are part of the living environment of all humans, human culture and society have to adapt to ever-changing conditions of pathogenic disease just as pathogens adapt to humans—an inherently ecological condition. The incidence of pathogenic diseases is known to be affected by agricultural practices, dietary customs, migration patterns, population densities, climate alteration, cultural hygiene practices, lack of potable water, sexual mores, modern transportation that transcends normal environmental barriers, and technological methods of intervention (see Ewald 1994, Kipple 1997).

Intervention methods typically disrupt population equilibria that might normally exist between pathogens and humans, thus preventing natural environmental controls from exerting themselves. Instead of stabilizing natural environments, technology implemented through the social organization of medicine and public health rather attempts to control pathogens so as to stabilize their relationship to humans. This method in itself, by intervening to change natural biota, provides a stimulus for microbic evolutionary adaptation. The general principle is that changed environments bring changed frequencies of microbic pathogens, human intentions notwithstanding. Some scholars (Mascie-Taylor 1993) have tended to conceive human ecology entirely in these epidemiological terms, however, this has not been predominant.

2.2 The Environmental Theory Frame

The environmental theory frame dominates modern research traditions of human ecology. It too presumes a biological interpretation of ecology, but in some cases substantially supplemented by considerations of social science targeted to problematics of subsistence and sustainability.

Anthropologists and geographers have a long tradition of investigating how human behavior, culture, traditions, settlements, built environments, spatial

location, territory, and humans' sense of place are affected by efforts to procure subsistence from natural—typically regional—environments. Research programs investigating cultural ecology, ecological anthropology, environmental geography, and environmental history consistently demonstrate how the development of culture and society vary with settlement patterns, technology and means of material resource acquisition, and how natural environments are modified by sociocultural variations in subsistence practices. A cultural materialism, which viewed culture and its symbolism as epiphenomenal, was implicit or explicit in many of these classic approaches, as was a dualistic construal of nature and culture. Modern approaches, especially political ecology, are different (see Biersack 1999, Scoones 1999). They focus on the interaction of spatial and temporal environmental dynamics with people situated in political, social, institutional, and cultural context, and emphasize the effects of human agency within the push–pull parameters of social, economic and political inequalities, on the one hand, and local or regional environmental transformations, on the other. Political ecology conceives human–environment interactions as mutual, thus linking human ecology to political economy and crossing from problematics of subsistence to those of sustainability (see *Feminist Political Ecology*).

No problematic has so dominated modern environmental discourse as the question of limits to growth, specifically, whether industrialism is sustainable into the indefinite future as it is adopted round the world. Biologists began the debate in the 1960s by importing from population ecology concepts of carrying capacity limits, and they averred that cascading world population growth augured for environmental catastrophe. Some social scientists amplified this neo-Malthusian argument, noting that industrialism is not a population but a way of life, one which produces too much consumption not just too many consumers.

Attentive to anthropogenic environmental degradation (aquifer depletion, biodiversity loss, deforestation, ozone depletion, global warming, etc.), the new social science tradition of examining environmental interfaces with human production and reproduction is now secure with the appearance of numerous textbooks and treatises on environmental sociology, environmental psychology, and ecological economics (see Costanza et al. 1997, Harper 1996). These specialties tend to conceive human–environment interactions within the existing theory traditions of their established disciplines. Recently, ominous neo-Malthusian analyses have been challenged by more optimistic theories of ecological modernization (Spaargaren and Mol 1992).

Theory aside, problematics of sustainability are routinely encountered as matters of practice in the concerted effort to promote sustainable development in economically less secure nations of the world. Specifically promoted by the United Nations, sustainable development is taken to mean eliminating world poverty while not compromising local environmental stabilities (Brundtland Commission 1987). In fact, sustainable development as practiced has promoted the transfer of industrial technology to promote economic growth. Where the ideal has succeeded, and by consensus it has not much, in effect sustainable development programs have promoted further industrialization—thus rekindling the question of the long term sustainability of human–environment interactions as local, regional, and global environmental degradation compounds, interactively cascading from industrialism's increased energy capture and waste disposal. The concern over environmental degradation directs the problematic of sustainability, which currently is targeted more towards local than toward global applications (see *Human–Environment Relationships*).

2.3 *The Analogic–Symbolic Theory Frame*

The analogic–symbolic theory frame works with a metaphorical interpretation of ecology, with different variants selectively emphasizing analogies or symbolic constructs as central to theory development. Generally speaking, the theory frame takes biological ecology just seriously enough to borrow some of its content (sometimes merely its words) so that nature can serve as a metaphor to understand society, thus advancing social science. In the classic sociological tradition, 'environment' usually had no biological referent, and neither does 'community' or 'ecosystem,' which are favorite analogs in modern sociological human ecology. As noted earlier, US sociology provided the first sustained research tradition of human ecology, something of an urban geography, concerned as it was with spatial relations in cities, that beginning in mid-twentieth century the influential Amos Hawley gradually transformed into an ecological demography. In this, territorially circumscribed human populations are characterized by technologically based organizational adaptations in the sustenance producing activities of populations within their social, political, and economic environments. These orienting concepts have not changed in more than a generation (see Micklin and Posten 1998). They reflect a social and demographic, but not a biological, materialism in the conception of purely sociological problematics. Direct descendants, such as organizational ecology, and distant cousins, such as family ecology, likewise depend on theoretical analogies to biological phenomena in order to relate social entities to social environments (see *Population Ecology*).

A wholly independent and more recent set of problematics relating society and environment applies a social constructionist interpretation to environmental social science, counterweighting its biological interpretation. In this, natural environments become

material for the analysis of symbolic meanings and understandings by which social groups perceive and define environmental events as real and respond to them collectively. One-to-one theory analogs with bioecology are not sought, but the metaphorical interpretation of ecology runs deep because symbolized realities are accorded primacy over biophysical realities. Natural environments are taken to have significance only as people socially construct, perceive, define, and negotiate them as real, and make contestable claims about them. The problematics address social responses to natural environments insofar as environmental issues are defined through shared meanings (Hannigan 1995).

Theory variants that are exclusively analogic or symbolic usually seek to separate not integrate human ecology and bioecology, so as to strengthen social science *per se*. Implicitly, sometimes explicitly, many variants reflect the species prejudice that nonhuman organisms represent 'lower' forms of life and the cultural prejudice that Western industrialism represents the 'highest' form of social progress. These two prejudices are explicitly criticized in many variants of the interactive theory frame.

2.4 *The Interactive Theory Frame*

The interactive theory frame for human ecology is the newest, most diverse and most numerous in its scholarly problematics. Its growing traditions may only be listed here. They include assorted environmental ethics, such as deep ecology, the land ethic, and animal rights; assorted spiritual ecologies, including native US land wisdom, Christian-based ecological process theology, and strains of Buddhist, Taoist, and Jainist thought; some applications of complexity theory for evolving interactive systems; Gaian ecology; politically grounded approaches, such as social ecology and green Marxism; ecofeminism; and more (see, for example, Bookchin 1995, Benton 1996, Callicott 1994, Tucker and Grim 1993, Warren 1996).

All of these assume some variant of the ideological interpretation of ecology, reflecting a wish to integrate ecological knowledge with selected priorities in human affairs. Some are based in science, while others are based in philosophy, politics, religion, or tradition, but almost none maintains a hard and fast distinction between objective and subjective knowledge. Almost all take a holistic rather than reductionistic approach to their problematics, in which the traditional boundaries of scientific disciplines, and even the classic boundaries between science and the humanities, are regarded as anachronistic. Most reject any nature–culture dualism, and many disavow anthropocentrism. Multiple distinct problematics are defined, depending on the point of view. The overriding theme construes human ecology as knowledge of the complex interactive connections that integrate human activities with environmental contexts. The overall result is an eclectic combination of biological, environmental, moral, and even esthetic, approaches to human ecology (see *Nature, Concepts of: Environmental and Ecological*; *Ecology, Deep*; *Feminist Political Ecology*).

3. *Conclusion*

Human ecological scholarship on the biological, environmental, and ideological interpretations, with their derivative problematics, is now being increasingly writ into the curricula of educational institutions. Calls for 'green education' are being implemented internationally, programs in environmental science that include a human component are expanding, and one US undergraduate institution of higher learning, the College of the Atlantic, devotes its curriculum entirely to human ecology. While still stymied by the traditional boundaries of academic disciplines, and sometimes by parochial scholarship, human ecology—the subject, not the name—is experiencing dynamic growth, as befits the coming century of the environment.

Human Ecology: Insights on Demographic Behavior

1. Introduction

Human ecology is the 'the study of the form and the development of the community in human populations' (Hawley 1950, p. 68, Hawley 1971) for which the unit of analysis 'is not the individual but the aggregate which is either organized or in the process of being organized' (Hawley 1950, p. 67) and where the concept of 'community' is defined as a 'territorially based system of functional interdependencies that results from the collective adaptation of a population to its environment' (Berry and Kasarda 1977, p. 12). Human ecology proposes that populations adapt to social, economic, political, and biophysical environments through organizational innovations, and that systems grow 'to the maximum size and complexity afforded by the technology for transportation and communication' in reducing the time cost of maintaining the accessibility and exchange required by interdependent populations (Hawley 1986, p. 7). It is important to recognize that it is this theoretical framework, not the mere fact that aggregate data are used, that places research in the human ecological tradition.

2. Contemporary Human Ecology

The intellectual lineage of human ecology traces from the emergence of plant and animal ecology in the late nineteenth and early twentieth centuries and its application to human populations in the work of Park and Burgess (1921), McKenzie (1933), and other scholars at the University of Chicago. The approach of these scholars, while innovative, was ultimately limited in scope. Perhaps most limiting was the initial insistence that cultural variables be excluded from the purview of human ecology in favor of a focus on spatial patterns resulting from a process of unplanned competition. By contrast, the insights into demographic phenomena described herein depend almost entirely on *contemporary human ecology* (hereafter, *human ecology*) which denotes the body of theory and research that began with the publication in 1950 of Amos H. Hawley's *Human Ecology*, a landmark volume which led to a major reorientation of the field. Hawley's work dramatically shifted the focus from the description of physical features of the city and mapping of social phenomena to 'the ways in which human populations organize in order to maintain themselves in given environments, thus relegating spatial analysis to a minor though still useful position in the discipline' (Hawley 1986, p. 3). It is not spatial arrangements themselves, but rather the social relations often reflected in spatial patterns and processes, that are of interest to human ecologists (Frisbie and Kasarda 1988 for further discussion).

Albeit something of an oversimplification, the human ecological paradigm can be thought of as encompassing four broad categories of variables: population, organization, environment, and technology—codified by Duncan (1959, 1964) as the ecological complex bearing the acronym POET. It is crucial to recognize that, in human ecology, population is defined generically to mean 'a number of units sharing one or more given characteristics…(which acquires) operational significance only when clothed with a set of institutions and located in a space-time context' (Hawley 1998, pp. 11–12). At least since Hawley's redirection of the field (1950), the primary unit of analysis for human ecology has been the organized population, not the individual units comprising populations. In addition, human ecology places a much heavier emphasis on analysis of the social and economic environment, as compared to the biophysical environment (Hawley 1998). This distinguishes (but does not isolate) human ecological concerns from those which characterize bioecology and the environmental movement.

The term 'demographic behavior' is used broadly here to refer, not only to the basic processes of fertility, mortality, and migration, but also to *social demographic* phenomena, with social demography defined as 'the analysis of how general social and cultural factors are related to population structure and pro-

cess' (Ford and De Jong 1970, p. 4). In this context, an impressive range of human ecological insights into a large number of demographic issues might be identified. This article primarily emphasizes contributions to the study of the systemic attributes and processes involved in population growth and societal development, the distribution and redistribution of population, and intra- and interurban morphology. While this selectivity is logical in light of human ecology's emphasis on systems, it warrants mention that the well-known contributions of human ecology to research on social networks and residential segregation are given little attention inasmuch as these are the subjects of other articles included in this volume (see *Social Networks and Fertility* and *Residential Concentration/Segregation*, *Demographic Effects of*, respectively). Further, while much of the present discussion concentrates on research conducted in the US, human ecology has been drawn upon rather extensively in cross-national research (Frisbie and Al-Khalifah 1998).

3. *Human Ecology's General Theoretical Contribution to Macrolevel Demography*

It is clear that human ecology has contributed substantially to the preservation and advance of macrolevel theory in the social and behavioral sciences, generally, and in demography, in particular (Poston and Frisbie 1998). However, in the mid-twentieth century, two events combined to diminish the interest of demographers and other social scientists in macrolevel analysis. The first was the publication of work dealing with what came to be known (erroneously) as the 'ecological fallacy.' Robinson (1950) argued that results of research in which aggregates are the units of analysis cannot be used to infer relationships among individuals and that a large proportion of research that employs aggregate data does so only because information on individuals is not available. The second was actually a sequence of events involving the emergence of modern techniques of sampling and survey analysis which greatly enhanced the opportunity for rigorous microlevel studies (Linz 1969). For a time, demography listed far toward reliance on individual-level research, even in the face of warnings by renowned scholars that the discipline was ill-served by a fixation at the microlevel (e.g., Ryder 1980).

A more balanced view prevails, partially due to the efforts of 'ecological demographers' both early on (Schnore 1961) and later (Namboodiri 1988). As it turned out, Robinson's thesis was only partially correct. The problem identified by Robinson is not 'ecological' in nature, but rather an issue that arises whenever cross-level generalizations of any kind are contemplated. Moreover, many of the central tenets of human ecology are inherently macrolevel constructs devoid of any counterpart at the individual level. For example, the concept of the division of labor makes sense only when applied to groups. Analogous reasoning applies to many demographic variables. Individuals are born, they die, and in between they may migrate, but only groups, not individuals, have birth, mortality or migration *rates*.

A signal contribution of human ecology has thus been the development of a theoretical framework for a wide range of demographic studies of organized aggregates. Examples include investigations of the relationship between commodity exchange and position of cities in the US metropolitan hierarchy (Eberstein and Frisbie 1982), as well as in the worldwide system of cities (Meyer 1986), the effects on the volume and rate of migration, of functional niche and extent of the division of labor (Murdock et al. 1992, Poston and Mao 1996), changes in the social stratification of suburbs (Guest 1978, Krivo and Frisbie 1982), segregation of racial and ethnic populations (Massey and Denton 1989), and the 'birth' and 'death' rates of formal organizations (Carroll 1984, Hannan and Freeman 1977). Such work, in turn, offers a substantive grounding for mutlilevel analyses, in which, e.g., the behavior of individuals is partially explained in terms of the social or ecological context in which they exist.

4. *Specific Insights on Demographic Phenomena*

4.1 *Population Growth*

Perhaps no demographic issue has seized and held the attention of scholars, policy makers, the media, and the general public as that of rapid population growth. Interest in the 'population explosion' intensified *circa* 1970 in the wake of publications which predicted exhaustion of resources and irremediable environmental pollution if population and economic growth continued unchecked (Erlich 1968, Meadows et al. 1974). A wide range of less apocalyptic, but still highly disturbing, publications focused attention on less developed countries (LDCs) and the actual or anticipated deleterious consequences of rapid population growth for development and increases in the standard of living in these nations—effects epitomized by the piling up of excess rural populations in peripheral slums of huge cities (Davis 1975).

Early on, some scholars challenged the view that continued rapid population growth spelled worldwide collapse (see Davis 1990 for a summary of the position of 'alarmists' and 'skeptics'). Regardless of whether one tends toward pessimism or optimism, it is evident that demography has to come to grips with the Malthusian contention that population growth will inevitably be limited by exhaustion of natural and/or nonrenewable resources. Before one can meaningfully discuss its utility for better understanding population

growth, it is necessary to recognize that, in human ecological theory, population is regarded as a necessary, but not sufficient, condition. An important analytical implication is that population

> cannot operate independent of organizational circumstances. In and of itself it cannot cause war, resource exhaustion, or environmental pollution, as Malthusians have argued. Such outcomes are explained as due to maladaptations or malfunctioning of organization (Hawley 1986, p. 26).

Human ecologists have also called attention to certain errant assumptions that are perhaps more apt to be found in popular or 'vulgar' interpretations than in Malthus' work itself (Keyfitz 1982). Among the most troublesome of these is the naïve perspective that the concept of manageable population size can be operationalized as a 'simple ratio of organisms to units of a resource or resources'—naïve because it fails to take into account 'the manner in which the population is organized to use the resources' (Hawley 1950, p. 151). This flaw apparently underlies the conclusion that concepts such as 'carrying capacity' and 'limits to growth,' have failed to provide either 'analytic power, or foresight, instead of hindsight' (Davis 1990, p. 13).

Constructive insights are found in the human ecological model of system change, growth, and equilibrium. In *system* terms, growth refers to 'maturation … through the maximization of the potential for complexity and integration implicit in the technology for movement and communication possessed at a given point time' (Hawley 1986, p. 52). This perspective has direct roots in Boulding's (1953) theory of nonproportional change which suggests that a limit to growth occurs, not when some ratio of organisms to resources is reached, but when the communications and transportation costs involved in maintaining the coherence of a system become prohibitively high. Growth of systems can be expected to take the form of a logistic curve which describes a period of rapid growth which gives way to slow or no growth. Equilibrium is this view is a *temporary* state, and population increase will resume in combination with system expansion as additional organizational and technological inputs allow breaking through the upper asymptote imposed by the costs of movement and coordination of activities (Hawley 1986, 1998).

Applied specifically to demography, this insight might be translated as follows:

> As to demographic growth, its initial acceleration is a natural byproduct of … economic transformation since, predictably, the fruits of economic improvement are in part used for obtaining better health and lowered mortality. Malthusian outcomes, however, need not be the inevitable result of rapid population growth. Such growth is transitory: given economic success, the spontaneous onset of "demographic transition" can be confidently expected. Pressure built into the reward mechanisms of modern industrial society induce behavioral changes that eventually lead to low fertility, hence to low or no population growth (Demeny 1990, p. 417).

Recent worldwide fertility declines are consistent with this perspective. A 1999 United Nations publication shows that the world total fertility rate (TFR = the number of children a female surviving to the end of her reproductive life would bear given prevailing age-specific fertility rates (Keyfitz and Flieger 1990, p. 16)), after hovering around 5.0 during the period 1950–70 had fallen precipitously to 2.93 in 1990–95, with an expected TFR = 2.71 for 1995–2000 (UN 1999). By 1975–80, fertility in developed nations was already below replacement level (TFR = 1.91; for replacement, TFR is approximately 2.1, allowing for mortality of children). In LDCs, the rate for 1990–95 was 3.27, but this represented a rather astonishing decline from TFR = 6.00 in 1965–70. Based on its medium variant, the UN (1999, pp. 520–1) projects that average fertility among today's LDCs will fall to bare replacement level within the first four to five decades of the twenty-first century.

Of course, even with this major slowdown in population growth, 50 years into the twenty-first century, the world will still have a population much larger than today's roughly six billion (UN 1999, US Agency for International Development 1999). Some scholars (e.g., Bongaarts and Feeney 1998) have argued that current low fertility rates are, at least in some contexts, temporarily, rather than permanently, depressed to below replacement, while others believe the contemporary trend is likely to be permanent or at least rather persistent (Lesthaeghe and Willens 1999).

5. *Urbanization*

The concentration, deconcentration, and organization of urban populations have been central to ecological theory and research. As noted, Hawley defined human ecology as the study of the form and development of the community, of which urban places are a prime example. Although neither the *highly stylized spatial* models of urban form and growth developed by Burgess and Park, nor those of other scholars, have remained central to urban studies, these heuristic representations had a basis in analytical constructs that are important building blocks for ecological theories of the distribution and interaction of populations in both intraurban and interurban systems.

5.1 *Intraurban Systems: Land Use and Population Distribution*

Among the most directly relevant of human ecological insights for understanding *intrametropolitan* systems are those having to do with land use and population concentration/deconcentration. Of special interest is

Burgess' notion of geographical gradient as a basis for the hypothesis predicting an inverse relationship between intensity of land use by a population and distance from center to the periphery of cities (cf. Hawley 1971). This relationship, formalized by Colin Clark (1951), can be expressed in the form of natural logarithms as

$$ln\, d_x = ln\, d_o - bx \qquad (1)$$

where d_x is the density of population at distance x from the center, d_o is the central density, and b is an empirically derived density gradient. Reflected in this equation is a theory of land use which begins with the premise that functional differentiation and interdependence of populations and organizations in a city require mutual accessibility. Since, *ceteris paribus*, the center of a city is the point most accessible to all other parts of the city, there will be competition for core location, thereby driving up the cost of land at or near the center which, in turn, requires that more intensive use must be made of space. As ease of access declines with distance from the core, so too does the cost of land and the intensity of its use (Berry and Kasarda 1977, Hawley 1971, Turner 1994). The magnitude of the insight afforded by the human ecological theory of urban land use for demographers and others interested in the distribution and redistribution of population is seen in the fact that the validity of this model has been demonstrated by research using data covering a period of over a century and a half and for more than 100 cities (Frisbie and Kasarda 1988, p. 634).

Ecological theory also predicts that reduction in the friction of movement of population, materials, and ideas over time and space will cause the slope of the gradient to become less and less steep. As modern means of transportation developed and dramatic advances were achieved in accumulating, processing, and disseminating information, simple models based on a core-to-periphery gradient in a monocentered city have become progressively less relevant as metropolitan areas have increasingly become multinodal. But, because it is the systemic relationships reflecting the need for mutual accessibility of functionally interdependent populations, not spatial patterns, *per se*, that are central to the theory, the relevance of the ecological perspective remains in the face of rapidly changing urban systems. To illustrate, in the 1970s, as documented by numerous scholars and summarized by Edmonston and Guterbock (1984), several factors seemed inimical to the continuation of the rapid pace of suburbanization. Transportation costs had risen dramatically due to the reduction of petroleum supplies by major producing nations, while income growth in constant dollars slowed notably and housing prices soared—all of which raised the cost of moving to, and commuting from, the urban periphery. In addition, demographic composition had shifted such that the types of families that had traditionally fueled movement to suburbs, i.e., larger households headed by couples of prime child-bearing age, became proportionately fewer. Taking the coefficients of Clark's equation as dependent variables for more than 200 metropolitan areas, Edmonston and Guterbock demonstrated that mean central densities of cities continued to decline over a 25-year time span and that 'the density gradient dropped consistently' (1984, p. 918). That is, the initial concentration at the core of cities occurred due to the need for accessibility. The large negative sign of the density gradient reflected the less developed transportation and communications technology available during the early stage of city building, but the slope flattened as technological innovations emerged. When the cost of movement over time and space rose sharply in the 1970s, the deconcentration of population nevertheless continued because, by that time, jobs and market outlets (industrial parks and shopping malls), recreational facilities, and utilities had also expanded well into the urban periphery (Berry and Kasarda 1977, Edmonston and Guterbock 1984). Thus, in the face of altered social and economic conditions, the human ecological paradigm continues to be a reliable guide for research on population distribution and redistribution. The reason, in part, is due to the conceptualization of space as a time-cost variable. What organized populations seek to minimize is not *distance* between interdependent enitities, but the cost in time, effort, and other resources required for regular interaction (Stephan and McMullin 1981).

Another crucial aspect of intraurban population distribution in the US is residential segregation by race and ethnicity. As mentioned above, this topic is addressed in detail later in this volume. However, a brief discussion is in order here because it is demographic analysis that has most fully documented segregation, and a substantial portion of the explanation for these findings has been provided by human ecological theory. A prime example is seen in the work of Massey and colleagues who, over many years, have traced the sharp separation of African Americans from whites (and the lower levels of separation of Latinos and Asians from whites), taking into account variation in socioeconomic status, nativity, and other factors (Massey 1979, Massey and Denton 1989, 1993, Farley and Frey 1994). Based on an examination of segregation in the US and five other nations, Massey concluded that 'the operation of common processes of *ethnic* concentration and dispersal are well-summarized by the ecological model' (Massey 1985, p. 315; emphasis added), especially as the model pertains to chain migration, invasion, and succession of populations, the urban economy, and the housing market. Although human ecological theory is much less helpful in accounting for black–white segregation, Massey and Eggers (1990) have usefully addressed this phenomenon in research on 'the ecology of inequality.'

5.2 *Interurban Systems*: *National and World Patterns*

A useful point of departure for many demographers interested in *intermetropolitan* organization has been the classification of cities according to horizontal and vertical dimensions. The horizontal dimension refers to functional specialization of cities in various goods and services at various stages of production for the market, as operationalized in terms of types of industrial activities (Duncan et al. 1960, Frisbie and Kasarda 1988). The vertical dimension refers to the level of dominance exercised by cities in a metropolitan hierarchy as measured by performance of coordinative functions, including financial services and organization of the market (Duncan et al. 1960, Eberstein and Frisbie 1982, Wanner 1977) on a scale that may be regional, national, or international in scope (Frisbie and Kasarda 1988, Wilson 1984).

Moving down the ladder of abstraction leads to a crucial hypothesis, viz., that a positive association will exist between the performance of higher-order functions and extensiveness of involvement in the urban web of interdependence. An empirical test (Eberstein and Frisbie 1982), using data on 171 US urban centers, with metropolitan function defined as performance of financial, commercial, administrative, and distributive activities and extensiveness of interdependence measured in terms of volume and variety of trade flows and number of exchange linkages among urban centers, provided considerable support for this hypothesis. In a study of the world system of cities, Meyer concluded that '(t)he hypotheses of ecological dominance were confirmed' (1986, p. 553). Specifically, Meyer found that, with a focus on the key functions of banking and finance, world core cities (e.g., New York, London, Tokyo) 'dominate the peripheral metropolises of South America, and within the core the upper level metropolises exert even greater dominance than the lower level metropolises' (1986, p. 553). In addition to the general support provided for ecological theory, such findings reinforce the social demographic point that 'while all metropolises are large cities, not all large cities are metropolises. Population size is a concomitant; function is the keynote' (Vance and Sutker 1954, p. 115).

6. *Migration*

'Change without movement is impossible' (Hawley 1950, p. 324). Based on this tenet, human ecology views migration (whether within or across national boundaries) as a means through which something approaching a balance between population size and life chances may be *temporarily* achieved. Many of the most fundamental concepts employed in migration research are rooted in human ecological theory, including the recognition that, because migration involves a destination as well as a place of origin, it is necessary to consider both 'push' and 'pull' factors. Recently, human ecological models, which also include population size and distances between origin and destination as predictors, have been able to account for well over half the variation in migration streams of interstate migration in the US (Poston and Mao 1996) and interprovincial migration in China (Poston and Mao 1998). The ecological view of the push of 'overpopulation' as an impetus to migration refers not only to an excess of population to land, food, or some other natural resource, but more generally to availability of ecological niches in the form of job opportunities, especially as these are generated by the movement of capital (Hawley 1950).

Another contribution is seen in the notion of 'chain migration,' a phenomenon to which classical ecologists called attention. Chain migration means that 'migrants do not select destinations randomly, but follow social networks … to specific jobs in particular neighborhoods of selected cities' (Massey 1985, p. 318). The concept has enhanced our understanding of how residential segregation occurs and of how migrants adapt at destination through drawing on 'social capital' provided by co-ethnics (Massey 1985, 1991).

Clearly, the human ecological perspective must be supplemented by other theories of migration (Portes and Fernandez-Kelly 1989). One problem with the 'push—pull' model is that it cannot explain, '(g)iven the same set of expelling forces and factors of attraction, why is it that some individuals leave while others stay' (Portes 1991, p. 76). This weakness is inherent in the macrolevel approach of human ecology. Microlevel studies essentially seek an answer to the question 'Who moves and why?' By contrast, for human ecological studies of migration, the central question is 'Where do people go and why?'

While ecological theories of migration involve much more than a simple 'push–pull' hypothesis, there is, nevertheless, a certain tendency to neglect population movements that are forced or 'impelled' by political agents at origin (Petersen 1958). An analogous gap is evident at destination due to the lack of attention paid by ecologists to the impact of immigration policies instituted by receiving countries seeking to restrict, and/or influence the composition of, immigration flows (Freeman and Bean 1997). Further, despite the importance attributed by Hawley to capital flows as a determinant of immigration (1950, p. 330), research in human ecology seems to have failed to appreciate fully the importance of the penetration of capital for the creation of economic imbalances that stimulate immigration (Portes and Fernandez-Kelly 1989).

The theoretical contributions of human ecology to this line of research did not cease with the appearance of Human Ecology. Hawley has extended his own ideas concerning the spatial movement and redistribution of population, particularly with respect to urban-oriented migration (1971, 1986). More recently,

as part of a comprehensive theory of 'assembling of human populations' that involves geopolitical as well as ecological processes, Turner has set forth a set of propositions that envisions the rate of net immigration as 'a positive and additive function of: (a) the level of transportation and communication technologies, (b) the rate and extent of contact with external populations, (c) the differentiation as well as volume and velocity of markets, (d) the diversity of the population, and (e) the size of population settlements' (Turner 1994, p. 88). Coupled with the notions of chain migration and population flows preceded by capital flows, Turner's formulation seems highly pertinent to many of the international population flows that have characterized the twentieth century.

7. *Summary*

Contemporary human ecology has sustained and helped extend the theoretical foundation of macrolevel demography. It has also contributed in numerous ways to the understanding of specific demographic phenomena, as illustrated by reference to research on population growth, urban form and process, and migration, with brief attention given to residential segregation by race and ethnicity. While other examples could have been employed, it is palpable that human ecology provides a paradigm that, in spite of certain weaknesses and oversights, greatly facilitates comprehension of how populations grow and distribute themselves within, and adapt to, the natural and social environments.

Human Evolutionary Genetics

Human evolutionary genetics is the inference of human history and evolution through the study of genetic variation. While much biological variation among humans is readily observable, variation at the DNA level typically is hidden. Only in the last decades of the twentieth century, with the development of molecular biological techniques, has this variation become detectable. The hidden patterns of human genetic variation have been shaped by events and processes of the past. For instance, the differing long-term census sizes of the human and chimpanzee species have led to dramatically different levels of genetic diversity within the two species. Chimpanzees are more genetically diverse, indicating that the species has undergone less severe bottlenecks than has the human species. While genetic data may not indicate why the human species went through a bottleneck, they provide at least a partial solution to the puzzle that is human evolutionary history.

The field of human evolutionary genetics is built on the premise that one can infer evolutionary history through the analysis of human genetic variation in the context of relevant theory and nongenetic data. Patterns of genetic variation are considered to be the outcome of a set of processes that can be modeled, primarily according to population genetics and molecular evolutionary theory. The goal is to 'undo' the process, in a sense, in order to infer the past. The extent to which nongenetic data are incorporated, either explicitly or implicitly, cannot be overstated. Geographic, linguistic, archaeological, demographic, historical, and climatological data, along with findings from other areas in biology, are incorporated to varying degrees as human evolutionary geneticists draw conclusions from the genetic data.

1. Two Directions within Human Evolutionary Genetics

The study of genetic variation provides two categories of insight into human history and evolution. Each category reflects an emphasis on one set of evolutionary processes. While the pattern of variation of some DNA segments may reflect both sets of processes, one set is often presumed to have predominated.

1.1 Phenotypic Evolution

A longstanding focus of human evolutionary genetics is phenotypic evolution, including changes in morphology, physiology, and behavior. By comparing patterns of genetic variation of humans and closely related species, for example, researchers can infer the processes that led to the current human phenotype (to the extent that this phenotype has an inherited genetic basis). Also included in this category is the study of the evolution of susceptibility to disease. To date, most findings regarding phenotypic evolution have been in this area. The more general question of what, at the DNA level, distinguishes humans from other species has only recently reached the forefront of research in human evolutionary genetics but promises to be an exciting research direction. Critical in this area of research is an understanding of the relationship between the variation at the DNA level and the variation at the phenotypic level.

1.2 Population Processes and Events

A second category, exemplified by the human–chimpanzee comparison above, includes population processes and events. Researchers attempt to infer, for example, population sizes of the past, rates of migration between groups, and the timing of population movements. This was a primary focus of the field during the latter half of the twentieth century, and remains so into this century. A central question has been the timing and location of the origin of anatomically modern humans.

2. 'Population' and 'Group'

Essential to the practice of human evolutionary genetics are definitions of the terms 'population' and 'group.' The less precisely defined term, 'group,' is used here to mean any collection of individuals. In a theoretical framework, the term 'population' is defined very precisely, as a set of individuals constituting a mating pool. All individuals of the appropriate sex in the population are considered to be equally available as potential mates. Groups of humans rarely, if ever, fit this definition of a population. The boundary between one population and another is obscure. In practice, therefore, human evolutionary geneticists delineate populations along linguistic, geographic, sociopolitical, and/or cultural boundaries. A population might include, for example, all speakers of a particular Bantu language, all inhabitants of a river valley in Italy, or all members of a caste group in India.

3. 'DNA Segment'

The term 'DNA segment' is defined here as any length of DNA that is passed intact (without recombination of paternal and maternal DNA) from parent to child. Under this definition, any single nucleotide constitutes a DNA segment, as does the entire non-recombining portion of the Y chromosome. The entire mitochondrial (mt) DNA genome can also be considered an independently evolving DNA segment. Essential to this definition is the consistency of history across the nucleotides of a DNA segment. That is, without recombination, all nucleotides of a given individual's DNA segment have been inherited via the same set of ancestors (e.g., father, paternal grandfather, etc., for the non-recombining portion of the Y chromosome). Success in inferring human evolutionary history depends in part on the extent to which we can infer the history of a particular DNA segment. It also depends on the number of independently-evolving DNA segments studied, as discussed below.

While there are, as exemplified above, stretches of the human genomes (nuclear and mitochondrial) that fit the above definition of a DNA segment, most stretches of the nuclear genome have the potential to undergo recombination. When human evolutionary geneticists analyze DNA sequences such as the Human Leukocyte Antigen (HLA) region on chromosome 6, they must either assume that recombination has occurred rarely enough to be ignored, or bring recombination into their analytical framework.

4. Summarizing Genetic Variation

In summarizing genetic variation, initially researchers count the number of copies of each genetic variant in each group under study. For instance, frequencies of the variants A, B, and O (also called alleles) of the ABO blood group system, one of the earliest polymorphic (variable) genetic systems studied, have been estimated for thousands of human groups around the world.

4.1 Within Group Genetic Diversity

Gene diversity (heterozygosity), defined as the chance that two DNA segments drawn randomly from a

group are different, summarizes within-group variation and is estimated from allele frequencies. Other measures of diversity take into account additional information, such as the number of differences between two DNA segments (nucleotide diversity), or the total number of variable positions along a DNA segment (number of segregating sites), within a group. Molecular evolution and population genetic models allow the interpretation of such diversity estimates in terms of mutation rates, population size changes, natural selection, and migration.

4.2 Among and Between Group Diversity

Human evolutionary geneticists often condense information regarding the genetic variation among a set of human groups into a single measure, typically called F_{ST} (Hartl and Clark 2000). Estimates of F_{ST} and similar statistics lie behind the oft-mentioned finding that the greatest proportion of the total genetic variation in the human species lies within human groups rather than among them. This has been interpreted as evidence for a relative lack of isolation among human groups. While F_{ST} summarizes variation among groups, genetic distances summarize the genetic difference between a pair of populations (Hartl and Clark 2000). Relatively small genetic distances are considered to be evidence that two groups have been less isolated from one another than have other pairs of groups. Differences in population sizes, however, strongly influence estimates of genetic distance.

5. Patterns of Variation for Different Segments of the Human Genome Evolve Independently

At each segment of the human genome, variation is introduced through mutation and subsequently modified through natural selection, random genetic drift, and gene flow between groups. The current pattern of variation of each such segment tells a story. Closely linked segments (those near one another on a chromosome that undergoes recombination, or on the same non-recombining chromosome) are likely to tell a similar story, at least going back a short time. In general, however, segments of the human genome evolve independently and therefore have different histories. The most recent common ancestor (MRCA) of all contemporary representatives of a particular DNA segment (e.g., the non-recombining portion of the Y chromosome) existed in a particular place at a particular point in time. The MRCA of another, independently evolving DNA segment (e.g., the mitochondrial genome) is likely to have existed in quite a different place, at a different point in time.

In the absence of natural selection, the pattern of variation at a particular segment reflects population sizes and movements of people. Even if each DNA segment evolves independently and therefore has its own history, population size and migration influence the variation at all segments of the biparentally inherited parts of the genome similarly. Human evolutionary geneticists, therefore, combine the information from multiple DNA segments to draw conclusions regarding population processes. This consideration of multiple gene histories increases the robustness of conclusions (Mountain 1998).

An important consideration is the rate of mutation at each genomic location. DNA repair mechanisms that influence the rate of mutation differ between nuclear and mitochondrial DNA. Furthermore, DNA segments that include repeated elements (e.g., CACACACACACA) tend to mutate more rapidly than do nonrepetitive segments. Indeed, even within a short DNA segment of one hundred nucleotides, mutation rates may vary by an order of magnitude. The rate of mutation strongly influences the time depth over which a DNA segment is informative. A slowly mutating segment, for instance, will be uninformative over a short timescale. Mutation rates are very difficult to measure or estimate, primarily because mutation typically is rare (usually far fewer than 1 mutation per 10,000 nucleotide sites per generation).

With respect to gene flow, it is important to distinguish between interspecific and intraspecific questions regarding history and evolution. For questions regarding multiple species (e.g., the Hominoids), it is typically assumed that gene flow between species is essentially nonexistent. One consequence of a lack of exchange between groups is a greater chance of observing fixed genetic differences. That is, all individuals of one group are of one genetic type, while all individuals of another group are of a different type. Intraspecific questions must be approached differently in that gene flow may have occurred between groups below the species level. The current paucity of fixed differences between human populations reflects, among other factors, a great deal of genetic exchange between populations. There is a great deal of debate regarding the precise nature of genetic exchange between human populations. Migration models typically include a constant rate of gene flow over time. While such a model is likely to apply to human history at some level, more appropriate models include changing rates of gene flow and the possibility of rare but influential major migration events (Fix 1999).

When natural selection has a stronger influence on genetic variation than random genetic drift, the pattern of variation within and among groups is affected. Natural selection has clearly played a strong role in generating human genetic variation, especially in constraining the observable variation. While an environmental factor such as average temperature may influence variation at a number of loci simultaneously, and in a similar direction, other factors may influence only one or two loci. This provides one

way of distinguishing between a model of natural selection and a model involving population processes alone; the latter are expected to influence all loci, while environmental factors influence only a subset. Incorporating natural selection in addition to population processes into evolutionary models greatly increases the total number of models under consideration, so that demonstrating the impact of positive natural selection (i.e., new alleles arise within an individual and provide that individual with a selective advantage over other individuals) is a serious challenge. One thoroughly investigated case of natural selection influencing human genetic variation is that of the rise of lactose tolerance in adults (Durham 1991).

6. *Development of the Field*

As currently practiced, research in human evolutionary genetics builds upon over a century of the development of a theoretical framework, of technical tools (data analysis and biological), and of collections of data. Prior to 1900 there was essentially no research in the realm of human evolutionary genetics. The latter half of the nineteenth century was critical, however, in that C. Darwin, G. Mendel, and their contemporaries provided the basis for a theoretical framework with an emphasis on variation and natural selection. This continued into the twentieth century with the classic work of G. H. Hardy and W. Weinberg in 1908 (Provine 1971). Independently, they described the simple but elegant relationship between the frequencies of an allele and the frequencies of resulting genotypes (in a population, with individuals mating at random with respect to genotype).

6.1 *Development of Tools and Theory: 1900–50*

The first half of the twentieth century saw the development of some of the essential elements in the field—technical tools and population genetic theory. Serological (blood typing) techniques, developed by 1900, made possible the genotyping of the ABO locus and led to a decrease in the risk associated with blood transfusions. Initial studies of the ABO locus focused on the variation among United States' soldiers. The resulting data are recognized as the first population data for what are now called 'classical genetic markers': Blood groups, and protein and enzyme polymorphisms. The discovery of blood groups and protein polymorphisms continued slowly during this period.

Other dramatic developments relevant to the field of human evolutionary genetics prior to 1950 lay in the area of population genetic theory, 'the quantitative synthesis of Mendelism and Darwinism' (Provine 1971, p. 129). As early as the 1920s Sewall Wright, Ronald A. Fisher, and J. B. S. Haldane were publishing in the field. Fisher's *The Genetical Theory of Natural Selection* (1930), Wright's 'Evolution in Mendelian Populations' (1931) and Haldane's *The Causes of Evolution* (1932) are part of a proliferation of theoretical work of this period. They were joined by Theodosius Dobzhansky, whose *Genetics and the Origins of Species* (1937) was just one of several major contributions. Together, these authors outlined the theory behind the roles of natural selection, mutation, migration, and random genetic drift in the genetic evolution of populations (see Provine 1971, for an accessible history of the origins of theoretical population genetics). These theoreticians continued contributing well into the second half of the century.

By 1950, a number of classical genetic markers had been studied across human populations (Cavalli-Sforza and Bodmer 1971). Variation within the Rh genetic system, discovered in 1939, was considered in light of population genetic theory, as researchers attempted to explain the existence of alleles that are clearly deleterious to individuals under certain conditions. While studies often focused on the health impact of genetic variation, there was also an anthropological component: Researchers sought to measure and explain the genetic differences among human groups. The elevated frequency of Rh − individuals among Basques, for instance, was initially seen as evidence that they were descendents of the earliest modern humans in Europe. In 1948, Linus Pauling and colleagues described the role of the different forms of hemoglobin in sickle cell anemia, developing a revolutionary technique called electrophoresis to distinguish the different forms. At about the same time, J. B. S. Haldane put forth a hypothesis to explain the high frequency of another hemoglobin disorder, alpha thalassemia. He suggested that the blood cells of individuals heterozygous (having two different alleles) at this locus were more resistant to attack by malarial protozoa. This hypothesis was subsequently extended to sickle-cell disease. The story of the advantage of the sickle cell allele in malarial regions remains one of the most convincing examples of the population genetic phenomenon known as heterozygote advantage. For a succinct summary of the research see Durham (1991).

6.2 *Development of the Field: 1950–75*

The third quarter of the twentieth century saw rapid development in several dimensions of human evolutionary genetics. In the mid-1950s, Mourant published his first *Distributions of Human Blood Groups* (1954) with tables of population frequencies for nine blood groups and the sickle cell trait. In the mid 1960s, Harris, Hubby, and R. Lewontin (see Lewontin 1974, for references) discovered that a large fraction of

proteins show variation within a species. This discovery led to a dramatic increase in the number of informative polymorphic systems typed across human populations: by the early 1970s, Cavalli-Sforza and Bodmer (1971) list 27 such systems. In 1972 Lewontin (1972) published a seminal article concluding that most human genetic variation is found within local human populations. Remarkably, today's more sophisticated techniques and larger data sets consistently confirm this original finding.

A number of research groups carried out detailed studies of nonWestern populations of particular interest to anthropologists at the time. J. Neel and colleagues focused on South American populations, particularly the Yanomama of southern Venezuela, beginning in the 1960s. They were surprised by the extent of genetic differentiation between Yanomama villages, attributing this to the small size of groups founding the villages. For details of this and other regional studies conducted during the 1960s, see Crawford and Workman (1973).

During this period new numerical methods, phylogenetic methods, and computer simulation were introduced and were immediately applied to the burgeoning set of data on classical genetic markers. In the early 1960s, L. Cavalli-Sforza and A. Edwards developed several methods for generating trees from population genetic data, and applied these to data for five blood groups for 15 human populations from around the world. While their initial results are not entirely consistent with results from larger, subsequent data sets, many of the features of that initial tree can be found in recent analyses as well. One surprising finding was that genetic and anthropometric traits (physical dimensions) gave very different pictures of differentiation among human groups. While anthropometric traits indicated a similarity between Africans and Australians, genetic traits (blood groups) indicated then, and still do, that these geographically distant populations are genetically distant as well.

Meanwhile theoretical population geneticists, particularly P. A. P. Moran and his students, as well as M. Kimura, continued to extend and develop models relevant to the field of human evolutionary genetics (Ewens 1979). In the context of new understanding about DNA and mutation, Kimura (1969) argued that most mutations, or variants, found in living individuals provide neither a survival/reproductive disadvantage nor advantage to the individuals whose genomes include these mutations. Instead, he claimed, these mutations are neutral, or nearly so. If most variation is neutral, then patterns of variation are to be interpreted in terms of population history rather than in terms of natural selection. During this period, statistical methods were developed to test the null hypothesis of no natural selection. The subsequent finding that the null hypothesis was difficult to reject (Lewontin 1974) had a direct impact on the field of human evolutionary genetics. It reinforced the idea held by some geneticists that random genetic drift (random changes in allele frequencies over time) plays an important role in microevolution (see Kimura 1983, for discussion of controversy). While drift was certainly recognized as a powerful evolutionary force prior to Kimura's work, his 'Neutral Theory' of molecular evolution combined with the results of tests for natural selection led to a pendulum swing, with increased emphasis on drift (Weiss and Buchanan 2000). This was particularly the case for recently derived variation such as that found within the human species.

A number of research developments in biology, such as the discovery of the structure of DNA by J. Watson and F. Crick in 1953, had a significant impact on the field only much later, after DNA sequencing became sufficiently routine for population studies. The development of the clarifying concepts of cladistics by W. Hennig during the 1950s and 1960s had a much more immediate impact within systematics than within human evolutionary genetics. Nonetheless, Hennig's work has clearly had an influence in recent years, as phylogenetic methods using parsimony criteria have been applied to human DNA sequence data. In 1960, L. Pauling and E. Zuckerkandl introduced the concept of mutations occurring regularly enough at a particular nucleotide site to be considered 'clock-like.' To the extent that evolution at the molecular level is clock-like, researchers can infer dates, at least relative dates, given the number of mutational differences between DNA sequences.

6.3 Development of the Field: 1975–90

By the early 1980s, new techniques for assessing genetic variation supplemented serological and protein typing. Restriction enzymes were used to cut DNA segments at very precise locations. The sizes of the resulting DNA fragments varied depending on the underlying DNA sequence of an individual. Gel electrophoresis, introduced much earlier (1948), enabled researchers to compare and estimate fragment sizes. This approach led to an explosion in the number of known human polymorphisms during the 1980s. These were initially ascertained for medical genetic research (in the search for genes associated with disease), but were immediately recognized as valuable for human evolutionary genetics research. While thousands of polymorphisms were discovered, only a few hundred were actually studied in a geographically broad set of human populations.

During the 1980s DNA sequencing began replacing restriction analysis as the tool of choice within human evolutionary genetics. The initial focus was on the most highly variable regions of the mitochondrial genome, with its large number of copies per cell. The comparison of mtDNA sequences from numerous individuals throughout the world brought public

attention to the field. The public was captivated by the notion of 'the mother of us all,' as the mtDNA ancestor was labeled. Many people were also surprised by the interpretations of the patterns of mtDNA variation: That the common ancestors of living members of the human species lived relatively recently (less than 200,000 years ago rather than 1–2 million years ago (Klein 1999)) and that these ancestors probably lived in Africa.

7. *Human Evolutionary Genetics at the Turn of the Millennium: Population Processes and Events*

7.1 *Human Genome Project*

The rapid development of human evolutionary genetics over the final decade of the twentieth century owes a great deal to the Human Genome Project. Much of the technology developed under the auspices of that project (e.g., improved speed and accuracy of DNA sequencing methods) is currently applied in the field. In 1991, a group of human evolutionary geneticists led by L. Cavalli-Sforza proposed that the Human Genome Project be extended to include consideration of variation among individuals. Almost immediately, the proposal encountered criticism from groups concerned that geneticists might exploit individuals contributing DNA samples. Nonetheless, a subsequent Human Genome Project plan did include consideration of variation across individuals as a major goal. New methods of detecting variation among individuals were developed. The result is hundreds of thousands of nucleotide sites known to be polymorphic in humans across the entire human genome. Very few, however, have been studied in a broad set of human populations.

7.2 *DNA of Ancient Peoples*

Under some conditions (e.g., low temperature, aridity) DNA persists relatively intact within bones and teeth for thousands, if not hundreds of thousands, of years (Wayne et al. 1999). During the 1980s human evolutionary geneticists began to take advantage of this preservation of genetic information of the past. DNA from the bones of Neanderthal specimens, for example, has been compared with that of living humans in order to address the question of whether Neanderthals and anatomically modern humans interbred on a large scale within the last 100,000 years. The DNA from early anatomically modern humans promises to provide even further insight into human evolution during this time period (Relethford 2001). With respect to more recent human evolution, ancient DNA of Native Americans living prior to 500 years ago has demonstrated no evidence of a dramatic loss of genetic variation in the intervening period, despite a dramatic reduction in the number of Native Americans (O'Rourke et al. 2000).

7.3 *DNA of Living Peoples: Inferences Across a Range of Time Scales*

While the DNA of ancient peoples has great potential to provide insight into human evolution, the DNA of extant peoples has been studied much more extensively (Cavalli-Sforza et al. 1994). The DNA of living people retains the signatures of events and processes at various time depths ranging from hundreds of thousands of years down to tens of years. Autosomal, Y chromosomal, and mtDNA of living people has shed light, for instance, on the peopling of Europe over the last 40,000 years. Researchers have estimated the relative contributions of Paleolithic and Neolithic Europeans to the present-day European gene pool. Independently evolving segments of the human genome are consistent in supporting the hypothesis of a relatively large contribution by Paleolithic Europeans to today's European gene pool, while Neolithic peoples from the Near East appear to have contributed roughly a quarter of that gene pool (Lell and Wallace 2000).

Two examples illustrate the potential for making inferences on a shorter time scale (a few thousand years at most). The social structure of the Hindu caste system, for instance, has been investigated using a combination of Y chromosome and mtDNA. Human evolutionary geneticists have compared the relative rates of male and female movement between castes, concluding that the caste system is driven by the social mobility of women (Bamshad et al. 1998). As a second example, oral traditions have been examined in light of DNA variation. According to oral history, the Lemba, a Bantu-speaking people of southern Africa, descend from Jews who moved from the Middle East to Yemen and then to southern Africa within the last 2,700 years. The finding that Lemba Y chromosomes are similar to those common amongst Jews and rare amongst the Lemba's African neighbors supports this tradition (Owens and King 1999).

7.4 *New Theoretical Tools*

While much of the population genetic theory and many of the data analysis tools relevant to human evolutionary genetics were developed prior to the 1990s, valuable new tools have been introduced more recently. Among these are Markov Chain Monte Carlo (MCMC) methods (see, for example, Griffiths and Tavare 1995), and coalescent-based approaches (Kingman 1982). MCMC methods make possible

estimation of effective population size, population growth rate, migration rate, and mutation rate. The coalescent approach to inference involves considering the history, or genealogy, of a sample of present-day genes. The approach has been most valuable in efforts to date events of gene histories such as the age of the MRCA of all human Y chromosomes (Thomson et al. 2000). Most applications of the genealogical approach have been in the context of lengthy, non-recombining segments of the genome (i.e., mtDNA and the non-recombining portion of the Y chromosome). A major goal in the field today is to apply the same approach to a large number of segments of the autosomes and X chromosome.

8. *Human Evolutionary Genetics at the Turn of the Millennium: Phenotypic Evolution*

For an unknown number of segments of the human genome, current variation among human beings or among primates reflects the impact of natural selection. In these cases, while population processes and events have played a role, differences in fitness between individuals with different alleles have had greater influence. The most readily detected evidence of selection is in the context of disease, as exemplified above in the case of sickle cell anemia, malaria, and the hemoglobin genes. The field of human evolutionary genetics overlaps with medical genetics in that researchers in both fields seek to understand the origins of any genetic variation that appears to influence disease. The history of the gene associated with cystic fibrosis, for example, has been explored extensively.

A current focus of human evolutionary genetics is phenotypic traits other than disease, such as locomotion, dentition, and skin color (Weiss and Buchanan 2000). While little is known about the genetic diversity underlying skin color, variation at one gene, the melanocortin-stimulating hormone receptor gene, is known to be associated with red hair and fair skin that burns easily. Genetic diversity at this locus is significantly higher than the average nucleotide diversity in human populations and is likely to be an adaptive response to variation in environmental factors such as the availability of sunlight (Owens and King 1999).

Recently, researchers within human evolutionary genetics have begun focusing their attention upon the question, 'What makes us human?' Primate evolutionary geneticist Morris Goodman (1999) and others have argued for a 'Human Genome Evolution Project.' The goal is to identify features unique to the human genome that influence such traits as cognition, the form of the hind limb, and susceptibility to disease. There are approximately 40 million nucleotide differences between the human and chimpanzee genomes amongst the roughly 2×10^9 base pairs of non-repetitive DNA. While most of these DNA level differences appear to confer no difference at the phenotypic level, a subset clearly does. The challenge is to identify that subset.

Known differences between humans and chimpanzees include chromosomal inversions and fusions, gene duplications, and repetitive element insertions (Varki 2000). Changes in the regulation of gene expression, however, are expected to be a more common source of phenotypic change (Varki 2000, Weiss and Buchanan 2000). Goodman and colleagues have described one example, wherein γ globin genes went from being expressed only within the embryo to being expressed primarily during the fetal stage. This change correlates with an evolutionary trend towards prolonged fetal life in the anthropoid primates (Goodman 1999). The search for other such changes is likely to occupy human evolutionary geneticists for the foreseeable future.

9. *The Human Evolution Puzzle: Genetics Provides Some of the Pieces*

The study of human evolution takes place within a broad range of academic disciplines. These include the fields of paleoanthropology and archaeology (Klein 1999), as well as such seemingly disparate fields as linguistics, developmental biology (Weiss and Buchanan 2000) and paleoclimatology (Hewitt 2000). Only within the context of findings in these fields can the study of genetic variation provide insight into some of the many details that constitute the evolutionary history of the human species. Human evolutionary geneticists face an exciting challenge as they attempt to integrate their findings regarding human evolution with those of counterparts in these linked disciplines.

J. L. Mountain

Human Genome Diversity and its Value

1. Introduction

The era of modern genetics began with the rediscovery of Mendel's laws in 1900. However, long before this rediscovery, Charles Darwin (1859) recognized that variation in characteristics among individuals provided the basis of origin of species. Evolutionary biologists and population geneticists have long been interested in studying such variations, especially those that have genetic bases, and their origins and maintenance. Genomic diversity of a population is the raw material for its evolution by natural selection. Genomic diversity of a population can be measured in several ways. The most commonly used measure is the probability that two genes at any particular position of the chromosomes chosen randomly from the population are different. Of course, it is not practically possible to choose genes, since at any position of the chromosomes, two genes remain in combination in an individual. The above probability is equivalent to the probability that if an individual is drawn at random, this individual will possess a combination of two different genes at the chromosomal location under consideration. The different gene variants at any chromosomal location (locus) are called alleles. The combination of two alleles at a locus in an individual is called the genotype of the individual. When the genotype comprises the same two identical alleles, it is said to be homozygous; otherwise, heterozygous. The higher this probability, the greater is the genomic diversity. When all individuals of a population have identical genes, this probability attains the value of zero indicating that there is no genomic diversity in the population at that locus.

1.1 The Beginning of Human Genome Diversity Studies

The fact that individuals can differ in inherited traits was first clearly established with the identification of the ABO blood group system by Landsteiner in 1900. Soon after World War I, the Hirschfelds (1919) first discovered that human populations differ in frequencies of ABO blood group types. This finding marked the beginning of human genome diversity

studies. Subsequently, the development of biochemical- and molecular-genetic techniques have provided greater understanding and more refined estimates of human genome diversity.

1.2 The Importance of Genetic Diversity

It is crucial for any population to be genetically diverse. Humans, like many other species, are susceptible to various infections, many life-threatening. There is an increasing realization from recent research that genetic factors are involved in conferring susceptibility/resistance to most such infections. If all individuals in a population were to be genetically the same, then in the event of an outbreak of a new infection, it is possible for the entire population to be easily wiped out by the infectious agent if no individual carries genes conferring resistance to this agent.

2. Human Genomic Diversity at Various Levels

The development of starch gel electrophoresis by Oliver Smithies in 1955, permitted genomic diversity to be estimated at the level of proteins. Electrophoretic surveys of a variety of serum proteins and red-cell enzymes indicated extensive polymorphism among humans (Harris 1966). He showed that about 30 percent of human proteins are polymorphic, however, the genomic diversity estimated on the basis of such polymorphisms averaged between 10 percent and 20 percent. What this means is that at loci that determine various proteins and enzymes, there is more than one allele present in roughly 30 percent of such loci, however, at these loci, only about 10–20 percent of individuals are heterozygous on the average. Since electrophoresis can only detect such genomic variation that result in electrical charge change, and since only about 25 percent of genomic changes result in charge changes of the corresponding protein molecules (Nei 1975), this technique can only detect a small fraction of genomic changes. Hence, estimates based on data of such polymorphisms necessarily provide an underestimate of the true genomic diversity. There are, however, large differences in estimated diversities using different human proteins. These differences are, in part, due to differences in the degree of functional constraint of various proteins (Nei 1987). Not all proteins are functionally equally important. Changes in genes determining such proteins that are functionally important are generally more detrimental to the individual than changes in genes determining functionally less important proteins. Random changes, known as mutations, in genes create new alleles and enhance genomic diversity. Since mutations in genes of functionally important proteins are more detrimental, the new alleles created by such mutations are quickly removed from the population by natural selection. Hence, genomic diversity is related to functional constraint.

The development of the Southern blotting technique in 1975, allowed polymorphisms to be studied directly at the DNA level. The first DNA variants using this technique were detected in the late 1970s as restriction fragment length polymorphisms (RFLPs). Such length polymorphisms are due to cleavage or noncleavage of DNA at particular sites, commonly caused by single nucleotide polymorphisms (SNPs), that are detectable using specific restriction endonucleases. RFLP data also showed significant genomic diversity in human populations. Nucleotide sequencing, however, is the most direct method to investigate genomic changes. While systematic nucleotide sequencing studies involving large segments of the human genome and a large number of individuals are just beginning, from the limited data that are already available it has been estimated that the average level of diversity per nucleotide varies between 0.0001–0.005 (see Chakravarti 1999 for a summary of recent results). Thus, in every 10,000 nucleotide positions along the human chromosomes, between 1 and 50 positions are estimated to differ between any two copies of that chromosome. This remarkable 50-fold difference in nucleotide diversity is again in part due to the fact not all regions of the genome are functionally equally important. Accumulation of mutations is tolerated in the functionally less important parts of the genome, but strongly selected against in the more important parts of the genome.

3. The Value of Human Genome Diversity in Understanding Human Evolution

With the passage of time, a population splits into subpopulations because of various cultural, economic, demographic, and ecological reasons. For example, after a period of demographic expansion of a population, subgroups of individuals may be compelled to move to another locality because of depletion of resources in the original habitat. Subsequent to this move, the original group and the newly founded subgroup may cease to have any genetic contact that is realized through exchange of mates. Generally, such subgroups are founded by a limited number of individuals, which impacts upon the genomic diversity of the subpopulation. When several such subpopulations are formed and remain isolated from one another so that individuals of one subpopulation do not exchange mates with other subpopulations, genomic diversification of the subpopulations is hastened. (Fusion of populations also occurs, but is possibly much less common that fission, especially in expanding populations.) Admixture, or the exchange of genes, increases the genomic similarity between two

populations. The primary barriers to admixture are cultural and linguistic differences and geographical distance. Thus, one expects genes, cultures, and languages to evolve in tandem. Indeed, genomic diversity depends on demographic size and history of a population. Recent advances in molecular and statistical techniques have shown, for example, that pairwise comparisons of sequence differences among people within a population can reveal past demographic patterns of the population (Slatkin and Hudson 1991, Rogers and Harpending 1992, Thomson et al. 2000).

3.1 Some Important Evolutionary Inferences

The above facts have been used to make important inferences on human evolution. By examination of worldwide human genetic variation, Cavalli-Sforza et al. (1994) have found a major concordance between language similarities and genetic affinities. Their studies have also revealed that the spread of agriculture was by human migration, rather than through the spread of customs and knowledge. The most interesting, and perhaps the most controversial, inference derived from genome diversity data has been that all anatomically modern humans evolved in a single geographical region, Africa. If one considers a segment of the genome on which the possibility of any strong effect of natural selection may be negligible, and if by comparing the nucleotide sequences of this segment in two individuals, one finds them to differ by a certain number of nucleotides, then it is possible to easily estimate the date of their common ancestor if the mutation rate (the rate at which nucleotide changes take place per year) is known and can be assumed to be constant over time. Based on nucleotide sequence data and several other lines of genetic evidence, it has been inferred that (a) modern humans are a relatively young population, (b) Africans are genetically the most diverse group of humans, (c) the largest genetic divergence among Old World populations is between Africans and non-Africans, and (d) modern humans arose in Africa between 200,000 and 100,000 years ago and dispersed throughout the Old World to replace archaic human species completely (Stoneking 1993, Nei 1995), although some geneticists (Ayala 1995) do not believe in complete replacement or even in the single-origin scenario for anatomically modern humans (Wolpoff 1999, Relethford 1995).

3.2 Human Genome Diversity Studies Can Answer Some Central Biological Questions

The nature and extent of genome diversity depend on various evolutionary forces, such as, mutation, natural selection, random genetic drift, admixture, and recombination. The relative importance of the various evolutionary forces in determining and maintaining diversities within and between human populations remains poorly understood. However, from past studies of human populations with diverse structures, it is clear that random genetic drift (genetic events dictated primarily by chance that result from the small size of local groups) and the flow of genes from one population to another through migration or mate exchange are responsible for much of the patterning within human populations. No reliable estimate exists of the fraction of the human genome which is under the direct effect of natural selection. Put differently, how much of the observed variation in the human genome has a direct bearing on the fitness of individuals is largely unknown.

With the clearer understanding of the features of the human genome that is now emerging, thanks to the Human Genome Project, it will soon become possible to answer some of these central biological questions. For this, it will be necessary to carefully partition the genome into different equivalence classes of segments based on particular features, such as function, tissue specificity, gene density, distance from chromosome centromere or telomeres, etc., and then estimating within- and between-population diversities separately for each of these classes.

4. Human Genome Diversity and Molecular Medicine

The practice of medicine today focuses on 'treatment after disease onset'; the promise of molecular medicine is 'prevention before disease onset.' The hope for this promise is that genetic bases for most diseases with be discovered as a result of the spectacular advances in molecular genetics. Genes for diseases will be mapped on chromosomes; mutations precipitating clinical conditions will be identified. These discoveries will permit delineation of genotypes that are predisposed to specific diseases. Knowledge of the genotype of an individual will allow prediction of risk to disease. Preventive measures, that will not only include lifestyle modification but also genotype-specific therapy, will be undertaken for high-risk individuals.

4.1 Genome Diversity Studies Can Lead to Gene Discovery

Genomic diversity data on human populations can be used successfully in localizing on chromosomes the genes that cause inherited disorders, identifying predisposing/susceptibility factors to various diseases, and estimating relative roles of genetic and environmental factors in disease causation. In a large population, alleles at a pair of loci generally combine randomly into possibly genetic types. Thus, in a large population, there is usually no association between loci, unless they are physically very close on the same chromosome. However, in small isolated populations

or in recently admixed populations, strong associations between alleles at different loci are expected. Put differently, in such cases genetic loci behave non-independently in a statistical sense. This phenomenon is known as linkage disequilibrium. Disequilibrium decays every generation at a rate dependent on how far apart the genes are on the chromosome, which is measured by the rate of recombination between the genes. By examining patterns of linkage disequilibrium between diseases and genomic markers, especially in small isolated populations, it is possible to map loci controlling diseases. For example, in recently admixed populations, disequilibrium can be observed over chromosomal areas as large as 5–10 cM, which is about 2–5 percent of the estimated linkage length of an average human chromosome (Morton 1991). These estimates, in turn, help identify mutations that cause various genetic disorders. Thus, genome diversity studies can lead to gene discovery.

Variations at the DNA level among individuals that occur, on an average, once in every 500–1000 base pairs (bp) along the 3 billion bp human genome can result in a wide range of susceptibility or resistance to diseases. Polymorphisms in different regions of the genome can interact among themselves and/or with the environment in conferring susceptibility/resistance. By DNA sequencing of appropriate genomic regions (e.g., those that are involved in detoxification pathway, signal transduction, etc.) in individuals exposed to various levels of pathogens and environmental toxins and correlating the information thus obtained with clinical outcomes, it is potentially possible to identify specific alleles as well as environmental exposures that precipitate disease. Genome diversity research will enable more precise identification of the interaction of genomic polymorphisms with environmental agents in disease causation. Such research can lead to implementation of public health programs for protecting susceptible populations and for targeting genetic screening to groups at greater risk to disease. Indeed, the focus is shifting from gene discovery to gene diversity.

4.2 *Risk Assessment via Genome Diversity*

One of the primary values of genome diversity research is that it will help define genetic polymorphisms and gene products that can predict development, progression, and severity of disease. While for rare diseases, single mutations with large effects are generally involved in the precipitation of disease, for common diseases, perhaps common variations in several genes are involved. These common variations singly do not significantly enhance the risk to a common disease, but jointly precipitate the disease condition. So the estimation of frequencies and effects of common genetic polymorphisms, particularly single nucleotide polymorphisms (SNPs), in defined populations, are expected to play an integral role in molecular medicine. These estimates may, one day, enable high-risk patients to be diagnosed at a very early stage of disease and be treated with effective therapies that reverse the disease process or even prevent disease from occurring. Drugs can be targeted specifically to those genotypically defined patients who will respond well to the drug with no adverse side effects.

5. *Debunking the Myth of Race*

Humankind is a reproductive community, all members of which are connected by ties of mating and parentage. Yet, any two individuals, identical twins excepted, carry different sets of genes. To systematically study this enormous genomic diversity, biologists and anthropologists have described and named complexes of organisms to identify for themselves, and to let others know, what they are talking and writing about. Thus, classifying and giving names to classes began as a convenience-tool of science. Human biologists too have named classes of populations as 'races.' For example, Garn (1965) recognized nine 'geographical races' and 32 'local races' of man. Most such racial classifications were based on visible characteristics, such as skin color, nose height, etc. Such characters are generally adaptive to environmental conditions. Further, such characters also influence mate choice. Therefore, racial differences that are recognized by such characters are really the products of natural and sexual selection. Darwin (1871) noted 'Although the existing races of man differ in many respects … yet if their whole organization be taken into consideration they are found to resemble each other closely in a multitude of points.' Studies on human genome diversity have gradually made the ineptitude of typological approaches evident to increasing majorities of anthropologists. Yet, racial classifications are often used in sociopolitical debates in which certain races are claimed to be 'genetically superior' to others. Past studies on genetic diversity have shown that there is usually much greater intra-populational genetic variation than interpopulational variation (Lewontin 1972, Nei 1975, Barbujani et al. 1997). This means that a pair of individuals from a so-called 'genetically superior race' may be genetically more different than when one of them is compared with another from a 'genetically inferior race.' This is clearly in contradiction to the notion of genetic 'superiority.' Indeed, genome diversity studies have provided further evidence that has helped debunk the myth of races. Through their analyses of data compiled from genetic studies in global populations, Cavalli-Sforza et al. (1994) have shown that frequencies of genes often form geographical gradients, which make the task of drawing lines on a map to divide the regions of different races nearly impossible. Thus, race boundaries are never sharp. Worse still, gradients of frequencies of different genes often criss-cross on a

geographical map. When boundaries of gene frequency gradients are steep, they often correspond with linguistic boundaries or other similar cultural barriers to gene mixing. Thus, observed genetic differences among populations have no relation with genetic 'superiority' or 'inferiority.' Such differences are primarily the results of natural selection, barriers to genetic intermixture and also chance effects (random genetic drift). Human genome diversity studies have been valuable in debunking the myth of race.

Human Genome Project: German Perspective

1. The Human Genome Project

The Human Genome Project differs from any previous biological or medical project in size and cost. Its ambitious goal is the deciphering (sequencing) of all 3 billion building blocks of our genetic make-up—the so-called DNA—by 2005, the identification of all genes encoded in that DNA, and the understanding of the role of these genes in health and disease. The knowledge of these genes and their function is crucial for basic biological research as well as for the improvement of prevention, diagnostics, and therapy of disease. It is the prerequisite for a targeted design of pharmaceuticals and for novel approaches like gene therapy. This knowledge poses hope to millions of affected people and contains also an immense economic potential.

The Human Genome Project was started in the USA in 1990, James Watson, the codiscoverer of the DNA structure being its first co-ordinator. It was clear from the beginning, due to the estimated cost of US $ 3 billion and the immense amount of work involved, that the Human Genome Project had to include many countries. The Human Genome Organization (HUGO), an independent international organization of genome scientists, was established to co-ordinate the duties. The US Human Genome Project started off with considerable public funding (US $ 87 million in 1990) and was soon followed by the UK and France. Between 1991 and 1996 France contributed a comprehensive genetic map of the human genome. It is noteworthy that this work was predominantly financed by private money from a patients' association. The British Wellcome Trust for its part set up the world's largest sequencing facility, the Sanger Centre. Smaller initiatives later emerged, for instance in Japan and Canada. No such activity, however, was seen in Germany until 1995. By 2001 a nearly complete 'working draft' of the human genome has been presented by the publicly funded Human Genome Project, including a significant German contribution. The complete sequence will be available in public databases some time ahead of schedule, probably by 2003. In 1998 an emerging competition to the Human Genome Project by private companies, namely by

Craig Venter's Celera, had speeded up the deciphering of the human genetic code tremendously. But the knowledge of our comprehensive genetic make-up is not considered as a benefit for mankind by everybody. Profound ethical issues are raised by the possibilities inherent in this knowledge. This had been realized by the founders of the project and therefore, about 3 percent of the budget was dedicated to exploring the ethical, legal, and social implications of the Human Genome Project. In most countries participating in the Human Genome Project, an extensive discussion took place about the opportunities and risks attached to these novel technologies. In Germany a parliamentary committee was established to elucidate the topic. But the discussion was much more polarized in Germany than in other countries.

2. *Cutting Edge Technology is Considered a Necessity for Germany's Industrialized Society*

Germany is a strongly industrialized country. Due to its lack of raw materials, its economy is heavily dependent on export-oriented manufacturing industries. To reach and maintain its high standard of living, and to survive on the world market, Germany is in permanent need of cutting-edge technologies. Traditionally Germany's strength lay in the engineering and chemical industries. Other fields like agriculture and coal mining have undergone deep structural crises and are nowadays only viable on the basis of high subsidies. This is particularly true for rural areas or areas that have been focused on one industrial branch for generations. German labor law and the strong position of German trade unions protect employees from unemployment and provide broad social protection, but on the other hand slow down structural changes. Revolutionary technical developments can give a well-developed industry an opportunity to solve structural problems and to gain new markets. During the 1970s and 1980s, progress in microelectronics and computer technology constituted such a revolution. But neither industry nor academia realized this development in time so that it was subsequently missed in Germany. During this time, future prospects for highly qualified young scientists became increasingly worse. Germany had to face a severe 'brain drain,' predominantly to the United States. The structural problems dramatically deteriorated following German reunification—the entry of the Five New *Länder* (states) of the former German Democratic Republic to the Federal Republic of Germany, which became known as 'German Disease' in the 1990s. The economic recovery—the so-called *Wirtschaftswunder*—of West Germany after World War II, often promised to East Germans after reunification by West German politicians, was not easy to repeat. The resulting increasing economic pressure led to a resumption of the debate about the pros and cons of biotechnology in general. After the end of the Cold War, other ethically controversial economic sectors such as the arms industry became less significant. Up to this time there had been no co-ordinated funding for biotechnology research, let alone any participation in the Human Genome Project, although the scientific basis was established and many technical developments pointed the way ahead. Though among a few scientists discussions on the need for genome-wide analysis had started in Germany around 1980, leading up to a proposal to sequence the entire genome of the bacteria Escherichia coli or even human chromosome 21 at the European Molecular Biology Laboratory in Heidelberg where much of the early technology had been developed, both the German scientific community, as well as funding agencies were at this point by and large not able to recognize the immense potential of genome-wide analysis.

While a large number of new powerful biotechnology companies emerged in the United States during the 1980s, recombinant pharmaceuticals had to be imported to Germany. The first version of the German Genetic Engineering Law was very restrictive and bureaucratic. It took the Frankfurt-based company Hoechst (now Aventis) years to get the approval to produce recombinant human insulin in their brand-new facilities. As a consequence, most large German pharmaceutical companies transferred their research departments to locations in the United States. Politicians realized very late the immense economic damage caused by this development. To take countermeasures two large co-ordinated research programs were started by the Federal Ministry of Research—the German Human Genome Project (DHGP) in 1995 and the BioRegio Competition in 1996.

3. *Genomic Research Against the Background of German History*

To fully understand the assessment of and the reservation about genetics in German society, it is helpful to take a closer look not only at economic aspects but also at intellectual history and the National Socialist period.

3.1 *The Idea of Eugenics*

At the beginning of the twentieth century various political and intellectual movements in search of a new order existed in Germany. As in many other countries at that time many of these were characterized by strong nationalism and/or antisemitism. Some of them had their roots in German romanticism or naturalism: movements like the *Wandervögel*—a ramblers' association and precursor of a new German youth movement expressing a strong love of nature.

This milieu, in combination with vague Darwinian ideas, ushered in the idea of improvement of the human race and prevention of its degeneration under the overwhelming influences of a modern and industrialized world: the idea of eugenics originally introduced by Galton in the 1870s. Many of these movements were infiltrated by National Socialists and forced to take the party line during the *Gleichschaltung* after the Nazis had seized power in 1933. Fragments of these simplistic ideas were soon adopted by the Nazis. When the philosopher Nietzsche talked about the 'overman,' a superior human, it was interpreted that an inferior human was the conclusive consequence. Eugenics was not a purely German affair. Many countries, including the United States, had a strong eugenics movement during that time. In none of these countries, however, was eugenics used as a justification for profound discrimination, leading to the Nuremberg Laws of 1935 and eventually the extermination of some 6 million Jews by 1945.

3.2 The Role of German Physicians and Geneticists During the National Socialist Period

The role of German physicians and geneticists during the Nazi period is complex and exceeds by far the scope of this article. It should be sufficient to illustrate their influence by some examples. After the rediscovery of Mendel's Rules many scientists were worried that mental diseases like schizophrenia or idiocy, or the mixing of the white 'race' with individuals considered to be inferior (e.g., members of ethnic groups from the former colonies) would lead to a decline of European culture. Already during the first two decades of the twentieth century, the superiority of the white race to other humans and the destruction of so-called 'life unworthy to be lived' was discussed openly even in international scientific circles. Eugen Fischer, a scientist at the University of Freiburg, published a book in 1913 in which he addressed 'the problem' of mixed marriages between white men and Hottentot women and considered the progeny of such marriages as nonviable without protection by a superior race. Many of the racist ideas of Fischer and others were ingested in the emerging National Socialist ideology at that time. In 1927 Fischer became the director of the newly founded Kaiser Wilhelm Institute (KWI) for Anthropology, Human Heredity, and Eugenics in Berlin; in 1939 he was elected president of the University of Berlin. In this latter position he was responsible for signing the dismissal notices of his Jewish colleagues. A motivation for most of the scientists was an almost paranoid anxiety of the decline of their own culture and 'race.' In many cases, personal advantages that derived from the dismissal of their Jewish colleagues might have encouraged this development. Scientists supporting the National Socialist idea of racial hygiene like Fischer, Rüdin of the KWI of Psychiatry, Hallervorden of the KWI of Brain Research, or von Verschuer, Fischer's successor as the director of the KWI for Anthropology, were welcomed by the leaders of the Nazi party. Most of the scientists involved, however, considered themselves as being apolitical. From their point of view they supported the system for the sake of science. Eugen Fischer wrote in a German newspaper: 'It is a rare and special good fortune for theoretical science to flourish at a time when the prevailing ideology welcomes it and its findings can immediately serve the policy and the state' (*Deutsche Allgemeine Zeitung*, March 28, 1943). Since most of these scientists did not have an official post in the Nazi administration and were not actively involved in the killing of people, only a few had to flee from Germany after the end of World War II. Josef Mengele, known as the 'Angel of Death' of Auschwitz, managed to escape to Brazil where he lived unmolested probably until 1979. Those who had deliberately worked with human experimental material like eyes, brains, etc., gained from concentration camps or psychiatric hospitals or had asked for this material from their coworkers, mostly avoided prosecution.

3.3 Germany Dealing with its Difficult Past

After World War II the faith of society in a detached and neutral science was profoundly disturbed. Genetics came under special suspicion because its advocates had provided 'scientific' basis for the National Socialist racial hatred. Scientific terminology had been adopted and occupied by the Nazis. As the Nobel Prize laureate Christiane Nüsslein-Volhard puts it quoting the term 'selection,' 'Scientists think of Darwin's fundamental theory of the origin of species while German society even today is reminded of the gas chambers of Auschwitz.' The reasons for this are diverse and many. Most geneticists did not differentiate themselves properly from the National Socialists. The borderline between fanatic followers and murderers like Josef Mengele, opportunists who profited from the system like Eugen Fischer and Otmar von Verschuer (who was Mengele's superior in Berlin), and those who had remained in their positions with tacit permission, remained hazy. After 1945 no genuine reappraisal of the role of physicians and geneticists during the Nazi period occurred. Directly after the war, Germany was too busy working on its economic recovery to ask questions about guilt. Many members of the intellectual elite had either emigrated or had been killed during the Nazi period. But many key proponents of the genocide reappeared in important academic positions. Otmar von Verschuer became professor of genetics at the University of Münster where in 1954 he even rose to the position of Dean of the Medical Faculty. The Kaiser Wilhelm Society was renamed Max Planck Society (MPS), and Adolf Butenandt, the Nobel Prize laureate of 1939 who was sometimes criticized for not differentiating himself clearly from the Nazi regime, became its first president.

Many of the experiments that were committed in Auschwitz and elsewhere were financially supported by the Kaiser Wilhelm Society or the Deutsche Forschungsgemeinschaft (DFG), the national German Research Council. It was, however, not before the late 1990s that DFG and MPS initiated an independent review of their own role during the NS period.

Because many natural sciences had fallen into disrepute after 1945, public discussion was completely dominated by intellectuals of the social sciences. This was in sharp contrast to the period from the turn of the century until 1933 when, for instance, physicists like Einstein, Heisenberg, and Planck were actively involved in the social and political debate, and disputes among artists, philosophers, theologians, and scientists were common. After 1945, genetics had not become common knowledge in Germany even in intellectual circles. Instead, a vague fear of genetic reductionism and determinism remained. This led Robert N. Proctor, a US historian of science, to state: 'The legacy of Nazism influences the attitudes many Germans show towards genetics today and is probably responsible for the absence of a prominent science-oriented intellectual elite. Where are the Goulds, Hawkings and Dawkins of Germany?' The polarization between social scientists and natural scientists who were mainly seen as technocrats still persists. The seizure of power by man over himself created the fear that humanity could be the first victim.

3.4 The German Human Genome Project

During the 1980s the tremendous successes of genetic engineering boosted the biotechnology industry in the USA and provided the prerequisite for the idea of the Human Genome Project. While in the US, companies like Amgen turned over more than US $ 1 billion per year, the production of recombinant pharmaceuticals was still hampered in Germany. At the same time, recombinant pharmaceuticals and vaccines had to be imported into Germany. One of the first dedicated centers for genome research in Germany, the *Genzentrum* in Munich had bulletproof windows installed in fear of an attack. The international Human Genome Project was started in 1990 without any German participation. But increasing economic pressure forced Germany to a rethinking of genome research. After a thorough investigation of the issue by a parliamentary commission, two programs of the Christian Democratic-Liberal coalition started in the mid-nineties. The BioRegio Competition aimed at exploiting the synergy of self-organization of whole regions as centers of excellence for biotechnology and was unexpectedly successful. The German Human Genome Project (DHGP), integrated into the international effort to decipher the human genome, was thematically much more focused. It was strongly industry-oriented and a special infrastructure was to guarantee the effective transfer of the knowledge gained to industry. Initial efforts to raise half of the budget from the German pharmaceutical industry failed. Subsequently, the whole budget of DM 40 million per year was granted by the Federal Ministry of Education and Research. To safeguard the interests of industry, a Patent and Licensing Agency (PLA) was established whose task was to screen the results of the projects granted within the DHGP and to guarantee a patent application if applicable. The patent is granted to the inventor at no cost. In turn, the Industry Association gets the right of first refusal on the patent.

The agreement also gave the Industry Association the right to screen the data produced in the German DNA sequencing centers—a clear infringement of the so-called Bermuda Principles—an agreement between all academic sequencing centers worldwide making all data immediately publicly available without any restrictions. The Industry Association waived their claims only after massive pressure from the international scientific community.

The DHGP has had a profound effect on the German biotechnological industry. Contrary to the expectation that the big pharmaceutical companies would exploit the scientific results, licensing of patents was sparse. Instead, many researchers preferred to start their own companies, a tendency up to then only rarely found in German academia. The success of the DHGP initiative led to Germany exceeding the United Kingdom in the number of biotech companies by the year 2000.

Initial concerns among scientists that funding of genome research would be cut after the change of government to a coalition of Social Democrats and the Green Party were groundless. Not only has the DHGP been maintained, but also a plant genome project—initiated by the prior administration—as well as a microorganism genome project were started, assisted by additional projects on bioinformatics and proteomics. In 2000, a long-expected concept document was released by the Federal Ministry of Education and Research. This paper draws up a long-term perspective for genomic research in Germany and safeguards the existence of central infrastructure units (resource centers) for genomic research. At the same time, boosted by the announcement of the draft version of the human genome, a tremendous increase in funding was approved that eventually brought Germany in line with genomic funding in countries like Japan, UK, and France.

The economic success as well as the prospects of new diagnostic and therapeutic possibilities has very much changed the German attitude towards human genetics. Medical genetics is now much more accepted than it was a few years ago. In contrast, due to concerns about health as well as to the aggressive marketing strategies of certain agrocultural biotech companies, plant genetic engineering has met with

deep disapproval in Germany. However, the fatalistic attitude in Germany towards fundamental natural sciences has somewhat changed. The former lack of discussion in society that permitted simplistic arguments to gain predominance has been overcome. The majority of the German intellectual elite has realized that an informed discussion within society is needed to solve the problems stimulated by genome sciences.

Human Genome Project: Japanese Perspective

The Japanese Human Genome Project (JHGP) was initiated in 1988. The project experienced some difficulties in the initial stages, such as scarcity of resources and the perception that genome research was not hard science. As a result the JHGP was unable to follow the specific aims of sequencing DNA of the human genome. This article explains how the JHGP adopted strategies to overcome these problems and how it became an effective contributor to the international human genome project.

1. History of the Human Genome Project in Japan

The drive toward an international approach to the Human Genome Project began in 1985. In 1988, as a response to this development and the progress of the human genome project activities in the United States and Europe (see *Human Genome Project: German Perspective*), the Japanese human genome project (JHGP) conducted a feasibility study. The study was supported by a general research grant from the Ministry of Education, Science, Sports and Culture (ESSC: MONBUSHO). As a result of this study, the research council of MONBUSHO proposed the formulation of a special human genome research grant and a five-year plan for the promotion of genomic research.

The genome research supported by this special grant had a project-like characteristic, and because of this was confronted by criticism from various sources. There was a strong belief among certain groups that this kind of project was not 'hard research' but rather mere routine work. Moreover, difficulties were experienced in relation to the scarcity of technicians skillful in this area who could support the genome researchers and also in the reluctance shown by the government and private institutions to invest heavily in a single project. As a result of these difficulties

Table 1
Mass DNA data submission to DDBJ (submitted and distributed January 1998–December 1998)

Organism	Accession number (number of entries)	Submitter (institution)
BCT (bacteria)		
Escherichia coli	ABO11548-ABO11549 (2)	Makino, K. (Osaka University)
Unidentified alpha proteobacterium	ABO11682-ABO11791 (110)	Shikano, S. (Tohoku University)
Unidentified nitrogen-fixing bacteria	ABO11841-ABO11964 (124)	Ohkuma, M. (RIKEN)[a]
Bacillus stearothermophilus	ABO20064-ABO26165 (102) ABO20234-ABO20235 (2)	Matsuura, T. (Osaka University)
Plasmid colIb-p9	ABO21078 (1)	Sampei, G. (The University of Electro-communication)
HUM (human)		
Homo sapiens	ABO14511-ABO14610 (100) ABO18254-ABO18353 (100) ABO20626-ABO20725 (100)	Ohara, O. (Kazusa DNA Research Institute)
Homo sapiens	ABO19437-ABO19441 (5)	Matsuda, F. (Kyoto University Graduate School of Medicine)

a The Institute of Physical and Chemical Research Japan. b STA, Japan.

JHGP could not follow the specific aim of sequencing the DNA of the human genome.

Instead, JHGP adopted the strategy of developing excellent genome-related research. By this strategy, JHGP successfully contributed to the construction of human genome physical maps, the development of full-length cDNA construction techniques, and the making of cDNA expression maps, leading to an enhancement of human genome research in Japan. However, JHGP was far behind the United States and Europe, particularly in the field of genetic disease analysis based on human genome mapping. More specifically, as most of the major human genome projects were still in their infancy, JHGP was behind in terms of planning rather than the research itself.

Although, for Japan, this predicament was partly due to some researchers failing to recognize the importance of the human genome project, the main reason was the failure to establish a single human genome research center coordinated by the relevant ministries and institutions. For instance, JHGP was planned independently by two ministries and a government agency. These bodies included the MONBUSHO, comprising many University researchers, the Ministry of Health and Welfare (MHW) supervising medical activities, and the Science and Technology Agency (STA) supporting various large-scale projects. As a result of the lack of collaboration between these government organizations, talented researchers, useful materials, and research money were unnecessarily dispersed. Moreover, because of the slow response of bioindustries to the human genome project, government agencies were unable to formulate a collaborative liaison with them in Japan.

Figure 1
Contribution of the three geographical areas to the DDBJ/EMBL/Genbank International Nucleotides Database (January 1996–January 1999)

These problems were essentially based upon the political and social infrastructures within Japan; however, in spite of these difficult situations, several success stories emerged from JHGP. For example, seven research groups in Japan successfully contributed to the completion of the *Bacillus subtilis* (*B. subtilis*) genome sequence by determining the nucleotide sequences of its shared region of 1.3 Mb. The complete genome sequence of *Synechocystis sp.* was determined by the Kazusa DNA Research Institute, which was established by Chiba prefecture and industries. The Ministry of Agriculture, Forestry and Fisheries of Japan (MAFF) launched the rice cDNA project, which is currently leading international research on the rice genome. In 1998, the *Escherichia coli* (*E. coli*) genome project team in Japan successfully completed three quarters of the *E. coli* genome sequence, although the American team completed the whole *E. coli* sequence in the same year.

Genome Informatics was initiated from scratch because there were no major research activities which could act as a focal point, except the DNA databank of Japan (DDBJ) within the National Institute of Genetics (NIG). In particular, the recruitment of talented researchers, education and training of research students, installment of a computer network for genome research, and the establishment of a DNA database had to be done within a short period of time. Although these were successfully dealt with to some extent, there were still some problems to be solved such as intimate collaboration among the different institutions in charge of various bioinformatics activities.

2. *The Present Situation of the Human Genome Project in Japan*

As genome research advances internationally, there has been increasing recognition that genome research constitutes the necessary foundation for the future development of biology, medical research, and biotechnology. In particular, the necessity of establishing a large-scale genome-sequencing center has been accepted widely. However, the realization of this plan has been difficult because of budget limitations.

Since the basic law of science and technology development was passed in 1997, the budget limitations have, to some extent, disappeared under the national goal that Japan should become a country of creative science and technology. Because of this basic law, the government invested approximately $US 200 million in the genome research project in the 1998 fiscal year alone. Presently, various activities in JHGP are conducted under the initiative of governmental organizations and private industries. MONBUSHO successfully established the Center for Information Biology in NIG to support DDBJ and the newly established Human Genome Research Center in Tokyo University. The Ministry of International Trade and Industry (MITI) and the MHW coordinated a promotion business venture of genome-related enterprise and the STA created the genome science center in Yokohama. Moreover, large research grants were made to many genome research groups through various funding mechanisms. However, not all of these activities are along the lines of well-planned strategies of genome research.

The general focus of JHGP is toward the determination of large-scale genome sequences and a functional analysis of the genes that will be discovered by sequence determination. JHGP is placing more emphasis on the areas of genomic structure, function, and information. As for genome sequence determination, Kitazato University, Japan Marine Science and Technology Center, and STA and the Product Evaluation Center under MITI are pushing the genome sequencing of microorganisms by producing 122 Mb each year. In 1995, the Japanese Science and Technology Corporation initiated the human genome-sequencing project. The subgenomic segments such as HLA, immunogloblin variable, Down's syndrome, and oncogene-related regions, have been determined for about 15 Mb by Kitazato University, Cancer Institute, Keio University and Tokai University.

In total, the sequence production in Japan is about 5 Mb per year, which is one order of magnitude smaller than that of the Sanger Center in the United Kingdom and the Sequence Center at Washington University in the United States. Therefore, JHGP has great expectations of the role of the newly established Genome Science Center, which is planned to produce 30–50 Mb per year. Kazusa Research Institute is producing several Mb genome sequences of *Arabidopsis* per year.

Moreover, the genome project team supported by MAFF has a ten-year plan of sequence determination of the complete rice genome of 400 Mb, producing 20 Mb per year for the initial several years. In summary, the sequencing capacity of genomes in Japan has so far been 15–20 Mb per year. Judging from recent increases of the number of genome research groups focusing on bacteria, fungi, lower organisms, insects, and fish and the enhancement of genome research on humans and the mouse, 200 Mb sequence production per year is expected in the near future.

JHGP has a slight edge over other countries in the field of functional genomics. In particular, the Osaka University genome team was the first to analyze a cDNA expression profile of human genetic data (called 'body mapping') and other genome teams have quickly developed a full-length cDNA determination technique. Although these activities were not directly connected to a bioindustry as they are in the United States, MITI recently pushed the utilization of these technical advances to industry. Moreover, human genome diversity has become recognized as important for disease gene analysis and functional analysis. In particular, the so-called 'complex diseases' such as multi component diseases are becoming important targets of the human genome diversity project (see *Human Genome Diversity and its Value*). This project will require a lot of genetic data concerning the Japanese population, in particular a large amount of polymorphism data from several thousand people (see *Race: Genetic Aspects*).

Several preliminary research projects have already started in Japan. The cDNA project of *Caenorhabditis elegans* (*C. elegans*) genome has been conducted by NIG in cooperation with the Sanger Center and Washington University. The *B. subtilius* and *E. coli* genome teams have already begun functional analysis of all genes contained in their respective organisms. Many researchers are participating in these genome projects by conducting bioinformatics research and constructing databases. Thus, JHGP has resumed its original goals in a more integrated and coordinated way.

3. The Future Challenge of the Human Genome Project in Japan

In Japan, the aim of the human genome project was redirected to not only sequence the human genome but also to include the functional analysis of genes as well as the elucidation of protein tertiary structures. Although this redirection has successfully eased various criticisms, the main focus of the human genome project has been diffused to a considerable extent, leading to an ambiguity of the Japanese contribution to the international effort of human genome sequencing. Given the expectation that human genome sequencing has been achieved mainly by the United States and Europe, the Japanese human genome project will be successful if it orients its major effort towards the promotion of functional genomics, comparative genomics, evolutionary genomics, and genomic diversity analysis, along with the development of DNA chips or microarrays.

Conducting functional genomics requires analytic technologies that are capable of dealing with a large number of genes and proteins. Toward meeting these requirements, genome researchers in Japan have started contributing to the development of differential display, DNA chips and the identification of variant DNA. In the near future, these efforts should be connected to advancement of industrial technologies to produce unique and significant methodologies useful to functional genomics.

For genome informatic research, DDBJ at CIB/NIG, the Human Genome Research Center at Tokyo University, the Chemistry Institute at Kyoto University, and other research groups are making efforts to incorporate information science into genome research, in the belief that 'genome science is virtually information science.' There is no doubt that informatic aspects are extremely important to genome research. In particular, the elucidation of gene networks will be crucial for understanding the development and evolution of organisms, and in this sense, bioinformatics will play a crucial role. Another aim of JHGP is the allocation of talented bioinformatitions and the education of students who understand both biological and information sciences. This will be an important component of the future activities of the JHPG.

Human Resource Management, Psychology of

Human resource management (HRM), as practiced in work organizations, includes five broad activities that together constitute the HRM system: staffing, retention, development, adjustment, and managing change (Cascio 1998). *Staffing* comprises the activities of (a) identifying work requirements within an organization, (b) determining the numbers of people and the skills mix necessary to do the work, and (c) recruiting, selecting, and promoting qualified candidates. *Retention* comprises the activities of (a) rewarding employees for performing their jobs effectively, (b) ensuring harmonious working relations between employees and managers, and (c) maintaining a safe, healthy work environment. *Development* is a function whose objective is to preserve and enhance employees' competence in their jobs by improving their knowledge, skills, abilities, and other characteristics; HR specialists use the term 'competencies' to refer to these items. *Adjustment* comprises activities intended to maintain compliance with the organization's HR policies (e.g., compensation, discipline), and business strategies (e.g., cost leadership). *Managing change* is an ongoing process whose objective is to enhance the ability of an organization to anticipate and respond to developments in its external and internal environments, and to enable employees at all levels to cope with the changes.

1. Responsibilities and Objectives

These activities can be carried out at the individual, work team, or larger organizational unit (e.g., department) level. Sometimes they are initiated by the organization (e.g., recruitment efforts or management development programs), and sometimes they are initiated by the individual or work team (e.g., voluntary retirement, safety improvements). It might appear that the activities of staffing, retention, development, adjustment, and managing change are the special responsibilities of the HR department. However, these responsibilities also lie within the core of every manager's job throughout any organization—and because line managers have authority (the organizationally granted right to influence the actions and behavior of the workers they manage), they have considerable impact on the ways workers actually behave. This implies two things: (a) a broad objective of HRM is to optimize the performance and productivity of all workers in an organization, and (b) a special objective of the HR department is to help line managers manage those workers more effectively. The HR department accomplishes this special objective through policy initiation and formulation, advice, service, and control in close communication and coordination with line managers.

Generally speaking, HR specialists provide the technical expertise in each area, while line managers (or, in some cases, self-directed work teams) use this expertise in order to manage people effectively. In a small business, however, line managers are responsible for both the technical and managerial aspects of HRM.

For example, in the area of retention, line managers are responsible for treating employees fairly, resolving conflicts, promoting teamwork, and providing pay increases based on merit. To help line managers do these things effectively, the HR department must devise a compensation and benefits system that employees will perceive as attractive and fair, establish merit increase guidelines that will apply across departments, and provide training and consultation to line managers on all employee relations issues, such as conflict resolution and team building.

2. The Evolution of Human Resource Management

To appreciate where the field of HRM is going, it is important to appreciate where it has come from. As it is practiced in most developed countries around the world, modern HRM has emerged from nine interrelated sources.

(a) Rapid technological change that increased the specialization of labor associated with the industrial revolution.

(b) The emergence of free collective bargaining, with constraints established for unions and for employers.

(c) The scientific management movement.

(d) Early industrial psychology.

(e) Governmental personnel practices growing out of the establishment of the Civil Service Commission in the USA.

(f) The emergence of personnel specialists and the grouping of these specialists into personnel departments.

(g) The human relations movement.

(h) The behavioral sciences.

(i) Social legislation and court decisions.

2.1 The Industrial Revolution

Three characteristics of the industrial revolution were the development of machinery, the linking of human power to the machines, and the establishment of

factories in which a large number of people were employed. The result was a tremendous increase in job specialization as well as in the amount of goods that workers could produce. 'Division of labor' became a rallying cry of this revolution.

Clearly, the industrial revolution greatly accelerated the development of business and commerce. Owners and entrepreneurs generally did quite well for themselves, but the average citizen fared poorly in comp-arison to today's workers in terms of purchasing power and working conditions. Labor was considered a commodity to be bought and sold, and the prevailing political philosophy of *laissez-faire* resulted in little action by governments to protect the lot of workers (French 1994).

2.2 The Emergence of Free Collective Bargaining

Because of the way they were abused, it was inevitable that workers would organize to protect themselves and to improve their lot in life. From the perspective of workers, the industrial revolution fostered specialization, along with the need for workers within each specialization to organize themselves against its abuses. Trade unions, also called 'labor unions,' spread rapidly, and so did the incidence of strikes (see also *Labor Unions*). For example, in 1886 employees at the McCormick Reaper Works in Chicago went on strike for an eight-hour work day (Cohen 1960). In the United States, courts generally adopted an antiunion stance until 1935. In that year the National Labor Relations Act was passed. It focused largely on labor's right to organize. It became an unfair labor practice for an employer to coerce or to restrain employees in the exercise of their rights, to dominate or interfere with a labor organization, or to refuse to bargain collectively with a legal representative of the employees. Subsequent legislation refined, broadened, and set legal limits on the scope of management and union activities. From the perspective of labor, the development of free collective bargaining and the USA labor movement created the need for what is now recognized as effective human resource management.

2.3 Scientific Management

From the perspective of management, the scientific management movement also created the need for effective HRM. Frederick Winslow Taylor was the prophet of scientific management, and the stopwatch was his 'bible' (Bell 1972). Taylor began his experiments in the steel industry in 1885. His objective was the systematic analysis and breakdown of work into its smallest mechanical elements, and then their rearrangement into the most efficient combination. In addition to the scientific study of the task itself ('time and motion' study), Taylor argued that individuals selected to do the work should be as perfectly matched physically and mentally to the demands of the job as possible, and that overqualified individuals should be excluded.

Employees should be trained carefully by supervisors (whose own work was also divided into specialties) to ensure that they perform the work exactly as specified by prior scientific analysis. In no case, however, should employees ever be called upon to work at a pace that would be detrimental to their health.

Finally, to provide an incentive for the employee to follow the detailed procedures specified (and closely supervised by line supervisors on the shop floor), Taylor felt that employees should receive an addition of between 30 and 100 percent of their ordinary wages when the task was done right and within the time limits specified. The first piece-rate incentive system had arrived.

Taylor also was interested in the social aspects of work, although he saw little good emerging from the social interaction within work groups. He felt that work groups fostered a level of individual efficiency equal to the level of the least productive worker in the group. In other words, he believed that the efficiency of the group would not be any greater than the efficiency of the least productive member. Thus Taylor tried to institute a kind of social physics into the workplace. While many of his ideas are controversial, there is no doubt that application of the principles of scientific management resulted in much higher productivity than would otherwise have been possible.

2.4 Early Industrial Psychology

In 1913, Hugo Munsterberg's book, *Psychology and Industrial Efficiency*, described experiments in selecting streetcar operators, ship's officers, and telephone switchboard operators. His contributions to human resource (or personnel) management are noteworthy for his emphasis on the analysis of jobs in terms of (a) the abilities required to do them, and (b) the development of testing devices—aptitude as well as work sample tests—that were able to forecast subsequent job performance (Munsterberg 1913).

Munsterberg's 1917 book, *Business Psychology*, included the results of questionnaires sent to hundreds of laborers. The questionnaires requested anonymous data on attitudes toward their work, their involvement in the labor movement, and their leisure activities.

Both Munsterberg and Taylor were concerned with how workers were selected for jobs, as well as with the individual worker's feelings and aspirations. Although they differed on several issues (notably, on how social structure affected productivity), Munsterberg's writings clearly suggest that he felt that the two emerging fields of personnel selection and social psychology (the study of how people affect and are affected by one another) were complementary (Landy 1992, Moskowitz 1977).

Other developments at about the same time included the use of rating sheets for interviewers, advances in checking references given by workers, and in statistical methods for estimating validity (the extent to which selection devices accurately forecast job performance). World War I accelerated the development of intelligence tests, such as the Army Alpha and the Army Beta, so that each individual could be matched more effectively with job requirements. Other kinds of psychological measures also appeared during and after World War I, such as measures of aptitude, interest, and personality.

2.5 The US Civil Service Commission

The Pendleton Act of 1883 established the US Civil Service Commission (today known as the US Office of Personnel Management). A forerunner in progressive personnel policies, the act provided that competitive examinations be administered as a basis for employment in the public service. It also provided a measure of employment security for those selected, prohibited discharge for refusing to engage in political activity, encouraged a nonpartisan approach to appointments, and mandated that a commissioner administer the act (Van Riper 1958). Perhaps the major impact of this act was to foster employment and promotion policies in the federal government based on merit. Over the years, these policies have influenced personnel practices in state and local governments as well as in private industry.

2.6 Private Industry's Approach to Personnel Management

Historians consider 1912 the approximate date of the emergence of the modern personnel department (Eilbert 1959). The term 'personnel,' with its connotation of managing people in organizations, began to appear about 1909. Between 1900 and 1920, while advances were being made in scientific management, industrial psychology, and the federal civil service, a number of personnel specialists emerged in companies such as B. F. Goodrich, National Cash Register, and Standard Oil of California. The specialists managed such areas as employment, employee welfare (financial, housing, medical, and educational), wage setting, safety, training, and health. This kind of specialization formed the basis for the organization of the modern human resources department.

2.7 The Human Relations Movement

In Chicago, in 1923, the Hawthorne Works of the Western Electric Company provided the setting for one of the most famous behavioral research efforts of all time. The purpose of the research was to study the effects of illumination on worker productivity. In one experiment, production went up when the illumination increased. In another experiment, production went up when the illumination decreased. After three years of continually inconsistent results, the researchers concluded that in a situation involving people, it was impossible to change one condition (the lighting) without affecting other variables at the same time. Employee motivation and work group morale seemed to be the really crucial factors.

The results of subsequent experiments at the Hawthorne Works by Professors Elton Mayo, Fritz Roethlisberger, and T. North Whitehead of the Harvard Business School indicated that productivity was directly related to the degree of group teamwork and cooperation. The level of teamwork and cooperation, in turn, seemed to be related to the interest of the supervisor and the researchers in the work group, the lack of coercive approaches to productivity improvement, and the participation afforded the workers in changes affecting them (Pennock 1930, Roethlisberger and Dickson 1939). In short, the researchers came to view the organization of workers as a *social system*, in contrast to Taylor's view of that organization as a *technical–economic system*.

The conviction that group behavior and workers' feelings were associated with morale and productivity characterized much of the research and theorizing in the human relations movement for the next two decades. In practice, unfortunately, many managers seemed to use human relations for the short-term purpose of manipulating workers to increase output, rather than for the long-term goal of satisfying worker needs while meeting organizational needs. Failure to find evidence that these programs made a difference in workers' satisfaction or that happy workers were productive workers helped kill this approach to HRM (Brayfield and Crockett 1955).

2.8 The Behavioral Sciences

The behavioral science approach to managing people is an outgrowth of the human relations studies, although it embraces a wider base of academic and applied disciplines and is concerned with a wider range of problems. The term *behavioral sciences* refers to the social and biological sciences concerned with the study of human behavior. Much of the knowledge of HRM and many of its practical applications have come from such behavioral science disciplines as the following:

(a) *Industrial/organizational psychology*: the study of the behavior of people at work (see *Industrial–Organizational Psychology: Science and Practice*).

(b) *Social psychology*: the study of how people affect and are affected by one another.

(c) *Organization theory*: basic philosophies about why organizations exist, how they function, how they should be designed, and how they can be effective.

(d) *Organizational behavior*: the study of the causes of individual and group behavior, and of how this knowledge can be used to make people more productive and satisfied in organizational settings.

(e) *Sociology*: the study of society, social institutions, and social relationships.

We now know that the ways people behave in organizations cannot be explained simply by human relationships. The organization itself, through its unique 'culture,' molds, constrains, and modifies human performance. The way the organization is structured, the authority attached to different positions, and job and technology requirements clearly affect behavior. Even though the present understanding of the determinants and effects of behavior is incomplete, there is a better sense of the ways in which separate influences interact with each other to affect individuals.

Another area that has exerted a considerable influence on HRM theory and practice is *general systems theory*. Systems theory has developed from such fields as biology, physics, and cybernetics (the study of mechanical–electrical communications systems and devices). It has been applied and elaborated in every behavioral science field.

2.9 Social Legislation and Court Decisions

Governments in most developed countries around the world have passed social legislation and courts have issued decisions on unfair discrimination in employment. While some countries are more progressive on these issues than others, the laws and court decisions frame national policy on equal employment opportunity (EEO). In the USA, discrimination in employment is prohibited on the basis of race, religion, national origin, gender, age, and disability. Aggrieved individuals have the right to pursue their claims in court. At the level of the organization, HRM specialists work with top managers to develop and implement EEO policies to ensure that individuals are treated fairly in all aspects of the employment relationship.

3. Growth Stages of Human Resource Management

The foundation for modern HRM rests on the factors described earlier. Beyond that, HRM as practiced in the USA developed in four stages.

3.1 File Maintenance

The first stage may be called the 'file maintenance' stage, for it typified HRM activities through the mid-1960s and the degree of emphasis on employee concerns. 'Personnel' was the responsibility of a special department. Its responsibilities included screening applicants, conducting orientation for new employees, collecting and storing personal data on each employee (e.g., date of birth, years of company service, education), planning the company picnic, and circulating memos 'whose impertinence was exceeded only by their irrelevance' (Meyer 1976).

3.2 Government Accountability

The second growth stage of HRM, the 'government accountability' stage, began soon after the Civil Rights Act of 1964 was passed. Laws governing antidiscrimination, pensions, and health and safety were enacted, federal agencies to enforce the laws were created, and court rulings affecting almost every aspect of the employment relationship were issued. All of these events accelerated the rise and importance of the HRM function. Class action lawsuits and the large financial settlements for the winning suits illustrated the costs of mismanaging people. Managers outside the HRM function began to take notice because top management let them know that ineptitude in this area would not be tolerated. Staying out of federal court became a top organizational priority. These trends also signaled the need for specialized competence in each aspect of HRM. Thus specialties began to appear in compensation and benefits, affirmative action (the promotion of minority concerns in all aspects of employment), labor relations, and training and development.

3.3 Organizational Accountability

In the late 1970s and 1980s, when many firms were struggling simply to survive, a combination of economic and political factors (high interest rates, growing international competition, shrinking US productivity growth) led to a demand for greater accountability in dollar terms of all the functional areas of business. HRM activities were no exception. Thus this third stage may be termed 'organizational accountability.' Although methods of assessing the costs and benefits of HR programs are available, they are not widely known (Cascio 2000). In addition, social trends, such as more women in the workforce, more minorities, immigrants, older workers, and poorly educated workers, accelerated the demands for improving the quality of work life, for managing cultural and ethnic diversity, and for continual training and retraining.

3.4 Strategic Partnership

In the 1990s and in the new millennium, HRM has evolved to a fourth growth stage as it assumes a central

role in the struggle of both large and small firms to gain and sustain a competitive advantage in the worldwide marketplace. This stage may be termed 'strategic partnership.' Top management looks to the HR department, as it does to line managers, to control costs, to attract and retain top talent, to enhance competitiveness, and to add value to the firm in everything it does.

4. Learning From the Past, Looking Toward the Future

As noted earlier, the field of human resource management is composed of five broad activities that together constitute the HRM system: staffing, retention, development, adjustment, and managing change. The field as it is known today has emerged from nine interrelated sources: the industrial revolution, the emergence of free collective bargaining, scientific management, early industrial psychology, governmental personnel practices growing out of the establishment of the Civil Service Commission in the USA, the emergence of personnel specialists and the grouping of these specialists into personnel departments, the human relations movement, the behavioral sciences, and social legislation and court decisions.

Since the 1950s, HRM has evolved through four growth stages: file maintenance, government accountability, organizational accountability, and strategic partnership. However, to be business partners who make genuine contributions to the success of an organization, HR professionals need to be proactive, not reactive. They must anticipate changes in the social, legal, political, and economic environments, and then facilitate effective organizational responses to them. Some of these issues include finding and keeping top talent in tight labor markets; capitalizing on the information revolution in ways that will benefit organizations, such as Internet-based recruitment and the development of interactive, company-based intranets to facilitate employee inquiries and inputs; managing the performance of geographically dispersed employees and teams (virtual teams); and providing training and development opportunities on demand. Indeed, this is the new paradigm of work: any time, anywhere, in real space or in cyberspace. HRM will contribute to the bottom-line success of organizations and to the betterment of employee welfare by developing proactive responses to the workplace challenges wrought by this new paradigm.

Human Rights, Anthropology of

Human rights constitute a field of increasing anthropological concern, not only for its substance but also for its inherent tensions. Since 1948, when the Universal Declaration of Human Rights (UDHR) was internationally accepted, anthropology has moved from an explicit opposition to the idea of a universal standard of human rights, over a more routinely skeptical attitude to a growing positive interest of both an empirical and a theoretical nature. This trend is related both to changing notions of anthropology and to the historical process of globalization. (See

Downing and Kushner 1988, and Messer 1993, and Hastrup 2001a, 2001b for overviews of the relationship between anthropology and human rights.)

1. *Precursors*

Although human rights, in the sense used here, were not on the international agenda before 1948, it was a latent idea for centuries, especially as far as civil rights were concerned. The American 'Bill of Rights' (1776) and the French declaration on '*Les droits de l'homme et de citoyens*' (1789) are often cited as ancestors of the UDHR (along with others), and from there the roots of human rights are traced back to classical Athens or early Christianity. In the nineteenth century, when a wave of humanism swept over Europe, one of the results was a new idea of an essential 'humanity,' deriving from seventeenth- and eighteenth-century treatises in political philosophy as well as from sixteenth-century renaissance humanism. Political philosophy in many respects was a forerunner of anthropology that was to take shape in the late nineteenth century. The idea of a universal humanity was a precondition of the nascent discipline, destined to give the proposition about a shared humanity empirical substance by way of qualifying cultural differences as variations upon the common theme of humanity.

In the early ages of anthropology the conjunction of the two concerns of equal rights and local difference is passionately testified to by Franz Boas, who, in his letter-diary from Baffin Island (1883–4), writes about his sincere wish to live in the USA:

> I should much prefer to live in America in order to be able to further those ideas for which I live. … What I want to live and die for, is equal rights for all, equal possibilities to learn and work for poor and rich alike! Don't you believe that to have done even the smallest bit for this, is more than all of science taken together? (quoted in Cole 1983, p. 37)

We know that later Boas was to fight fervently against racism, and on the whole most anthropologists see their discipline as genuinely respectful of all peoples. This collective sentiment makes no simple entry into the discussion of a universal standard of human rights, however, as this is conceptualized and articulated in those declarations, conventions, charters, and protocols that have been passed in the decades following the UDHR.

2. *Anthropological Reactions to the Universal Declaration of Human Rights*

Human rights in the modern sense were born in 1948 with the adoption of the UDHR. In the drafting process, advice and comments were sought from various bodies, including the American Anthropological Association (AAA). A statement was produced by Melville Herskovits (1947) in the name of the AAA which carefully considers the idea of a universal standard and notes its local cultural implications, each of which is firmly anchored in contemporary anthropological knowledge. Noting that human rights appertain to the individual, the argument proceeds through the following successive conclusions:

(a) 'The individual realizes his personality through his culture, hence respect for individual differences entail a respect for cultural differences' (p. 541);

(b) 'Respect for differences between cultures is validated by the scientific fact that no technique of qualitatively evaluating cultures has been discovered' (p. 542);

(c) 'Standards and values are relative to the culture from which they derive so that any attempt to formulate postulates that grow out of the beliefs or moral codes of one culture must to that extent detract from the applicability of any Declaration of Human Rights to mankind as a whole' (p. 542).

This is clearly a stand against what was perceived as a Western bias in the UDHR, and it leads to the final conclusion: 'Only when a statement of the right of men to live in terms of their own traditions is incorporated into the proposed Declaration, then, can the next step of defining the rights and duties of human groups as regards each other be set upon the firm foundation of the present-day scientific knowledge of Man' (p. 543).

What transpires is a profound skepticism, grounded in the state of the anthropological art, including the general professional sentiment that culture is the sole legitimate source of moral values. Herskovits expresses it thus: 'Even where political systems exist that deny citizens the right of participation in their government, or seek to conquer weaker peoples, underlying cultural values may be called on to bring peoples of such states to a realization of the consequences of the acts of their governments, and thus to enforce a brake upon discrimination and conquest' (p. 543).

As pointed out by Richard Wilson (1997, p. 2), this is an attempt to play anthropology's trump card: its unique ability to elicit and assert any culture's underlying values. In addition it could be said that it also features the comparative knowledge inherent in anthropology, a knowledge both of cultural difference and of its translatability into valid, and more or less shared, human standards of good governance and respectable political action. In spite of the disclaimer, which was militantly underscored by Julian Steward (1948, p. 251), when he said 'we are prepared to take a stand against the values in our own culture which underlie … such imperialism,' the UDHR was passed in 1948.

Together, the two attitudes exemplified by Boas and Herskovits, both of which are understandable and laudable, take us right to the core of anthropology's

comparative consciousness and its ambiguous implications. Since 1948, the discussion of the concept of human rights in anthropology has centered on the unsolved question of universalism or relativism (Dembour 1996). Another target has been the cultural translation of human rights concepts, allegedly deriving from a Western, and Christian, liberal democratic system, into 'like' cultural concepts within other moral and political systems. This is neither an easy task (as shown by e.g., Wilson 1996, and Asad 1997), nor is it an obvious way to go (Hastrup in press).

In actual practice the anthropological concern with human rights has taken various forms since 1948, and has been named accordingly as advocacy, activism, antiracism, and anti-imperialism. It is characteristic, though, that most of these trends have continued the relativistic attitude embedded in the AAA statement (and the implied skepticism toward human rights), while also advocating equal rights on the basis of a vision of a shared humanity. At the beginning of the twenty-first century, when human rights are appealed to by the international community under the banner of a 'culture of human rights' with increasing force, anthropologists have also taken a renewed interest in this culture.

3. *The Culture of Human Rights*

The intense talk of human rights since the early 1990s is not necessarily a symptom of a high moral profile worldwide, rather it is a symptom of the malaises of the times and of the will to confront them by way of new international laws. The choice of cure reflects a general process of legalization of culture in a postmodern era fraught with ontological insecurity, if we are to believe Anthony Giddens (1991). Where, earlier on, local cultures provided people with a sense of belonging and identity, the present globalization and fragmentation of identities have allegedly left people at a loss. They then look toward the law as the glue of community, whether local or global; the law is the new means of inclusion or exclusion *par excellence*.

Whether it is possible to single out causal links in this complex process or not, we do experience an increasingly strongly articulated 'culture of human rights.' We encounter this notion in most recent statements made by the UN high commissioner for human rights, Mary Robinson, as well as by academics of various kinds (e.g., Rorty 1993). From an anthropological perspective it is a peculiar culture in the sense that it is declared rather than lived, and that it is future-oriented rather than based in tradition. As such it parts company from those cultures that were the traditional object of anthropology, but so does, indeed, anthropology itself, becoming increasingly concerned with connections between the local and the global, and their mutual implications. This provides a theoretically significant conjuncture between anthropology and the human rights discourse.

The culture of human rights is distinct also in its explicit acknowledgement of multiple sources. Whereas, traditionally, nations and other self-declared ethnic groups have referred to a particular genesis, an ultimate ancestor, or a culture-hero, the human rights culture draws upon all kinds of ancestry. As Mary Robinson (1998) puts it:

> Today the Universal Declaration of Human Rights stands as ... one of the great documents in world history. The *travaux préparatoires* are there to remind us that the authors sought to reflect in their work the differing cultural traditions in the world. The result is a distillation of many of the values inherent in the world's major legal systems and religious beliefs including the Buddhist, Christian, Hindu, Islamic, and Jewish traditions.

Not surprisingly, after the demise of colonialism, and with the increasing critique of Eurocentrism and the hegemony of Western values, the search for roots has changed from the attempt at establishing a one-stranded genealogy to suggesting multiple sources. Mary Robinson's statement may be empirically doubtful, but it goes to show that there is a will to shift whatever Western legacy one might like to trace in the human rights instruments to a truly global commitment.

The declaration of a global culture of human rights is thus closely related to the historical process of globalization. In one sense, the notion of globalization simply states the obvious; due to increasingly rapid information and money exchange systems, we experience a time–space compression, that accounts for a new global consciousness. This global consciousness has important implications, one apparently being the appeal to a transcendent 'culture of human rights.'

To invoke a culture is also to invoke a shared language; as far as the human rights culture is concerned, the language is decidedly legal. As 'declarations' the international charters are exemplars both of language and of law. Whether hard or soft law, it is inevitably an expression of particular ideas about society, while not necessarily embracing its total reality. Far from being simply rules for social behavior, law is part of a distinctive manner of imagining the real (Geertz 1983, p. 173).

In the case of the international discourse on human rights, there is a concept of the modern nation-state as the responsible agent vis-à-vis the citizens, and a vision of an international community that transcends the more narrow interests of the states. Clearly, this community is no less 'imagined' than the nation (cf. Anderson 1983). It is imagined in terms of precisely those international charters that are its main expression. As a literally *declared* culture, its language comes to carry a much heavier burden of representation than any 'natural' language, being just one among other media for storing cultural knowledge.

Any culture in some ways rests on representation; for it to be conceivable as a whole, it must be demonstrated as such. In a 'legal culture,' such as the international culture of human rights, the representation becomes of a particularly reductive kind, because the experiences, by being represented as if on permanent trial in a courtroom, become subjected to an unavoidable process of reduction, or as Clifford Geertz has it about law in general, a 'skeletonization of fact, the reduction of it to the genre capacities of the law note' (Geertz 1983, p. 172). Legal thought and vocabularies, then, are constructive of social realities rather than merely reflective of them; this also applies to the legal vocabulary of human rights, and anthropologists naturally take an increasing interest in this particular social construction of a (global) community.

According to some anthropologists, globalization and human rights conjoin in a social transformation of unprecedented magnitude. Ellen Messer, for one, writes like this:

> Since the close of World War II, the United Nations has been assembling declarations, legislation, and enforcement mechanisms to promote human rights. Both the ongoing efforts to establish a global community and to base membership on a universal, but evolving standard of values constitute perhaps the greatest social transformation of this century. (Messer 1996, p. 1)

This transformation is part of a larger trend that has often been seen as the end of modernity, implying an end also to ontological security. This could be one of the reasons why human rights have become the new standard of hope to many. The historical changes are matched by new scholarly efforts. We have witnessed important changes in the conception of the anthropological object, that can be summed up under the rubrics of a de-essentialization of the object (culture, society) on the one hand, and a humanization of the subject, seen now to be an active agent of history, on the other. This facilitates a truly anthropological investigation into issues of human rights.

Intellectually, one of the greatest advances of the twentieth century was a willingness to learn from history and anthropology that humans are extremely malleable (e.g., Rorty 1993, p. 115). Thanks to comparative knowledge of humanity in time and space we have realized the flexibility and the self-shaping character of humans, and given up on the idea of a naturally rational animal.

The historical and intellectual climate is thus very much in favor of achieving a 'human rights culture.' While the dominant trends in present day anthropology—the stress upon globalization, on process, and on agency among other things—make a new approach to universal human rights possible, there is no theoretical reason why we should not at the same time maintain a distinct, more or less bounded object of analysis: the local worlds of people. This has fueled a new interest in what are known as cultural rights.

4. *Cultural Rights*

In view of the traditional anthropological ambivalence toward human rights, generally based in view of culture as an inviolable and inherently valuable entity, the notion of cultural rights might ease the tension. This is not self-evident, however.

In the early instruments, such as the UDHR and the 1996 International Covenant on Social, Economic, and Cultural Rights (ICSECR), 'cultural rights' are individual rights to 'enjoy culture,' in compliance with the general emphasis on individual rights and the obligation of the state to facilitate them. In addition to this focus on the individual's cultural rights, a more challenging (politically and theoretically) perspective on cultural rights is opening up with increasing force, however. This is a notion of collective cultural rights, in relation to which the individual enjoyment of culture gives way to, or is at least supplemented by, a right of a particular group to protect and develop their culture. It was notable already in the *International Covenant on Civil and Political Rights* (ICCPR 1966, Article 27): 'In those States in which ethnic, religious, or linguistic minorities exist, persons belonging to such minorities shall not be denied the right, in community with the other members of their group, to enjoy their own culture, to profess and practice their own religion, or to use their own language.' It is surprising, perhaps, that the protection of minorities is placed within the civil and political rights, and not the social, economic, and cultural rights; if nothing else, this confirms the lack of clarity with which the concept of culture is hampered in the international instruments.

In spite of the weak beginnings and the unclear focus within the field of cultural rights, there is an increasing interest in them at the beginning of the twenty-first century. It is related to the historical fact that most conflicts today are so-called ethnic conflicts, at closer inspection often rooted in economic discrimination or scarce resources. Ethnic difference often covers other inequalities, at least when they are expressed in conflict. The ethnic conflicts take place within states, that are the traditional duty-holders in the human rights system, and they raise endless new questions of how to define those peoples, minorities, or indigenous populations that are the new beneficiaries of collective rights. In spite of the definitional problems, the UN system proceeds toward an increasing proliferation of instruments dealing with collective rights.

One such instrument is the UN *Declaration on the Rights of Persons Belonging to National or Ethnic, Religious or Linguistic Minorities* (DM) of 1992. As a Declaration it is not legally binding in the strict sense of the term, but state signatories nevertheless commit

themselves to the spirit of the Declaration. In many ways the DM can be seen as an extension of Article 27 of the ICCPR quoted above:

> States shall protect the existence and the national or ethnic, cultural, religious and linguistic identity of minorities within their respective territories and shall encourage conditions for the promotion of that identity. (DM, Article 1)

> Persons belonging to national or ethnic, religious and linguistic minorities … have the right to enjoy their own culture, to profess and practice their own religion, and to use their own language, in private and in public, freely and without interference or any form of discrimination. (DM, Article 2)

From an anthropological perspective, what seems problematic is the recurrent emphasis on people's own culture as a natural property. The embedded concept of culture is an (outdated) essentialist one that goes counter to more recent anthropological notions of culture as a more or less temporary framework of understanding.

In the 1993 *Draft Declaration on Indigenous Peoples Rights* (IPR) the notion of culture as essence is further cemented; to give just one example:

> Indigenous peoples have the right to practice and revitalize their cultural traditions and customs. This includes the right to maintain, protect, and develop the past, present, and future manifestations of their cultures, such as archeological and historical sites, artifacts, designs, ceremonies, technologies, and visual and performing arts and literature, as well as their right to the restitution of cultural, intellectual, religious, and spiritual property taken without their free and informed consent or in violation of their laws, traditions, and customs. (IPR, Article 12)

While one cannot deny that the indigenous peoples have suffered the more sinister effects of colonialism, it is unlikely that such collective rights that are propounded in the IPR will undo history. It is still only a draft declaration but seen in conjunction with the previously cited instrument there is evidence of a gradual transformation of cultural rights from individual to collective rights, that may potentially threaten the very foundation of human rights: their claim to universality. It seems, then, that at a time when anthropologists have left behind the notion of culture that prompted the AAA to take a stand against the idea of universal human rights, the very same notion hits back from within the system of human rights itself, potentially undermining it.

5. *New Anthropological Avenues*

The brief discussion of cultural rights shows that there is a need to reconsider the issue of human rights in the light of recent theoretical developments. If the notion of culture as essence is obsolete and cultural relativism generally self-refuting, human rights can no longer be invalidated as a matter of course. The comparative perspective of anthropology itself is based on an idea of a shared humanity and a cross-cultural comprehensibility that tallies with the idea of equality and dignity in all humans. One of the things that anthropology has helped realize is the imaginability of 'others' as somehow like 'us' in spite of diversity.

Ethnographies of violence and suffering are still needed to add a dimension of experience to the (legal) language of rights, and thus contribute to a shared understanding of those sufferings that a universally accepted standard of human rights may help alleviate. Not only ethnography, but also our regained confidence in anthropological theory will contribute to the achievement of human rights, because anthropology's theoretical language can embrace cultural differences within a single (scholarly) discourse. Theory expresses what is not otherwise said; as such it is a social practice and contributes to the making of the world—not unlike the representation of society in legal terms, as discussed above. This imaginative contribution makes room for the renewed rapprochement between anthropology and human rights that we are witnessing.

Human Rights, History of

The expression 'History of Human Rights' has two different meanings. It can be understood (as it usually is) as the history of the idea and the concept of human rights, or (less frequently) as the historical occurrence and study of human rights and their abuses. Therefore, the basic debates about the idea and concept of human rights are first clarified here from a historical perspective. Then, a range of methodological and ethical problems in the historical study of human rights are presented.

1. History of the Idea and Concept of Human Rights

1.1 Moral vs. Positive Rights

In 1689–90, just after the Glorious Revolution of 1688, the English philosopher John Locke (1632–1704) wrote his *Two Treatises on Government*, which contained the first classical formulation of human rights (then still called 'natural rights'). In retrospect, this work stood at the juncture of a set of amazingly diverse ideas, some of which went back to antiquity and some of which will survive the twenty-first century. Locke's point of departure was the doctrine of natural law as it had developed since antiquity and had been transformed, in certain respects almost beyond recognition, by medieval Christianity and early-modern philosophers. According to Locke, the doctrine maintained that nature endowed all humans with certain basic moral entitlements (such as the right to life, liberty, and property), to which the man-made laws of society, both positive and customary, had to conform.

These natural rights were thought to possess five distinct characteristics: they were discoverable by reason, itself a faculty of human nature; they existed before humans entered society; they applied to all humans by virtue of their being human; they were inalienable; and they were restricted only by the recognition of the rights of others. As such, these rights limited the power of the society—generally in its predominant historical-political form, the state—and its laws, and respect for them was the first test for the legitimacy of political power. Ancient ideas on rationalism, equality, and the restrained exercise of power formed the substratum for this natural law doctrine, which proved to be very influential. Despite its claim of eternity, however, many of the doctrinal components, such as the exact catalog of moral principles or the source of authority for these principles, turned out to be rather flexible.

Although temporarily in eclipse because of the ascendancy of the sixteenth-century absolutist state, the natural law doctrine would be fostered by three developments initiated in that very period. With the Renaissance came an emphasis on individualism and secularism, the outcome of the religious struggles following the Reformation taught the necessity of tolerance, and the seventeenth-century scientific revolution marked the triumph of rationalism. These developments reversed the philosophical priorities of the hierarchical medieval societies: natural law gradually became associated with rights rather than with duties and with individuals rather than with groups.

The perception of the source of these natural rights also changed. Whereas Christianity had maintained that God was the ultimate source and political absolutism had invested the monarch with divine rights, the consent of the governed came to be seen as the final authority. Individuals gave this consent in a social contract, which presupposed that they possessed rights before entering society. Governments owed their origin to that contract, by which free and equal citizens agreed to entrust to a neutral sovereign body some of their rights, to accept its authority and rules as long as it protected them, and to rebel against it if it did not. This formed the basis for the rule of law and the separation of, and balance between, the legislative, executive, and judicial functions of government.

Although previous theories (such as Hugo Grotius') paved the way and later ones expressed similar ideas, it was Locke's political theory which was to prosper, especially outside England. In the age of Enlightenment it exerted profound influence upon the politicians behind the great revolutions at the end of the

eighteenth century. In the United States and France, natural rights, mainly of a political and civic character, were incorporated into the declarations and constitutions of the revolutionaries. In 1789 natural rights transformed into the 'rights of man' (*droits de l'homme*). This marked the beginning of a process of codification of rights within the constitutions of most states and in international law that still has not ended.

From this brief historical overview, it is clear that, although many aspects of the human rights conception have an ancient pedigree, other crucial ones have not. The concept was the result of a unique historical combination of a series of events and philosophical thought reflecting upon them, and developed relatively late in Western history. The natural law doctrine itself knew a curious fate: with unprovable tenets and with the possibility of abusive claims 'in the name of nature,' it became overshadowed by the powerful state-centered thinking of the nineteenth century (as it had been in the sixteenth), but it survived. It was rehabilitated in a modest form after the two world wars. The twentieth-century approach did not derive human rights from nature any longer, but from (historically determined) rational ideas on human dignity.

1.2 Absolute vs. Relative Rights

The debate on moral vs. positive rights was continued by liberal, conservative, and socialist critics of human rights. Typical of this criticism were the works of Jeremy Bentham (1748–1832), Edmund Burke (1729–97) and Karl Marx (1818–83). These critics argued against the abstract and absolute character of human rights. They maintained that rights had to be related to the society in which they were to be exercised. The liberal utilitarian Bentham believed only in the force of positive legislation. For him, natural rights were imaginary, 'nonsense upon stilts.' He feared that they were powerful rhetoric in the hands of rulers and a substitute for effective legislation.

Unlike Bentham, the conservative Burke did not deny the existence of natural rights. However, he feared them for reasons contrary to Bentham's: in the hands of the common people, natural rights would stimulate revolutionary sentiments and cause social upheaval leading to terror and to the destruction of the social fabric. Rights (and the duties linked with them) ought to be derived from the principles and values emanating from the particular traditions of a society.

For the socialist Marx the human rights doctrine was not radical enough. It left the inequalities generated by capitalism untouched (particularly private property) and therefore served the interests of the ruling bourgeois class. Because of these inequalities, the workers were unable to enjoy their rights fully, which therefore remained largely formal. As a class, the workers had a duty to create the conditions for social change by claiming collective social and economic rights with which to overturn the economic system. The new, egalitarian society would be one without a state, laws, or rights.

These thinkers did not stand alone in their criticism, but their arguments gained a classic character and inspired powerful currents. Bentham's ideas gave impetus to the tradition of legal positivism. Ideas similar to Burke's would feed the romanticism and historicism of the nineteenth century to the extent that they too emphasized cultural identity and diversity. Marx's concerns heightened awareness of the need for social legislation and influenced the 1917 Russian Revolution.

1.3 Men vs. All Humans and Individuals vs. Groups as Rights-holders

Clearly, until long after the era of revolutions, the concept of 'rights of man' covered only very restricted categories of humans, usually male tax-paying citizens. The large majority of women, slaves, and foreigners were excluded. The struggle to include these categories in the ranks of rights-holders would lead to the final transformation of the concept into 'human rights.' As early as 1791, Olympe de Gouges struggled for women's rights. With the movement against slavery, another group followed. Categories of individuals deemed particularly vulnerable (women, children, aliens, refugees, prisoners, the disabled) were eventually protected by special regulations.

Likewise, the difficult problem of how to realize group rights was introduced at an early stage in the human rights debate. Groups deemed vulnerable (minorities, colonized peoples, indigenous peoples) increasingly received special attention. Specific treaties for national, ethnic, or religious minorities were drafted long before general treaties came into effect. The idea of self-determination appealed to peoples under colonial rule or comparable alien subjugation and proved to be a crucial concept. It was a dangerous concept too, because the narrowing of self-determination to only one of its possible interpretations—secession—was potentially explosive and because consensus was lacking as to whom the rights-bearer ('a people') exactly was. Self-determination was promoted to a group right only in the 1966 covenants (see below).

From an acute attention to making the concept 'human' all-embracing, two further questions on the extension of rights can be derived. First, do past and future generations have human rights? As to past generations, one could think of the right to a decent burial or the right to be treated with respect in historical works. As to future generations, the preservation of the cultural heritage of humanity and of the

natural environment are chief concerns as is the relationship between human rights and the human genome. As to future generations in relation to past generations, the accountability of successor governments for human rights abuses committed by their precursors and the obligation to investigate them are matters of legitimate debate. Second, what consequences does the anthropocentric character of human rights have, as it excludes other sentient beings and is often based on restricted and exploitative conceptions of nature?

1.4 Domestic vs. International Jurisdiction Over Human Rights

Since 1800, two tendencies, one international, the other national, partly opposite, partly complementary, have dominated the debate over who was to control the protection of human rights. A process of internationalization started when human rights were incorporated into the constitutions of growing numbers of countries. At the same time, human rights became part of the agenda of intergovernmental meetings, leading to the humanitarian interventions of the nineteenth century (continuing a tradition dating from the seventeenth century) and the gradual incorporation of human rights into international law. That human rights abuses often created conflicts that threatened international peace was a lesson learned slowly. Treaties were drafted to protect selected vulnerable categories such as slaves, war prisoners, and minorities. The League of Nations, founded in 1919, did not formally recognize human rights but added pioneering treaties for minorities, refugees, and mandate territories.

The decisive historical moment for internationalization, however, came during World War II, when the link between human rights violations and war (hence the link between human rights protection and international peace and security) became clearly visible and, shortly after, when the Nazi and Japanese atrocities led to worldwide condemnation embodied in the international war crimes tribunals of Nuremberg and Tokyo. Although the United Nations only paid secondary attention to human rights in their 1945 Charter, this did not prevent work on an International Bill of Human Rights, consisting of a morally compelling but not legally binding Universal Declaration of Human Rights, adopted in 1948, and two International Covenants, one on economic, social, and cultural rights, and one on civil and political rights, both approved in 1966 and entered into force in 1976.

In the efforts to transform human rights into positive rights by making them enforceable in positive law, usually three stages are distinguished: standard-setting (codification of standards), ratification (making standards binding), and implementation (enforcing standards via sanctions). Seminal steps for enforcing standards were the elaboration of complaint mechanisms for state and nonstate actors (mainly since the 1970s), the appointment of a High Commissioner for Human Rights (1993), and the adoption of the Statute of an International Criminal Court with universal jurisdiction to prosecute alleged perpetrators (including heads of state and government) of genocide, crimes against humanity, war crimes committed in international and internal conflicts, and crimes of aggression (1998). Important preparatory work for these new devices was done by a coalition of nongovernmental organizations, the representatives of civil society. The elaboration of human rights institutions and mechanisms on a world scale was parallelled, and often preceded, by similar developments on a regional scale in Europe, America, Africa, and the Arab world.

In the midst of this evolution, the state was the key player. The cherished principles of the Westphalian world order, established in 1648, were national sovereignty and interstate equality. Their corollary, domestic jurisdiction, excluded interference from abroad in the internal affairs of the state. The vigorous doctrine of nationalism and successive waves of decolonization since the late eighteenth century strengthened these principles. Paradoxically, recognition of national sovereignty made possible progress in international law with its core principle of interference in the internal affairs of states. In the first place, states slowly realized that when they adopted human rights as the basis of the rule of law, they implicitly created a duty to protect them everywhere, including beyond their borders. In the second place, it was painfully obvious that the states themselves were the main perpetrators of human rights abuses. Therefore, states reluctantly but voluntarily began to accept an international monitoring element that restricted their sovereign domestic power. The number of humanitarian interventions increased drastically in the 1990s, but their enabling conditions, forms (diplomatic, political, economic, or military), potential abuses, and effects were hotly disputed.

1.5 First- vs. Second- vs. Third-generation Human Rights

As the success and the criticism of the human rights doctrine expanded the list of human rights, analysts grouped them into generations. The first generation, tied to the idea of liberty, were the traditional or individual rights of a political and civic nature. They were characterized as negative rights ('freedoms from') because they favored governmental abstention. The second generation, tied to the idea of equality, were the modern or collective rights of a social, economic, and cultural nature. They were characterized as

positive rights ('rights to') because they favored governmental intervention. The third generation, tied to the idea of fraternity, were modern or collective rights of a global nature. They were characterized as solidarity rights and usually included the rights to development, human security, peace, and self-determination. The rights of indigenous peoples and the right to a life-sustaining environment are frequently added, but these are also listed as fourth-generation rights by some.

Each generation emerged in a particular historical context. The first generation was the result of the late-eighteenth-century revolutions led by the bourgeoisie that abolished feudalism (and colonialism in the case of the United States). Increasing political emancipation and democratic participation in the next two centuries gave further impetus. The second generation developed in the nineteenth century as the socialist tradition with its reformist and revolutionary strategies, and introduced ideas of welfare and social legislation to counter the exploitation of working classes and colonial peoples and to create the necessary conditions for the full exercise of rights. The third generation is usually associated with the Third World demand for a worldwide redistribution of power and wealth; another factor is the tension generated by the staggering increase of interdependency and global problems on the one hand and the need to safeguard cultural identities and diversity on the other. The three generations of rights can be placed on a continuum with justice at the one end and solidarity at the other.

This bewildering diversity of human rights occasioned controversies on their compatibility, priority, and indivisibility. Because all human rights were conceived as inalienable, they sometimes came into mutual conflict. A classic example of a conflict within the same generation of rights is the tension between expression and religion: what is called 'an opinion' by one person, might be labeled 'blasphemy' by the next. But most conflicts occurred between, rather than within, generations. Whereas first-generation rights assumed the character of universally enforceable standards, second- and third-generation rights were rather aspirations whose fulfilment was utterly dependent on the creation of specific conditions. Faced with all these demands, some states, mainly in the First World, gave priority to first-generation rights, while others, mainly in the Second and Third World, struggled, if not for the primacy, then at least for the equivalence of second- and third-generation rights. Acrimonious debates were held on whether political freedom or economic development was to be accorded priority. Those defending the priority of political freedom ('free minds') were accused of perpetuating inequality, those defending the priority of economic development ('full bellies') of perpetuating dictatorial government. In the Cold War era (and beyond), these arguments were used as political propaganda. The hypothesis that political freedom or democracy should be suspended until certain levels of economic development are attained is contradicted by the bitter experience that in such cases freedom is usually trampled underfoot, while no economic development is attained after all. Unaccountable governments generally exacerbate economic and environmental crises. Moreover, how can a present suspension of freedom be conceived as preparing for its future protection? The reverse hypothesis seems to have firmer ground: with their political rights respected, citizens will participate more fully in the economic development of their society. The correlation between economic development and political freedom seems to be accepted, but under which conditions, for which precise political and economic areas, and in which causal direction the correlation is valid remains largely unresolved.

At the 1993 World Conference on Human Rights in Vienna, the second such conference ever and the first after the Cold War, the indivisibility of human rights was strongly reaffirmed. Even so, seven rights acquired a special status as they were the only ones stipulated by the 1966 Covenant to be nonderogable, even in times of public emergency. They are the rights to life, to be recognized as a person before the law, and to freedom of thought, conscience, and religion; and the prohibitions against torture, slavery, imprisonment for nonfulfillment of contractual obligations, and retroactive application of criminal laws.

1.6 Universality vs. Relativity of Human Rights

Seen from a historical perspective, most major religions and ethical systems have been concerned with human dignity. Opinions differ, however, on whether they were also concerned with human rights (viewed as one specific way to realize human dignity). Developing the human rights concept took two millennia in Western history and was so full of unforeseen links, ruptures, reversals, and coincidences, that it may convincingly be called a unique product of that history (see above). The quasi-universal emphasis on the community in which individuals had mainly duties switched in Europe and its American colonies to an emphasis on individuals and rights. Elements of the human rights concept, such as some natural law principles, were available outside the West, but the combination of factors that led to its formulation was not. As the West conquered the rest of the world, it introduced its dominance and violence. At the same time, its notions of freedom, nationalism, and cultural diversity, developed initially for home consumption, fell on fertile ground overseas. These notions, including human rights, proved able to transcend their particular roots and context. In the hands of colonized peoples, they echoed similar indigenous values and served to justly criticize Western exploitation in the language of the West itself. Thus, whereas human

dignity is a universal value with venerable traditions everywhere, the claim of the universality of human rights has an anthropological basis, not a historical one, and is rooted in the universal appeal of a specific system of thought.

The anthropological debate was no less vivid than the historical debate. During the preparatory work on the 1948 Universal Declaration, leading American anthropologists emphasized the cultural relativity of values and denounced the universalist pretensions of the intended declaration as cultural imperialism. Moreover, the historical critics of the universality of human rights (presented above) were succeeded by neo-Marxists, communitarians, and postmodernists. But the most influential group of critics were the vociferous ruling elites of some non-Western countries, especially in Asia and Africa. They challenged specific formulations of private rights such as religion or marriage, and advocated, instead of universality, the principle of domestic jurisdiction or the primacy of second- and third-generation rights over first-generation rights. Remarkably, the surviving victims of imprisonment, torture, and other abuses in non-Western countries (among them many future elites of these countries) found such criticism unconvincing. These victims argued that denying universal human rights to citizens outside the West was itself a sign of cultural arrogance. A new consensus seemed to emerge when 171 states unanimously reaffirmed the universality claim at the 1993 Vienna Conference and thereby made the claim far more representative than at the time of the 1948 Universal Declaration which was approved by a vote of 48 to zero with eight abstentions. At the same time, care for second- and third-generation rights is growing. In 1998 a draft of a Universal Declaration of Human Responsibilities was submitted to the United Nations General Assembly, as an attempt to achieve a better balance between freedom and responsibility and between justice and solidarity.

2. *History and Historiography of Human Rights and Their Abuses*

The second interpretation of the expression 'History of Human Rights' points to historical research on human rights. When looking at this area, we are confronted with a paradox. On the one hand, as human rights encompass so many spheres of life, large parts of the historiographical production inevitably deal with concrete aspects of human rights and their abuses (e.g. the history of education, the history of slavery, the history of censorship). Equally, historians endeavored to write histories of emancipation movements or of freedom. Grand theories of history and world histories sometimes had implicit views on human rights, and the more recent they were, the more they covered the whole of humanity in an equitable manner. Indeed, with little exaggeration one could say that almost all history touches on some present human rights concern. On the other hand, it is hard to find research explicitly designed to study a particular right in historical perspective. Some of the methodological and ethical problems involved in this type of research are outlined below.

2.1 *Methodological Problems*

In the following example, a general question is analyzed to demonstrate the methodological complexities of human rights research. That question is: 'Do human rights abuses increase or decrease over time?' A historical question because of its time dimension, it is also an ethical question to the extent that the answer gives clues about the moral progress of humanity (philosophers of all times have been in dire need of such clues). Questions as broad as this one should be rendered operational. This may be done by narrowing the 'human rights' of the question to one of its categories, 'civil and political rights,' by selecting from this category one important right, 'the right to life,' and, finally, by selecting from this right its most serious abuse, 'genocide.' Reformulated in operational terms, the question thus becomes: 'Do genocides increase or decrease over time?' This question can be approached logically and historically.

A priori logical considerations distinguish between absolute and relative levels of abuse. In absolute terms, the case of an overall increase of genocides is defensible. The population growth on earth, the increasing sophistication of repressive bureaucracies and technologies, and the anonymity often physically and morally shielding the perpetrator are all contributing factors in making this statistically probable. Our perception, however, may be deficient in two contradictory directions: we may overestimate the present absolute level of cruelty because of our lack of knowledge of past cases; alternatively, we may underestimate the actual level because we are too impressed by the countervailing forces, especially since the recent expanding human rights awareness has led to a higher state of general alert and perhaps to more deterrence. In relative terms, the question is very different: given that an equal amount of cruelty probably leads to greater destruction in modern times, were societies more repressive or more human towards their citizens in the past than they are today? In tackling this question, one ought to apply criteria for measuring the degrees of cruelty, but which ones? The number of victims in relation to the total population? The presence of especially vulnerable categories of victims? The occurrence of particularly cruel types of repression? In addition to this difficulty, there is the danger of anachronistically projecting back contemporary conceptions and values into the past. In the

face of the pain suffered by each individual victim, however, such considerations on the moral economy of death may sound superficial or scornful. A probable absolute increase of cruelty or repression in history, then, does not imply that humanity is now more barbarous than in the past, nor that it is less.

Does a historical approach shed more light on the problem? The 1948 United Nations Genocide Convention called genocide 'an odious scourge' that 'at all periods of history (…) has inflicted great losses on humanity.' Thus the term 'genocide'—coined in 1944 by Raphael Lemkin—seems to cover phenomena in all historical periods. Which phenomena? The Convention provides a definition (a series of 'acts committed with intent to destroy, in whole or in part, a national, ethnical, racial, or religious group') that genocide scholars reluctantly accept or decline all together. These scholars argue that many more group types than the ones from the definition have been genocide victims (notably political and social groups) and debate the boundaries between genocides and comparable crimes. They also report that many researchers suffer from psychological barriers in studying the almost unbelievable cruelty of genocide. The body of genocide research only began to grow after 1945, and with the exception of the relatively well-studied Holocaust, it is still lacking in many instances.

Not only do definitions and psychological resistance raise problems, so do heuristics and epistemology. It is often excruciatingly difficult to know how many died and what exactly happened during each specific genocide. Drawing statistics on the number of victims that are more than 'guesstimates' is a skill in its own right. Rudolf Rummel's elaborate statistics (1994) show that the democide rate (a concept including genocide, politicide, and mass murder but excluding war dead) was almost certainly higher in the twentieth century than in any previous century: he presents a calculated total of 169,202,000 dead for the period 1900–87 (including 38,566,000 genocide victims) vs. a hypothetical total of 625,716,000 dead for the period from the thirtieth century BCE to 1900. However, these figures do not allow conclusions about a possible increase of democide, and by implication of genocide, because Rummel derived his hypothetical total of pre-twentieth-century democide from the twentieth-century democide rate and the population for each century since the thirtieth century BCE. Linked to the statistical problem is the source problem: few sources normally survive, at least for the earlier genocides, in history. The sources were either not kept, hidden, lost, or destroyed. When they are available, they come from either perpetrators, victims, or bystanders. When there are sources from two or all parties, they frequently conflict with each other. Finally, their authenticity and reliability have to be tested. In short, the usual techniques of historical criticism have to be applied with unusual sharpness. Even when sources allow the historian to distill a picture of the killings, proof of the intention of the perpetrator to destroy a group as such (an essential component of all genocide definitions) is difficult. Openly stated motives are exceptional and notoriously unreliable and, therefore, intent generally has to be ascribed. This is precarious, especially where the genocide is unanticipated.

Once we have reliable descriptions of the events, the question remains whether they catch the essence of the horror. The limits of representing the unrepresentable have been much debated in recent decades. The analysis and interpretation of the data pose their own problems. First, genocide is a complex interdisciplinary phenomenon with historical, psychological, sociological, political, legal, philosophical, and religious aspects. Second, the systemic and human factors conditioning genocides and the extent to which they are unique and comparable are open to much controversy. Third, it is important to know whether the nature of genocide has changed over time. Among the dozen or so typologies of genocide, some address this problem, however inconclusively. Frank Chalk and Kurt Jonassohn, for example, distinguish between retributive genocide (to eliminate a real or potential threat), despotic genocide (to spread terror among real or potential enemies), developmental genocide (to acquire economic wealth), and ideological genocide (to implement an ideology). They then classify 22 cases from history under the most relevant type. The distribution of cases reveals that the fourth type is a predominantly twentieth-century phenomenon with few historical antecedents. Even if this suggests that the nature of genocide has (partially) changed, the question remains why. With all its methodological difficulties summarily depicted above, the historical approach is obviously far from conclusively answering the initial question either.

2.2 Ethical Problems

The historical study of human rights and their abuses also involves ethical problems. Some of these are related to the researching historians, others to the human beings they study. Most are not unique for this type of research, but they present themselves cogently here. Human rights research can be dangerous, especially when the historians are working on contemporary material in their own society or on cases of the past which suggest easy analogies with the present or endanger the legitimacy of present rulers. This may lead to the persecution of the historians and entail reflection on their professional ethics: what are the rights and obligations of historians working under such restrictive conditions and what should their colleagues working under freer conditions do?

What rights do the human beings under scrutiny have, apart from the right to be treated with respect in historical works (see above)? With regard to the perpetrators of crimes, the question is whether moral

judgments of their acts are possible, and if possible, permissible, and if permissible, obligatory. Opinions of historians widely differ on these points. Few believe that they are judges for eternity, but nevertheless most will admit that there is something like a right to historical truth, for which it is never too late. They would probably subscribe to the professional obligation not to deny or forget the fate of the dead and surviving victims. This justified claim, however, can be at odds with impartial research. It is a task with many risks. Without the passion of the survivors, historians may 'normalize' the cruel abuses of the past by inserting them into the stream of history. They may omit crucial findings for fear of breathing new divisive fever into the collective memory. But still, the distinctive professional contribution of historians to the protection of human rights, if any, is to see that the dead do not die twice.

Human Rights in Intercultural Discourse: Cultural Concerns

Though human rights are generally recommended, there are still some strong criticisms. One criticism refers to human rights, somewhat derogatorily, as the civil religion of modernity and, by this, takes them to be only a historical phenomenon of a particular culture. Other critics fear that the spread of human rights is nothing but a new and subtle version of Western colonialism or imperialism, namely a supremacy of a its legal culture, which forces values on other cultures. But actually, human rights belong to a universal legal morality, which is common to all mankind although it was thought of in the most radical manner by Western modernity.

Within Western legal culture, human rights are taken as a matter of course. But as far as their foundations are concerned, there are difficulties which are partly of a political, partly of an intercultural, and partly of an anthropological nature. A specific philosophical justification, a transcendental foundation of human rights might help to overcome

these difficulties. This foundation, at the same time, might permit one to show the universal validity of human rights beyond liberal legal cultures.

1. Human Rights and Basic Rights

The first, political difficulties arise when one considers the possibility that a declaration of human rights might simply remain a declaration. For instance, the People's Republic of China used tanks against demonstrating students, although it recognizes freedom of procession and demonstration as stated in Article 87 of its constitution. The answer to this may simply be compliance with positive law. In order to give human rights an actual power in the world, instead of remaining just word on the page, they have to become solidly embedded in human practice. To this purpose human rights have to make their way into the sometimes written, sometimes unwritten constitution, thereby doing both: obliging the branches of government to human rights and restricting their power, among others rendering possible proceedings before the court of law against any abuse of governmental power and of the nonrecognition of rights. Wherever this occurs, human rights, which were previously just a component of universal legal morality, become elements of positive law. They are transformed from mere human rights into basic rights of a particular legal community.

Not only does this differentiation of human rights and basic rights direct itself against simple declarations, it also draws attention to those origins of basic rights which lie before and beyond the state. In particular, history's first declarations are aware of this elementary meaning. In this respect, the French *Déclaration* (1789) follows the Virginia Bill of Rights (1776). Their beginning establishes valid rights at a level which lies before the state. Subsequently, the basis for legitimation is laid for the exercise of political power; Virginia's Article 2 and France's Article 3 state that the people is the origin of all government. It is not until the third step that the function of the state is touched upon; here the limitation of the exercise of political power as well as the positive tasks of the state is mentioned. In that sense, from a philosophical point of view, we have to reverse Benjamin Barber's title: not 'Democracy first, then Rights,' but 'Human Rights first, then Democracy.'

This sequence contains my first thesis: human rights are rights of all human beings raised against all other human beings. From the standpoint of legitimation the claims in question are primarily raised by all men against one another and they are at the same time granted to one another. With regards to human rights, people recognize themselves as beings with equal rights. Positive law and the branches of government are legitimized in relation to human rights only at a second and, more specifically, subsidiary level: they are incumbent upon transforming innate rights in the process of the establishment of a constitution and further legislation into positive law. The scholar of law says, 'rights are guaranteed'; with this he means a secondary accomplishment that is strongly differentiated from a primary accord. In German, we distinguish *gewähren* which is done by men themselves, and *gewährleisten* which is the task of the branches of government: the legislator, the executive power, and the courts.

2. An Intercultural Legal Discourse

The second difficulty with human rights is constituent of the fact that we expect the recognition of human rights from all cultures, but that the discourse on human rights only takes place within one of them, namely the Western culture. For this reason there is a risk that human rights, instead of constituting the core of a universal legal morality, will give away their essence and will thereby decline to the level of an 'export-article of Western culture.' In this sense, the objection of 'ethnocentric thinking' can be raised, for a legal institution like human rights, Western culture claims to be valid for the whole of mankind.

Although itself a product of the West, philosophy lends its voice to non-Western cultures. It does not do so in a now current form of a mutation, an act which turns philosophers into a kind of fundamental anthropologist, into theoreticians of a world society who, like Lyotard (1983), Feyerabend (1987), and Rorty (1989), place themselves in the tradition of American anthropology—one thinks, for example, of Herskovits' 'Statement on Human Rights' (1947)—and who, in their fear of destroying the characteristics of non-Western cultures, support a pure relativism. Instead of getting lost in the byways of fundamental anthropology, and its exaggerated relativism, philosophy engages in an intercultural legal discourse.

This discourse begins, in passing, by invalidating the mentioned fear. What Lyotard describes, somewhat drastically, as the 'tyranny of the universal' is based upon a misunderstanding, namely, the confusion of universality with uniformity as though universal legal principles should be equated with the removal of social and cultural differences. Let us take an example: the equal rights of different religions or that of different languages, from the standpoint of human rights, do not undermine the existence of one of them; by contrast, the principle of equality guarantees coexistence of the different parties.

In the next step, our discourse turns the reproach of ethnocentric thinking into a philosophical challenge, in other words, into a question whose answer is still open: how can a regionally developed institution which is not always taken seriously—we recall that the Virginia Bill of Rights was proclaimed in a slave state—lay claim to an absolute universality? Obviously, such a claim is permitted only on a condition which, from the standpoint of legitimation, is self-

evident but which is all too readily overlooked in the case of human rights. Legitimation must be separated from the historical genesis and evolution. My *second thesis* is this: whoever wants to impute the idea of human rights to other cultures must for once divorce himself from their intellectual history, also from their legal and social history, for instance from the question regarding economic prerequisites. If human rights are truly to exist, then they should do so not for the reason that capitalism, the modern form of the economy, requires a global protection of economic rights. Besides, there are well-known practices which contradict the idea of human rights and are nonetheless compatible which a global protection of economic rights, namely, slavery and human bondage, inequality of man and woman, the lack of rights for children and, last but not least, colonization. Furthermore, the legitimation of human rights also needs to be uncoupled from a certain phase of the modern state's development, namely from Reformation and Absolutism. If innate rights truly exist, then the Western experience can have a thoroughly heuristic significance; but in the end, only culturally invariant arguments have the power of justification.

3. *A Copernican Revolution of Anthropology*

A third difficulty with human rights is expressed in the question: what remains when one considers the separation of legitimation from the historical genesis and abstracts from the particular context of European modernity? The view that the idea of human rights is connected with a certain image of mankind is widespread. To this there is an annexation which not only profiles the matter as far as its content is concerned, but also limits its validity; namely that an image of mankind presents itself as Jewish, another as Christian, a third as Muslim, a fourth as Buddhist, and finally a fifth—a definitive neither/nor!—as atheist. Moreover, the modern European picture of mankind is individualistic and relatively ahistorical, whereas the African image of mankind is determined by a characteristic solidarity of two dimensions: a solidarity with fellowmen and with the ancestors. We can generalize: all specific images of mankind, all views of human nature are therefore culturally dependent.

The consequence for our justification: we even have to rid ourselves of Western images of mankind and evolve a *logos tou anthropou*. In other words, we have to evolve a concept of mankind which, valid for the whole of humanity, is independent of different histories and cultures.

A concept of mankind which is independent of cultural particularities, and therefore interculturally valid, has for a long time be no stranger to Western thought. Since Greek Antiquity, we know two anthropological definitions: men as *zoon logon echon* and as *physei politikon zoon*. Recently, however, skepticism is the rule. If one lends an ear to philosophers like Rorty (1989, p. 44), then skepticism towards anthropology becomes such a matter of course that one may content oneself with only a short aside: 'fruitless by way of anthropology.' But scepticism is not new. Since Rousseau's concept of *perfectibilité* (*Discours sur l'inégalité*, part 1) and Nietzsche's dictum that man is 'more indeterminate than any other animal' ('*unfestgestellter als irgendein Tier sonst*': *On the Genealogy of Morals*, 3rd essay, section 13), philosophy has doubted whether it is possible to fix an essence of man that is independent of history and culture. In the 1920s it was Georg Lukàcs who supports this skepticism which was reinforced later in the 1930s by Max Horkheimer (1935). Their critique was not directed specifically at human rights, but it was partially to blame for the fact that Western Marxism has had such difficulties with this legal institution up to now. Lukàcs (1923, p. 204) sees it as 'the greater danger of every anthropological standpoint,' that it 'causes man to ossify as fixed objectivity and thus pushes dialectics and history to one side.'

The idea of human rights counters skepticism by weakening its claim. According to Aristotle's classical topos, *physei politikon zoon* (*Politics* I, 2), the specifically Greek form of a community, the *polis*, is the only place where man can lead a really meaningful life. Even if Aristotle is right and human potentialities can be fully realized only in a political community, the form of this community remains open. The above mentioned difference between universality and uniformity first becomes important here: human rights favor neither the Greek city state nor the modern form of territorial state nor any other form of political communities.

Anthropological relativization goes even further. In contrast to Aristotle's *Politics*, human rights allow a largely instrumental understanding of the political community. The state does not have to represent what the great neo-Aristotelian philosopher, Hegel, termed '*die Wirklichkeit der sittlichen Idee*' ('the actuality of the ethical Idea': *Philosophy of Right*, para. 257), at least not its full actuality. What a sociologist, a 'pupil' of Luhmann, Willke (1983) terms a 'demystification of the state' remains possible. The idea of human rights admits that the 'political system' establishes no more than premises and framing conditions, whereas true humanity can be sought elsewhere, and then in different ways. (Contemporary philosophy speaks of the difference between the right and the good.)

Where this openness for different ways is lacking and where what counts is a normative concept of man, a concept of the humane man alone, one runs the risk of denying elementary rights to people who are not so human. According to Aristotle, anyone who suffers a fundamental deficiency in terms of rational endowment—in short, anyone who is mentally handicapped—is *physei doulos* and rightly viewed as having lesser rights, in other words, he is taken as a slave. To

prevent this consequence, the idea of human rights is not allowed to favor particular forms of self-realization; with regard to the humane, we need an intentional nonspecification.

The institution of human rights intentionally contains what I shall call a fragmentary anthropology and for that reason alone can be imputed to other cultures. Although *prima facie* a drawback, nonspecification is in fact an advantage: far from being indifferent to more demanding definitions of man, it is, by contrast, open, ensuring that not only different cultures, but, within those cultures, different subcultures and individuals, enjoy the right to be unique, different, and even eccentric.

Nonetheless, this right is not unlimited. Human rights resist a radical pluralization. They alone make possible the very thing that critical intellectuals such as the 'fundamental anthropologists' mentioned earlier are so keen to achieve but which they are unable to situate adequately within their intellectual framework. The plurality of cultures and subcultures can exist only under conditions which are no longer pluralizable. Thus, in the idea of human rights modesty and immodesty enter into a characteristic union. To limit all plurality and to assume that conditions exist which are equally valid throughout history is an immodest aim. On the other hand these conditions make a modest claim, not demanding to present the form of a human life but to be only a condition of a plurality of forms of life and thus abandoning any normative concept of what is humane.

This connection is possible only if we readjust the anthropological perspective; philosophical anthropology has to undergo a conversion which fully deserves the ambitious title of a Copernican revolution. Instead of defining man from the standpoint that has normally been adopted since classical antiquity, that which allows him *eudaimonia*: happiness, self-realization, or a meaningful existence, we dispense with any teleological or normative concept. My *third thesis* is this: human rights are not concerned with perfecting what is humane but with its initial conditions, with elements which deserve the qualification of the relevant rhetoric: as elements inalienable to each person they are his inherent birthright. Here, we find my initial thesis: since we are dealing with conditions of the possibility to be a man, and not a man in a biological specification but as a responsible agent, we can speak of transcendental elements or o(relatively) transcendental interests, relative to (responsible) agency.

Transcendental interests alone leave the task of legitimation underdefined. This much is clear from even a cursory glance at legal history. Since man was regarded by Judaeo-Christianity as having been made in the image of God or as *zoon logon echon* by the Greeks, the West has been familiar with a universal concept of man. Yet, no legal consequences have been drawn from this; both the Jewish-Christian tradition and the Greek one allow slavery and the inequality of women. A correlative phenomenon, familiar since the thirteenth century, is the sort of bill of rights typified, for example, by the Magna Charta Liberatum and the Golden Bull of Andrew II of Hungary. Although these charters were drawn up in states in which both ideas—'the image of God' and 'rational endowment'—were taken for granted, freedoms were not given to man as man. This deficiency remained—not, it is true, in the legal text, but in legal reality—until the time of the earliest declarations of human rights (we remember the case of a slave state proclaiming a bill of human rights).

Indirectly we stumble across a further difficulty here, which, from the point of view of legitimation, is even greater. Man should have a subjective claim to certain transcendental or anthropological interests. A claim can be made where another person has to meet that claim; subjective rights are bound by their very concept to correlative obligations, human rights to corresponding human obligations.

Three factors deserve emphasis here. First, the claims do not exist in an absolute sense; the right to exist does not mean, for example, that one does not have to die at all. Second, the right which, although only relative is not conditional, refers to ones fellow men and demands that they refrain from using force.

In an intercultural legal discourse, an objection arises at this point which is familiar from the liberalism/socialism debate: particular attention is given to civil rights and liberties, which, on the African side, are accused of favoring the individualist picture of man familiar to the West. To the extent that our fellow men are required to perform a service, not even civil rights are based on any individualistic anthropology. A social nature is assumed in an entirely traditional way, only its manner is no longer traditional. According to Aristotle, the *polis* is natural because man is invested with certain social impulses which ultimately produce the *polis* through a series of certain intermediary stages. The anthropology of human rights does not question these social impulses; it extends its horizons and discovers a complication which is the third factor deserving emphasis.

The complication has two consequences. In the first place, what has hitherto been called simply the 'social being' is given a qualifying rider: it becomes a *positive* sociality providing mutual help, with a *negative* counterpart in the form of a reciprocal threat. From an extended social anthropology—let us say 'co-operation plus conflict'—our legal institution singles out only one aspect, the conflict, namely, a threat from one of our equals, a threat, moreover, which affects the anthropological interests; these are threats of truly existential weight. Since these threats come from our fellow men, each individual is both a potential agent and, at the same time, a potential victim.

The anthropology bound up with being both victim and agent recalls Hobbes' dictum, *homo homini lupus*,

and, like that dictum, sees itself exposed to the reproach that it presents a pessimistic image of man. But, at least as far as the idea of human rights is concerned, this reproach is unjustified. Being modest once more, negative social anthropology is not claimed to be exclusively valid but, once again, to be fragmentary anthropology—not a basic feature of the individual but a danger which cannot be excluded.

The complication caused by threat has a second consequence, inasmuch as the evolution of the *polis* can no longer be regarded as the mere development of pre-existent social impulses, a far greater contribution of ones own is necessary; although he is a social being, man has to produce himself as a social being. Society arises through mutual recognition, which can assume a variety of forms; human rights emphasize only a small part, and that part concerns the elementary level of anthropological interests.

The anthropology of human rights relates to existential threats but refrains from passing judgement on the nature of the conflict, whether that judgement be positive or negative. Therefore, a *fourth thesis* reads as follows: the danger of conflict is accepted as an anthropological fact which is favored in relation to man's cooperational nature only to the extent that it is his conflictual nature alone which makes human rights necessary. Where social relations consist only of mutual help and where help is not only always spontaneous but can be relied on, in a word, where man's positive social nature exclusively is involved, human rights lose their task.

4. *Transcendental Interests and Transcendental Reciprocity*

It is the fact that elementary interests are at stake that constitutes the seriousness, even existential seriousness of human rights and explains the feelings and the pathos bound up with this institution. An indispensable element—the character of a claim—is not yet clear, however. In many arguments there is a hiatus at this juncture, a legitimate leap which fails to explain why a subjective claim insists on the recognition of transcendental interests. I do not dare to suggest that I can justify this claim in the face of every doubt, but I am making a proposal based on a generally recognized principle.

A moral claim insists on the recognition of a service where the service is rendered on condition that a corresponding service be rendered in return. This generally recognized principle regards the obligations of legal morality (and not of all morality) as a giving that is made on condition that a countergiving is made; it operates with the reciprocity of giving and countergiving, you could say, with an exchange. Anyone who lays claim to those services which are rendered only under the condition of reciprocity now stands under an *obligation*. Conversely, a (subjective) *right* is involved as long as one actually renders the service which is performed under the condition of a service in return.

In terms of human rights, this general principle must now be applied to the particular case of anthropological interests. For them, there is a correlation between rights and duties where certain interests not only have an anthropological status but also fulfil the condition that they are realized only in and through reciprocity. Here, and only here, in the case of an 'inherent reciprocity,' or an inherent sociality, is one no longer free to say whether to accept an exchange or not. To the extent that, in keeping with their qualification as anthropological, the interests are indispensable and to the extent that they are also bound up with the idea of reciprocity, the indispensability is transferred to the reciprocity; the corresponding exchange is similarly indispensable.

The proposal obtains a moral, albeit undemanding moral element: at the basis of human rights is a modest morality that is withdrawn from the usual controversies. This morality—fairness in exchange—applies in those cases where it is not a question of one person giving and the other taking, but, rather, where there is a reciprocity of giving and taking and where, moreover, the giving and its recompense are more or less equal in value.

Since a moral element is present, the legitimation of human rights obeys the structure 'anthropology plus morals.' In this legitimation the moral part is as good as uncontroversial, but the same cannot be said of the anthropological part. Human rights represent a problem that is very much bound up with legal *ethics*, and yet it is their other aspect, that of legal *anthropology*, which contains the greater difficulties. At least on *their* account what was formerly a great discipline, philosophical anthropology, merits a minor revival.

It is the both-victim-and-agent anthropology which allows us to describe human rights as an exchange which anyone can enter into with anyone else. Each of us exchanges his own potential for committing an act of violence for the interest of not falling victim to another's violence. Characteristic of this exchange is its inherent reciprocity: one can realize one's own interest only by virtue of a service which the others—*all* the others—perform. In addition, we rediscover a difference to traditional social philosophy. Mutuality consists not of positive services but of a negative reciprocity, in an all-round rejection of violence. Nonetheless, the exchange has a positive significance as such, and not only as consequence, otherwise there would be no reason to agree to it. When the corresponding human *obligations* are fulfilled, human *rights* should be granted. From the reciprocal refusal to kill one's fellow man, to rob them, or to prevent them from practicing their religion issue the right of life and limb, the right to property, and the right to religious freedom.

The question which now arises is whether, for the sake of the positive purpose, each of us should agree to this negative exchange. Does the condition 'innate interest' apply just as much as the condition 'inherent reciprocity'? The question has the character of a preferential choice which is decided on the question of what people prefer. Do they prefer to have the right to kill, but coupled with the danger of being killed themselves, or do they prefer the integrity of life and limb, but at the price of having to accept the corresponding obligation and no longer kill any person? Or, put another way: does the individual prefer to be both the victim and the perpetrator of violence or does he prefer a neither/nor situation?

According to a first attempt of philosophical legitimation—that of Hobbes—every man has an overriding desire: not to die at the hands of a fellow man. The English Civil Wars of that time make it clear enough that many people see religious freedom as more important, while others prefer political or cultural ideas, and a third group prefers honor.

The counterexamples can be subsumed under the heading of self-preservation. What is preserved, however, is not the physical self but a 'moral self.' Is it here, therefore, that the predominant interest is to be found? In the conflict of 'physical vs. moral self,' one can certainly decide in favor of mere survival. If there is really an innate interest, it must be sought on a logically higher level, beyond the conflict of 'physical or moral self.'

A third attempt remains with the idea of an overriding desire, but takes that desire not as something negative but, rather, positive, something, moreover, which is no longer a dominant but an all inclusive interest. The interest that includes all other interests within it we call happiness. As it fulfils all needs and interests, it forms the natural guiding principle of every individual. With so formal a definition, however, it is not possible to answer the question, whether a person would rather perpetrate a violent act and at the same time be its victim or whether he would prefer neither one nor the other. If we introduce a further definition, therefore, and insist on defining the content, the individual is left with the possibility of sacrificing his happiness to a fellow man or to a religious, cultural, or political ideal. As a formal definition, happiness is unrelinquishable, but it forms too weak a premise; conversely, a definition which takes account of content reflects a predominant desire which can be seen in relative terms and, like this, represents too powerful a premise.

Anyone who concludes from this that there is no interest in the corresponding exchange fails to see that many people want nothing more than their own survival, while others want only religious freedom, others again only political freedom, and so on. On each occasion, the corresponding rights are advantageous, but they are not the same rights for each person. In other words, people are happy to vote for human rights, but they interpret that vote very differently.

We need to look for a fourth answer which preserves the strengths of the first three attempts while overcoming their weaknesses. On the one hand, we need a stronger premise than a merely formal definition of happiness; on the other, the undue assumption of an absolutely overriding desire must be abandoned; what we are looking for is an interest that is both substantial and nonsubstitutable. My *fifth thesis* is as follows: this double condition is met by interests which one can neither abandon in favor of higher interests nor weigh against interests of equal importance. Truly indispensable—and, therefore, anthropological—interests consist of elements which, logically, are on a higher level and which, *faute de mieux*, are called (relatively) transcendental interests. To the extent that, in our abstaining from the use of force, our interests are realizable only in reciprocity, in other words, in an exchange, one can speak—with the same proviso—of a transcendental exchange or a transcendental reciprocity. Human rights refer to conditions of agency based on reciprocity.

The idea of human rights presupposes that there are indeed interests on this higher level and that there is, therefore, an exchange on a logically higher level. Let us take an intentionally uncontroversial example—the protection of life and limb. Even someone not especially attached to life has an interest—conscious or unconscious—in that life, since he can otherwise neither desire anything nor seek to satisfy his desire. Independently of what one strives to achieve or seeks to avoid in terms of life's content and, therefore, a condition of our ability to act, a condition of agency, life is the precondition of a practical desire. It is at this point that the singular nature of human rights emerges most clearly, without the corresponding acts of renunciation, the very thing that distinguishes man—his agency—is not capable of existing within a social perspective. This is true even of those who are prepared to sacrifice their own lives: the martyr wants to decide in what cause he lays down his life, in other words, he acts out of religious or political conviction and not, say, because of some robber's act of violence.

The natural law of the Enlightenment appealed to the principle of self-preservation. If I consider the principle of agency to be more convincing, it is because it is more formal and, therefore, has fewer preconditions attached to it. When I speak of agency, it is not, of course, an ability to act *sans phrase* but simply that part which involves reciprocity.

5. *Against a Liberalist Restriction*

Man is not merely a living being. More than life and limb are involved in the indispensable conditions behind his agency; in consequence, there is more than

just this one particular human right. We can argue directly on the basis of our agency. Since the concept of action involves intentionality, the conditions for agency also include the conditions of intentionality, in other words, the ability to speak and think. Furthermore, in accordance with the claim that man cannot become a man but within a society of fellow men, agency is bound up with positive social relations and cooperative conditions, thereby opening up an additional field of transcendental interests. (We find the traditional anthropological definition of man: he is *zoon*: an animal, *logon echon*: endowed with reason and language, and *zoon politikon*, a social being.)

My proposal: the majority of human rights can be reconstructed on the basis of these three aspects, which, taken together, make the ability to act or agency, a real possibility, in other words, the living being, the being who is able to talk and to reason, and the cooperational being. The insight contained herein, namely, that there are further transcendental interests, is not of course sufficient to proclaim corresponding human rights. In order to do that, we also need to prove a transcendental reciprocity.

The politics of recent decades have grown sensitive to other aspects, including questions of personal, social, and cultural identity, of economic and social prerequisites and, not least, ecological conditions. Here, too, there are forms of reciprocal threat for which our legitimation model remains applicable. At all events, we are dealing with new forms, with threats which are both indirect and which involve a collective responsibility, so that the legitimation model needs to be developed further. But even here it can be stressed—and this is my *sixth thesis*—that the last word has not yet been spoken on human rights within the classic, liberalist canon.

According to classical liberalism each should know his interests best; but since Nietzsche and Freud this view has prevailed as naive. The concept of transcendental interests reaches far beyond this controversy. Within elementary interests, transcendental refers to a stratem that we have not only independent of attitude but also independent of being man or woman, Christian, Muslim, or nonbeliever. The singular character is due to the fact that one does not want anything else but the following: to be an entity capable of action.

According to Rorty (1989, p. 28), the thought that the belonging to a biological species implies certain rights is a type of metaphysical consolation, which the pragmatist renounces. The preceding legitimation shows on the one hand that it is not the biological belonging that establishes rights, but rather the interaction of transcendental and moral arguments; and on the other hand, that for a metaphysical consolation not only the pragmatist but also the theoretician of human rights can renounce.

A legal order cannot safeguard human rights without governmental powers. My *seventh thesis*—a thesis which is itself subdivided—argues against anarchism. According to this thesis, a public power is needed first to provide a more detailed definition of human rights; this is the task of the legislator. But even with more detailed definitions there are controversial interpretations, so that an unpartial and authoritative interpretation, i.e. an independent judicial system has to settle the relevant controversies. Finally, there is another complication, and once more a complication in the form of a danger: one can vote for the recognition of rights and still attempt to enjoy the advantage of a mutual renunciation of freedom without paying the price of renouncing of one's freedom. It is above all in those instances where countergivings do not occur at the same time as the giving that one can enter into an exchange of freedoms in the manner of a fare dodger. This possibility reveals a further element of negative social anthropology, namely, the danger of parasitically exploiting a universal advantage. Public powers are demanded a third time, therefore being needed here as an implementational force—a kind of 'sword of justice.'

Even if more detailed considerations are needed for a convincing legitimation (see Höffe 1987, Chaps. 13–14), this hypothesis of differentiation appears nonetheless plausible. Looked at from the standpoint of the institution of human rights, the classical—specifically Aristotelian—idea of a political nature develops as two partial natures, one of which is concerned with the law, the other with the state. Man is a being that needs, on the one hand, elementary rights and, on the other, the public definition and implementation of those rights, and in this context, he needs democracy. By consequence: rights first, but in any case, democracy, too. Against an overrating of the state, this aspect is secondary, however, being subsidiary to the primary task, which is that, in order to be a human being among his fellow men, man needs elementary rights and correlatively elementary obligations.

Human Rights: Political Aspects

Human rights are, literally, the rights that one has simply as a human being. Although the fate of human rights is largely determined by national political struggles and practices, the focus of this article is international, because only in international studies has human rights become a well-established 'mainstream' concern of a social science discipline.

Prior to World War II, human rights was an ignored, even suppressed, issue in international relations. Even the notoriously 'idealistic' Covenant of the League of Nations does not mention human rights. The turning point was the creation of the United Nations, in the shadow of the Holocaust. The UN Charter lists promoting human rights as a principal objective of the Organization. Even more importantly, the Universal Declaration of Human Rights, adopted by the General Assembly on December 10, 1948, established substantive international human-rights norms that have come to be accepted, at least in word, by almost all states and most leading movements of political opposition in all regions of the world.

In the first two decades after the Universal Declaration, however, both superpowers used international human rights largely as an instrument of partisan political abuse. Although decolonization helped to spur relatively nonpartisan international attention to self-determination and racial discrimination, through the early 1970s no prominent state pressed international human-rights concerns except in the presence of strong political interests.

Rights that are given, either by 'benevolent' dictators or foreign powers, usually end up being rescinded. Only when right-holders are able to, and at least periodically do, act to vindicate their rights are they likely to be enjoyed securely. Thus foreign states and international organizations, as well as transnational nongovernmental organizations (NGOs), have increasingly focused their efforts on supporting the development of autonomous, intermediate associations in civil society, in recognition of the fact that international action usually can only be a supplement to national action.

The other major change of the post-Cold War era has been the growing integration of human rights into other areas of the international action. For example, at the UN during the Cold War, human rights were rigorously segregated from peace and security, and development activities. Today, a human-rights mission is a standard part of peace and security operations. Furthermore, the threats to peace and security to which the UN responds are most likely to arise from systematic human-rights violations.

The penetration of human rights into other domains of international action is far from complete. Most notably, although the United Nations Development Programme stresses the links between human rights and development, human rights have made almost no headway in the work of the International Monetary Fund, which regularly imposes structural adjustment programs that have significant negative impacts on economic and social rights. Nonetheless, at the start of the twenty-first century human rights are increasingly seen as not merely a regular part of international relations but a concern with vital rights enumerated in the Universal Declaration. Thus the Vienna Declaration, adopted by consensus by 171 participating states, in its first operative paragraph 'reaffirms the solemn commitment of all States to fulfill their obligations to promote universal respect for, and observance and protection of, all human rights and fundamental freedoms for all.'

As human-rights values have filtered into the consciousness and practice of states, bureaucrats, citizens, and civil societies across the globe, the bases of national and international political legitimacy have been transformed. The Vienna Declaration, again in its first operative paragraph, proclaims protecting and promoting human rights 'the first responsibility of Governments.' And in sharp contrast to half a century ago, governments today can expect to be reminded, often loudly, of their human-rights responsibilities by foreign states, international and regional organization, the transnational human-rights movement, and, to the extent that they permit it, their own citizens.

The global human rights regime, however, is based on *national* implementation of international human-rights norms. Norm creation has been thoroughly internationalized: the UN Commission on Human Rights drafts treaties and declarations through a process that emphasizes consensus. Implementation, however, lies almost exclusively with sovereign states.

Although the UN Security Council has asserted its enforcement powers in a handful of cases, multilateral human-rights institutions have monitoring rather than enforcement powers. The UN Commission on Human Rights, in addition to its vital work in developing international norms, investigates violations in particular states and substantive issues of broad international concern. The Human Rights Committee (HRC) and the Committee on Economic, Social, and Cultural Rights, which supervise state compliance with the 1966 International Human Rights Covenants, are restricted principally to reviewing periodic reports submitted by states. (The HRC also investigates

individual complaints, but these procedures have been used infrequently—less than 250 decisions in more than 20 years—and its findings have no legal force.) Supervisory committees created under other international human-rights treaties—dealing, most prominently, with racial discrimination, women, torture, and children—are also largely restricted to reviewing and commenting on periodic state reports.

Such reporting schemes have considerable value. In conscientiously preparing a report, states often identify areas where improved performance is possible. At minimum, states know that they are subject to periodic scrutiny by an impartial international body. But these supervisory committees cannot even order, let alone, compel states to alter their practices. Multilateral action thus is most likely to bring change not where violations are most extreme, and thus 'most needed,' but in countries where violations are less severe and where governments have a significant internal motivation for change.

The principal exception is genocide, where a system of international enforcement (although not prevention) does seem to be emerging. The Statute of the International Criminal Court, adopted at Rome in 1998, establishes individual criminal responsibility for genocide, crimes against humanity, and war crimes. Furthermore, antigenocide norms are increasingly enforced through armed humanitarian intervention (e.g., Bosnia, Rwanda, East Timor). But for all other human-rights violations—that is, all but a tiny (if important) handful of violations—multilateral institutions monitor state practices rather than enforce international norms.

The powers of regional human-rights organizations vary immensely. At one extreme, the European Court of Human Rights provides authoritative judicial enforcement of the 1950 European Convention on Human Rights for the members of the Council of Europe. At the other extreme, there are no regional human-rights institutions for Asia and the Middle East. The Americas lie about halfway in between. Members of the Organization of American States (OAS) are subject to investigation by the Inter-American Commission on Human Rights, but the Inter-American Court of Human Rights has been much less active, and considerably less effective, than its European counterpart. The African (Banjul) Charter of Human and Peoples' Rights has created only a very weak commission and no court.

In looking at international implementation, we also must recognize that states, for all the talk of globalization, remain the central international human-rights actor, not merely through their control of international and regional organizations but in their bilateral relations. But they still typically apply only the weaker of their available means—praise and protests, symbolic actions, and occasional financial incentives and penalties—in the pursuit of human-rights objectives. No state, weak or strong, 'nasty' or 'nice,' has been willing to sacrifice vital national interests, or even very much in the way of economic, security, or political interests, to human rights goals.

But states also lack the authority to use force unilaterally against international human-rights violators. And whether undertaken by states or regional international organizations, sanctions short of direct military intervention, as the embargos against Cuba, Iraq, and Serbia suggest, typically inflict far more harm on innocent victims than the targeted regimes. Furthermore, even where external coercion ends abuses or topples a repressive regime, this usually is only a first step toward establishing a rights-protective regime, as Somalia and Bosnia suggest. Thus even where external actors are willing to use coercive means to pursue their human-rights objectives, it is not clear that they have the capabilities to have a decisive positive impact.

This suggests an unusually important role for transnational human rights NGOs. They have been, and remain, important transmitters of international human-rights norms. They have a single-minded focus on human rights, in sharp contrast to states and international organizations, which must balance a range of often competing interests. And they increasingly understand their role as supporting the local human rights advocates and progressive elements in 'civil society' that, along with local governments, hold the key to the future of human rights.

Four events of the mid-1970s signaled the maturing of human rights as an international issue. The 1973 coup in Chile provoked a major and sustained international reaction that for the first time cut across Cold War divisions, with many European states joining the criticism of the US-backed military dictatorship. The Helsinki Final Act of 1975 introduced human rights into the mainstream of East–West relations. The award of the Nobel Peace Prize to Amnesty International in 1977 marked the emergence of transnational NGOs as significant international human rights actors. And when Jimmy Carter became president of the United States in 1977, one of the world's two leading powers began to raise human rights issues with allies as well as enemies.

Human rights violators continued to meet criticism with vigorous appeals to sovereignty and nonintervention. States rarely went beyond verbal and symbolic action in support of their human rights objectives. The moral power of international and nongovernmental organizations to mobilize shame often ran up against shameless governments. Nonetheless, by the early 1990s the international human-rights landscape had been significantly altered.

At the 1993 World Human Rights Conference in Vienna, the Cold War ideological wranglings over the relative priorities of economic, social, civil, and political rights, and parallel North–South debates over the relationship between human rights and development, were largely discredited. Although national

or regional culture continues to be used to justify substantial derivations from international norms, such arguments are generally rejected for the linkages to a wide range of other national and international interests.

We can see a comparable maturing of human rights as an area of scholarly inquiry. Just twenty-five years ago, one could count on one's fingers the number of social scientists who specialized in human rights. Through the end of the Cold war, the scholarly literature on international human rights was largely legal, institutional, and policy oriented, as well as poorly integrated within the leading disciplines. In recent years, human rights has moved into the mainstream of political science and international studies, at least in the English-speaking world. And we are beginning to see a new generation of scholarship that increasingly adopts mainstream disciplinary methods. Thus this encyclopedia appropriately includes an entry on human rights, whereas a comparable project just a quarter century ago almost certainly would not have.

Human Sciences: History and Sociology

Reference to 'the human sciences' is loose and variable. With few exceptions, there is no correspondence between the term and existing disciplines. Indeed, the term has different connotations for different academics. For some, it refers to what they hope will be a field constituted by debate about what sort of systematic knowledge of human beings is possible, not by a particular body of knowledge. By contrast, others think the field is simply the biology of human beings. Most commonly, the term is one of convenience: 'the human sciences' covers the past and current pursuit of knowledge of human activity, without specifying precisely what is included. The term may cover psychology, linguistics, sociology, anthropology, economics, human geography, and political science, and also parts of the organizational sciences, history, biomedicine, cognitive science, neuroscience, and other areas as well. Nevertheless, it is increasingly common, and significant, for the term to signify a cluster of debates about knowledge and the achievements—or limitations—of existing disciplines.

1. Comparative Meaning and Usage

The difficulty of providing precise definition comes from the subject. 'Man' is not an empirically delimited subject. Theoretical argument about how to characterize the subject, rather than empirical investigation of a given domain, is central. At the same time, empirical research from areas of activity as divided from each other as evolutionary biology and cultural studies have considerable influence. The content of the field is variously said to include the biological human species, the 'Being' of 'Man,' language itself, socially and historically constructed culture, practices of ordering human life, and so on.

When the term refers in an open-ended way to knowledge of humans, usage relates to the '*sciences de l'homme*,' a phrase denoting a conventional division of Francophone academic life covering the psychological and social sciences. There is also overlap between the human sciences and the '*Geisteswissenschaften*,' the sciences concerned with the activity of the human mind or spirit. As German-language usage indicates, the meanings of the word 'science' itself enter argument about the human sciences. In Continental Europe, a disciplined, rational body of knowledge forms a 'science' (theology, for example, may be referred to as a human science), while in the Anglophone world, 'science' is often shorthand for 'natural science.' Except in the usage of some natural scientists, reference to the human sciences follows Continental European usage and includes humanities disciplines as potential 'sciences.' Looked at historically, the human sciences have roots in the eighteenth- and nineteenth-century 'science of man' and 'the moral sciences.' These English-language expressions referred to areas of knowledge thought to be distinctive by virtue of human reason, language, morality, and society.

In the social sciences, it is becoming common for 'the human sciences' to include disciplines that are not subsumed by the natural sciences and that share in

common the goal of understanding human activity and its products. Institutionally, these disciplines often form social science faculties, though they may also spread into natural science faculties (e.g., psychology) or humanities faculties (e.g., history). Reference to the collective term is more than a matter of convenience. Deep and complex issues are at stake. One view holds that debate about the nature of knowledge, or 'science,' of the human subject is intrinsic to being human; 'human science' is therefore an essentially contestable area. The long history of disagreement about the identity, content, and methods of all aspects of the human sciences supports this view. This disagreement continued in the late twentieth century, especially in controversy about the respective contribution of the natural sciences and humanities.

But sometimes scholars have held the view that one particular science provides the foundation for a unified human science. Around 1800, French intellectuals argued on behalf of '*idéologie*,' a science of the origin of action and ideas in sensation and organization. In the USA in the 1950s, there was an attempt to fashion 'behavioral science' as unified human science; more recently, some scientists have promoted evolutionary biology as the basic science of human existence.

2. *The Evaluative Connotations of Usage*

Earlier encyclopedias of the social sciences contain no reference to the human sciences. Recent usage reflects changing arguments and values in the academic community. First, a number of scholars welcome the interplay of different approaches, and do not think disagreement is a failing of science; according to some, disagreement is intrinsic to knowledge of humans. Second, they argue that the natural sciences do not, and cannot, provide explanations for much of the human sphere. This point is made because natural science knowledge does not address certain topics (e.g., symbolization, and meaning), not because natural science is thought undeveloped.

Third, many scholars hope to establish new relations between the psychological and social sciences and the humanities (that is, disciplines like art history and literary theory). Fourth, an interest in the human sciences often indicates sympathy with the view that history of belief in human realities and their representation is necessary to knowledge. Finally, usage expresses conviction that the existing social science and humanities disciplines are historical, social constructs, which structure knowledge in contingent and possibly restrictive ways. Deeper knowledge may need an overarching conception, signaled by reference to 'the human sciences.'

The spread of the term therefore correlates with the critique of positivist views of the social sciences and of 'behavior' as a unifying concept, and interest in rethinking the relations of history and scientific knowledge and overcoming disciplinary specialization in the psychological and social sciences. Some observers see correspondence between these values and the spread of a postmodern ethos. The welcome given to open-ended argument, skepticism about the unification of knowledge, and turn to the examination of 'science' using theories and methods developed in other areas of academic culture, does suggest that spreading interest in the category, 'the human sciences,' is part of a wider change.

Yet, there are some scientists for whom the term 'the human sciences' simply describes the extension of the natural sciences to encompass the human sphere. This usage is rejected by most academics. They do not deny that human beings are part of nature (and hence a subject for natural science), but they maintain that human activity is self-created through historical processes of reflection and language (and hence that there are non-natural science forms of objective knowledge). There are major differences of emphasis among those scholars who have no pretension of creating a unified human science. Some, such as the philosopher Charles Taylor, may be called 'humanist.' They have argued for the distinctiveness of the human sciences because of values thought intrinsic to human activity. This orientation has been critically dissected in 'the linguistic turn,' a cluster of arguments about language or representation—rather than 'nature,' 'Being,' or 'Man'—as the subject matter of knowledge. Scholars such as Michel Foucault may be called 'antihumanist,' as their projects deny reference to anything 'essentially human,' and instead consider only the conditions of possibility for knowledge at a particular time. Yet others, such as the philosopher of science, Ian Hacking, find, ways to hold in tension this polarity while opening new views of the human subject.

3. *History of the Human Sciences*

The modern disciplines of psychology and the social sciences are creations, for the most part, of the late nineteenth and early twentieth centuries. Their establishment is part of the modernizing process, the recreation of human activity as subject to rational discipline, evident at least from the early modern period in Europe. During what historians call 'the Enlightenment,' there was a deeply influential attempt to extend knowledge of laws of nature to include individual and social activity. Scholars worked in a variety of settings, outside as well as within the academy, and according to many intellectual agendas. Giambattista Vico, whose '*scienza nuova*' encompassed myth, poetry, and history as human creations, was a professor of rhetoric at the University of Naples. David Hume wrote 'of human nature' as a literary essayist, while his friend Adam Smith taught about 'the wealth of nations' in courses on moral philosophy at the University of Glasgow. Montesquieu was a French aristocrat whose comparative study of legal systems, government, and custom enhanced notions of

the relativity of social life, while J. G. Herder, a civil servant in Saxe-Weimar, linked the fate of peoples and the fate of culture and language.

There was, however, no reference to 'the human sciences' but rather to 'the science of man.' Historians use the former term to encompass the background for all the intellectual activity divided since the late nineteenth century among the modern disciplines. The philosopher of the social sciences, Peter T. Manicas, for example, claimed that political economy was the first 'scientific' human science. Historians of 'the human sciences' distinguish themselves from historians of psychology, economics, or other disciplines, by stressing the historically relative classification of knowledge and practice.

In the nineteenth century, G. W. F. Hegel, Auguste Comte, Karl Marx, Herbert Spencer, and Charles Darwin each brought human existence within the scope of a unified 'science.' Each attempted to make human existence intelligible through historical forms of explanation. The very generality and scope of their work, however, contributed to the major revisions associated with discipline formation in the social sciences. Speculative historical reconstruction integrated poorly with the disciplined search for precise, empirical knowledge, and with the knowledge generated in the context of social problems.

The outcome was a commitment to differentiating professional and amateur, to institutionalizing research and training within universities as disciplines, and to separating what was held to be science from application. There was debate about the foundations of knowledge and relations between knowledge of nature and knowledge of culture. J. S. Mill, under the heading of 'the moral sciences,' stated the case for explanatory continuity, though he thought that an enormously complex task lay ahead to explain social life by laws of human nature. In the German- and French-language universities, there were arguments, still cited at the end of the twentieth century, about the need for hermeneutic, or interpretative, understanding of human actions; about the distinction between nomothetic (or law-like) and idiographic (or particular) explanations; about structural versus historical explanation (especially in economics and linguistics); and about how values relate to science. The participating scholars—such as Wilhelm Dilthey, Gustav Schmoller, Emile Durkheim, Ferdinand de Saussure, and Max Weber—give the human sciences many of their primary reference points.

In the English-speaking world, especially in the USA, the outcome was the establishment of empirically based disciplines, often accompanied by belief that this followed natural science example. The US model of professional research became dominant almost everywhere after 1945. For many researchers, this carried forward the enlightenment vision of improving human life on the basis of objective knowledge. But only when there were hopes for a more unified and more effective social science was there discussion of a global project comparable to 'the science of man.' In the interwar years, the Rockefeller Foundation supported a science of personality and society. The Ford Foundation's entry into the social science field in 1952 fostered 'the behavioral sciences.' A commitment to unification was matched at the level of national politics by a perceived 'moral lag,' belief that natural science and technology had outstripped the political and moral capacity to order human affairs.

Reference to 'the human sciences' dates mainly from the 1980s. Weaknesses in both Marxist and empiricist philosophies of social science led to an historical as well as philosophical re-examination of theory. Developments in the humanities and social sciences directed empirical research to the 'representation' of knowledge and power rather than to questions, customary in the empiricist mainstream, about objective truth and material reality. By contrast, some biologists concurrently claimed that their field was uniquely competent to understand human beings. Thus, different groups, with different interests, found it useful to promote the same generic term. The only English-language term available was 'the human sciences,' a term preferred to 'the science of man' in the English-speaking world, as it appeared neutral in relation to gender.

The social circumstances were not propitious for new large-scale institutional arrangements, and the number of scholars who identified themselves as primarily occupied with the human sciences, as opposed to occupied in one of the existing disciplines, remained small. Nevertheless, some organizations, particularly emphasizing history, appeared: a journal, *History of the Human Sciences* (founded 1988); the European Society for the History of the Human Sciences; the *Société Française pour l'Histoire des Sciences de l'Homme*; and a Forum for the History of the Human Sciences within the History of Science Society in North America. When institutions or conferences use the term 'the human sciences,' it tends to be a utilitarian response to local organizational needs, bringing under a common administrative, and sometimes research, umbrella such disciplines as anthropology, applied social science, and social psychology.

4. *Theoretical Content*

If we take the view that the content of the human sciences is open-ended, the field has the following character. First and foremost, the field does not presuppose what the human subject *is*, but seeks to analyze and understand the historical and epistemic conditions of human activity at any particular time and place. There is therefore a literature about the representation of human action and human nature—

in practice as well as in written, visual, or other sources—and about such basic categories as 'economy,' 'modernity,' and 'the self.' The field, understood in this way, does not presuppose evolutionary biology or, in common language, 'human nature,' as the subject of objective knowledge, but rather seeks to understand how what is accepted to be objective knowledge is created through historically or humanly constituted processes. The humanities disciplines have a marked influence, encouraging interest in such topics as symbolic representation, rhetoric, and identity formation, whether of individuals, gender, ethnicity, or culture.

The field overlaps with 'the history and philosophy of the social sciences.' But whereas earlier English-language philosophy tended to take for granted the empiricist agenda of social science, and examined, for example, the nature of law-like explanation, realism, and reason and agency, the new field does not. It is more concerned with the constitution of agendas in the first place, and hence examines topics such as the influence of disciplinarity on knowledge, power and representation, and the 'given' quality of such basic concepts as 'society' and 'emotion.' Empirical studies of particulars, rather than abstract theorizing, often suggest the form of analysis.

Recent history and sociology of science (i.e., of natural science) developed independently, for the most part, of questions specific to the psychological and social sciences. But, of course, the sociology of scientific knowledge and technology is itself a major contribution to, and part of the history of, the social sciences. Some scholars, like Kurt Danziger, have extended the sociology of knowledge to the psychological and social sciences. More commonly, however, historians have informally employed the new sociology of science to explain activity in the social sciences in terms of specific factors of time and place—that is, to provide 'contextual' explanations.

Much research in the human sciences expresses general shifts, like the increased stress on 'reflexivity' and 'the linguistic turn,' in intellectual culture. The former term has multiple uses, but in the most general sense it denotes the activity of reflecting—'reflecting' in the double sense of making representations of existence and re-creating existence through the process. The most obvious instance is language: language both represents and constitutes the world as it is in human activity. Argument about the impossibility of going 'beyond' language to the world, society, or human nature encouraged research focused on language (or other signs, understood as forming a language) as the content of the human sciences. This is 'the linguistic turn.' What such claims and shifts imply is subject to intense, and often esoteric, debate. But it is an implication that a field built around such debate is open-ended in its scope and prospects.

Influential discussions derive from Foucault. Foucault, at one stage, claimed that the human sciences are part of a modern 'episteme,' or framework establishing the conditions of truth. This, he held, came into existence around 1800 through practices creating reflection on human beings as subjects, especially in educational and reformatory institutions. He described reflexivity as a special condition of the modern age, and he contrasted this with the manner in which knowledge became possible through language, classification, and political economy in the earlier 'Classical' age. While many scholars controvert the specifics of Foucault's disparate statements, his general exposure of the conditions of knowledge remains significant. His search for the sources of the human sciences in practical arrangements for discipline and government, his exploration of knowledge as power, and his use of discourse bridging the social sciences and humanities, are also conspicuous features of modern research.

Thus, the human sciences exist as an unstable and variable cluster of social science and humanities disciplines and topics, sometimes grouped merely for convenience, but also grouped because shared questions about knowledge and values are at stake. How usage of the term will develop is unclear. But the future will take account of the way the 'historical turn' has expanded and rethought historical knowledge about the sources and content of representations of human activity. It will continue to work through the implications of 'the linguistic turn' and of representation itself as human activity.

The human sciences add up to a critical reflection on the constitution of disciplines, and indeed of science, in the century and a half since the modern system of legitimating knowledge became established in universities. At the beginning of the twenty-first century, it would be surprising if past prescriptions remained unquestioned. New social forces, such as appear in feminist and postcolonial perspectives, have considerable impact. Different views of how the field is constituted obtain—from an extreme opinion that the human sciences are a branch of biology to the opposite extreme that ignores biology in toto. Within the social sciences, a conception of theory as the unifying and causally explanatory framework for knowledge is diminishing in appeal. Rather, scholars working under the rubric of the human sciences offer empirically researched accounts of matters that, through much of twentieth-century psychology and social science, were taken for granted. If earlier social scientists thought it relatively unproblematic to develop knowledge on the basis of existing categories and concepts, the human sciences open new perspectives by making that unproblematic quality itself the subject of research.

Human–Computer Interaction

The increasing contribution of other disciplines is making human–computer interaction focus less on the individual, with the consequence that a great deal can be gained from other fields within the social sciences, and perhaps, provide more insight into human behavior in return.

Human–computer interaction, more widely known by its acronym HCI, is primarily the study of how people use the complex technological artifacts that now pervade their lives. A secondary, but arguably more important focus, is on how these artifacts can be designed to facilitate this use. As an applied discipline, HCI encompasses theoretical and academic researchers from psychological and computer science backgrounds, who may be interested in the area as a domain within which to apply and evaluate their theories of human or system behavior, as well as designers and engineers from industrial and commercial backgrounds, for whom the pay-off is a saleable product, built faster and more economically than their competitors'. In recent years, with the rapid technological development of computing devices and their increasing ubiquity within telecommunications, the field has expanded to include social and organizational researchers, who examine the impact that the technologies have upon human–human interaction. This itself feeds back to the identification of novel applications and the development of further devices. HCI is now an active, multifaceted, and methodologically diverse component of the domain that it studies, both following and directing technical innovation.

1. Origins in Human Factors and Cognitive Psychology

The roots of HCI predate the invention of computers, and the term itself has only been used since the 1970s. At their simplest, computers are just machines, built to help people carry out tasks, and the dominant paradigm for studying HCI has been that of ergonomics or human factors, with study of the *interaction* between the human and computer subjugated to that of the human's *use* of the computer. An earlier name for the field was man–machine interaction, and within the field, the words person and human are still generally replaced by the term 'user.' In the same way that early time and motion researchers would analyze the tasks that a factory or office worker performed, breaking their job down into its constituent elements, measuring the time each part took and assessing their relationships to each other to identify any 'wasted,' redundant, or unnecessary actions, so too have HCI researchers attempted to decompose the user's task, and to identify task steps that are difficult to perform, hard to learn, or confusing.

This emphasis on task analytic decomposition reflects the early predominance within HCI of cognitive psychologists, who brought with them information processing models of human thought. These models were themselves based on a metaphor of the mind as a computer: one that received sensory input, processed it with access to memory and inferential resources, and produced motor output to act upon the world. By far the most influential of these within HCI has been the GOMS model (Card et al. 1983), which stands for Goals, Operators, Methods, and Selection. Based upon an intentionally simplistic conception of a model human processor (MHP), a GOMS analysis would identify the goals that the user has to reach, and the operators or mental actions available to the user to

carry out the task of reaching the goal. Frequently used series of operators become chunked as easily accessible 'methods' that are linked to a subgoal or specific part of the task, and selection routines enable the user to 'decide' which alternative methods or operators to apply if there is more than one possible route to the goal. The MHP provides estimates of the length of time that executing each basic sensory, cognitive, and motor operator takes (these values being empirically derived from cognitive psychology experiments), and so once an accurate GOMS analysis of the task has been produced, it is possible to sum the durations of each component to produce a prediction of the time taken for the whole task to be performed. Subsequent elaboration of the approach to allow the perceptual, cognitive, and motor parts of the architecture to operate in parallel, and to model the processing of concurrent activities using critical path analysis, has had notable success in modeling the efficiency of telephone toll and assistance workstations (Gray et al. 1993).

Despite successes such as this, a limitation on the application of GOMS in practice is that it is intended to model only the optimal performance of a skilled user in ideal circumstances, and so it is best suited to industrial-style settings where a particular task may be executed hundreds or thousands of times a day. An interface design that is a second or two quicker to use in these situations will thus result in a large saving in time, and presumably money, for the organization that is paying for it. GOMS is unable to say anything about another crucial aspect of interface use, that is, how long it might take someone to become an expert, how many errors a nonexpert might make, or how pleasant or unpleasant the experience of executing the operations might be. Indeed, the critical assumption within GOMS that operators can be chunked as methods is not actually addressed by the model itself. It remains the job of the analyst to recognize which sequences of operators can be represented as methods, and how finely these methods need to be related hierarchically. Recognizing that this development of knowledge about the task is the key to learning about an interface, Newell (1990) proposed what he termed a unified cognitive architecture specifically to allow problem solving and learning to be modeled as a process of goal decomposition, such that goals are iteratively broken down into subgoals. By specifying the operation of this architecture within a 'programming language' called Soar, Newell provided a technique for predicting the way that users would integrate their postulated initial knowledge with information derived from the computer interface through their interaction with it. In effect, a Soar analyst writes a program in the form of 'If, … Then …' rules, and this is then 'run' to simulate a user's learning behavior.

The GOMS and Soar research communities have had a great deal of influence within the cognitive psychology side of HCI, but as simulation models, their attention to detailed aspects of the interface is both their strength and weakness. While it allows them to identify small but critical aspects of a design as crucial problems for a user, they both require complete specifications of an interface, and for Soar, the task context and information available to a user. They therefore come into their own for the contrastive evaluation of extant alternatives, but are hard to apply systematically at earlier stages of design, when the question is 'how?' rather than 'which?' The same is arguably true of newer, more detailed techniques such as LICAI, which is based on Kintch's construction–integration model of goal formation in text comprehension (Kitajima and Polson 1997), and EPIC (Kieras and Meyer 1997). EPIC builds on the model human processor by incorporating many theoretical concepts such as the distinction between declarative and procedural knowledge drawn from Anderson's ACT class of models, and limited capacity visual and auditory working memories coordinated by executive processes. However, as Kieras and Meyer themselves note, 'EPIC was not developed primarily for addressing HCI problems but is a larger scientific endeavor to represent important theoretical concepts of human intelligence or abilities' (Kieras and Meyer 1997, p. 394).

2. *Development of Usability Evaluation Methods*

The apparent concentration of cognitive psychologists on the development of cognitive architectures that would ideally explain all of human behavior, as well as the human use of computers, can justifiably be seen as a problem from the point of view of their colleagues who are involved in the day-to-day design of computer interfaces. It was accepted fairly quickly that full GOMS models were too laborious to be practical, and a simpler (but inevitably less reliable) 'keystroke level model' was developed that avoided the need for a full task analysis. Soar models also require a programming and analysis commitment that can seem disproportionate in the context of design, especially when an apparently small modification in the design requires the whole model to be reprogrammed and rerun. It can also be difficult to identify reasons for the simulated behavior that results from an analysis. These cognitive architectures, then, may prove to be more useful in informing their core disciplines than in practical application.

In reaction to these perceptions of too much cost for too little benefit, a number of 'cut down' usability evaluation methods have been developed. All are to some extent derived from well-founded and principled psychological theories, but by encapsulating key components of the modeling techniques within a process of some form, seek to minimize the overhead costs of learning the theory itself, and to provide a positive cost–benefit trade-off by reducing the need for user

trials to be conducted with early prototypes or mock-ups of interfaces (Nielsen and Mack 1994). Cognitive walkthroughs, for example (Polson et al. 1992), provide a checklist by which aspects of the interface can be compared with the user's notional task, step by step, and screen by screen. The steps of the checklist are in fact derived from cognitive complexity theory, and the method focuses on the semantic appropriateness of the verbal labels or commands used throughout the interface, although the practitioners applying it do not need to know this.

Other approaches seek to avoid any role for theory at all, and base themselves in the codification and reuse of practical experience. From the earliest days of HCI, sets of guidelines have been compiled, both within design teams to provide a 'house style' and in a wider sense as a shared set of 'best practices,' so that designers encountering a problem for the first time have access to the solutions found or attempted by others. Some, such as those presented by Gardiner and Christie (1987), have an empirical basis, and specify specific design features such as acceptable screen color combinations and choices for typefaces. Others are less formal, and direct the designer towards desirable attributes or practices such as aiming for consistency, compatibility and coherence. The rapidly evolving nature of the domain conspires against such stored knowledge, however, for anything designed before the mid-1990s is almost certain to be based on expired technology, whose constraints no longer apply. Concrete prescriptions about design solutions become outdated too quickly for their promulgation, while the more abstract (such as 'be consistent') have proven too abstract to be of much real use.

3. *HCI and the Design Process*

This focus upon evaluation reveals a fundamental problem in early notions of the relationship between design and modeling. An implicit assumption of many HCI approaches was that design could be thought of as a sequential or 'waterfall' process, with discrete stages progressing from a requirements analysis, through specification layers, to implementation, with a final evaluation of the finished product. By locating evaluation at this final stage, HCI staff found themselves limited to what became known as a 'fire-fighting' role, being asked to repair problematic designs at a point when any redesign would result in a product falling behind schedule, further worsening the cost implications of their involvement. Organizationally, it is very difficult to convince people that the design they have been committed to for months has some basic usability flaws.

As Landauer (1995) has pointed out in his econometric analysis of the computer industry, design flaws have to be identified much earlier in design if their identification is to be helpful and cost effective to repair. Fortunately, few designs actually proceed in such a strictly formal manner, with a more serendipitous, parallel, and iterative process being more typical. Such cyclical processes allow HCI contributions to be made at more appropriate junctures, and have lead to an emphasis upon user-centered design (e.g., Norman and Draper 1986), in which user testing becomes a central aspect of design throughout the process, design itself is directed towards prototyping, and designers are encouraged to 'plan to throw one away,' following Brooks' seminal advice (Brooks 1975).

A very different approach to providing support to designers in these less structured situations comes in the form of a notational decision support tool called QOC, or questions, options, and criteria (MacLean et al. 1991). Aimed at recording the 'design rationale,' QOC represents the design space through which a product has traveled, listing the questions that the design team were trying to answer at various points, the options that were considered, and the criteria that they used to choose one option over another. By making decisions and trade-offs explicit, and recording the reasons that were cited for making them, QOC provides a mechanism both for managing the decision process and for recording it for later review. It has been found to be particularly helpful in providing background information for people who were not part of the decision at the time, either because they only become involved at a later stage or because they were working on some other part of a large project. QOC is important in that it represents a wider concern with design as a process, rather than simply with evaluating its final products.

Involvement in design at a point before the final product has been created means, inevitably, that HCI methods need to provide advice to designers rather than evaluating finished designs. While 'cut-down' usability inspection methods and heuristic evaluations can be conducted on partial designs and mock-ups, it has been argued that their pragmatic separation from theory weakens their value. While they may well identify problems in a design, the fact that they are not associated with an explanatory theoretical underpinning means that the causes of the problems can remain unexplained. The benefit to the designer of a rapid identification of problems is accompanied by the cost of working out why the problem has occurred and what is to be done about it. May and Barnard (1995) recommended that HCI researchers should work towards providing 'supportive evaluation methods' that assist the designers by accounting for usability problems in terms of some theoretical concepts that are helpful in suggesting redesigns.

They referred to a distinction made by Long (1987) between the 'discovery representation' of a scientific theory and its 'application representations.' The discovery representation allows academics and researchers to explore phenomena, such as typical error patterns in HCI, or the way that users learn about interfaces

and solve problems. The application representations, on the other hand, are encapsulations of the theory specifically targeted towards practical application. These may take several different forms, depending upon the intended practitioners and the expected purpose. Unlike cut-down methods, the application representations retain a direct link to the parent theory and, in order to use them, information has to be expressed in theoretically important ways. The advantage for practitioners is that the results of their use is also couched in theoretically relevant forms, and so is linked to an explanatory body of ideas that can be recruited to assist in redesign.

May and Barnard (1995) present the example of a cognitive architecture called interacting cognitive subsystems, or ICS. As a discovery representation, it is unlike GOMS, Soar or EPIC in that it does not seek to simulate cognitive processing, but provides a framework for identifying bottlenecks in the flow of information through a series of cognitive subsystems, each of which is specialized for processing a different level of mental representation (see *Cognitive Science: Overview*). Like the simulation models, these levels include sensory, cognitive, and motor representations. The modeling process involves describing the likely pattern of exchanges between the various levels, the degree of skill-based behavior of relevant aspects of a task, the involvement of the user's recent and longer-term memories, and, crucially, the structure of the user's conceptual task or of perceptual representations of the interface. In this discovery form, the modeling is too complex to be carried out by anyone other than an expert in the theory itself, and the results are couched in terms of the processes and their configuration, rather than specific design consequences.

To support the use of ICS within design, two alternative application representations have been developed: one is a production rule-based 'expert system,' which partly replicates the role of the ICS theorist in constructing a principled model of an interaction; the other is a pencil-and-paper technique for reasoning about the changes over time in the structure of the mental representations encoded at the various ICS subsystems (Barnard and May 1999). Both of these application representations require some familiarity with the core concepts of ICS, but neither requires practitioners to construct a full ICS model themselves. Their value lies in providing problem-solving tools for designers to apply to partially specified or speculative ideas about interfaces, before any commitment has been made.

4. *Influx of Novel Approaches*

In moving away from a simulation of a user interacting with a computer, ICS is part of a trend away from the concentration upon a dyadic, turn-taking relationship between a single user and a single computer. Classical HCI models can be caricatured as having a human issuing commands to a computer, waiting for it to carry them out, and then inspecting the screen while the computer patiently waits for them to form some new goals. While this might have been an appropriate model for HCI in the early 1980s, the advent of distributed computing architectures and the massive interconnection of computing systems over the Internet means that it is inadequate. Even modern personal computers will be carrying out multiple tasks, doing background processing almost in-between each keystroke. The humans are not always isolated users pursuing solitary goals, either, but are using computers as part of their everyday activities, often in social or work settings that involve interacting with other humans with the support of their computers. An analysis of interaction that does not allow for such factors has inevitable flaws.

These developments have led to a new involvement within HCI of social and organizational psychologists, as well as researchers from other social sciences such as ethnomethodology, anthropology, and sociology (Dourish and Button 1998). This has led to an influx of novel theoretical ideas, in particular Vygotsky's activity theory (e.g., Nardi 1995) and Suchman's situated action (Suchman 1987). These ideas re-emphasize the relevance of the context within which human actions are formed, and as Carroll (1997) noted, have brought a continental European perspective into what had previously been a largely North American and British endeavor. Instead of the user and their system, activity theory deals with an 'activity system' composed of social aspects such as attitudes, beliefs, and experiences as well as technological factors.

Another development which moves away from the traditional HCI dyad has come from a computer science perspective, where the idea of a system as a single entity has long been outdated. With the introduction of 'object oriented' ideas, computer scientists have moved towards seeing complex systems as built up from a large number of quasi-independent 'interactors' that exchange information and tasks, with no constraint for these interactors to be part of a single machine. A large body of theory has evolved to model such distributed and concurrent activity, and a logical step has been to see a user's cognitive processes as just another set of interactors. The unit of analysis for such 'syndetic models' (Duke et al. 1999) is the overall system composed of human and computer interactors, and their conjoint activity can be modeled using mathematical formalisms to prove literally that certain interactions can or cannot occur, or that certain assumptions must be met for them to be possible.

5. *Prospects for HCI as a Discipline*

Both the social and the computational contributions to HCI currently fall into the discovery mode of analysis, in Dowell and Long's terms, rather than the

application mode. It is not yet clear whether these novel directions will crystallize into methods or representations that are directly applicable by design practitioners, or whether they will serve more to direct the commercial development of products away from the classical PC in an office towards other niches. They may also represent the evolution of HCI as a discipline in its own right, with its own methods and theories, rather than as an interdisciplinary area colonized by theories developed in cognitive psychology and artificial intelligence. The tension between academic theorists and practical developers will undoubtedly continue to be a major dynamic upon the field, with its predominance of conference papers enabling non-empirical presentations of novel technologies or design tools to share the limelight with hard-nosed experimental evaluations. In recent years, the increasing theoretical quality of the few specialized HCI journals may provide justification for those who have argued for universities to establish HCI departments in their own right, with their own undergraduate courses. On the other hand, the progressive involvement of computing artifacts within our everyday lives is making their use an ordinary part of human behavior. The increasing contribution of other disciplines is making HCI focus less on the individual, with the consequence that a great deal can be gained from other fields within the social sciences and, perhaps, provide more insight into human behavior in return.

Human–Computer Interface

1. Definitions: The Interface as a Carrier of Epistemologies

The computer/human interface refers to the modalities through which people interact with computational technologies. These include different data input devices: you can give the computer information through punched cards or through typing numbers on to a screen. And these include different ways of manipulating software: one can type symbols at a 'command line' or can 'navigate' a data field that appears as a three dimensional space. Specialized applications—software designed for the physically challenged, software designed to simulate airplane flight—have increased the number of available interface technologies. Computer users may employ joysticks, headsticks, trackballs, voice recognition, and touch sensitive screens to communicate with the software that governs the machine's behavior.

The breadth of the topic of computer/human interfaces and how to improve them for usability and ease is too vast to review comprehensively here (Norman 1998, Raskin 2000). This essay examines the most common shifts in interface use over the last half century up to 2000, and centers on the social and psychological implications of interface experience rather than its technical details. Interface design has not only changed the instrumental computer: what the

computer can do for us; it has changed the subjective computer: what the computer does to us, to our ways of relating to others, thinking about ourselves, seeing the world. As the dominant knowledge technology of our era, computational machines offer us images of what it means to know (Penrose 1989, Dennett 1991, Turkle 1995).

Over the last half century to 2000 the trend in interfaces has been from favoring a style of interaction in which the computer is approached as a mechanism towards interactions in which the computer is approached as a behaving and aware organism. Otherwise put, the trend has been from people acting directly on the machine to interacting indirectly with its increasingly elaborate 'self presentation' in which many layers of programming stand between the underlying mechanism and what is presented to the user. The movement has been from interface as an environment for commands (Weinberg 1971) to interface as environment for conversation or theater (Laurel 1990).Whether the computational object presents an interface that demands small or large bodily gestures or particular words or sounds, this direction (increased layering; increased opacity) has had significant psychological and epistemological implications. The computer has moved from being the primary technological model of a culture of calculation towards modeling a way of knowing in a culture of simulation. In a culture of simulation, users are encouraged to take computers 'at interface value.'

1.1 The Recent History of Personal Computing Interfaces

The first personal computers of the 1970s and early 1980s, like the mainframes and minicomputers, required users to know how to issue exact instructions. Being comfortable with their command-line required users to put themselves into the frame of mind of those who had programmed the computer, who had given it its fundamental rules. Those who were most comfortable with this kind of information interface were those who knew something about programming and its intellectual aesthetic (Schneiderman 1987).

Through the late 1970s, the computer interface presented the machine as a giant calculator. The interface carried the message that no matter how complicated a computer might seem, what happened inside it could be mechanically unpacked. The computer interface was a set of command lines that would get you close to those rules that lay beneath the surface of the machine.

The presentation of the machine through its interface captured the essence of the computer in a culture of calculation. This essence corresponded to a modernist or enlightenment model of what it means to understand: it means to have knowledge of what makes the 'clockwork' tick, and the programmed computer was conceived of very much as mechanical clockwork. When computer users talked about 'transparency' what they meant is that the interface was a window for looking beyond the 'magic' of the machine's extraordinary powers to the mechanism that made them possible.

What was true of the language that surrounded the large mainframes and mini-computers was even more true of the language that surrounded the first personal computers. These machines, first appearing in the late 1970s and early 1980s, required users to know how to issue exact instructions and they were encouraged to optimize their computers' performance by learning assembly language, by going deeper and deeper into the lower levels of a machine's structural organization. By the mid-1980s, increased processing power made it possible to build graphical user interfaces, commonly known by the acronym GUI, which hid the 'bare machine' from its user. The new opaque interfaces—the first popular one on the mass market was the 1984 Macintosh—represented more than a technical change. The Macintosh 'desktop' introduced a way of thinking about the computer that put a premium on the manipulation of a surface simulation. The desktop's interactive objects, its dialogue boxes in which the computer 'spoke' to its user, pointed toward new kinds of experience in which people did not so much command machines as enter into conversations with them (Apple 1985). In personal relationships, we often interact without understanding what is going on within the other person; similarly, when we take things at (inter)face value in the culture of simulation, if a system performs for us, it has all the reality it needs.

In 1980, most computer users who spoke of transparency were referring to a transparency analogous to that of traditional machines, an ability to 'open the hood' and poke around. But when users of the Macintosh talked about its transparency, they were talking about seeing their documents and programs represented by attractive and easy-to-interpret icons. They were referring to an ability to make things work without needing to go below the screen surface. Today, the word 'transparency' has taken on its Macintosh meaning in both computer talk and colloquial language. In a culture of simulation, resonant with a post-enlightenment or postmodern aesthetic, when people say that something is transparent, they mean that they can see how to make it work, not that they know how it works.

2. Simulation and Its Discontents

Suppose you receive this message on a computer screen when playing a simulation computer game: 'Your orgot is being eaten up.' (Turkle 1995). You do not need to know what an orgot is to play the game

although you can infer from the context of the game that it is a kind of organism. Players interact with the interface of the computer game in the same way they interact with the interface of a video game. In computer games, as in video games, one learns from the process of play. You do not first read a rulebook or get your terms straight. The game allows you to manipulate its variables directly; it enables you to avoid commands, but experiment with trial balloons. You are able to act on an intuitive sense of what will work without understanding the rules that underlie the game's behavior. Your game will teach, for example, that you that you must give your 'trilobytes' algae or they will become extinct. Thus, you can keep playing even without any clear idea of what is driving events. Clarity and a grasp of the rules are not essential to the process.

People use their contact with objects to keep in touch with their times, to discover 'what's important.' They use objects to work through powerful cultural images, to help arrange these images into new and clearer patterns. From this point of view, the opaque interfaces of simulation games and simulation tools help to help us think through current challenges to traditional epistemologies where the manifest refers back to the latent, the signifier to the signified. The personal computer culture began with small machines that captured a utopian modernist vision of transparent understanding, but the scintillating, pulsating surfaces of simulation computer games are dynamic, seductive, and elusive, a world without depth, a world of surface. *Players can stay on the surface, taking things at (inter)face value*. The computer interface serves as a carrier object which, in a significant sense, brings postmodernism down to earth.

The culture of simulation presented by the computational interface is our everyday experience of the postmodernist aesthetic. And since it is common to experience the computer as a 'mind machine' this aesthetic influences computational models of mind. For example, 15 years ago the computational models of mind that dominated academic psychology were modernist in spirit: nearly all tried to describe the mind in terms of centralized structures and programmed rules. In contrast, today's models often embrace a postmodern aesthetic of complexity and decentering. Mainstream computer researchers no longer aspire to program intelligence into computers but expect intelligence to emerge from the interactions of small sub-programs. If these emergent simulations are 'opaque,' that is, too complex to be completely analyzed, this is not necessarily a problem. After all, these theorists say, our brains are opaque to us, but this has never prevented them from functioning perfectly well as minds.

Beyond this, the development of the windows metaphor for computer interfaces was a technical innovation motivated by the desire to get people working more efficiently by 'cycling through' different applications much as time-sharing computers cycle through the computing needs of different people (Microsoft 1995). In practice, however, windows have also become a potent metaphor for thinking about the self as a multiple, distributed, 'time-sharing' system. The self is no longer simply playing different roles in different settings, something that people experience when, for example, one wakes up as a lover, makes breakfast as a mother, and drives to work as a lawyer. The life practice of windows is of a distributed self that exists in many worlds and plays many roles at the same time.

2.1 Conversation, Cuddles, and Creatures

Computers have been thought of as 'artificial brains' for generations. What is new in the current analogies of computers to the brains of behaving systems is the development of interfaces through which we can interact with computers as though they were creatures, either human or animal. An example is the conversational interface used to communicate with software programs known as 'agents' or 'bots.' The computer users types out their side of a conversation in colloquial language; the software agent responds more or less in kind. Of course, such conversations work best if the domain of discussion is highly proscribed, but the experience of such interfaces is quite dramatically that of interacting with an 'other.' Computer agents that literally present 'faces' as their interfaces dramatically increase the degree of anthropomorphism of the computational object. Voice recognition software enhances the conversational effect and the experience of the machine as a being.

Computational creatures are being designed as toys for children. Today, children are asked to interact with these creatures through gesture and touch; in the near future, the interactions will be through language and tone. In the case of the Furby, a furry, cuddly, robotic toy that seems to learn and love, the computational interface presents a creature successfully 'learning' language and being nourished by food; the child is able to respond with gestures expressing affection. In the case of another computational creature, Sony's pet dog robot, AIBO, the computational interface presents a 'trainable' dog whose personality can be shaped by the quality of the user's ministrations, communicated by speech and sound. In the case of My Real Baby, a robotic doll, the interface enables the doll to speak increasingly complex language and show emotional expression through facial musculature while affording the user the possibility of showing nurturance through feeding, caressing, diaper changing, burping, and similarly anthropomorphic 'creature comforts.' Here, perhaps most dramatically, computational design has created an interface that through its emulation of the human explicitly diverts attention from the underlying mechanism and focuses it ex-

clusively on the meaning of the 'baby's' expressions, sounds, and words. Almost no children express curiosity about how the object 'works' in the traditional sense of understanding anything about its 'innards.' They accept its behavior as that of a creature, a creature that while not human, is frequently categorized as 'sort of alive.'

3. Future Trends

Traditional approaches to studying user interfaces have focused on usability, human factors (including level of stress), and psychological studies that have examined sensorimotor adaptation, problems of information overload, ergonomics, and the resonance of interfaces with varying intellectual styles. The projected future of computation and its interfaces suggest that philosophical and even theological concerns might well be added to this mix since the interface is promised to become not only more transparent but more intimately engaged and ultimately fused with its users.

With the computer/human interfaces that researchers project in the near-future the user will experience the interface as a creature (as in increasingly advanced robots) as prosthetics (a pair of glasses that also serve as a computer screen for mobile net browsing), a piece of clothing (with embedded processors that for example use the temperature of the human body as the input to warm or cool the skin), or as a virtual world that people can fully immerse in and navigate by moving their bodies as one would move in the real physical world. Finally, there are proposals for the interface to become part of the self. In this scenario the interface becomes a digital sensor embedded in human flesh. Creatures, prosthetics, immersive environments, and in the end, the interface disappears and people reappear as cyborg.

Human–Environment Relationship: Carrying Capacity

Carrying capacity is the maximum population that a specified environment can support indefinitely without degradation of that environment (Ellen 1982, p. 41). Ecological carrying capacity links population of biota to a given habitat in which biophysical elements of the habitat determine the maximum population. In human–environment relationships, however, carrying capacity involves the added dimension of technology and management strategies; as these human-based elements change, so does the carrying capacity (Brush 1975 and Street 1969). Thus, humankind maintains the ability to expand and reduce carrying capacity, and vastly different assessments of the actual trends underway follow from the spatial scale of analysis (i.e., landscape, region or biosphere) and perspective (i.e., environment as resource commodities or as environmental services) taken (cf. Ehrlich et al. 1977 and Simon and Kahn 1984).

Contemporary uses of carrying capacity suggest that the concept was borrowed from the ecological sciences by the human sciences. In reality, however, the ecological sciences took a cue from the ideas of Robert Malthus and subsequent developments of Malthusian principles about human population–resource relationships. The carrying capacity idea can be found in various kinds of works, even though that label was or is not applied. For example, the geographer–geomorphologist John Wesley Powell used the concept in his assessment of the Homestead Act of 1862 (USA), which allowed people to claim 160 acres of public land for farming. He warned that 160 acres were insufficient in most cases because the land in question, that west of the 100th meridian, was arid and much of it lacked access to water. He maintained that these lands, absent the potential for irrigation, had value primarily for livestock and thus 'a farm unit should not be less than 2560 acres' in the arid West of the USA (Darrah 1951, p. 233).

Such examples notwithstanding, the nineteenth century development of the carrying capacity concept

in the human science is often credited to geographical and anthropological research among indigenous peoples in the less developed world, who typically maintained a fairly direct relationship between subsistence and the immediate biophysical environment (Brush 1975 and Street 1969). The British geographer William Allan (1965), for example, used the concept of carrying capacity to evaluate the Native Reserve resettlement process in southern Africa. The essential data required for the calculation were: '(a) a soil or land map based on a suitable form of land classification; (b) an estimate, for each of the land classes employed, of the proportion of land which is practicable for cultivation under the prevailing system of agriculture; (c) a survey of the customary land-usage of the people concerned, with particular reference to the duration of cultivation and subsequent rest on the soils of each land class; and (d) an average for the acreage under cultivation per head of population at any one time' (Allan 1965, p. 8). He found that the carrying capacity of the Native Reserves, registered as persons per unit area, was exceeded at their founding, based on the customary land uses of the inhabitants. Other versions of carrying capacity assessments have been called for and employed for planned occupation throughout the tropical world, including the colonization of the Amazon basin (Fearnside 1986).

As noted, technology and land resource–use strategies play an essential role in the use of carrying capacity. As these change, so does the capacity assessment. The 'Green Revolution' is a case in point. This massive change and transfer of technology and land-management strategies greatly expanded the production and hence 'carrying capacity' of many areas throughout the world by making possible the intensification of agriculture through hybrid seeds, fertilizers, pesticides, herbicides and irrigation schemes. Yet, this revolution and its land-use impacts also expanded the reach of environmental drawdown, from increased downstream flooding and sedimentation to large-scale releases of trace gases to the atmosphere, raising serious questions about the spatial and hierarchical scales at which carrying capacity should be addressed. While earlier studies could concentrate on a village or small area as a well-defined population–resource entity, it is now recognized that, particularly in industrialized countries, such entities no longer conform to such well-defined boundaries. Technology permits a place-based population to substitute for its environment by importing resources and exporting waste. Thus, carrying capacity now involves an assessment of the worldwide 'ecological footprint' of a place-based population (Rees 1992), or the full extent of the use and environmental impacts of that population. Through this lens, what may appear to be a sustainable carrying capacity in an area, registered by arrested or slowed environmental degradation, or even its reversal, may be obtained by transferring elsewhere the environmental consequences of the area's occupation and the population's consumption. This situation necessitates an examination of carrying capacity on a global as well as a local basis, as the recognition of the 'silent' services provided by environment, such as pollinators for crops, necessitates an examination that includes more than immediate population–resource relationships (Vitousek et al. 1997).

Human–Environment Relationship: Comparative Case Studies

A comparative case study is a research approach to formulate or assess generalizations that extend across multiple cases. The fundamental intent of a compara-

tive case study—development of knowledge—applies equally in the natural and social sciences, with the latter incorporating qualitative analysis in a discursive mode as well as the quantitative and positivist modes of the sciences. Comparative case studies are particularly important to questions of human–environment interaction, combining case study and comparative traditions and thus extending the depth of the individual case study across several instances in time and/or space.

1. Case Study and Comparative Method

A case study is a rigorous, detailed, spatially bounded, temporally limited description and analysis of an event, process, place, or community intended by the researcher to exemplify a more general insight, principle, or theory. It 'is an exploration of a "bounded system" or case (or multiple cases) over time through detailed, in-depth data collection involving multiple sources of information rich in context' (Creswell 1997, p. 61). Case studies of particular communities or places are a common and classical mode of analysis in anthropology, human geography, and sociology.

Comparative analysis, in contrast, explores similarities revealed in different situations or cases sharing some common element(s) while differing in others. Comparative analyses are also common among social sciences, varying in the depth to which components are explicated, from statistical abstractions through vignettes to a level of detail common in individual case studies. Often, a case study has unique elements whose effects on the validity of generalizations may be ambiguous or uncertain. Thus case studies addressed through a conjunction of insights from alternative perspectives will reveal commonalties of particular interest. Comparison between cases can help to delineate such relationships and potentially to clarify ambiguity in a singular case.

1.1 Qualitative and Quantitative Aspects

Comparative analyses may proceed via quantitative analysis of numerical abstractions from cases, through detailed narrative description and qualitative analysis. There is no necessary relationship between qualitative and quantitative approaches in case studies and comparative analyses. Qualitative case studies are frequent in anthropology, some schools of sociology, and contemporary cultural geography. Case studies can also be internally as well as comparatively quantitative, particularly in human and economic geography. Whereas comparative studies are often qualitative, they may be quantitative when there are a large number of cases with a small number of variables, as in social survey research.

1.2 Explanatory Status of Comparative Case Studies

Both case studies and comparative analyses can be *inductive* or *deductive*. However, case studies and qualitative comparative analyses share a common explanatory limitation with models—they are fundamentally *heuristic* rather than *definitive* in that they cannot prove the validity of generalizations beyond providing persuasive evidence in particular contexts (Oreskes et al. 1994). Conversely, a case study illuminating and supporting a general principle does not preclude another case casting doubt. As Leach (1968, p. 344) stated about the comparative method in anthropology,

> …comparison…is not, and cannot be, a disguised form of scientific experiment leading to an explanation.' Moreover, neither misinterpretation of the case nor failure of the case to illustrate a generalization necessarily means that a hypothesis is not valid. However, a comparative case study approach strengthens the heuristic value of individual cases by bringing in-depth understanding in different circumstances, with greater confidence in the conclusions drawn from them. 'The generality of the case study…is relative to the methodological value of the test process involved in the experiment itself and "holds until proved otherwise" (Hamel 1993, p. 40).

Multiple cases strengthen the confidence of the researcher that the generality is sound.

2. Comparative Case Study Strategies

Researchers investigating human–environment issues can avail themselves of many alternative strategies for developing comparative case studies. Strategies included here are certainly not exhaustive nor mutually exclusive, but they suggest ways in which comparative case studies can be structured creatively for investigation, presentation, and analysis. Often, the power of the comparative analysis is strongly related to the selected strategy. These strategies include research on the basis of community, place, perspective, structure, system, scale, transects, gradients, time, events, analogs, or theory as organizing principles. In practicality, the major organizing principle of a comparative case study often includes others that are subsidiary, but inherent in the nature of the cases selected. For example, selection of case communities along a transect incorporates both community and place perspectives as well, even though the transect is the organizing theme. Examples of each strategy are included in Table 1.

2.1 Community

Comparative case studies in disciplines such as sociology and anthropology often focus on studying

different social communities to ascertain, for example, generalities surrounding a particular cultural pattern (relations between matrilineal systems and matrilocal residence); social experience (immigrants in the new world city); or community structure (comparative political systems). In human–environment studies, comparison between communities is also important. Examples of such comparative case studies include investigation of traditional or vernacular architecture; studies of pastoral life-styles and range management strategies; cross-cultural studies of local environmental relations; analysis of ethnic farming populations in

the same locale; and studies of traditional navigation technologies and knowledge systems used by island inhabitants.

2.2 Place

Places which provide examples of a shared geographical setting or similar human–environmental process may be comparatively studied. Examples include studies of human–environment relations in specific kinds of environment, such as mountains, flood plains, and island or coastal areas; research on societal responses to extreme population density; and investigation of places affected by technological transformation, such as impacts of transportation change (super highways, dieselization of railroads), agricultural mechanization leading to rural depopulation, management of water resources, and transitions in household energy use in developing countries.

2.3 Perspective

An alternative to selection of different cases analyzed from a similar perspective is to bring multiple perspectives to a single case. Such an approach explicitly invokes a multioperationism desirable in all case studies—the convergence of different kinds of evidence toward a more complete and rich understanding. One common method for an approach based on perspective is the *emic* vs. *etic* familiar from anthropology—the understanding held by the individuals involved in contrast to the analytical viewpoint of the researcher. This distinction is now an important element of postmodern qualitative inquiry across the social sciences. The use of perspective in comparative study includes landscape analysis, analysis of environmental controversy, and multiperspective community or place studies.

2.4 Structure

Comparative case studies may be developed on the proposition that selected cases reflect the functioning of a common underlying structure, somewhat analogous to comparative linguistics. For cross-cultural translation of color terms, a formal Munsell color chart can provide a common structure on which to map various language terms for color. Less formally, comparative analysis may be based on typologies which provide the framework for comparison. In the human–environment realm, structural frameworks used as the basis for comparative case studies include Linnean plant classification compared to indigenous ethnobotanical plant classification; fundamental requisites of a society; comparative farming systems; and human response systems in the face of natural hazards.

2.5 System–Subsystem

A comparative case study may be organized to look at various levels of a complex system to establish relationships, mechanisms, and emergent properties that vary by the level under investigation. Examples include studies of the public role in environmental management at local, state, and national levels; studies of agricultural change viewed at the family, village, society, and regional levels; and studies of the driving forces of deforestation, from family- and farm-level decisions, through regional and national forces to the global economy.

2.6 Scale Analysis

Case studies of the occurrence of phenomena at different spatial scales may be undertaken to ascertain variance or invariance of form or process. Scale analysis has become an important element in the study of the natural environment, including hydrological, climatological, and ecological systems. In human–environment investigations, scale analysis is undertaken in studies of the causes and potential impact of climate change to suggest local and larger-scale determinants of greenhouse gas emissions; appropriate levels of generalization of impacts, such as climate change on farming; and initiatives for mitigation.

2.7 Transects

Geographical transects provide one kind of spatial sampling that researchers can use to develop information and insight that can be generalized across a society or region. A transect provides one means of minimizing sample bias in an attempt to develop generalizations and analysis of differences within a society or region that might reasonably be assumed to be homogeneous. Such studies include investigation of market towns along a transect in an agricultural region; research on the dynamics of colonist settlement along new roads in rainforest areas; or exploratory archeological investigation of settlement remains in a region. In transect studies, the area being investigated may be found not to be homogeneous, suggesting comparative study of social differences (such as ethnic enclaves in an agricultural region) or environmental

differences (such as local availability of ground water in the High Plains of the USA). One special kind of transect selected in recognition of difference rather than homogeneity is the gradient.

2.8 Gradients

Cultural ecologists in geography and anthropology often undertake comparative case study analyses using sample cases selected across environmental, spatial, or social gradients rather than in areas representative of a homogeneous area. One principle underlying such studies is that society adapts to environmental differences; thus the purpose of study is to understand the nature of adaptations and how they function in the face of environmental change. Examples include studies of agricultural adaptation along an altitudinal or climatic gradient; investigation of the impact of proximity on market involvement in a developing country; or research on the human–environment interactions in different societies occupying similar environments, either across a social gradient within a similar environmental region, such as farmers in Africa, or living interspersed in the same location, such as pastoralist and agriculturalist land use management.

2.9 Time

A temporal approach to comparative case study examines the same place at different times, different places at the same time which reflect temporal differences, or different places at different times. In the first approach, a single place is examined at different times. Such a study might show the development of successive human–environment relations as population or other variables change through time. When a geographical location was occupied by different societies through time, such studies in geography were offered as evidence of 'sequent occupance (sic),' one of the strategies used to refute environmental determinism. Investigation of different places at the same time could be seen as a quasi-temporal process when diffusion of an innovation or process of change is spreading geographically and some areas represent an older core location with earlier adaptation while others represent preadaptation or emerging stages. An example might be the diffusion of a cash-cropping complex in a traditional rural society where various locations along a space–time gradient represent stages of adaptation of a new technology.

2.10 Events

In the evolution of comparative case study in the human–environment realm, one salient mode of analysis focused on human response to natural hazards. Natural hazards research sought commonalties, first, in human response to floods, followed by attention to other natural hazards, to the hazardousness of places, and eventually to technological hazards. In all of these realms, comparative case studies provided the core strategy for the development of general frameworks for natural hazard analysis. Seen more generally, selection of hazard case studies for comparative research may be organized around extreme geophysical events, such as tornadoes, hurricanes, and floods, or longer term environmental threats such as drought, deforestation, or soil depletion and erosion. Comparison was also based on spatial dimensionality and temporal occurrence of hazards, as well as on hazard geometry. The event-based approach can be extended to other kinds of events: human and ecological impacts of dams; local resistance to imposed political or technological change; or suburban sprawl.

2.11 Analogs

An analog is based on the premise that objects or events having some similarity may also have other similarities. Thinking by analogy in fact underlies the comparative case study approach, in that the similarity among cases makes them in fact analogous in some respect. As a formal organizing principle, analogs inherently involve two or more cases that share sufficient commonalty that insight can be gained by comparison. There is no formal procedure for developing analogs; rather, good analogies depend on 'pragmatic considerations regarding contexts, interests and purposes' (Jamieson 1988, p. 81) and represent *a priori* insight before the full development of the comparative cases. In comparative case study using analogs, there is no necessary juxtaposition of the cases in time or space; rather, comparison originated in a conceptual linkage that appeared promising to the researcher. Analogous case studies are strengthened when they are selected with explicit similarity criteria.

Comparative case studies developed within an analog framework include studies of the impact of modern technology in developing countries; society's response to acid rain, ozone depletion, and future greenhouse gas stabilization; responses to past climate change; and adaptation to drought. Often, comparative case studies built upon analogs are future-oriented, asking whether insights gained from the analogs can be applied to future decisions.

2.12 Theory

Comparative case studies can address theory, wherein the cases are selected to test hypotheses from the theory. Examples include comparative case studies of the process of agricultural change with respect to population growth; modeling society's progress through economic, demographic, disease, or mobility

transitions; testing Wittfogel's concept of the hydraulic civilization; or explicating a framework for understanding the processes of environmental adaptation. In such studies, individual cases are not only compared with other empirical cases, but compared also with the expectations from *a priori* theory.

3. The Comparative Case Study Method

The comparative case study approach draws upon the same kinds of method that are common to the case study and comparative methods. The researcher links a hypothesis to certain cases using one or more of the strategies described previously, gathers information about the cases, develops evidence from the cases, presents the cases, and constructs explanation or generalization from the evidence. Insight, creativity, intuition, and even serendipity cannot be dismissed as important elements that the researcher uses to formulate hypotheses and to develop the strategy of research.

The depth of analysis of the constituent cases in a comparative study selected for *instrumental* purposes may not be equivalent to that of an individual case examined for its *intrinsic* interest (Creswell 1997). Focus on an issue or hypothesis draws attention to specific relevant issues or variables in the cases. Yin (1989) referred to this difference as *holistic* versus *embedded* analysis, the latter connoting the selection of cases within a wider research question.

3.1 Tools for Analysis

Researchers developing new case studies for comparative analysis have a wide variety of available tools and data sources, including interviews, surveys, participant observation, ethnographic research, field observation, officially collected information, archival research, environmental analysis, remote sensing, qualitative analysis, quantitative analysis, systems analysis, structural analysis, and various modes of modeling. In contrast, researchers undertaking meta-analysis of previous studies may be confined to information developed through other researchers' selection of tools and information; the researcher may undertake further study to amplify information on the case. As with individual case studies, the results of comparative analyses are usually narrative, although normative, probabilistic, statistical, simulation, or graphic models are possible modes of conceptualizing and communicating research outcomes.

4. Evaluation of Comparative Case Studies

Although there are no formal rules for evaluating comparative case studies, there exist reasonable criteria against which studies can be assessed. These include establishing the relevance of the cases; thorough identification and consultation of information sources; the adequacy and accuracy of reflecting information from sources; correct interpretation of sources; objectivity in reporting and interpretation; and internal consistency as evidenced by triangulation or multioperationism. If the cases purport to be a 'natural' experiment, controls provide an important strengthening of the argument. Additional criteria include the possibility of replication; reporting of contrary evidence and/or interpretation; specification of exceptions and special circumstances; recognition of and explanation for contrary cases; rigor versus superficiality; and value-added insight and understanding. Primary case studies must also meet the canons of field or archival work in the relevant discipline; comparative case studies built from meta-analysis of previously published work have potential for review by original researchers.

5. Conclusion

Comparative case studies offer a richness of insight that may be lost in the abstractions of statistical analysis, while maintaining the tradition of the case study as a means to explore generalities in the complexity of the real world. The intriguing variety of strategies for organizing comparison means that this approach to understanding human relationships to the environment will continue to be a vital part of human–environment scholarship.

Human–Environment Relationship: Indicators

In 1987 the World Commission on Environment and Development introduced a resonant idea: 'Sustainable development,' the commission wrote (1987, p. 43) 'is development that meets the needs of the present without compromising the ability of future generations to meet their own needs.' Sustainable development names a hope—that human prosperity can be reconciled with the natural world upon which all material economies ultimately rely. It is a notion that has exercised a broad influence in public discussions, notably in the United Nations Conference on Environment and Development in 1992 and the document *Agenda 21* (see Sitarz 1993) adopted at that conference in Rio de Janeiro.

Finding an operational definition of sustainable definition has proved difficult, however. In a dynamic global economy where substitutes for a wide range of goods and services are readily available—at a price—it is difficult to define 'needs' in a way that makes clear what must be conserved or preserved so that future generations can meet their needs (as they define them). In addition, we have yet to develop a generally accepted accounting system that can render authoritative judgments when an ecosystem verges on environmental bankruptcy. But there is no question that biodiversity is being lost at a historic pace, that fossil fuels cannot be replaced on the timescales on which they are now being burned, or that soil erosion diminishes the agricultural capability of some desperately poor people.

It is in this context that indicators play a significant role as people and societies search for ways to meet the requirements of nature and humans. Sustainable development is a long-term, large-scale phenomenon, if it is feasible at all, and it is likely to emerge slowly and unevenly in the world economy. Like other historical phenomena, sustainability may be hard or impossible to see at the level of everyday experience until it is well underway. Indicators rooted in scientific measurement provide an alternative way to perceive and to assess progress toward a sustainable future.

Indicators are quantitative measures of human well-being, economic activity, and natural processes and conditions; they are needed to sense the degree to which human activity may be continued or expanded in the future. The most useful indicators are repeated, precise measurements of natural and social phenomena. Such data series illuminate trends and identify changes; accordingly, indicators can sound alarms, define challenges, and measure progress. The measure-

ment and interpretation of indicators requires sustained efforts and resources from governments, firms, nongovernmental organizations, and the scientific community. Indicators communicate, sometimes evocatively and often across cultural and national boundaries. The indicators described below illustrate how both social and natural realms have been affected by human action over the long term and on large scales.

Measurements of carbon dioxide levels in the atmosphere warn of climate change, but the warning is ambiguous in policy terms (see Fig. 1). Like other gases, carbon dioxide mixes and spreads in the atmosphere, so that its impacts are widespread even when its sources are localized. (Note the seasonal oscillations, however: blending within the northern and southern hemispheres takes place faster than global mixing.) Like other changes in climate, responses are delayed in time and reflect multiple perturbations, many not of human origin. Nonetheless, the steady long-term trend reflected in this data series has triggered worldwide scientific attention and international agreements. The attention commanded by this indicator is a measure of the influence of environmental concerns in formal decision-making, the arenas in which quantitative indicators are indispensable for communicating credible information.

Estimates of economic output demonstrate that economic growth has been substantial in all parts of the world over the past two centuries. Although even the poorest have seen their incomes increase, the gap between rich and poor has also widened (see Fig. 2). Over the next several decades, indicators will be needed to monitor and report on human welfare and life support systems, with measurements on different spatial and temporal scales to inform social choice and debate. Some of these indicators may come to define whether human populations are heading toward sustainability, in the way that infant mortality and life expectancy symbolize progress in public health. Some indicators can also aid navigation, helping individuals and societies to steer a course toward sustainability.

This article sketches current work on indicators and outlines an approach grounded on a widely shared set of normative objectives.

1. *Indicators of Sustainable Development*

Humans have made repeated, precise measurements of some phenomena since ancient times; astronomical and meteorological signs have guided agriculture for millenia. The use of indicators expanded as industrial societies sought to measure and manage a widening variety of environmental and societal parameters (see Porter 1995).

Today, many people routinely scan prices, news and weather reports, and other sources to inform action and expectation in the short run. Indicators can perform similar functions with respect to long-term, large-scale changes. A striking example of the influence of indicators is provided by the adoption of a common European currency at the turn of the century. In preparation for monetary union, the governments of the European Union agreed to harmonize economic policies by meeting and maintaining budget deficit targets, defined as specified fractions of gross domestic product.

For complicated social objectives such as sustainable development, no single indicator provides a definitive benchmark. Instead sets of indicators have been proposed, identifying multiple parameters that together provide assessments of three basic dimensions—prosperity, environmental quality, and human well-being. Indicators have usually been interpreted using the Pressure-State-Response (PSR) framework, which posits linkages between human action and environmental consequences (Adriaanse 1993). Human activities exert *pressures*, such as burning gasoline in cars, that alter the *state* of environmental variables, such as the quality of air in a city. Impaired states, in turn, elicit *responses*, such as regulations governing pollution-control technology. PSR makes use of data that often are already collected for administrative purposes. The approach captures an important element of sustainable development:

humans can impair the life-support systems of the natural world, calling forth responses aimed at protecting environmental quality. It is straightforward to expand PSR to include the impact of economic development on human welfare.

There is widespread agreement on the utility of PSR but no convergence on a single set of indicators for the measurement of sustainability. There have been numerous efforts to assemble indicators of sustainable development, however, ranging in jurisdictional scope from municipal to international and spanning ecological scales from watersheds to the planet as a whole. (For a compilation, see International Institute for Sustainable Development 2001.) Many indicators in these sets do not have long time series, so the ability to discern trends is limited. Coverage is uneven. Although environmental indicators outnumber the rest, there is greater depth in economic and some social dimensions. Many variables are available for nation-states but few at smaller spatial scales. Information on land cover and land use is weak, especially in developing countries, and institutional indicators are sparse. Some proposed indicators reflect considerable imagination, notably those proposed by the international Balaton Group (Meadows 1998) and in many community-scale projects. For instance, gardening activity was used as a measure of community vigor in Seattle, Washington.

Indicator sets assembled by the UN Commission for Sustainable Development (CSD) and the World Bank complement one another in an illuminating fashion. The CSD indicators (1996) were assembled using the PSR framework. Selected through a consensus process without an agreed operational definition of sustainable development, the CSD indicators are numerous, diverse in the methods used to measure development or sustainability, and include a large number of indicators where reliable measurements do not exist.

The World Bank (1997), in contrast, estimated three national capital accounts. Each attempts to capture the value of an aspect of national economies. 'Produced' capital includes physical capital and financial claims, both familiar in standard accounting practice. A second account measures natural capital, the resources and services provided by the natural world. In principle this includes standing timber and soil fertility. Estimates of natural capital are as yet primitive. A third component of wealth, quantitatively the largest, is human resources, the economic value of labor, knowledge, and social institutions.

The Bank's indicators are highly aggregated and have been estimated using drastic assumptions, but they are conceptually clear. The wealth of nations should be considered in three parts. At least at the margins, wealth can be transferred from one account to another in ways advantageous to people—as when productive farmland is fenced off to create a nature reserve. By contrast, the United Nations CSD indicators do not warn unambiguously of imminent hazards in any ecosystem or society, nor do they provide guidance on how to pursue sustainable development.

The United Nations indicator set does include variables that are not now being measured, however. This is a notable strength of its process, reflecting a realization that much of what needs to be sensed about sustainable development remains unclear. The UN also has sponsored a wide-ranging research effort under the aegis of the International Council of Scientific Unions (Moldan et al. 1997).

In sum, the existing indicators of sustainable development are limited in their effectiveness by the lack of agreement on what to develop, what to sustain, and for how long—that is, a lack of agreement on the meaning of sustainable development. Proposed indicators of this politically popular idea have drawn upon work done in past decades on the measurement of human welfare and the condition of the environment. These efforts bring together many sources of illumination but have yet to produce a set of measurements of social and natural conditions that could plausibly lead to prosperity for all while conserving the life-support systems on which human economies rest.

2. *Trends and Transitions*

That we do not have a clear path to a sustainable future is hardly surprising: identifying indicators that point to a sustainable future is a normative task, one that is inescapably difficult in a fractious world of multiple cultures. One approach, used recently by the US National Research Council (1999), suggests directions in which indicators of sustainability might evolve over the next several decades. In a report entitled *Our Common Journey*, the Research Council's board on sustainable development (BSD) focused attention on a sustainability *transition*, a decades-long process in which human economies might move toward a durable relationship between meeting needs and conserving nature. Instead of the elusive endpoint of sustainable development, the BSD sought to highlight the scientific, technological, and societal innovations required to 'feed, house, nurture, educate, and employ many more people than are alive today, while preserving the basic life support systems of the planet and reducing hunger and poverty.'

The underlying metaphor is the demographic transition, the long-term slowing of human population growth which is projected to lead to a stable population size in the latter part of the twenty-first century. The transition in population, already underway for more than two centuries, has brought the human species from a situation of relative stability with high birth rates and high death rates to a situation of stability at low birth rates and low death rates. Because death rates were lowered before birth rates, there has

been a large net increase in population size. A sustainability transition would correspondingly carry human economies from an agro-ecological past, through a rapidly growing industrial phase, into a future in which materials would be used far more efficiently, generating less pollution. As population sizes stabilize, moreover, wide disparities in material standards of living may be moderated by addressing hunger and poverty. Like the demographic transition, a sustainability transition would evolve over decades.

The sustainability transition is an optimistic scenario; signs that it may be in progress are mixed. The indicators above show rapid, perhaps exponential growth rather than stabilization. Yet forests have regrown in advanced industrial nations; famine has been significantly reduced in poor countries, even as the number of hungry people in the world continues to expand; and environmental concerns arose, perhaps surprisingly, in societies that suffered from some of the worst pollution. None of these indications points to a turning away from unbounded expansion, and there is nothing so clear as the peak in the rate of growth in human numbers which occurred in the late 1960s.

Calling for research to make a sustainability transition possible is an unsurprising message from groups of natural and social scientists. What is less apparent at first sight is the intellectual strategy and its implications for indicators. The sustainability transition eschews prediction in favor of a *normative* definition of the task ahead, to meet human needs while preserving the life-support systems of the planet. The BSD found a basis for defining human needs in treaties and the declarations of international conferences devoted to nutrition, housing, social welfare, education, and employment. While such statements articulate aspirations with few resources or implementation plans to back them up, on the decades-long timescale of a sustainability transition, one can imagine quantitative changes large enough to make a qualitative difference with respect to both human needs and the conservation of the natural world.

3. Navigating Transitions

Like the carbon dioxide trend above, a sustainability transition may well require quantitative indicators to be seen at all. The BSD proposed two families of indicators, one to perceive transitions and one to guide social choice in pursuit of deliberate transitions.

Seeing a sustainability transition using the BSD definition implies sensing the degree to which human needs are met and the degree to which life-support systems are put under stress. Human welfare has been monitored since the depression of the 1930s drew attention to the role of governments in meeting basic needs. Appropriate quantitative indicators have been developed, but at the turn of the century they were not yet being reported regularly in a forum, such as the annual report of the United Nations Development Program, where crises could be highlighted and emergent transitions discerned.

Environmental indicators are numerous and need conceptual organization. The BSD's proposal was geographic, focusing attention on four scales of significance to a long-term transition:

(a) *Global circulatory systems* are affected by human activity, including the atmosphere, climate and ocean circulation, trade and travel, and the spread of exotic species and diseases. Trouble in the circulatory systems is important because the scale of circulation can implicate the entire planet more rapidly or persistently than governments can regulate. Although greenhouse gases and ozone-depleting substances were carefully studied by the end of the twentieth century, biological and information-intensive flows were not yet being assessed as components of a global circulatory system.

(b) *Regions vulnerable to critical environmental damage* are being identified (Kasperson et al. 1995). For instance, the Aral Sea and the Valley of Mexico are experiencing severe, possibly irreversible damage. Because the governing factors—including a vulnerable natural setting, lack of feasible alternatives, and governing institutions unable to take effective action—vary among regions, there is not a single set of indicators that can monitor the combination of social and natural factors that lead to irreversible damage.

(c) *Ecosystem services for urban areas* are only beginning to be monitored systematically (e.g., Baltimore Ecosystem Study 2001), even though urbanization is continuing to accelerate in developing countries. Because many ecosystem services are unpriced (e.g., flood control) or allocated by monopolies (e.g., water supply), market signals are absent or misleading. Yet ecosystem services tend to be irreplaceable when damaged and inflexible because they are supplied by costly infrastructure.

(d) *Parks and protected areas*, managed to enable their biota to persist indefinitely, have been identified on a place by place basis, rather than through a consistent set of appraisals of their long-term sustainability. Attempts to conserve biodiversity on larger scales (Olson and Dinerstein 1998) are just getting started.

In each of these settings, indicators form an indispensable but incomplete part of the intelligence needed to discern a sustainability transition in the decades to come.

A complementary function of indicators is to inform public policy and other decisions, large and small. Some navigational aids are available, although it seems likely that others may also come into wide use.

(a) *National capital accounts*, emerging from the World Bank's work, could provide a simple but crude measure of sustainability: each of the three kinds of capital might be transformed by human activity, but so long as a nation's total capital increases over time,

its trajectory may lie in roughly the direction to contribute to a sustainability transition. The word 'roughly' is important: a utilitarian metric is inadequate to assess sustainability. But the capital accounts draw attention to transformations among forms of wealth—transformations that will continue through, and beyond, any long-term search for sustainability.

(b) *Assessing policies* using indicators assembled under the PSR framework can lead to adaptive management. Adaptive management treats policies as experiments, designing them so that lessons may be learned reliably from the implementation of policies, even those that fail (Lee 1993). In the PSR context, this means using pressure and state indicators to test the effectiveness of responses.

(c) *Monitoring ongoing transitions* provides analysis of trends, particularly those that carry large future commitments, such as population growth. Even if the population continues to stabilize, it will be essential to improve technology and energy efficiency so that humans can accomplish more, economically, with less impact on the natural world.

(d) *Surprise diagnosis* will be needed because a sustainability transition is an improbable development. Reflecting on environmental surprises over the past three decades, Kates and Clark (1996) concluded that we can learn from surprises, so that we can better anticipate, avoid, or mitigate their consequences. But knowing how to improve management is also a temptation to operate closer to the edge. Surprises could therefore become *more* frequent as humans gain better knowledge of the world; this possibility qualifies the conventional notion that science is valuable because it improves our ability to control or at least to predict danger. From this perspective, surprises are valuable indicators in themselves. It is well accepted that surprise should produce humility. Surprise should also produce curiosity. On the timescale of the sustainability transition, curiosity and the learning it prompts are likely to be important, whether or not control can be extended in the short term.

4. Indicators and Social Learning

There is no agreement about which indicators to use to measure the movement of economies toward or away from sustainability. One should accordingly expect spirited debates over the value, biases, and meanings of indicators. In the related sphere of economic policy one can observe over the past half-century sharp disputes in the US over economic growth, the incidence of poverty, unemployment, and inflation. All these have been indicators that American politicians think will influence voter behavior (Tufte 1978). Remarkably, the independence of the data-gathering and analytical organizations has survived, despite their location within government agencies (see Duncan and Shelton 1978).

This is an important lesson: the independence of science is central to the social value of scientific information. Another lesson is that surprise is itself a valuable indicator. Governments and societies should anticipate unexpected things to happen. In a policy context, this idea is a kind of precautionary principle: because surprise is likely, action should be undertaken with thought, humility, and caution.

Indicators used to report on a sustainability transition are likely to be biased, incorrect, inadequate, and indispensable. Getting the indicators right is likely to be impossible in the short term. But not trying to get the indicators right will surely compound the difficulty of discovering, inventing, and achieving sustainable development.

Human–Environment Relationship: Prehistoric

Human–environmental relationships comprise a web of culturally imposed constraints in a complex environment, within which people adopt a variety of subsistence pursuits. These may or may not have long-term effects on that environment. During the course of Pleistocene prehistory, humans were few in numbers and constrained by their technology and social organization from unlimited spatial expansion or assuming the trophic role of a super predator. But they may have influenced megafaunal extinctions or vegetation change through manipulation of fire. By the beginning of the Holocene, greater subsistence success allowed exponential population growth, coinciding with agricultural origins in several world regions. Domesticated plants and animals became artifacts, allowing humans to achieve ecological dominance and incrementally transform their environments. But the management strategies followed and the landscapes created were constructed culturally.

1. *Inter-relationships*

Human–environmental inter-relationships are complex and nuanced. On the one hand, resources vary over time and are unevenly distributed in geographical space, so that strategies for utilization will differ for the short and long term, and at small or large scales (Butzer 1982). On the other, human communities subscribe to a wide array of subsistence and cultural modes, and attempt to reconcile new information with traditional values. Alternative pathways for possible change are evaluated through economic and cultural choices, which presume a major role for cognition, information, and decision-making. Environmental factors set 'boundary conditions' to human behavior at a particular technological and organizational level only in so far as they pose socially unacceptable risk. Short- or long-term environmental crises may be met by routine accommodation, active mitigation, or shifts in subsistence pursuits or social organization. Outcomes therefore are unpredictable.

2. *A Pleistocene Prelude to Change*

The roughly two million years of Pleistocene prehistory—the Paleolithic—were critical for human evolution and presumably influenced the 'hard-wiring' of basic human behavior. Emerging human–environmental interrelationships not only suggest a datum to examine such patterns in more recent times, but may have set a trajectory for later environmental behavior. Given the rudimentary archaeological record and in the absence of direct 'observation,' it is next to impossible to grasp the cognitive assessment of environmental problems, or even to infer a response or to understand attenuated processes of systemic change. A very real danger in Pleistocene prehistory is to posit a cause and effect relationship, based on little more than coincidence of several categories of proxy data. There are no simple answers to the broad, interdisciplinary questions about Pleistocene human–environmental relationships.

2.1 *Human Vulnerability to Pleistocene Environments*

The expansion of early human groups to higher latitudes and new continents during the course of the Pleistocene gives the impression that they learned progressively to cope with cold or arid environments, where resources were different than in tropical Africa. But the Paleolithic record is strikingly discontinuous in space and time, raising doubts as to the ability or choice of Paleolithic peoples to colonize 'marginal' environments with widely dispersed but clustered resources (Butzer 1982, Chaps. 12–14, 1991).

In what is now the semiarid interior of southern Africa, settlement was limited to periods of substantially moister climate and closely linked to water sources. Even some valleys with dependable rivers were unutilized for repeated spans of many tens of

millennia, and not all periods of moister climate were accompanied by an automatic territorial expansion of settlement. Effective human occupation across the dry interior of southern Africa was delayed until well into Holocene times, after 10,000 before present (BP).

Paleolithic people probably avoided this region because food resources would have been few and thinly spread during the dry seasons of poor years. Plant foods would have had low predictability and low net productivity, while the available game would have been difficult to hunt without bow and arrow, sophisticated traps, or complex game drives. If bands of hunters did penetrate such dry regions, they would have been so widely dispersed as to encounter neighboring bands only sporadically, leaving them with incomplete information as to the status of resources, e.g., animal movements or the condition of plant foods (Butzer 1991). During periods of severe drought stress, starving animals also lack fat while excessively lean meat poses severe metabolic problems for starving people (Speth 1987).

The true capacity of drought-prone, low productivity, and low predictability environments (see Butzer 1982) to sustain human life is a great deal less than its overall resources, averaged over time and space, would suggest. A similar 'marginality' model is offered by Bocquet-Appel and Demars (2000) for western Europe between 40,000 and 11,000 BP In glacial-age France settlement was concentrated in a 'refuge zone' located in northern Aquitaine. During less harsh, subarctic conditions prior to 22,000 BP small temporary sites extended northeastward to the Rhine, but then retracted to southwestern France during the glacial maximum, c. 22,000–16,000 BP Thereafter, as the climate ameliorated, an increasing number of larger sites are found in areas previously not occupied, as far afield as Britain and Germany. Across these 30 millennia, regional population may have increased from 4,000 to as many as 40,000 people, in part facilitated by improved hunting skills.

There was a vast 'marginal' environment in western Europe where not drought, but the low productivity and predictability of a subarctic environment, with dangerous turns of weather and hard, snowy winters, made glacial-age occupation hazardous except for summer-season hunting forays. Risk-prone environments such as semiarid thorn bush or arctic tundra seem to have been avoided, in favor of demographic clustering in dependable, productive environments. The persistent and extensive spatial gaps of the Paleolithic archaeological record in better-investigated areas appear to be real, rather than simply a function of site visibility and preservation.

Until the close of the Pleistocene, human groups did not demonstrably 'push the envelope' by venturing far or long into marginal environments. Incremental human expansion into higher latitudes, especially during the late Pleistocene, probably targeted environmental mosaics capable of supporting sizeable population clusters on a long-term basis. That implies a cognitive ability to explore new regions, so as to assess viability and risk, in the context of available technology and subsistence skills.

Changing hunting proficiencies are demonstrated by quantitative differences in the animals slaughtered in South African or western European sites of different periods. Before about 40,000 BP hunting focused on relatively docile animals, whereas in Late Palaeolithic times more dangerous animals or those from difficult montane environments were hunted regularly, and aquatic resources were systematically exploited on defined, seasonal rounds (Klein 1999). In part this reflected the invention of the bow and arrow, more versatile throwing javelins, and a variety of harpooning and fishing gear. But better tactical and collaborative organization of hunting and fishing activities will have been just as important.

The exponential increase in hunting efficiency evident across Eurasia between 25,000 and 10,000 BP implies a revolutionary growth in food-energy exploited, making possible rapid demographic expansion during the closing millennia of the Pleistocene. In both Cantabrian Spain and interior South Africa site sizes or artifact concentrations increase exponentially during the Late Pleistocene, and there were some 30 to 70 times as many sites (per millennium) about 10,000 years ago than there were about 100,000 BP. The 'take-off' in site numbers and implicit population growth begins at different times in different regions, namely 22,000 BP in Cantabrian Spain, 16,000 BP in France, 14,000 BP in northwestern Siberia, 10,500 BP in North America, and 8000 BP in temperate Australia (Butzer 1991, Bocquet-Appel and Demars 2000).

This carries implications for the relative proficiency of prehistoric peoples to utilize environmental resources. Paleolithic populations remained very small and vulnerable across nearly two million years, precisely because they lacked the technology and cognitive ability to move higher up the trophic pyramid. They only achieved the role of a major predator during the closing millennia of the Pleistocene.

2.2 *Late Pleistocene Megafaunal Extinctions*

The disappearance of mammoth, mastodon, woolly rhino, great sloths, or sabre-tooth 'tigers' from the Holarctic fauna at the end of the Pleistocene continues to intrigue. Giant kangaroos and cow-sized diprotodons from Australia also belong on this list of 'megafauna' (Martin and Klein 1984). But unlike the end-Cretaceous extinction of the dinosaurs, those of the terminal Pleistocene did not eliminate the dominant orders of larger animals, but fell within the scope of evolutionary 'turnovers' incompletely documented for earlier phases of the Pleistocene.

Species extinctions are a grim reality of recent centuries, and can be attributed to chemical impacts,

habitat destruction and harassment, predation by overhunting, or deliberate extermination. Some such extinctions or near-extinctions were rapid, others followed many centuries of sustained attrition. But for Late Pleistocene megafaunal extinctions there is neither direct testimony nor a promising analytical method to identify cause and effect, such as for the demise of the carrier pigeon, or the near-extinction of bison, bald eagle, or whooping crane.

The scope of this problem is illustrated by the catastrophic extinctions on New Zealand after its first colonization by the Polynesian ancestors of the Maori, less than a millennium ago (Anderson and McGlone 1992). Two families of large wingless birds (moas) became extinct, as well as an array of songbirds and marine taxa, all prior to European intrusion during the early 1800s. Although moa extinction within 4 centuries is well-enough documented, together with butchery, woodland fragmentation, and introduced dogs and rats, we will never know the human dimensions of this event, on the very threshold of oral history. Yet catastrophic extinctions on isolated islands of the Pacific Ocean during the last 2 millennia involved fewer variables than the response of more complex, continental ecosystems to a familiar human predator before 10,000 BP. These recent examples do not therefore provide a model applicable to the Late Pleistocene.

The case of extinctions in Australia makes the point. Between perhaps 30,000 and 14,000 BP a total of 42 larger vertebrates, mainly marsupials, and several taxa were subject to size reduction. Two of the vertebrate families that disappeared were huge, clumsy and slow-moving browsers, reminiscent of large mammals of the early Tertiary. The kangaroo family (Macropodidae) lost six genera (or 30 species), but it could be argued that the surviving kangaroos and wallaby (10 species) are 'modernized,' efficient, and smaller forms of the same lineages (phyletic replacement). In the big picture, this suggests the consequence of intergeneric and interspecific competition.

There also were several major environmental discontinuities during the same time span, including filling and drying of lakes, expansion and 'downsizing' of river systems, and extensive activation of eolian sands (Ross et al. 1992). Pollen profiles suggest re-expansion of browsing habitats about 10,000 BP (Dodson et al. 1992). In combination with the sudden, drastic climatic perturbations for which Australia is noted today, that implies repeated episodes of fragmentation and reduction of habitats during the Late Pleistocene, rather than a single and unidirectional change at its close. Environmental flux of sufficient amplitude would selectively disadvantage the demographic viability of 'archaic' forms, accelerating competitive exclusion among genera with overlapping niches.

People settled parts of Australia before 40,000 BP, but they were few in number, their distribution limited to more productive environments, and they introduced no animals other than the dingo, at a much later date (Kohen 1995). Artifacts have been found at a handful of faunal sites that lack patent evidence of butchering activity. How does one link the coexistence of human hunters or scavengers with extinctions over a time range of 25 millennia? Alternatively, how does one distinguish an evolutionary turn over from human predation? Temporal correlations do not provide process-links.

The case of North American extinctions is equally puzzling. Seven common genera disappeared 12,000–10,000 BP, at a time of demonstrated human predation, but of the 31 other extinct genera or species (all poorly dated), at least several phased out while even a human presence on the continent is contested (Grayson 1991). Twenty-seven of the extinct genera and six extinct species were found only in North America. In effect, this great faunal turnover primarily impacted New World forms, many of which were 'archaic,' to select for a smaller group of expansive ruminants (bison, deer, pronghorn), and carnivores (bear, wolf, coyote). But not all niches were refilled, and Spanish equids successfully recolonized grassy shrublands of the American West and Argentina.

Late Pleistocene environments in North America have no modern analogs: both grasslands and woodlands were 'patchy,' with fine-grained mosaics, greater local plant diversity, and unfamiliar seasonal productivity patterns (Graham et al. 1996). Both the extinct grazers and browsers were unspecialized, filling their energy requirements with a broad range of plants, as is typical for monogastric ungulates. At the close of the Pleistocene, such 'patchy' biomes were replaced by monotonous grasslands or closed-canopy forests, more suitable for specialized ruminants (bison, deer, caribou), whose stomachs can degrade plant toxins and more rapidly assimilate energy. All the large, monogastric grazers (mammoth, horse) and mixed browsers (mastodon, ground sloths, camelids), which had long gestation periods, became extinct. Also symptomatic of environmental stress, but inadequately understood, is the progressive reduction of size ('dwarfing') of the disappearing taxa during the Late Pleistocene, as is the 'dwarfing' of phyletic replacements among surviving genera worldwide.

Unlike Australia or North America, the contiguous continents of the Old World were little affected by extinctions (Martin and Klein 1984): a few phyletic replacements here and there, and the more dramatic disappearance of elephant and rhinoceros in Palearctic Eurasia for the first time since the Tertiary. Unimpeded contact and faunal interchange in the Old World implies a steady intergeneric competition for overlapping niches, which may have driven Old World faunas to modernize earlier. As on the other continents, that does not exclude human predation as a triggering mechanism for extinction of some vulnerable taxa. But neither does the present evidence single

out humans as super-predators ten millennia ago, whatever the environmental inputs and biological feedbacks of end-Pleistocene extinctions.

2.3 Fire Ecology and Vegetation Change

The human use of fire is a potent tool of habitat alteration or destruction. That is supported by both ethnohistorical evidence and quantification of charcoal particles from pollen profiles. Fire depends on the availability of fuel, climate, and ignition. 'Natural' fires, ignited by lightning strikes, have facilitated expansion of grassland and savanna since mid-Tertiary times (Kershaw et al. 1997). Less clear is the degree to which prehistoric peoples manipulated fire so as to alter vegetation ecology, because it is difficult to separate the evidence for artificial vs. 'natural' fires.

In Australia, indigenous people continue to use fire for many purposes: to drive game, to clear undergrowth for visibility and stimulate fresh growth, and to serve a range of defensive, domestic, and social purposes. The popular truism that indigenous fires were 'controlled' habitually is not supported by the facts, nor is it consonant with the experience of wildfires on other continents. Fire was an instrument of environmental management in that it once kept most Australian eucalyptus woodlands grassy and free of shrubby undergrowth, although such woodlands had already evolved across five million years in an interactive relationship with fire.

Pollen profiles from south-eastern Australia that cover most of Holocene time show charcoal particles increasing exponentially during the last 2 millennia or so, to culminate shortly before or after AD 1800, even though there is no consistent climatic trend during that period. It is possible that the elaborate burning culture recorded after 1788 only evolved during the late Holocene, after changes in cultural practices. The density of archaeological sites in south-eastern Australia doubled during the last two millennia, compared with the previous three (Dodson et al. 1992), suggesting that increasing use of fire primarily reflected demographic expansion or greater mobility. Given the much smaller and disjunct Australian populations of the Late Pleistocene, it seems improbable that human manipulation of fire could have produced a striking charcoal peak 38,000 BP in northern Queensland (see Kershaw et al. 1997), since the 'event' saw rainforest replaced by eucalyptus woodland, which instead implies climatic change. To argue that early use of fire was a co-agency in megafaunal extinctions will require a comprehensive, ecological case and an archaeological context.

Unlike Australia, which has a desertic core, sub-Saharan Africa is dominated by grasslands with scattered trees (savannas), mosaics of savanna and open woodland, or open woodland with patches of grass. Although extensive tracts of such open vegetation reflect either sandy substrates or extensive seasonal flooding, others have been modified and maintained by recurrent fire. It was once believed that Africa's savannas were created and expanded progressively by deliberate burning through much of human prehistory, but that is no longer tenable. The great diversity of cursorial ungulates for which Africa is noted began to evolve during the Miocene, while Pliocene deposits reveal abundant pollen of grasses as well as evidence of charred wood. During glacial-age intervals of drying, such as 30,000–10,000 years ago, much of sub-Saharan Africa was an almost treeless grassland, with woodland or forest reconstituted at the beginning of the Holocene.

Pollen profiles from the highlands of Malawi show that a mosaic of grassland and forest remained unchanged from the Pleistocene to the present (Meadows 1984). In interior South Africa, the distribution of grass and semidesert shrub shifted according to climatic trends and was little affected by the first appearance of indigenous herders. Until agricultural activities began to create patches of disturbed vegetation in tropical Africa, mainly after 3000 BP, increases in grass pollen and charcoal currently are attributed to episodes of drier climate, thus the opening of the Cameroon 'Grass Fields,' formerly believed to be anthropogenic (Zogning et al. 1997). In Africa and elsewhere it is important to distinguish slash-and-burn agriculture, as a focused form of micromanagement within forest environments, from the modification of savannas or open woodlands to attract game or improve pasturage for livestock. Prehistoric fire ecology primarily concerns the latter, and assumes that deliberate burning reinforces natural processes.

3. Changing Holocene Relationships with the Environment

Regional population growth at the end of the Pleistocene sooner or later set in train a variety of adaptive responses to new or changing environmental opportunities. In some areas, increasingly skilful hunter–foragers turned to a more specialized exploitation of coastal resources, while others remained more conservative generalists, despite technological innovation. Elsewhere hunter–foragers chose to diversify their ecological niche by investing more time in the harvesting of large numbers of small mammals, at least on a seasonal basis. Tapping into a more predictable food supply, such strategies repaid the effort by allowing a more sedentary residential pattern, even if small hunting parties fanned out in pursuit of bigger game at opportune times. Longer-term residence at central encampments, in caves or out in the open, in turn allowed a more persistent exploitation and manipulation of diversified plant foods.

In several world regions this strategic shift led to the domestication of plants or animals, or both. This was

not a socioeconomic revolution, but a long trajectory of co-evolution, during which people experimented with and eventually 'managed' a selection of plant and animal resources. They favored and tended more desirable strains until new domesticated species emerged, to be maintained through deliberate planting and breeding. This inaugurated a novel set of relationships between people and the environment in that both plants and animals became artifacts with which people fundamentally changed their habitats, involuntarily or deliberately replacing native biota with cultivated plants and domesticated livestock.

3.1 The Impacts of Early Agriculture

Agricultural origins have been amply documented by multidisciplinary archaeological research in the Near East and in southern Mexico; similar processes are apparent, but imperfectly understood in Andean Peru, sub-Saharan Africa, and south-eastern Asia. Morphological ('hard') evidence for domesticated grasses and legumes is available for sites along the Near Eastern steppe-woodland ecotone by 10,500 BP, implying that the process of experimentation and manipulation began several millennia earlier. Agricultural origins in the New World may have been even more attenuated, but that database is spotty.

As long as communities practicing complementary agriculture remained few, small, and confined to the natural habitats of their cultivated plants and livestock, environmental impact would be minor. But these new pursuits were contagious across the Near East and much of Europe, introducing new plants or animals to environments where indigenous biota were displaced. Agricultural villages appear on the coasts of Greece, Crete, and Cyprus by 8,000 BP, and a distinctive new agrosystem had emerged around the coastal plains of the western Mediterranean about 7,000 BP In some areas, resident hunter–foragers domesticated local wild cattle prior to agricultural penetration (Yugoslavia), while elsewhere expanding agriculturalists allowed outbreeding of livestock or cultivars (Hungary), to produce new domesticated variants. Dispersal across western Europe before 5,000 BP proceeded in stages, each with a probable sequence of ecological readjustment in new settings, indigenous innovations, interchange between resident hunter–foragers and intrusive farmers, and eventual indigenization of agricultural traits.

This early, Neolithic agriculture was localized and often ephemeral, and most pollen evidence shows that woodlands soon regenerated. But strong counter-examples verify repetitive fire clearance, cultivation, and stockgrazing that converted extensive areas into grass, weeds, or secondary vegetation 6,000–5,000 BP (Poland) (van Zeist et al. 1991). In parts of the Mediterranean Basin, early Neolithic pastoralists probably used fire clearance to open up pasturage in native woodlands as early as 7,000 BP (Greece, Dalmatia, eastern Spain), with reforestation delayed up to five centuries. Such impacts were local rather than general, but in some areas they may have initiated or reinforced a trend to more xeric forest types. Yet settlement was spatially discontinuous, even in 'preferred' environments, until about 4,000 BP, judging by repeated episodes of woodland recovery and presumed local abandonment (Butzer 1996).

3.2 Plow Agriculture, Pastoralism, and Ecological Change

Towards 3,500 BC (5,400 BP) the invention of the plow (Mesopotamia) marked a significant transformation in the complexity and productivity of agriculture. The plow required a draft animal and opened larger fields to cultivation, while also exposing soil to potential erosion. Animals no longer served only as meat on the hoof. Cows, sheep, and goats were milked, and the milk converted to butter or cheese. Wool was skeined and woven into cloth as new breeds of woolly sheep were selected. The fertilizing properties of animal manure were probably recognized, as animals and their products became interlinked systemically with the range of subsistence activities.

More work was invested in a plot of land, including preparation, planting, weeding, and harvesting, to increase productivity. Plowing along hillsides deliberately or inadvertently created stepped slope profiles that may have suggested the principle of terracing. Swamps were drained and heathlands ameliorated with transported soils. In arid environments, opportunistic local manipulation of runoff developed into more complex methods of water control, including canal irrigation. Orchard crops, olive oil, and wine emerged as commercial products. Exchange networks and growing urban markets further reduced risk and, spurred by metals, metal products, and pottery, began to favor economic integration over wider areas.

Particularly in the Mediterranean Basin, much land was unarable, but animals were mobile and could be moved to rough upland pastures when the snows melted or lowlands became subject to summer drought. Short and long distance mobility patterns (transhumance) emerged that brought stony uplands into productivity. Controlled burning began to be used to manage such pastures on a regular basis, keeping woodlands open (but not deforested) and burning back woody or thorny shrubs. By the end of the Bronze Age (1,200 BC), much of the Mediterranean world was used and modified by farmers and herders, even though vast tracts of montane forest remained. A familiar cultural landscape was in place (Levant, Greece), expanding to the far west by Roman times, and bringing a simplified version to higher latitudes during the Middle Ages Ages (van Zeist et al. 1991).

Intensified agriculture represented a quantum jump in production, demography, and interregional

networking, in managed environments that were increasingly artificial. Native biota were replaced progressively, with cultural controls over natural selection, succession, and diversity. To maintain such managed ecosystems required constant or increasing investment of labor, in order to maintain artificial equilibrium conditions and avoid ecological degradation (simplification). This was the case in the Bronze Age Mediterranean Basin and Near East, as well as China. A millennium later, similar transformations are apparent in parts of Mesoamerica, the Andean world, and several nuclei in southeastern Asia.

Changing human–environmental relations were not limited to agricultural regions. In the central USA sedentary utilization of rich, riparian resources incorporated controlled use of a variety of minor plant foods well before the appearance of standard domestication. In arid lands and the sub-Arctic, or in the high Andes, mobile herding patterns emerged that were based on new domesticated genera such as camel, reindeer, and llama. Even in the Arctic, groups of hunter–foragers devised new collaborative methods to effectively exploit coastal resources, by mobile strategies such as those of the evolving 'Eskimo' cultures (Alaska to Greenland). A mastery of the environment is broadly evident that was qualitatively and quantitatively different from that of the Late Pleistocene.

With increasing environmental exploitation by expanding populations, the potential for ecological impairment or degradation was rapidly enhanced. But the fact that discernible damage did not keep pace suggests that farmers built on the cumulative experience of trial and error in familiar environments, to articulate more conservationist strategies (Butzer 1996). Ideally, land use seeks to minimize both long-term environmental damage and short-term subsistence risk. Pollen and geomorphologic records show that for the most part, Mediterranean farmers and herders were successful in doing so during the last four millennia, despite sporadic 'accidents' of mismanagement in some areas. Only during Late Medieval times, when population was substantially greater than in Classical times, was supplementary food imported from outside the Mediterranean region. Until the early 1900s, productivity was maintained or enhanced, which implies sustainability across 7000 years of agricultural land use (Butzer 1996).

An anomalous episode of disturbance is dated to the transition of the Bronze and Iron Ages, c. 1,000 BC. It saw intense and often prolonged vegetation disruption (Spain, northern Greece, Northwest Turkey) by pastoralists moving into the Mediterranean environment from temperate Europe or the Balkans. Presumably they misapplied management methods better suited to humid environments. Much the same happened during the Middle Ages, after desert nomads moved into the Levant and North Africa, or Slav herders occupied northern Greece. In other cases initial agricultural occupance led to a flush of soil erosion (Greece), and soil loss was locally problematic after pastoral expansion or agricultural decline, thus during the later first-millennium BC (Palestine, western Turkey, Greece, Italy, Spain) and again in Byzantine or Medieval times (Palestine, Greece, Italy, North Africa, western and central Europe). Although the cultural landscape and its humanized woodlands were repeatedly rehabilitated, soil thinning had to be compensated for with manure, but cumulatively this does not compare with watershed destruction by mechanized agriculture or industrialization since the 1950s.

In the New World, where the focus of recent discussion has been on the impacts of European-style land use, more pragmatic work shows extensive forest disturbance or removal, and even soil erosion, during indigenous demographic expansion many centuries before 1492 (Central America, Mexico, eastern United States) (Pohl et al. 1996, Butzer and Butzer 1997, Peacock 1998).

The human imprint on the landscape at the threshold of history was profound. In combination with the devastation of island ecosystems, such as New Zealand or Madagascar, it includes episodes of biotic impairment and even extinction, with enduring imprints. Yet most environments today, even 'wilderness' areas, are humanized to some extent and many if not most agricultural landscapes provide esthetic comfort and psychological anchoring in their particular cultural contexts. The human ascent to unprecedented demographic success and ecological dominance has impoverished floras and faunas the world over, often replacing them with vast monocultures or a handful of livestock species—even before the side-effects of industrialization could pollute the waters or turn machinery loose on the soil mantle. But until the dawn of a global consciousness, the transformations of the last 10 millennia were guided by community decisions, made through culture-specific lenses, with the goal of subsistence success across the generations, guided by imperfect information, despite conservative and conservationist strategies. That is the *reality* of human-environmental relationships, however they are judged today in the face of global ecological crisis.

Human–Environment Relationships

The relations between human activities and their biophysical milieu have never been a subject of deep and sustained interest to the Western social and behavioral sciences. Such attention as they have been given has been fitful and partial, and it has arguably always been much less than their importance merits. Environment—in the sense of the biophysical world—has not been a topic that the orthodox human sciences have felt comfortable in addressing. This article traces the general scope of human–environment relations and of the past and present study of them in the human sciences.

1. *The Term 'Environment'*

'Environment' is a troublesome word in that it can mean quite different things in different contexts. In some fields, it has long been used to refer to the social surroundings of human existence and behavior. In that sense, it encompasses much of the standard subject matter of the social and behavioral sciences. Elsewhere, it denotes the biophysical surroundings of human activity. In that sense, it encompasses much of what the social and behavioral sciences have deliberately chosen not to study. An emphasis on 'environment' is associated confusingly in the one case with the rejection of 'nature' as an important factor (as in the 'nature–nurture debate') and in the other with its affirmation (as in 'nature–society relations'). An 'environmentalist,' depending on the context, can be one who believes that social influences outweigh hereditary ones in human development (a frequent meaning of the term today in psychology and sociology); that human beings are molded by climate, terrain, and other elements of their biophysical surroundings (the meaning given the term in the 1968 *Encyclopedia of the Social Sciences*); or that vigorous action should be taken to slow or reverse human-induced change in earth systems (the usual meaning of the term in ordinary parlance today). Only the second and third of these meanings correspond to that of 'environment' taken, as here, in the biophysical rather than the social sense. Both of them, moreover, exemplify a second problem: the frequent usurpation of the term by a narrow and particular sense of it that obscures its full scope.

Even if 'environment' denotes not the totality of the biophysical universe, but only those portions of it that are relevant in some way to human activity, its boundaries are not easy to fix. They can and often do change as human activities change or as understanding of their relations with their surroundings does. At or near the boundaries, the environment can include the mineral deposits of the deep ocean floor (now that the technology for their exploitation exists), the strato-

spheric ozone layer (now that its role in protecting life on the earth's surface is recognized), the stars when they were used for navigation, and a comet or an asteroid threatening to hit the earth. If the outer limits are always uncertain and always in flux, however, the core elements are easily defined: climate, soil, terrain, bedrock, mineral and fossil fuel deposits, atmosphere, fresh and salt water, and biota. They are the basic elements that compose what the Russian geochemist Vernadsky (1929) called the biosphere: the zone in which life as we know it can exist and which life, in turn, can affect and transform.

To speak of nature or the biophysical world as the environment of human existence is at least to some degree to separate the two realms. Such a separation is often challenged and resisted. The question has long been debated whether humans are fundamentally a part of, or apart from, the natural world. The grounds on which they are asserted to, or not to, belong to nature are of the most varied sorts. Social arrangements can be described as given by nature in order to justify and 'naturalize' them and rebut criticism of their injustices. Nature, as in the concept of natural rights, can at the same time be used as a standard by which existing social arrangements are measured and found wanting. During the nineteenth century, Darwinian and Lamarckian theories of human origins tended to dissolve certain boundaries between humanity and nature by emphasizing the importance of the organism's evolution from its surroundings and its continuous shaping by the demands that these impose. They were and have continued to be adopted and employed for widely varying ends by both conservatives and radicals.

At the same time, the American geographer Marsh (1864), a contemporary of Darwin's, tended rather to emphasize the distinctions between the human and the natural. He insisted forcefully, and with a wealth of evidence, that human actions modifying the earth were distinct in kind rather than merely degree from natural processes of change. They were, Marsh pointed out, far more rapid and abrupt in occurrence and far more radical and destabilizing in their character. But the very scale and scope of human impact, which have both grown enormously even since Marsh's time, tend in another way to blur the boundaries between society and environment: by making the latter less and less of a distinct entity. Undoubtedly human impact has altered and even transformed many aspects of the earth. Human actions, both deliberately and incidentally, have reshaped them into what is sometimes called a second nature that can no longer be regarded as something quite separate from society. Many people now spend their lives in climates that, at the scale of the built environment, are controlled closely and deliberately; that locally and regionally have in many cases been altered by human actions though rarely by conscious human intent; and that globally may or may not already bear the marks of greenhouse gas emissions from fossil-fuel burning and land-cover change. Little of the environment can be considered wholly 'natural' if that term means pristine and unaltered.

Much of the environment has not been transformed, however, and all of it, however much altered, remains distinct from the human realm in another sense. Human beings possess certain characteristics of reasoning and reflexivity different in kind or at least in very significant degree from the rest of the known world. No other species or biophysical agent has equivalent attributes allowing it to carry out equally elaborate projects affecting the environment, nor have the actions of any changed the globe nearly so drastically in so short a time as have those of the one species possessing them. That humanity and environment are in some important ways separate is implied by the very existence of the social and behavioral sciences (and the humanities) as core fields of study distinct from the natural sciences.

Yet their separation very often is challenged from the margins by two broad programs for reducing one to a branch of the other and asserting their unity in terms of both substance and appropriate methods of study. Extreme forms of biological determinism propose to account for human and social action as the product of heredity and evolutionary imperatives, environmental determinism as the product of the shaping forces of climate and other elements of the human habitat. Both seek to annex the social realm to the natural. Annexation of another kind is envisioned by the more radical approaches found in the social studies of science, which propose to treat the knowledge generated by the natural sciences not as a means of explaining social action and processes but as itself one of their products. Science is seen not as a privileged source of fact but as a social activity like any other and governed by the same rules and to be analyzed in the same terms. These perspectives offer valuable correctives to an unthinking separation between the human and the natural. Weaker forms of them—evolutionary psychology, for example, or the study of the social correlates of environmental attitudes and activism—have been fertile sources of challenging new findings and explanations. Thus far, at any rate, some basic distinction between humanity and the biophysical world has continued to be accepted as unavoidable in practice.

2. *Human–Environment Relations*

But even if environment and society are distinct realms, not so simply and unproblematically related as reductionists on either side would argue, they are closely interdependent and interacting ones. If the autonomy of the social from the natural sciences (or of the natural from the social) is justifiable, what is less so is the thoroughness with which the social sciences, by

and large, have cleansed themselves of contact with the biophysical world. They have, in general, ignored the fact that all human activities, though not reducible to the biophysical plane alone, nonetheless have a biophysical side to them. All human actions require energy and matter from the environment and release both back into it. All have certain prerequisites in the form of the basic necessities of human existence—air, food, water, a tolerable temperature range, and so on—that the environment must provide; and these only begin the list of significant relations between society and its biophysical milieu.

Broadly speaking, the environment can represent a source of services (a term now coming into use to replace the narrower one of 'resources'). Such services include background benefits from the environment that are enjoyed even though they are not consciously and deliberately exploited as natural resources. Among these are the key life-support systems of the biosphere. Other environmental services range from the absorption of wastes to the provision of spiritual and esthetic satisfaction and natural amenities such as scenery and agreeable weather. The environment can equally serve as a source of disservices, ranging from the hazards of violent natural events such as storms, earthquakes, and epidemic and endemic diseases to disamenities and constraints on human activity. To the extent that the environment acts as a determinant of human qualities, its effects can again be classified into services (the formation of valuable qualities) and disservices.

But there is no such thing as a service or a disservice without a recipient thereof. If some aspects of the environment are essential to the existence of any kind of human life as we know it—though not necessarily as it might exist in the future—whether and how any other plays either role depends crucially on the variables of what it is that people do and wish to do. Environmental features that help them do what they wish to do represent services, those that interfere represent disservices. Actors differentiated by location, occupation, class, status, gender, and any number of other variables will benefit or suffer differentially. The significance of the environment, then, is never determined solely by the characteristics of the environment; it is determined also by the ways of life that people lead within it.

As a result, a change on either side may be sufficient to change the relationship. It is by now clear that the environment on its own cannot be presumed to be stable or equilibrium seeking. Natural processes of change and fluctuation on many different scales of time and space are ubiquitous. Over time, they have increasingly been supplemented and, in some cases, overshadowed by human-induced changes, both those made consciously and those resulting unintentionally from actions taken. These may enhance or lessen the biophysical services and disservices received by different groups and individuals. Possible environmental instability must be considered in the study of past environment–society interactions and in planning for future ones.

But environmental change, while it can be sufficient to alter environment–society relations, is not necessary for an alteration to take place. Equally sufficient can be shifts occurring on the social side. Changes in technology may mean that some aspects of the environment will cease to provide services or disservices, while others will begin to do so. Falling water was a vital source of industrial energy through direct-drive waterpower in the era before widespread fossil fuel use, and it became one again with the development of the means of hydroelectric power production. Uranium became an important resource only through the development of nuclear power generation. Some technologies are developed to alleviate existing problems in environment-society relations: those of weather monitoring and forecasting, for example. Others incidentally create new problems: the new role of clouds, fog, and downdrafts as hazards created by the development of aviation. Technological changes themselves are entangled closely with changes in social organization, which themselves may also alter society–environment relations. Such variables as the structure of ownership and exchange, household and gender relations, and political system, for example, all play an important mediating role between natural events and their possible human consequences. Famine, for example, may follow drought that drastically reduces the crop harvest, but a severe drought is neither a necessary nor a sufficient condition for famine. One of the few well-established regularities in the social sciences, documented by the economist Amartya Sen, is that no modern famine has occurred in a country, however poor, with well-functioning democratic institutions. They act, it would seem, to prompt effective government interventions preventing disaster. A certain environment, environmental feature, or environmental event, even if unchanged, will thus bear different relations to society at different times. Changes in the environment itself, of course, whether themselves natural or human-induced, can also alter alter the role of the environment in the lives of its inhabitants.

But an account of human–environment relations in these largely utilitarian terms remains only a partial one. It excludes, most notably, questions about environmental ethics or the proper relations between humanity and environment. The social sciences have found it difficult enough to address issues of values where only human actions are involved. Their particular focus has almost disabled them from assimilating or even recognizing arguments about the rights of other species and other features of the environment: the American biologist Leopold's (1949) 'land ethic,' to take one example. Their usual tendency is to treat such beliefs—and understanding of the environment more generally—as expressions of social position

rather than to grapple with their possible validity. But the rise of Green parties and ecocentric groups and movements and of expressed support for notions of the rights of nature pose external challenges to the use of purely human-centered criteria, ones that have grown in urgency as human power to alter the environment, with likely effects including the widespread extinction of other species, has also grown.

3. Human–Environment Relations in the Social Sciences

These observations suggest the wide range that human–environment interactions cover. The actual range of interactions recognized and studied by the mainstream social sciences at any one time has always been much narrower. The most important early form in which environment impinged on the fledgling social sciences was that of environmental determinism. This doctrine offered one promising and plausible way of solving the formative puzzle of the social sciences: explaining why human behavior and institutions varied so widely from one place and people to another. The French political and social theorist Charles-Louis de Secondat, Baron de Montesquieu, in the eighteenth century treated climate and soil in *L'esprit des lois* as important factors in social life. He asserted, for example, that the people of cold or barren or mountainous areas tended to be vigorous and freedom-loving and those of warm, fertile plains to be more indolent and passive. Political and social institutions suited to one environment, he maintained, would be inappropriate to another. Many thinkers of the French and the Scottish Enlightenment echoed Montesquieu in seeking to explain differences between societies as at least in part growing out of differences in climate or other aspects of the physical environment.

But the concept of environmental influences soon changed from a useful part of the social theorist's conceptual baggage into an irksome burden. The shift proceeded in step with the organization of the social sciences into separate disciplines of sociology, anthropology, history, geography, economics, law, and so on. A few nineteenth-century historians—Henry T. Buckle in England, John W. Draper in the US, and V. O. Klyuchevsky in Russia among them—continued to assert the fundamental importance of environment in human affairs, but the trend of studies ran strongly in the opposite direction. Far more typical was the stance taken by Emile Durkheim in sociology. In his chief empirical work, he rejected meteorological and climatic explanations of patterns of suicide in favor of ones involving the character of social organization. At a more general level, he proposed that social facts be explained solely in terms of social causes. The approach excluded not only psychological or individual-level explanations in sociology, but also biological and physical-environmental ones. Not all of sociology was Durkheimian, but the rejection of environment as a significant factor in social life was not one of its claims to be contested widely within the discipline. It was paralleled by the work of Franz Boas and others in anthropology who likewise insisted on the liberation of social inquiry from environmentalist as well as biological theories of cultural differentiation. Environmental determinism lasted longest in geography, but even there it faded under strong criticism from within and without the discipline.

Classical political economy from the outset recognized environmental conditions as determinants of scarcity and cost. It attributed the key phenomenon of land rent to differences in the inherent quality of the soil. Malthusian population theory presented the disparity between limited natural resources (the ability of the land to produce food) and potentially unlimited human wants as a basic condition of social life. The classical labor theory of value, however, tended to promote human activity over nature as the key source of wealth. Environment was demoted to a secondary role in another and more decisive way in neoclassical economics. Natural services were absorbed into the wider stock of capital and deprived of any distinctive qualities vis-à-vis human-produced goods. Natural capital and services were presumed to be perfectly replaceable by non-natural and the possibility of absolute scarcity of vital elements of nature neglected. Market mechanisms would ensure that nonrenewable resources would be depleted at the socially optimal rate and would also ensure that substitutes for them would be devised as necessary. These assumptions were questioned only by fringe schools of thought that had the standing of heresies vis-à-vis the orthodox consensus: theorists who proposed energy rather than monetary measures of wealth and efficiency, conservationists who warned of the exhaustion by waste of key resources not readily replaced by others.

In orthodox Marxist thought, not only the labor theory of value, but also the violent rejection of Malthusian notions of absolute scarcity as ideological fictions and the emphasis on class conflict and on a universal sequence of stages of evolution left environment little room to play a serious role. The chief exception was the much debated concept of distinctive 'hydraulic societies' expounded in the mid-twentieth century by Wittfogel (1957). Developing the earlier notion of the 'Asiatic mode of production,' he proposed that the formation of stable centralized despotisms was favored by the demands of large irrigation and water-control systems in dry climates—the characteristics of the environment thus playing an important role in social outcomes. But the idea only represented such a heresy within Marxism as energy economics did within the neoclassical discipline.

Elsewhere in the social sciences, determinism was for a time replaced by the opposed doctrine of possibilism, prefigured in the work of late nineteenth and early twentieth century French regional geo-

graphers led by Paul Vidal de la Blache and influentially expounded in the 1920s by the historian Febvre (1922). Possibilism pointed to the fact that different societies maintained quite different relations with similar environments as proof that the environment itself never determined any particular way of life. It offered, rather, a wide range of possibilities for habitation and use, some of which any particular society would be inclined to exploit and many of which it would not. In the postwar years, a possibilist approach was one of the many novelties informing the work of a school of historical research centered on the journal *Annales: Economies, Sociétés, Civilisations*. Close study of nature–society relations remained an important endeavor not only in *Annales* history, as it came to be known, but also in the subfield of anthropology and geography known as cultural or human ecology. It too was possibilistic in showing how society–environment relations, especially those of subsistence in nonindustrial settings, could be understood only by study of the characteristics of culture and habitat both. The very strength of environmental research in these precincts, however, only tended to reinforce the notion that environmental differences mattered and continue to matter chiefly for less advanced societies employing primitive technology and engaged in primary production.

That was not the only belief that tended to discourage wider attention to the environment. Another was the fear that taking the environment seriously led easily to environmental determinism and in turn to political implications of a necessarily reactionary sort. The fear, though excessive, gained plausibility both from some of environmentalism's earlier associations and from an easy analogy with biological determinism. According the natural world any significant role in human affairs seemed to some, given the unevenness of natural patterns across the earth's surface, a step toward legitimating inequalities of power and position. Environmental determinism was most reliably expelled by expelling environment altogether.

It is understandable and by no means unfortunate that there should have been a strong reaction against a doctrine that had shown itself so intellectually barren and empirically untenable as environmental determinism. It is more regrettable that environmental relations of nondeterministic sorts should have come under the same ban. But their neglect was also a predictable result of the way in which academic research and training increasingly came to be organized. Environmental studies of any sort suffered from the deepening institutional and intellectual division of territory between the social and the natural sciences. Part of the price at which the hard-won autonomy of the social sciences came was the disenfranchisement or marginalization of subjects located in their new boundary zones. Part of the price of the increasing specialization of work within them was the increasing difficulty of acquiring an adequate training in both the natural and the social elements of any research problem. The way in which the social sciences tended to be defined in opposition to the natural split even geography into human and physical and anthropology into cultural/social and physical branches. It was thereby made most difficult for any topic relating the two realms to be studied with any degree of sophistication.

The 1968 *Encyclopedia of the Social Sciences* appeared at a particular low point in social science attention to the biophysical environment, and the entries reflected it. The entry on 'Environmentalism' was a short account, largely historical, of environmental determinism, and the entry on 'Pollution' discussed not chemical contamination of air and water but ritual defilement in the purely cultural sense. Also included were a short piece on 'environment,' chiefly an exercise in definition (albeit a very useful one), and essays on 'conservation,' cultural ecology, and land and water resources. Biographical sketches of a few important figures such as Marsh and Malthus rounded out its treatment of the theme. Taken together, the entries conveyed no sense of the biophysical environment as an important topic for the social sciences.

But events were already taking place outside of the academic world that would again force environmental questions, at least in some form, on their attention. The environmental movement beginning in the 1960s and 1970s expressed a widespread public sense of concern over the impact of human activities on the earth. The list of new fears included ones as varied as forest damage from acid rain, desertification in arid and semi-arid lands, water supply shortages and water pollution, air pollution at various scales, the loss of biodiversity, and climate change at local, regional, and global scales. Activists called for intervention to protect the environment and combat the social forces—be they overpopulation, overconsumption, capitalist greed, socialist mismanagement, or any other—that they saw as responsible for the degradation and fraying of the biosphere.

Closely following the rise of public concern, attention to human-environment relations has reemerged in the social sciences, but only in the narrow form of study of the human dimensions of human-induced environmental change. For some social scientists, it has been a characteristic and congenial task to examine environmental concern itself as a social movement having social causes, without necessary reference to any truth that the claims that it makes might possess. Such can be a fruitful path of analysis, one that asks how environmental problems are selected by certain groups and actors for attention among many others that are ignored. It is not difficult to show that public concern about many environmental issues substantially outruns understanding of the scientific basis for concern. Thus, the roots of concern may lie less in the objective situation (even if the scientific account of it is accepted as objective) than in other

areas that many researchers, particularly in Western Europe, have sought to identify. A second line of work has been much more visible and on the whole more generously supported by governments and other funding agencies. This form of attention to human–environment relations has largely accepted the idea that a global environmental crisis genuinely exists or threatens and has sought to shed light on its human dimensions: its causes, its consequences, and the ways by which it might be managed or mitigated. This approach, perhaps the dominant one in the US, evidently stems less from the traditions of social science research than from the pressures of external concerns.

Unfortunately, such research has still more often than not been conducted with the tools and within the assumptions and frameworks of the existing social science disciplines and subfields whether appropriate to environment or not. Orthodox social theory developed with little or no reference to environment is, thus, brought to environmental questions and used to recommend policy as if it required no modification to meet them. Yet its inadequacy to deal with many questions without being modified is plain. The long-standing neglect of biophysical issues of scale, scarcity, and irreversibility in economics has been challenged by the emergence of ecological economics, but to date with little apparent impact on the larger field. Sociological, anthropological, and political paradigms developed in other contexts tend to be applied indiscriminately to environmental questions without careful consideration of how applicable they are. The anthropocentrism of the social sciences as a whole makes it difficult if not impossible for them to deal with notions of the rights of nature and inherent value seriously. Most recently, many adherents of postmodernism in the social sciences have had to struggle with the labor of trying to reconcile their reluctance to acknowledge anything as objectively true with their belief that a genuine global environmental crisis exists and must be addressed.

The long separation between the study of society and the study of the earth has hindered the growth of theory indigenous to and appropriate to nature–society issues that does not oversimplify either side of the relation. The natural sciences have been no less reluctant than the social sciences to modify their favored theories and approaches in order to address the full range of links between society and environment. Where they have not ignored the human role, many have tended to fall back on a narrow and reductionist set of social theories to make sense of it. A characteristic example is the currency in natural-science discussions of environmental problems of the concept of 'carrying capacity,' the supposed maximum population that an area can support. It is a concept largely rejected as too mechanistic by social scientists who emphasize the culture-bound nature of the assumptions that must be made to define capacity in particular cases. The view that human overpopulation and overconsumption are the key driving forces of environmental degradation is more widely held in the natural than in the social sciences, whose practitioners, for their part, are sometimes prone to suppose that the capacity of the environment to support life and activities is infinitely flexible or that the only serious limits are social. Many natural scientists also show an affinity for technical solutions to environmental problems—such as carbon sequestration, albedo modification, or a shift to nuclear power as a response to the threats of global climatic change—without adequate consideration of the crucial problems tied up with their social feasibility or public acceptance.

Human–environment relations may now be far more urgently important a research topic than ever, given the possible dimensions of rapid global environmental change and the measures that coping with it might demand. Yet a long period of neglect means that the knowledge base in this area is weak. Little is known about what environmental change might mean for society because little is known about what environment means for society. The present atmosphere of crisis does offer some hope that at last a detailed understanding of human-environment relations will begin to be constructed. Yet an adequate assessment of many environmental issues cannot be achieved from a background only in the natural or social sciences, and it remains to be seen whether the organization of education and research will prove capable of providing the necessary conditions to nurture such work.

Humanistic Geography

Humanistic geography studies people's relationships to nature, space and time, their behavior, feelings and perspectives on environment. Sharing enquiry with other branches of the discipline, its domains of interest overlap strongly with the humanities and social sciences. Its scholarly value and main contribution to society consists in its ability to raise people's levels of awareness about taken-for-granted ways of life and thought, inviting critical reflection on humanity's relationships to the earth.

'Diversity is at the heart of geography—from the varieties in continents and climates to the interrelationships between natural resources and how people live. Diversity is also central to human rights.' Thus, Mary Robinson, UN High Commissioner for Human Rights, addressed delegates at the 29th International Geographical Congress in Seoul, August 14–18, 2000, upon receipt of the *Earth and Humanity Medal 2000* from the International Geographical Union. She was honored for not only her championing of civil liberties and economic opportunity, but also for proclaiming access to intact and healthy environments as basic human rights. A few weeks later, scholars from all over the world assembled in Rome to explore the potential role of universities in the quest for a 'new humanism.' Renaissance humanism, one speaker recalled, 'set up a new idea of truth as a dynamic statement, not previously defined or constructed, but something to be discovered and then applied … the joint venture of new scientific discovery with the humanistic approach to mankind's problems enabled the university to nourish innovation and offer a rigorous critique of institutions and social relations' (Bricall 2000). Such 'airing' of university life, he noted, was sadly lacking today. 'Humanistic geography' may have been a twentieth-century invention, but many of its central themes at the dawn of the twenty-first century resonate with centuries-old melodies.

1. Geography and Humanism

Humanists down the centuries have explored the nature of humanity, its passions and powers, while geographers have studied the earth where humans, among many other life forms, make a terrestrial home. For each facet of humanness—rationality or irrationality, faith, emotion, artistic genius, or political prowess—there is a geography: for each geographical interpretation of the inhabited earth there are implicit assumptions about the nature of humanness. To slogans such as Protagoras' 'man is the measure of all things' and Alexander Pope's 'the proper study of mankind is man,' geographers would note that *Homo sapiens* is a terrestrial species, with projects and plans played out in particular environments, even if diverse cultures have created and been inspired by myths and symbols. *Humanus*, literally, means 'earth dweller.'

The term humanism evokes at least four distinct connotations. First, it implies questions regarding the nature of humanness (*humanitas*) with concerns about individuality and sociality, freedom and responsibility, rationality and hedonism, conservatism and creativity. Second, it refers to humanist modes of knowing which oppose scientific reductionism, aiming to elucidate rather than to explain, emphasizing the subjectivity of consciousness and the need for intersubjective dialog. Third, it is expressed in the humanities—fields of learning in the arts, classical literature, and the cultivation of civic virtue. Fourth, it is evident in an enduring concern about the human condition, e.g. in humanitarianism, which has sought to encourage social responsibility and liberal politics. Historically, from whatsoever ideological stance it has emerged,

humanism has included a call for critical reflection on conventional ways of interpreting reality and a plea for integrity and authenticity in everyday life (von Wright 1978, Buttimer 1990).

Humanistic geography also reveals these four lines of concern. What is subsumed under this rubric varies from one country or language tradition to another, the terms 'social,' 'radical,' 'critical' and 'humanistic' often being seen as virtually interchangeable (Buttimer 1974, 1976, Tuan 1976, Relph 1981, Rowntree 1988, Pellegrini 1992, Claval 1999). For some the main goal is still to restore human subjectivity to a field where scientific objectivism has been so dominant, some emphasizing human attitudes and values, others cultural patrimony; some focusing on the aesthetics of landscape and architecture, others on the emotional significance of place in human identity (Ley and Samuels 1978, Buttimer and Seamon 1980). Several also advocate humanitarian concern and engagement in the resolution of social or environmental problems. Virtually all would agree with the formulation of Yi-fu Tuan that 'the humanist's competence lies in interpreting human experience in its ambiguity, ambivalence, and complexity' (Tuan 1976, p. 275). For over three decades humanistic geographers have explored the aesthetics of landscape, issues of memory and myth, moralities and imaginations, and the multifaceted textures of place (Adams et al. 2001). This 'humanist turn' has thus evoked sharper sensitivity to the inextricable connections between thought and context, experience and expertise, and the adequacy of geography to elucidate contemporary reality.

Some have looked askance on these developments as a retreat from problems or as simply a critique of the status quo (Entrikin 1976, Relph 1981). Anti-humanist strains have also been heard from doctrinaire structuralists, and staunch advocates of positivist spatial analysis. In the 1980s many, disillusioned about contradictions in Western legacies, condemned humanism as the arch culprit, a source of *hybris* and vaunting ambition, a myth overdue for dismissal. Postmodernist scenarios of texts reproducing texts in a labyrinth of self-reflecting mirrors precluded assumptions about human intentionality or meaning in lived reality. By the late 1980s there was a growing awareness of the extent to which the entire intellectual heritage of the West had shaped, and been shaped by, the peculiar social history of Western humanity. By century's end there was a notably increased interest in critical emancipatory elements which had previously remained marginal within the profession. These diverse currents pointed to weaknesses in the inherited lore and have opened up new worlds of exploration. And linked to this, there has also been a re-affirmation of geography as fundamental education for mature citizenship, for cross-cultural understanding and for environmentally sustainable ways of life. The 'new humanism' promises to be far more 'geographical' than its predecessors.

An enduring concern of humanistic geography has been the increased level of specialization among knowledge fields. While the narrowing of analytical focus has yielded sharper insight into particular processes, the overall fragmentation of research horizons has seriously diminished the geographer's capacity to deliver comprehensive perspectives on humanity and environment. In a so-called *Magna Carta* for the 'Humanities,' William Caxton (1422–91) insisted that attention be confined to mankind as an object of study in itself, not as part of 'nature,' which was the concern of biology, nor as an object of divine grace, which was the concern of theology. Hence emerged a clear separation of scientific and humanist modes of knowing. The former was to provide analytical guidelines for the analysis and representation of research results, while the latter was to invite discovery and understanding, processes which might not only vary from one individual to another, but also imply elements of emotion, aesthetics, and moral judgment which, strictly speaking, were to be eliminated from the scientist's agenda. At the dawn of the twenty-first century, there are resounding cries for liberation from such institutional dogmatism and inherited meta-discourses which obfuscate and distract attention from the far more tyrannizing meta-discourses of commercially-driven globalization.

An essential quality of humanist discourses in Western scholarly traditions, it could be argued, is a plea for freedom: freedom from bonds of ignorance, fear, oppression or oblivion, freedom to create and to explore new horizons in thought and life (Buttimer 1990). The emergence of a 'humanist' turn within geography during the latter half of the twentieth century might be described as a liberation cry for aspects of thought and experience which had been ignored or suppressed within the practices of previous generations. At the heart of humanist concern at the dawn of a new millennium is the patent failure of well-intentioned scientifically-based attempts to alleviate poverty, inequalities and injustices worldwide. Ironic indeed is the apparent paradox that, as volumes of environmental research have grown, so too has the magnitude of environmental problems. Questions now arise as to whether our taken-for-granted sectorally specialized kinds of science are adequate for elucidating these problems, or whether, in fact, taken-for-granted application of scientific results is part of the problem (Escobar 1997).

The twentieth century ended with a litany of 'post-' and 'anti-'movements in the scholarly world—emphasis placed on elements from which many sought to be free; horizons toward which a humanist spirit would aspire remained unclear. And yet there emerged a resounding chorus proclaiming plurality and diversity. Far from one orthodox brand of geographical knowledge, there are varieties of geographical knowledges—those based on everyday lived experiences, those of women, children, minorities, immigrants and

emigrants, professionals and clients, rich and poor. In fact, many of the major challenges facing humanity and environment today could be redefined in terms of competing, contested or conflicting geographical knowledges.

2. Humanistic Geography

Geography today is recognized as not only a professional field of expertise, an academic discipline, but also a reality of everyday lived experience. Humanistic geographers have consistently promoted attention to everyday geographical experience, not only for individual human persons, but also for the diverse cultural worlds whose home territories are increasingly invaded by globally organized technological and commercial systems. They advocate coresponsible engagement in matters of territorial and social discretion in humanity's modes of dwelling. Illustrations of contemporary themes for research and reflection in humanistic geography include (a) Dwelling, (b) Nature and Culture, (c) Mindscape and Landscape, and (d) Text, Image and Construction of Regional Knowledges.

2.1 Dwelling: Essential Quality of Humanness

Geography is the stuff of everyday experience for all forms of terrestrial life. Mountain and plain, river and lake, woodland and wildlife may be 'explainable' in the categories of natural science, but in reality each cultural group understands nature, space, and time through its own special filters. To survive on planet earth, all creatures develop a geographical sense, a sense of place, space, time, and movement. How to negotiate our diverse geographies is surely one of the enduring challenges of existence, from the politics of empire to the arrangement of one's kitchen, office, and garden. A geographer tells stories of dwelling, and the interplay of mindscapes and landscapes, in terrestrial environments.

The progressive 'humanization' of the earth over the past half-million years, offers fascinating ground for study and reflection (Glacken 1967). Humanity has assumed a dominant role in shaping landscapes, harvesting resources, tipping the natural checks and balances among other life forms, in culturally and technologically diverse ways of life. Each cultural group has devised its own variety of ways in which the bio-physical environment was understood and how humans should relate to it. Some, as in the Judaeo-Christian and Hellenic traditions, have placed humanity above all other life forms and have regarded intellect as the highest manifestation of human spirit. In Hindu and Buddhist traditions, humanity has been regarded as an integral part of cosmic order, recycling, like other life forms, in a continuous process of reincarnation. Symbolic transformations are quintessentially human projects: the representation of reality in art and artifact, monument and metaphor, science, technology, and national flags. The human body itself has been a universal catalyst for symbol making in many civilizations, most common of which has been the organic analogy of the human person as a whole (body, soul, personality) as a microcosm of the universe.

Human modes of dwelling, with central themes of place and space, home and horizon, memory and identity, remain a primary focus of attention for humanistic geographers (Buttimer and Seamon 1980, Seamon and Mugerauer 1985). Emphasis is placed on the aesthetics and appropriateness of human settlements and the dramatic differences in built environments throughout the world. Humanistic geographers are skeptical of universal generalizations such as those which glorify or demonize humanity. Latecomers anyhow to earth history, some have argued, humans may now be en route toward self-destruction. While acknowledging some grounds for such gloomy prognoses, humanistic geographers continue to probe diverse landscapes, documenting evidence of human ingenuity in adapting lifeways to environment throughout history, and reiterating the perennial challenge of environment and ecology for global humanity today.

2.2 Nature and Culture

Throughout human history nature has constituted the source of inspiration and foundation for cosmology and human identity. Australian Aboriginals revere rocks as dreaming centers and song-lines evoke a sense of on-going creation. The *Upanishads* celebrate the eternal Asvatta (fig tree) and banyan tree, while North American Sioux build their entire cosmology around the sacred cottonwood tree. For East Asian societies, life was seen to emerge from the sacred lotus, and devout Hindus bathe in the sacred waters of the Ganges. Artefactual and cartographic evidence suggests that most cultures have imaged their own place as the center of the world, with horizons varying in shape and extent depending on their livelihoods and travel. The cargo cults of Polynesian islanders re-enact the stories of colonial occupation, Obijwe and Cree have detailed mental maps of trapping lines across the North American Plains—territory viewed by Euro-settlers as a vast undifferentiated arena for conquest by railway, lumber company, or settler (Brody 1981).

Humans everywhere have looked to nature for insight into the secrets of creation, birth and death, meaning and purpose in everyday life. Human inventions such as the domestication of animals and plants, technological innovations in agriculture, transport, and commerce have been construed and defended in

terms of cosmology and value system. The enduring salience of symbolism in shaping contemporary landscapes constitutes a central platform for 'new cultural geography' (Cosgrove and Martins 2000).

For the 350 million so-called indigenous peoples of the earth today, nature and human identity are inseparable. Multinational companies, often in league with national governments, find themselves confronted with a resounding *cri du coeur* from autochthonous populations eager to protect the integrity of their home environments and maintain discretion over minerals, forest, fish, and wildlife in their ancestral lands. The dramatic clash of human interests which characterizes the use of earth resources has at last found its way to public consciousness. The languages within which such clashes are overtly negotiated are characteristically those of technical expertise in the service of governments, corporations or transnational lobbies; the voices of *dwelling*, by people in place, are often ignored. Humanist geographers seek alternative bases on which human discourse about earth resources might be negotiated. Acutely aware of the extent to which scientific and popular notions of 'nature' have been socially constructed and applied in sometimes contradictory ways, they provide catalysts for critical reflection on taken-for-granted policy and programmes.

2.3 Mindscape and Landscape

The visible forms of landscape are the texts that geographers read and seek to interpret. To understand the humanized landscape one needs to understand cultural diversity among societies: not only their economies and traditional skills, but also the sense of sacred and profane in their perceptions of nature, space, and time. Successive groups have migrated over time from one area to another bringing their talents, images, hopes and prejudices with them. Characteristically, they try to recreate the new landscape in the image of the past, usually an idealized version of it. Contemporary landscapes have all been formed through the sedimentation of many layers of human occupance.

Among the strongest advocates of the 'humanistic' turn in geography were scholars who already acknowledged the hermeneutic value of landscape interpretation (Meinig 1979). 'Our human landscape,' Pierce Lewis remarked, 'is our unwitting autobiography, and all our cultural warts and blemishes, our ordinary day-to-day qualities are there for anybody who knows how to look for them' (Lewis 1985, p. 13). Landscape interpretation, adopting some of the models of literary criticism, 'read' landscape texts and signs as products in their own right, while also inviting enquiry into culturally varying modes of symbolic transformation in history. Debates over agency versus structure in the social construction of landscape features became the *sine qua non* preamble to many research ventures of the 1980s and 1990s, as reflected in new scholarly journals such as *Ecumene* and *Géographie et Cultures*.

To communicate insight on the interactions of mindscape and landscape naturally poses critical issues of language, a challenge which geographers share with colleagues in literature, philosophy and art (Pocock 1981). It has surely been on questions of language and power, semiotics and symbolism, that humanistic geographers found challenging moments of interaction with structuralists. Slogans of 'death to the human subject,' short-lived but militant, scoffed at notions of potential human creativity to transcend structural imperatives. The deconstruction of inherited meanings, as suggested in the work of Derrida, could reveal the multiple and conflicting readings that could be made on particular texts. In the 1980's, post-structuralist discourses emphasized the multiplicity of potential interpretations and the undecidability of scientific propositions. In sharp contrast with the previous generation's deeply held convictions about epistemological certainty and images of the world as a mechanical system, many voices of the late 1980s were casting doubt on all scientific claims to objectivity.

2.4 Text, Image and Construction of Regional Knowledges

Humanistic geography is concerned not only with ways in which humans, in their everyday lifeworlds, have interpreted their surroundings. It is also concerned with images of the earth projected in academic (scientific) products (Dematteis 1985, Buttimer et al. 1999). As with the earth's landscapes, the mindscapes of professional geographers have reflected the cultures and world-views of their sponsors and audiences. Geography's status as an academic discipline has mirrored the fluctuating fortunes of nations and empires, flowering at moments of societal self-confidence, altruism, or expansionary challenge; relaxing in routine operational tasks of housekeeping and inventory, text-book writing, and functionally specialized research in times of stability or depression. And as active participants in a global community of scholars, geographers have also negotiated their practices within the reigning scientific paradigms of particular periods.

Once national ministries of education established geography in university departments, the discipline's agenda became harmonized with that of its major sponsor, the state. To this day, with some notable exceptions, the practice of geography has borne a distinctively national character. From its beginnings as an academic discipline, geography has been valued as training ground for the exploration and conquest of space and resources; for the imposition of order

deemed rational by the conqueror; for the delivery of information on areas, distances, flora and fauna, peoples and cultures, in language categories and narrative frames which could be understandable and useable 'back home.' It is indeed ironic that while most places are subject today to influences which transcend territorial boundaries, the practice of geography is so tightly shaped by national and institutional contexts.

Humanistic geography is interested primarily in examining the geographical knowledges which have been promulgated in various settings. Starting from the accounts of geographers themselves, it examines the story of ideas in practice, the interplay of creativity and context in the practices of various periods, seeking to evaluate the implications of such practices for everyday life and landscape. Such approaches have not been popular, as Yi-fu Tuan warned in the mid-1970s: 'self-knowledge, the prime reward of the humanistic enterprise, has always been suspect in Western culture' (Tuan 1976, p. 276). While little evidence of its popularity in other cultures is available in geographical literature, it is certainly laudable that Yi-fu Tuan, indubitably the most influential writer of humanistic geography, has now shared his own autobiographical reflections on a fascinating, and possibly unique career journey (Tuan 1999). This account should prod readers to think critically about their own career journeys and taken-for-granted perspectives on life and world.

3. *Conclusions*

Each discovery in humanity's geographical understanding of the world has heralded changes in its self-images, hopes, and fears. The dawn of a new millennium reveals radically revised perspectives on mindscape and landscape. Geographers have dared to look inwards, exploring cultural differences in environmental perceptions and experience, while colleagues in the humanities dare to look outwards, freely exploring themes such as landscape, identity and place, space and time. Today's world map of power and politics has taken on radically new dimensions due to transformations in technology and trade. The explosion of information and the transcontinental circulation of people, commodities, and ideas raise exciting new possibilities for thought and life. The spatial juxtaposition of culturally diverse peoples should become the springboard for new creativity in politics and social life, rather than problems to be solved by social engineering. Humanistic geography has much to offer by way of cross-cultural and historical evidence of creativity in discovering environmentally appropriate solutions. Gaia's human envelope, the anthroposphere, needs to be understood more as a complex drama than simply as battleground of ecological versus economic rationality; more as *oecumene*, potential home for humanity, a species which urgently needs to rediscover the art of dwelling.

Much rhetoric has been aired on the Western world's anthropocentric perspectives, critics usually implying alternatives such as the deification of nature, of the social collective, or the reification of ideologies playing out their purposes with humanity and nature. Perhaps the West, far from overestimating *humanus*, has grossly underestimated it. Recovery of the human subject, and recognition of human agency as an integral part of the lived world, the creativity again apparent on peripheral and previously marginalized regions, all betoken fresh potential for humanistic geography today. As a stance on life, humanism welcomes the challenge of discerning the creative potential of individuals and groups to deal with the surface of the earth in responsible and co-responsible ways (von Wright 1978). Nor is human creativity confined to the intellectual sphere; it involves emotion, aesthetics, memory, faith and will. The humanist turn in geography has delivered inspiration to practitioners of physical, economic, cultural and social geography. Its aims are not well served by investing energy on staking claims for becoming a special branch of the field. Humanism should thus more appropriately be considered as a leaven in the dough rather than as a separate loaf in the *smörgåsbord* of geographic endeavor. The emancipatory *élan* recuperable even from our Western traditions could enable geography itself to perform as leaven in the mass of contemporary science and humanities. The Renaissance of humanism calls for an ecumenical rather than a separatist spirit; it calls for excellence in special fields as well as a concern for the whole picture. From our Western corner, perhaps the greatest challenge is that of bridging worlds through dialog and mutual understanding.

A. Buttimer

Humboldt, Wilhelm von (1767–1835)

1. Politics

When Wilhelm von Humboldt, born June 22, 1767 at Potsdam, resigned from his office as the Prussian Minister of Constitutional Affairs at the end of 1819, this was a major catastrophe for the political future of Germany. For Humboldt himself it was an act of liberation and a step towards what he regarded as his real vocation, the study of languages, to which he dedicated the rest of his life. Chateaubriand, the French poet and politician, considered this strange scientific activity as the spleen of somebody who had to kill his time as a consequence of the loss of political influence. But it was in fact the achievement of a philosophical and anthropological quest which had started in Humboldt's youth. Studying the languages of the world was not at all something completely extraneous to his political work. The same motivation which would guide his linguistic work had also governed his political activities: it was a quest for the creative center of the human mind and for the achievement of individual felicity and autonomy within the totality of other individualities.

This is exactly what had created his political difficulties. At the end of his political career, Humboldt had elaborated a project for the constitutional transformation of Prussia: a proposal to establish a constitutional monarchy with a gradually developing representational system. The French Revolution, which he had welcomed as a decisive step in the history of humanity, had failed in Humboldt's eyes because of its rationalistic one-sidedness: the transformations of France had been governed too radically by abstract rational principles and had not taken into account historically grown entities. For Humboldt, the creation of the new should always be the result of a 'synthesis,' of a sympathetic union of two entities which, creating a new entity by their union, maintain their identity (the alternative—and lesser—methods of uniting two entities are 'isolation' and 'incorporation,' the former being only the juxtaposition of the two, the latter the brutal destruction of their integrity through their unity). Humboldt proposed a 'synthesis' of the traditional prerogatives of the monarch and the interests of the economically active classes (with a consideration also for the traditional rights of the nobility), a 'marriage' which would have transformed Prussia eventually into something new, a constitutional monarchy—and which would have had a model function for the rest of Germany. Not only for the inner organization of Prussia, but also for the whole of the area called 'Germany,' Humboldt projected a political structure according to the same principle of a 'synthetical' union: a confederation which would have left quite a lot of autonomy to its members but nevertheless have given important political functions to the whole (like warfare, freedom of movement and free trade within the union—very much like the USA).

But, in 1819, the times were not propitious anymore for reforms and for the creation of new political structures as after the defeat of Prussia by Napoleon which was the beginning of so many happy reforms in Prussia, like the reform of the educational system, the renewal of the municipal administration and the emancipation of the Jews. Now Napoleon was defeated and the old classes were striking back and were not willing to make any concessions to the bourgeoisie, to the memory of the 'people's war' or to the experience of freedom and civil rights imported by the Napoleonic armies. Humboldt was the representative of liberal political reforms, and, as such, he had to disappear—in the time of Austria's Metternich, of Hardenberg and a reactionary king in Prussia.

2. *University and* Bildung

But if Humboldt did not succeed in realizing his constitutional dreams, he seems to have had an overwhelming success with the establishment of the University of Berlin some years earlier. Humboldt is best and generally known for this activity, which in fact occupied him for little more than a year (from February 1809 to June 1810) and which was only a part of the reorganization of the whole Prussian educational system. Humboldt indeed made the decisive administrative step for the establishment of the University of Berlin. But what was established was only partially Humboldt's University. He planned the university as a state-independent, economically autonomous institution, with an independence that would guarantee the freedom of research and instruction. Therefore, Humboldt requested that the university should be given a donation of land as the economic basis of that autonomy. Instead, the Berlin University was from the very beginning a state establishment which—it is true—set unprecedented standards by the quality of its new faculty, by new forms of teaching, by the unity of research and teaching for professors as well as for students. The concept of the research university was successfully realized. As a state-dependent institution it would forge a well-trained loyal elite for the King of Prussia rather than free citizens of the realm of the spirit.

Humboldt's proposals for the establishment of the Berlin University and the other educational institutions became, however, seminal texts for a pedagogical theory whose central concept was that of *Bildung* (educational and cultural development). Following the convictions of German idealistic philosophy and the classical German poets (Schiller and Goethe), Humboldt wanted human individuals to be given every possible means to develop their physical and intellectual capacities. The educational institutions have to grant access to that formation of the human individual. The main aim of *Bildung* is not the acquisition of professional skills but the unfolding of the highest intellectual and artistic aspirations. Ancient Greece as the absolute summit of human development is the cultural reference of that educational program. The concept of *Bildung* certainly gave an ambitious aim to the educational institutions of Prussia and of Germany as a whole. This concept even served as a justification of otherwise unexplainable investments of the state in intellectual enterprises like the humanities, which have no practical ends. *Bildung* was an enormously successful concept as one of the central values of German identity, giving education a very high position in the value system of the nation. But just as Humboldt's University project was only partially realized in the Prussian University, the idea of *Bildung*—a generous and grandiose idea—did not so much create the (also politically) autonomous and free individuals Humboldt was thinking of, but had more of a compensatory function: consoling the German bourgeoisie for its nonparticipation in political power. Hence, all that wonderful *Bildung* did not prevent the German catastrophe.

3. *Anthropology*

The establishment of the University of Berlin and *Bildung* secured Humboldt's place in the pantheon of the German nation. But his main activity and—in the long run—also his most successful intellectual achievement, was his linguistic and philosophical work. In this domain, however, Humboldt is not—as some historiographers tend to think—a founding father of the scientific project of historicocomparative linguistics that is linked to the names of Franz Bopp and Jacob Grimm. Bopp and Grimm invented the principles for a historical reconstruction of the unity of Indo-European, Germanic, Romance, Slavic, and other languages and for the comparison of historically related languages. This was to be the successful—romantic—project of the mainstream linguistics of the nineteenth century. Humboldt is, on the contrary, the founder of an alternative linguistic project, which is more the summary of the linguistic ideas of the Enlightenment: the study of the diversity of the languages of the world. *Verschiedenheit*, or diversity, is the key term of Humboldtian linguistics which was to flourish—at least in part—in the twentieth century, when the historicocomparative paradigm was relieved by synchronical descriptive linguistics.

Humboldt's linguistic project was integrated into a larger 'anthropological' project. 'Anthropology' in the eighteenth century was a term which designated the empirical study of human beings, as opposed to philosophy, which investigates the universal nature of the human race. Humboldt sketched a vast research program for the investigation of the cultural manifestations of humankind. Understanding the creativity of the human mind was the philosophical motive that gave Humboldt's anthropological project its special dynamics. Two events which occurred in his lifetime were decisive for this research into creativity: first, as for any young intellectual of his generation, the French Revolution, the creation of a completely new, enlightened, political organization. Hence, one of his first publications was an article on the first French constitution (1791) and for his friends he wrote a booklength political treatise 'On the limits of the activity of the state' (1792), which was printed only after his death and which became a founding document of political liberalism. The other revolutionary event in Humboldt's lifetime was Goethe. Here again, what fascinated the young intellectuals was the 'genius,' the mystery of an unprecedented creativity. Humboldt lived in Jena, as a friend of Schiller's, in close contact with Goethe. He studied Immanuel

Kant, whose philosophy was to become the framework of his own theoretical developments. Humboldt's work is centered around the Kantian concept of imagination, *Einbildungskraft*, the faculty of the human mind that is responsible for the creation of the new.

Since imagination as the mediation between the senses and the intellect had remained rather mysterious in Kant's philosophy, Humboldt set out to find its roots. He discovered them in the difference between the sexes. The opposition of the male and the female in nature is the very basis of every new creation, not only of physical generation (*Erzeugung*) but also of the most 'sublime creature' of the imagination: thought. The loving embrace of the female and the male generates new living beings in the physical as well as in the intellectual world. Kant was shocked by Humboldt's somewhat pre-Freudian interpretation of his philosophy. But despite Kant's criticism, sexual union, 'matrimony' (*Vermählung*), love, would be the structural model for everything Humboldt set out to investigate: art, politics, education, and language. Just as dialectics is the fundamental figure of thought in Hegel, the erotic encounter is the basic structure of Humboldt's thought.

After his reflections on the anthropological roots of creativity, Humboldt wrote a book on Goethe (1798) which contains a very modern theory of aesthetics: art is not only a creation of the artist's imagination but also a (language-like) communicative event between the producer of the work of art and the observers, the readers, the listeners who recreate the work of art in their act of reception and thereby accomplish the creative process.

4. *Language*

While still in Jena, Humboldt wrote his first reflections on language: 'On thinking and speaking' (1795–6), a short sketch which already contained the main features of his language theory. Humboldt's sojourn in France and in Spain (1797–1801) would be decisive for his making language the very center of his intellectual endeavours. In Paris, he discussed philosophical issues with the *Idéologues*, in whose philosophy language played a crucial role, and here and in his journey to the Basque Country, he encountered the Basque language whose profoundly divergent structural properties intrigued Humboldt. Later, his brother Alexander would bring linguistic material from America, and in Rome Humboldt had access to the linguistic materials of the Jesuits (Lorenzo Hervás). For years, the Amerindian languages were Humboldt's empirical linguistic objects before he turned to the Malayo-polynesian languages to which his main—posthumous—work *On the Kavi Language on the Island of Java* (1836–9) is devoted. The introductory volume of that book, *The Diversity of the Human Language-Structure*, completed before his death on April 8, 1835 in Tegel (near Berlin), is Humboldt's major work. With language, Humboldt arrived at the very heart of his general quest for the creation of the new by that mysterious Kantian faculty of *Einbildungskraft*.

Language is not just a means for the communication of thought, it is the very creation of thought. According to the Kantian system, the senses and the intellect create the concept through their synthesis. But for Humboldt, the concept is not created independently of the word: word and concept form an undissoluble synthetical unity; thought is created as sound. Language is the 'formative organ of thought' ('*das bildende Organ des Gedanken*,' 1903–36, VII, p. 53), 'labor of the mind' ('*Arbeit des Geistes*,' 1903–36, VII, p. 46). Like art, language (thought-sound) also needs the dimension of the other: it must be heard and understood. Language as a cognitive activity reckons with the other, language is thought in the dimension of the other: *Mitdenken*, or cocognition. But surpassing art, language is a reciprocal creative activity: the hearer becomes speaker, 'the word formed by me resounds from the mouth of the other' (1903–36, VII, p. 56). This ultimate reciprocity is the completion of the linguistic syntheses. The duality of I and Thou is the 'fundamental type' of language.

Humboldt discovered that language is actually at the center of the Kantian system. Humboldt's language philosophy was a linguistic turn of transcendental philosophy. Since Bacon's discovery of the *idola fori*, European philosophy had become gradually aware of the fact that language is not just a device for the communication of thought but first and foremost a cognitive activity. This insight finds a coherent post-Kantian formulation in Humboldt.

The second important moment of that philosophy of language is the insight that the formation of thought, the linguistic 'transformation of the world into the property of the mind' (1903–36, IV, p. 420), always proceeds according to the special ways of historically particular communities, that is, according to particular languages. There is no such thing as language in general, language comes in languages. Thought generated by language, hence, is not uniform and universal but historically and culturally fragmented in different 'worldviews' (*Weltansichten*). The task of language, the generation of thought, is universal, but that task is realized in thousands of different ways in the different languages of humankind.

Now the new—or Leibnizian—moment of that insight is its positive interpretation: from Bacon onwards, philosophy has lamented over the particularity of worldviews in the different languages and wanted to get rid of those 'prejudices'; the semantics of natural languages is like 'a mist before our eyes' (Locke) which philosophical enlightenment must discard. Only Leibniz gave an optimistic twist to the discovery of the linguistically generated diversity of thought when he envisaged a study of all the languages

of the world in order to know the 'marvellous variety of the operations of our mind.' Herder took that idea from Leibniz, and Humboldt not only integrated it into the Kantian framework but also developed a huge program of descriptive linguistics.

5. *Comparative Study of Languages*

All the languages of the world were to be described according to what Humboldt calls their 'inner coherence' (*innerer Zusammenhang*), their particular structure. The languages of the world had mostly been grasped according to the traditional categories of Greek and Latin grammar. But the structural properties of a language can only be captured through its own categories. Humboldt envisaged an encyclopedia of the languages of the world, a new *Mithridates*. He started a whole series of descriptive works on different languages of the world of which only the *Mexican Grammar* (Humboldt 1994) has been published up to now. A second kind of structural studies aimed at a revised form of general grammar (which was also based on the Greco-Latin grammar): comparative investigations of linguistic categories throughout the languages of the world. Humboldt's article on the dual (1827) is an example of that research. After the completion of these structural descriptions, research into the parental relationships of languages (genealogy) or into structural similarities among languages (typology, classification) can be undertaken.

What is often considered as Humboldt's main contribution to linguistics, the so-called Humboldtian 'typology,' is neither central to his linguistic aims nor did Humboldt propose typology as an alternative to the dominant linguistic school, that is, to the historicocomparative studies of languages. On the contrary, in his last book, his unfinished work on Kavi, Humboldt eventually envisaged a comparative study of the Malayo-Polynesian languages which would follow Grimm's and Bopp's work on the Germanic and Indo-European languages. Humboldtian typology is a linguistic myth created by superficial readings of his texts. Humboldt was very sceptical about the classifications of the Schlegels, and eventually he explicitly refuted the legitimation of classifying languages, since languages are individuals and should be described as such.

The summit or keystone of Humboldtian linguistics is therefore the investigation of the 'character' of languages. This is just the opposite of classification and typology, of grouping similar entities together. It is a tentative attempt to grasp the very individuality of each individual language. Humboldt was not sure whether 'characterization' was still a scientific task. But whatever it is, it has to be tackled since it is the ultimate aim of linguistics to see how the human mind uses the instruments it has created, to investigate the very end of language: speech and discourse. The—necessary—structural description of a language is only 'comparable to its dead skeleton' (1903–36, VI, p. 147), the life of a language is discourse (*verbundene Rede*), a life giving 'character' to that language. Therefore, only languages that have a multifaceted literature yield the possibility of being described as having characters.

Nearly two centuries after Humboldt's sketch of a huge linguistic program, it can be said that the structural description of human languages he envisaged was the main task and achievement of linguistics in the twentieth century. It is not by chance that Humboldt is present in the seminal theoreticians of modern linguistics (Saussure (see *Saussure, Ferdinand de (1857–1913)*), Bloomfield (see *Bloomfield, Léonard (1887–1949)*), Hjelmslev). The nineteenth century was not very Humboldtian, with its emphasis on diachronical research as well as in its naturalistic research methods. Humboldt's 'keystone' of linguistics, the 'characterization' of languages, was attempted by some literary-minded linguists (e.g., Vossler), but was discredited by nationalistic and ideological interpretations of linguistic structures. Since the structural descriptions of the languages of the world have now virtually been completed, it is not astonishing that in actual linguistics typological attempts are again very important. The so-called Humboldtian typology is often quoted in that context. But it is—even more than the other famous Humboldtian invention, 'Humboldt's University'—rather a myth than a creature of the author. Without any foundation in Humboldt's work is also the widespread conviction that Humboldt discovered fundamental principles of Chomskyan linguistics, like the 'infinite use of finite means.' Humboldtian linguistics as a whole is in direct opposition to that kind of linguistic research: it is a hermeneutical research into the cultural diversity of human languages in historical communities, preferentially through (literary) discourse, and not a naturalistic investigation of the structure of the universal human mind considered as a universal grammar.

Hume, David (1711–76)

David Hume, a leading figure in the Scottish Enlightenment, contributed significantly to the disciplines of psychology, history, political science, and economics—as well as to more theoretical discussions in ethics, aesthetics, epistemology, and philosophy of religion. He was a controversial figure in his own day because of his criticisms of both natural and revealed religion and because of the political opinions he was thought to express in his *History*. His skeptical arguments concerning induction are still discussed by philosophers interested in probability theory, and his account of the foundations of morality enters into current disputes about the source of moral obligation.

1. *Life and Writings*

Hume was born in Edinburgh on April 26, 1711. The family was of genteel but of modest means: His father, Joseph Home, an advocate and member of the minor gentry of Scotland, died when he was 2 years old and his mother Katherine, who never remarried, brought up him, his sister, and older brother on their small estate of Ninewells in the Scottish Borders. Hume probably began taking classes at Edinburgh University in 1721 where he studied the Latin classics, moral philosophy, mathematics, natural philosophy, and possibly history. There is no record of his ever having taken a degree (which was not unusual at this period) and, in a short autobiography written just before his death, he notes that, while his family intended that he study law, his own interests were in 'Philosophy and general Learning.' He probably began planning his first philosophical work, *A Treatise of Human Nature*, in 1729 when he was about 18 years old.

Suffering from complaints which we would now consider to be largely psychosomatic, Hume decided in 1734 that he needed to pursue a more active life; he left Scotland for Bristol where he worked briefly for a merchant. After a few months he went to France, where he spent the next 3 years writing and studying. He went first to Reims, but soon settled at La Fleche in Anjou, in the vicinity of the Jesuit College where, more than 100 years earlier, René Descartes had been a student. The first two books of his *Treatise of Human Nature* ('Of the Understanding' and 'Of the Passions') were published in 1739, about a year after he returned to England, and the third ('Of Morals') was published in 1740 after he returned to Scotland. The *Treatise*, from which he hoped to gain literary fame, 'fell dead-born from press,' though it is taken by modern scholars as an important and seminal work. It was followed in 1741–2 by his very successful *Essays, Moral and Political* which were written to reach a more popular audience.

Hume unsuccessfully applied for university chairs at Edinburgh University in 1744–5 and at the University of Glasgow in 1751–2, where he had strong support from his friends (among them William Cullen) but was opposed by many of the clergy, who accused him of irreligion. While his *Treatise* contained no explicit discussions of religion, this was changed in the rewriting of its first book, which was published in 1748 under the name of *Philosophical Essays Concerning Human Understanding*. It contained his famous argument against rational belief in testimony for miracles, as well as the basis for his later attack on the design argument for the existence of God. Continuing to search for a career, Hume spent some time during the 1740s as secretary to General St. Clair and participated in a rather futile attack in 1746 on the coast of Brittany during the War of Austrian Succession. In 1747 he traveled with the General as his aide-de-camp on a Military embassy to the capitals of Britain's allies, Austria and Sardinia.

In 1749, Hume returned once more to Scotland and began an immensely productive decade. In 1751 he moved to Edinburgh from Ninewells; he was to live

there much of the rest of his life as a leading figure of the Scottish Enlightenment. Hume was elected secretary of the Philosophical Society of Edinburgh—a group devoted to the study of science and technology. (He was later, in 1762, to present to the Society Benjamin Franklin's paper describing the use of lightning rods.) In 1751 he also published his *Enquiry Concerning the Principles of Morals*, a reworking of the third book of his *Treatise of Human Nature*. His correspondence at this time also indicates that he had already written substantial portions of his posthumously published *Dialogues Concerning Natural Religion*. In 1752 Hume published his popular *Political Discourses* and began work on what was to become his most successful piece of writing, namely his multivolume *History of England*. He became Keeper of the Advocates' Library (later incorporated into the National Library of Scotland) in January, which gave him direct access to a large collection of historical sources. The first volume of the *History*, concerned with the reigns of James I and Charles I, was published in 1754 and the remaining volumes between 1756 and 1761. In 1758, Hume published *Four Dissertations*, which included his *Natural History of Religion*, *Of the Passions*, *Of Tragedy*, and *Of the Standard of Taste*.

In 1763, after the end of Seven Years War, Hume was invited to go to France as Secretary to the Ambassador, Lord Hertford. In France, where his writings were admired, he was lionized both by the mighty and intellectuals. He developed close relations with many of the philosophes, especially d'Alembert. Hume was *Charge d'affaires* for about 4 months in 1765 after Hertford left Paris. He returned to England at the beginning of 1766 bringing with him Jean-Jacques Rousseau, on the advice of Parisian friends; Rousseau sought refuge in England from persecution on the Continent. Hume and other British friends procured a pension for Rousseau from the King. However, this whole affair turned into a disaster as a result of Rousseau's paranoia. Rousseau denounced Hume as his enemy. Hume's defense of his own conduct was published by d'Alembert and Suard in Paris in October of 1766. Hume's last public appointment was as an Under Secretary of State from February 1767 to January 1768. He retired to Edinburgh where he continued to publish new editions of his works and died on August 25, 1776 as Britain's foremost man of letters.

2. *General Philosophical and Psychological Principles*

Philosophers still disagree about the nature of Hume's basic philosophical principles. It is agreed that he was a skeptic who argued throughout his writings that our basic commerce with the natural and social worlds is not founded on reason, but on the non-rational processes of the imagination and passions. What is in dispute is the nature of his scepticism, and the degree to which he sought to radically alter the conceptions of the natural and social worlds as conceived by his contemporaries (Read and Richmond 2000). While early twentieth-century philosophers saw Hume as an early forerunner of positivism, this interpretation has been challenged by recent scholars (Wright 1983). The question concerning Hume's adoption of conservative or liberal principles has also been a subject of dispute—though he claimed neutrality in discussing the political debates of his own day (Livingston 1998, Stewart 1992).

In his *Treatise of Human Nature* Hume set out to found all the other sciences on the science of human nature, and stressed that this science itself must be based on experiment and observation. Hume's foundational science of human nature was a science of the human mind. The basic psychological principle that he sought to establish in his *Treatise* was that of the association of ideas and impressions through resemblance, contiguity in space and time, and causality. He followed Locke in rejecting innatism and holding that the elemental building blocks of our ideas must be based on experience—the impressions of external and internal experience; however, he argued against Locke that these sources cannot supply us with our common sense or scientific conceptions of reality. Rather, the latter arise through irrational processes of the imagination and habits, based on the principles of association.

In a famous analysis, Hume argued that the principle of scientific induction by which we infer from past instances to future ones is based on custom and habit, and is not susceptible to rational justification. He denied that we have any understanding of the principles by which the natural world operates; at the same time, he argued that we naturally believe in causation between successive events that we observe to be constantly conjoined.

Hume held that we have as much reason to believe in necessary causes in the human as in the physical world. He argued that 'the conjunction between motives and voluntary actions is as regular and uniform, as that between the cause and effect in any part of nature' (1999, p. 154). At the beginning of his *Treatise of Human Nature* he set out to apply the experimental method to man, as it had been applied by Galileo, Newton, and others in the previous century to physics. At the same time, he believed that there is a problem in carrying out controlled experiments in the human sciences, because 'reflection and premeditation' would disturb the natural processes of the mind (2000, p. 6). He proposed to base his experiments on an observation of human behavior as it manifests itself 'in the common course of the world, by men's behaviour in company, in affairs, and in their pleasures.' While much of his data throughout his writings is taken from history, in Book 2 of the

Treatise, Hume made a series of observations of contemporary social behavior, testing his hypotheses concerning the causes of the passions of pride, shame, love, and hatred. He asked his reader to do thought experiments in which the antecedent circumstances were varied and the resulting passions were predicted. He regarded the subjects which we today call sociology and psychology as closely intertwined.

3. *Historiography, Economics, and Politics*

Hume was both a philosopher of history and a philosophical historian. He both articulated and applied principles for the assessment of historical sources. These principles are carefully laid out in his essay *Of Miracles* where he discusses the criteria we ought to use to judge the reliability of witnesses, as well as the need to balance those results against the intrinsic likelihood of the occurrence of an event (1999, p. 169ff). Following discussions of probability in John Locke and other early modern writers (Stewart in Stewart and Wright 1994, p. 171ff), he formulated criteria for the reliability of written or oral testimony: these included considerations such as consistency with other reports of the event, the determination of the character and expertise of the witnesses, the number of witnesses, and the self-interest of the witnesses in convincing others of the truth of their accounts. Hume held that we need to balance these considerations of the reliability of testimony against the absolute likelihood of the occurrence of a miracle. He held that in identifying an event as a miracle (i.e., a violation of a law of nature) we are already committed to the view that it has a 'proof' against its very occurrence. This claim is based on his argument that the only evidence we have for laws of nature is past regularity. He concludes that in the case of miracle reports the witnesses would have to be absolutely unimpeachable—a state of affairs that has never obtained. More generally, Hume argues that we must balance the testimony given by historical witnesses against the probability of the occurrence of any event. Thus, in his essay *Of the Populousness of Ancient Nations*, in *Essays Moral, Political and Literary* (1987, p. 377ff), he denies the claims of his ancient sources concerning enormous populations and armies of the ancient world. He argues, mainly on economic grounds, that the ancient nations, unlike modern ones, could not have supported such high populations as ancient writers claimed (D. Wootten, in Norton 1993, p. 281ff). In his *History of England*, Hume frequently appealed to general principles of human nature—those which he believed to be established by the newly emerging human sciences—to evaluate the credibility of his historical sources.

Hume is an important forerunner of classical economic theory. He argued that economic forces influence political structures, and that the development of modern liberty and government by law had been due to the development of trade and industry. Indeed, in the *Wealth of Nations*, Adam Smith states that Hume was the first writer to reverse the accepted view that political liberty precedes economic development. Hume saw in the rise of the merchants and tradesmen a check to the despotism that existed in premodern society. He argued that it was in the interest of these classes to live by equal laws and to limit the power of the aristocracy and the monarch. His analysis was based not only on his study of the rise of parliament in the early seventeenth century that led to the English civil war, but also in comparisons of modern European society generally with that of the ancient and medieval worlds. While Hume accepted James Harrington's social determinist view of the development of modern society, his originality lay in his postulation of the commercialism as a key factor in limiting the absolute power of the monarch (D. Wootten, in Norton 1993, p. 281ff).

Hume regarded man's economic behavior as deeply rooted in his psychological makeup. He argued that there are three factors that constitute human happiness—action, pleasure, and indolence (*Of the Refinement of the Arts*, in *Essays Moral, Political and Literary* 1987, p. 268ff). He regarded industry as a key to the leading of a balanced life in which pleasure and indolence follow naturally after a period of engaging activity. But, above all, he claimed that there is no pleasure that feeds on itself so much as the desire of the merchant to see his fortune grow. The habit of industry stimulated by this desire creates a frugality that does not naturally exist in an agrarian society based on inherited wealth. The love of gain which marks the activity of the tradesman and merchant results in large sums of money which can be lent at interest to stimulate further economic growth (*Of Interest*, in *Essays Moral, Political and Literary* 1987, p. 301). Low interest rates will be maintained by continuing increase in wealth.

Hume also argued that 'the encrease and consumption of all the commodities, which serve the ornament and pleasure of life, are advantageous to society' (*Of the Refinement of the Arts*, in *Essays Moral, Political and Literary* 1987, p. 272) and that a consumer society encourages the development of hard-working persons whose labor can be turned to the service of the state in times of national need. Key to his analysis is the idea that habits of hard work motivated by self-interest strengthen the nation–state. Developing the ideas of Bernard Mandeville, Hume argued against those in his day who complained that wealth and self-indulgence of the individual enfeeble both the individual and the society as a whole.

While Hume argued that 'Politics may be reduced to a Science' (1987, p. 14ff), he was skeptical about the ability of theorists in his own day to arrive at more than a few general principles of political behavior that would always apply (*Of Civil Liberty*, in *Essays Moral*,

Political and Literary 1987, p. 87ff). Certainly, he thought that history has taught us some general political principles concerning the different political behaviors of men under the different forms of government such as monarchy, aristocracy, and democracy. For example, from the ancient world we have learned that nonrepresentative democracy results in constant 'tumult and sedition.' However, he also argued that, given the relative newness of civilization, and the potential effects of 'education, customs, or principles' on human beings, it is impossible to predict how political behavior might evolve under circumstances which have not yet existed. He noted that among a number of other false generalizations, Machiavelli had concluded that if a prince relies on a single advisor that advisor would overthrow his master. Hume acknowledged that the evidence of ancient history, as well as that of 'the little disorderly principalities of Italy' of Machiavelli's own day, encouraged such a generalization; but he pointed out that it had been proved false by the experience of European hereditary monarchies of the seventeenth and eighteenth centuries. In general, while Hume thought that while there were a few generalizations that could be relied on in the science of politics, a cautious scholar needed to put principles forward as mere hypotheses to be modified by future circumstances.

Hume argued that political institutions evolve slowly, and that a necessary condition for civil liberty, namely the balance of power between parliament and the monarch, is the result of complex historical factors; liberty, he believed, is always under the threat of disappearing if one side or the other develops too much power. This caution, and his fear of the mob, made him a profoundly conservative thinker, especially toward the end of his life.

Hunger and Eating, Neural Basis of

Eating is a familiar behavior. In humans, it is strongly influenced by cultural, social, and experiential factors. Consequently, eating has been a subject of considerable interest to social and behavioral scientists. In mammals, including humans, food intake is also a regulatory behavior with the primary function of supporting the continuous energy demands of body tissues. When considered from this perspective, food intake is influenced by hunger, satiety, and the biologic mechanisms that couple eating with internal caloric supplies and a stable body weight. This article discusses the signals that are important in enabling the central nervous system to control food intake, and also describes mechanisms thought to integrate these signals.

1. Historical Perspective

Biologic and behavioral studies on the control of appetite and satiety have shifted their focus markedly during the past three decades. The earlier preoccupation with the 'dual center' model, whereby food intake was controlled by a lateral hypothalamic feeding center and a medial hypothalamic satiety center, was based largely on investigations in which the putative centers were destroyed by stereotaxic electrolytic lesions (Stellar 1954). This once-dominant idea has now been discarded by most investigators in light of subsequent observations that have led to reinterpretation of the initial results. Specifically, the prolonged period in which animals do not eat after lateral hypothalamic lesions has been reproduced by destroying the dopaminergic neurons that ascend through the diencephalon; this aphagia and other related behavioral impairments appear to reflect a

decrease in cerebral arousal that precludes all voluntary behaviors, not just feeding (Stricker and Zigmond 1976). Moreover, the syndrome of overeating and obesity after medial hypothalamic lesions seems to derive primarily from the greatly increased level of insulin in the circulation associated with a decrease in sympathetic neural tone, as a result of which ingested calories are rapidly and preferentially stored via lipogenesis rather than being used gradually for ongoing metabolic demands (Friedman and Stricker 1976, Powley 1977).

More recent studies have emphasized metabolic and humoral factors in peripheral organs, in addition to the brain. An increasing number of investigations have related food intake to the functions of the stomach, liver, and adipose tissue, and have suggested an important role of peptide hormones, especially insulin, cholecystokinin (CCK), and leptin, in the control of food intake. In considering these issues, most contemporary investigators have abandoned the traditional depletion–repletion model, whereby a deficiency of caloric nutrients somehow triggers an appetite for food, the ingestion of which then leads to nutrient repletion and satiation. It is now clear that there are no true shortages of metabolic fuels under normal physiologic conditions. Instead, the key variable in controlling food intake seems to be the alteration in the source of the metabolic fuels used during each of the two phases of caloric homeostasis: during the absorptive phase metabolic fuels are supplied from recently consumed food that still is in the alimentary canal and being assimilated, whereas in the postabsorptive phase metabolic fuels are generated from accumulated triglyceride, glycogen, and protein stores derived from food consumed more remotely in time. Thus, according to this perspective the shift from satiety to hunger is not associated with an absolute metabolic deficit, but instead occurs when animals enter the postabsorptive state and must mobilize calories from tissue stores in order to maintain caloric homeostasis. Moreover, eating does not correct a true deficit or restore some aspect of tissue function to normal; rather, it simply re-establishes the pattern of an ample supply of usable calories from the gastrointestinal tract instead of from stores in adipose tissue, liver, or muscle (Woods and Stricker 1999).

2. *Satiety Signals*

Because the cells of animals cannot long survive depletion of calories, hunger cannot result from cellular nutrient shortages. Instead, the sensation of hunger apparently does not need to be stimulated but is always present, and animals are constantly stimulated to eat unless they have just eaten, in which case the inhibitory effects of satiety generated from the previous meal are still operative. In support of this perspective are laboratory findings that (a) experimenters cannot easily precipitate eating in satiated rats but can do many things to stop eating by hungry rats, (b) the size of spontaneous meals eaten by laboratory rats is unpredictable, but however much the animals eat in a given meal, meal size predicts how long they wait until they eat again, and (c) food deprivation does not cause a shortage of caloric nutrients in the circulation. The point here is that food intake appears to be initiated by the gradual disappearance of inhibitory satiety stimuli that were generated by the previous meal, not by the gradual increase in an excitatory hunger stimulus (LeMagnen 1985).

2.1 *Gastric Distension*

Several signals appear to stimulate satiety after a meal. One results from gastric distension, detected by stretch receptors on the walls of the stomach; the greater the distension, the greater the inhibition of eating (McHugh and Moran 1985). This afferent signal projects to the caudal brainstem via the gastric branch of the vagus nerve; as expected, animals eat unusually large meals when the gastric vagus is cut or its projection sites in the brain are destroyed. Experiments in rats have revealed that an intestinal hormone secreted during the meal, CCK, potentiates the gastric vagal signal and produces a heightened sensation of satiety related to gastric distension. This signal is related to the volume of the gastric contents, not its nutrient contents, because there are no known detectors of calories in the stomach. Drugs that acutely block CCK receptors increase food intake during a meal, as if the animal were less aware of gastric distension signals (Smith and Gibbs 1992).

2.2 *Ingestion of Calories*

The ingestion of calories, detected in the liver and possibly in the intestines, provides a second satiety signal, which is sent to the brainstem by another branch of the vagus nerve. This stimulus appears to develop only in the presence of insulin, a pancreatic hormone secreted when food is consumed. Thus, satiety normally is not lost as the stomach empties because the gastric signal related to distension is replaced by the postgastric signal related to caloric delivery (except in animals with insulin-deficient diabetes mellitus).

2.3 *Thirst and Nausea*

Two other meal-related signals also are known to be potent inhibitors of food intake. One is thirst,

resulting, for example, from the presence of relatively large amounts of salt in the food. The other is nausea, which might result from the inadvertent intake of toxins in food. However, these two variables are not relevant to most meals. Receptors that detect dietary salt have been located in the hepatic portal vein, which receives ingested food soon after it has been absorbed from the intestines. Receptors for circulating toxins are located in the area postrema in the brainstem. These two signals, together with gastric distension, provide three noncaloric stimuli that have marked inhibitory effects on food intake (Stricker and Verbalis 1991).

2.4 Body Weight

The influence of body weight on food intake must also be included in any consideration of satiety signals because food intake and body weight have been shown to be closely related. Thus, following a period of food deprivation, food intake is increased until the lost body weight is restored. Similarly, following a period in which food has been consumed in excess, food intake is diminished until the body weight that has been gained is lost.

Changes in body weight largely reflect changes in the storage of calories in adipose tissue. These stores are diminished during food deprivation to provide the calories needed for cellular function, and they are replenished when food intake resumes. Thus, as ingested calories are siphoned off to the adipose tissue, their effects on the liver are diminished, thereby reducing the duration of this postgastric satiety signal. In addition, food empties from the stomach more rapidly, thereby reducing the duration of gastric satiety. The opposite effects occur when calorie stores in adipose tissue have been augmented during a period of excessive food intake; both gastric and postgastric satiety signals are prolonged because the rate at which calories are stored in the swollen adipocytes is decreased (Stricker 1984).

2.5 Leptin

Aside from this indirect influence of body weight on food intake, in recent years a direct inhibitory signal to the brain from adipose tissue has been discovered. This satiety stimulus is a blood-borne protein, leptin, that is secreted from adipose tissue in proportion to adipocyte size; the fatter the animal, the more leptin is secreted and the less inclination the animal has to eat. Leptin receptors have been found in the basal hypothalamus, and when they are stimulated food intake is reduced (Woods et al. 1998).

The discovery of leptin illuminates genetic obesity in two strains of mice. Mice of one strain are born with leptin receptors in their brain but without the capacity to synthesize leptin; mice of the other strain are born without leptin receptors in their brain but with the capacity to synthesize leptin. As might be expected, an intravenous infusion of leptin reduces food intake in the first strain but not in the second.

3. Central Neural Systems

Food intake is a simple behavior influenced by a very complex array of stimuli and situational variables, the details of which remain to be fully illuminated. However, it is already clear that there are many levels at which the central nervous system exerts control over eating. For example, the spinal cord and brainstem influence all aspects of caloric homeostasis via the autonomic nervous system. The hypothalamus and limbic forebrain receive diverse signals related to the food being eaten and the degree of body adiposity, and integrate them with information about the taste of the food, the memory of that food and previous eating opportunities, competing motivations, and other aspects of the environment. Among the numerous neural controls of food intake, those located in the brainstem and hypothalamus are perhaps the best known, so this section will focus on these two brain areas.

3.1 Brainstem

Considerable evidence has accumulated that some control of food intake can be exerted by the brainstem. For example, it is well established that the nucleus of the solitary tract and the adjacent area postrema in the brainstem receive sensory fibers from gustatory receptors in the mouth and throat as well as afferent information from the stomach, intestines, and liver. Thus, these linked brainstem sites likely are the first locus at which relevant sensory input from the viscera is integrated with taste sensations in the central control of food intake. Other evidence derives from investigations of the decerebrate rat, in which all axonal connections between the caudal brainstem and the forebrain are severed at the midcollicular level in the midbrain (Grill and Kaplan 1990). The animal cannot seek food or initiate spontaneous meals but, like intact animals, it will reflexively swallow liquid food put directly into its mouth. Thus, when investigators deliver sucrose solution through an oral fistula, the decerebrate rat will swallow the sweet fluid, provided its stomach is empty, as after a period of food deprivation. However, it will not swallow water or saline when deprived of food and it will no longer swallow sucrose solution (but instead lets the administered fluid passively drip from its mouth) when its stomach is full, or after having received a systemic injection of CCK. Hence, sufficient control of food

intake for such appropriate responses exists entirely within the caudal brainstem, although decerebrate animals clearly are incapable of receiving input from forebrain sites that could modify their intake based upon learning or other experience.

Recent experimental observations provide additional support for an important role of the brainstem in the control of meal size. When the area postrema is ablated, rats eat much larger meals than normal, although total daily food intake is normal; that is, they compensate for their large meals by eating less frequently, indicating that long-term controls of food intake are not impaired. Similar effects are obtained in rats pretreated with capsaicin, a neurotoxin that destroys (among other things) most gastric afferent vagal axons and thereby eliminates the food intake-reducing effects of CCK, and therefore is assumed to damage the signal of gastric distension.

The food-related sensory information that enters the brainstem is relayed along prominent neural projections to the hypothalamus, amygdala, and other portions of the limbic system, as well as to the thalamus and gustatory cortex. Reciprocal neural connections to the brainstem from these rostral sites allow cognitive functions and emotions to influence the control of eating. Linked elements participate in the central control of the gastrointestinal tract, the liver, and autonomic function generally.

3.2 Hypothalamus

Complementing these controls of meal size are the influence on meal frequency exerted by body weight. As mentioned, changes in body fat stores are reflected in the levels of leptin in the circulation. Receptors for leptin are concentrated in the *arcuate nucleus*, which is located in the ventrobasal portion of the hypothalamus. Receptors actually have been associated with two different types of neurons in the arcuate nucleus. One, located in the medial arcuate nucleus, uses *neuropeptide Y* (NPY) as a neurotransmitter. These cells are of interest because it is well-established that injection of NPY into the brain of rats evokes eating, and that chronic infusion of NPY into the brain leads to obesity. Furthermore, axons of NPY-synthesizing neurons project from the hyopothalamic arcuate nucleus to the same focal site in the lateral hypothalamus at which eating is elicited by direct administration of NPY. Food deprivation stimulates activity in these NPY-containing neurons, whereas obesity or systemic administration of leptin depress their activity (Woods et al. 1998).

The other group of cells, located in the lateral arcuate nucleus, contain pro-opiomelanocortin (POMC). Those cells also have leptin receptors but, unlike the NPY-containing cells, the POMC-containing cells increase their activity when stimulated by leptin. The POMC-containing neurons use α-melanocyte stimulating hormone (α-MSH) as a neurotransmitter, and activate melanocortin receptors on lateral hypothalamic cells to decrease their activity and thereby inhibit eating. As might be expected, food deprivation decreases activity in the POMC-containing neurons, whereas their activity is elevated when rats are obese and circulating leptin levels are high. In short, there is a dual control by the arcuate nucleus over lateral hypothalamic activity and its control of food intake, one neural input (NPY) stimulating feeding and the other (α-MSH) inhibiting it; this influence is normally stimulated by alterations in blood-borne leptin reflecting changes in body adiposity (Elmquist et al. 1999).

The noncaloric signals (i.e., gastric distension, thirst, nausea) all have been shown to stimulate oxytocinergic neurons in the paraventricular nucleus of the hypothalamus (Stricker and Verbalis 1991). Projections from NPY- and POMC-containing cells in the arcuate nucleus also terminate in the paraventricular nucleus, allowing the integration of these various stimuli so as to influence output systems that control autonomic function and, indirectly, food intake. The central neural circuits that integrate the peripheral signals that control meal size (i.e., signals associated with the gastric, intestinal, and hepatic stimuli generated by a meal) with those that control meal frequency (i.e., signals associated with blood-borne leptin and perhaps other signals reflecting adiposity) are also currently under investigation.

E. M. Stricker

Hunter–Gatherer Societies, Archaeology of

Hunter–gatherer societies traditionally have been regarded as representing the 'original' human society—that is, preagricultural peoples reliant upon 'wild' foods and interacting with 'natural' landscapes. In this way, they have been differentiated from other, agricultural, societies. From a sociological perspective, hunter–gatherers emerged as the 'precapitalist' baseline in Marx's evolutionary framework—functioning as the original 'communal' society, practicing an economy different from those of others (Lee 1988). From a biological perspective, Darwin, among others, envisaged them as the human prototype, a position they still hold in more recent biological–ecological frameworks (Bettinger 1991). Anthropology and archaeology have absorbed these viewpoints, but more recently there has developed a significant change in emphasis—a redefinition of hunter–gatherers incorporating a much wider range in societal variation (Ingold et al. 1988).

Narrower, more traditional definitions had emphasized the following features. Hunter–gatherers had been perceived as small-scale, essentially egalitarian societies, of low population size and density and generally rather mobile. These societies were seen largely as *avoiding* accruing an economic surplus, practicing storage and impacting significantly upon land and resources. In contrast, recent revisions consider that hunter–gatherers also incorporated more complex societal formations within their ranks. These included extensive social networks and signs of social hierarchy—as well as chiefdoms based on hereditary ranked lineages. Demographics included relatively high population sizes and densities, heightened territorial behaviour, and levels of sedentism. Hunter–gatherer economies can be composed of significantly high levels of intensification achieved through economic surpluses and storage. It is envisaged that they had considerable impact upon land and resources via firing and other practices now recognized by recent ecological impact assessments (Williams and Hunn 1982).

Ethnographic studies of the northwest coast peoples of North America (from northern California to British Columbia) included many of the characteristics described above, some living in permanent wooden-housed villages of up to 1,000 people. These hunter–gatherer peoples placed a strong emphasis upon fishing and practiced no agriculture (Suttles 1968, Ames 1985). The Calusa of Florida, another North American ethnographic example, reflect all these features and more—including a centralized state formation which extracted tribute from subservient villages, a royal family, and a standing army. The Calusa also were without agriculture (Marquardt 1988). Recently the ethnographies of more classic hunter–gatherers have also been considerably revised (Schrire 1984, Lourandos 1997). In all, this evidence points to the possibility of a similarly broad range of pre- and nonagricultural peoples having existed in the past, when most of the habitable environments of the world were occupied by hunter–gatherers. Archaeology can provide answers to these questions, as recent investigations have unearthed.

1. *Archaeological Examples*

Archaeological examples of the historical evolution of these more varied features of hunter–gatherer society have been studied recently in a number of time periods and regions of the world. We now discuss five of these case studies in turn.

1.1 *European Upper Palaeolithic*

The Upper Palaeolithic in Europe took place during the final stages of the last ice age, from about 35,000 to 10,000 years ago. Modern people, *Homo sapiens*, had colonized the continent by this time. While the cultures of this lengthy period have much in common, clear trends towards more complex hunter–gatherer patterns are discernible in the last half of this period. For

example, after the coldest, driest phase which occurred around 20,000–18,000 years ago (the glacial maximum), climates were milder, especially in well-located southern latitudes such as southwestern France. At this time, known as the Magdalenian period, spectacular painted rock art, including images of extinct herd animals such as mammoth and bison, appear in limestone caves across the region. Occupation sites at this time are more numerous and much larger than previously. The suggestion is of increased numbers and densities of people living a more sedentary lifestyle. Hunting strategies were to target large numbers of herd animals that migrated seasonally to the highlands and back again, following the bloom of pasture grasses. The cave art which occurs in varied, regionalized styles, suggests the development of more territorial social units, each with their own set of artistic repertoires. Cave art, site numbers, and the economy, therefore, among other things, reflect a more populous, sedentary hunter–gatherer society. Burials, which are more common during this period, indicate that certain individuals were afforded more attention in death, suggesting the appearance of aspects of social differentiation (Conkey 1985, Gamble 1986, Jochim 1983, Mellars 1985).

At this time, out on the frigid and largely treeless southern Russian Plain, hunters resided in permanent hamlets of well-constructed mammoth bone dwellings. These bases were located in the lengthy riverine corridors, such as the Don and Dnepr, through which myriads of large herd animals migrated annually. Meat was stored in frozen subterranean pits. Hamlets were part of an intricate network of long-distance exchange—in exotic stone, shell, and 'Venus' figurines—which united peoples resident in a harsh, vast arctic desert. Social inequality is suggested by unequal numbers of storage pits around individual dwellings, and perhaps 'status' burials, in a prior phase (Soffer 1985). More intensive economic strategies are evident during this period, as was the case also in southwestern France.

1.2 Eurasian Mesolithic

Traditionally, the Mesolithic of Eurasia was considered a depauperate period when contrasted with the more spectacular Upper Palaeolithic. Recent reevaluations, however, point to complex trends, culminating in patterns of land and resource management, and ultimately, in some areas, to agriculture. This was a time of major climatic change, as warmer, moister conditions, similar to those of today, followed upon the colder glacial Pleistocene period around 10,000 years ago. The Mesolithic, therefore, is a time of adaptation by hunter–gatherers to changing environments both natural and cultural. The temperate zones of central and northern Eurasia were transformed from arctic deserts to mosaics of deciduous forests, lakes, and marshes. Following upon melting glaciers, the seas rose, creating, for example, the vast Baltic Sea and its resource-rich coastline in northwestern Europe. Populous, semi-sedentary hunter–gatherer societies appeared on these coastlines, of for example present-day Scandinavia, as sea levels stabilized about 6,000–5,000 years ago. They established large shell middens and practiced a wide range of fishing, hunting, and gathering (including storage of nuts). Comparable societies appeared in estuaries and river valleys throughout Europe (Price 1987, Zvelebil 1986).

At the same time in Japan, beginning around 12,500 years ago, the Jomon hunter–gatherers on the rich environments of the main island of Honshu lived in semi-sedentary subterranean pit houses along the coast and inland. They fished intensively and stored quantities of nuts, acorns, and seeds in underground storage pits. It has been suggested that nut groves may have been an economically managed resource as perhaps also were seeds, including grass seeds. These populous, territorially based and ritually complex hunter–gatherers intensified still further their fishing/storage economies through time. In the final stages of their history they resisted for some time the introduction of agriculture (from the Asian mainland) (Akazawa 1986, Crawford 1992), as did also the Scandinavian hunter–gatherers.

It was in drier regions of the Middle East (southwest Asia), however, that Mesolithic hunter–gatherers developed complex societies and economies that also gave rise to agriculture. The Natufian hunter–gatherers of present-day Israel and Palestine between 12,500 and 10,500 years ago practiced intensive collection and storage of wild grass seeds and nuts. They resided in hamlets of small, round huts, and practiced the long-distance exchange of obsidian and shells. Shrines are found within their hamlets where they also buried their dead. Around 10,000 years ago, the domestication of wild grasses—including wheat and barley—took place, signaling the shift to agriculture. However, all other cultural features were essentially similar to those existing before. Agriculture, therefore, was but an extension of the complex hunting–gathering out of which it had sprung. And later agricultural villages, including the walled town of Jericho, were centered upon previously existing Natufian hamlets (Bar-Yosef 1987, Henry 1985). The dynamics of complex hunting–gathering, therefore, gave rise to agriculture as we know it today.

1.3 Archaic North America

The Archaic period of North America, like the Mesolithic, takes place as climate shifted from glacial to modern after about 8,000 years ago. Long-term trends, taking thousands of years, can be recognized in the rich riverine regions of the American mid-continent, where the densest hunter–gatherer populations resided. In riverine corridors such as those of the Mississippi and Ohio, population grew slowly over

thousands of years, while in the Illinois valley, semi-sedentism in the form of cold-weather bases appeared in time. Intensification of the hunter–gatherer–fisher economy accompanied these developments. It took some 4,000 years for long-term trends towards more complex social formations to develop in these regions during the Middle Woodland period. By about 2,100 years ago complex ceremonialism in the form of extensive mounded burial precincts and exchange and trade in a wide range of exotic material (copper, obsidian, pottery) united most of the regions of mid and eastern North America. The richness of the natural environment cannot be the only factor controlling the development of these complex hunter–gatherer societies, as prime environmental conditions had been established as far back as 6,000–5,000 years ago, long before the above cultural features appeared and flowered. Some of the most complex societies—such as those of the Ohio Hopewell—were located outside the riverine corridor itself, on the more arid plains and were relatively mobile rather than semi-sedentary. Their most common unifying feature lay in the ceremonial realm (Bender 1985, Brown 1985). Although agriculture was known to these peoples, it was not adopted by them until more recent times—held at bay, as we have already observed, for some Mesolithic hunter–gatherer societies.

1.4 Preagricultural Mesoamerica

Less archaeological evidence is available for observing trends towards hunter–gatherer cultural complexity in preagricultural Mesoamerica, the region which lies between the two continents of North and South America. Hunter–gatherers of this region also developed agriculture independently. Very long-term trends, however, spanning some 4,000 years, suggest a gradual shift towards higher levels of 'domesticated' produce since about 7,000 years ago. Even by about 4,000 years ago less than one third of the diet was agricultural. By this time some of the main domesticated plants included the staples of later times, maize and beans. Sedentism, in the form of villages, occurred *after* this time, when agriculture had been more firmly established. Aspects of complex exchange and trade had accompanied these trends, and agricultural villages (and later cities) were constructed around ritual precincts, which strongly suggests that one of the key driving forces behind communal aggregations (that is, sedentism) was inter-group ritual itself (Flannery 1968, 1976, MacNeish 1970).

1.5 Holocene Australia

Recent evidence from the continent of Australia suggests that comparable trends towards more complex hunter–gatherer societies, similar to those of the Mesolithic and Archaic periods discussed above, are evident in Australia, especially from about 4,000–3,000 years ago. Aspects of these trends are also evident long before, for example after the glacial maximum or from about 16,000 years ago. In more recent times, however, long-term trends towards greater numbers of archaeological sites and use of sites occurs in many regions of the continent, including most major environmental zones—arid, tropical, and temperate. Demographic changes, including increasing populations and greater levels of sedentism, or reduced mobility, are suggested here, and are accompanied by other sociocultural changes (Lourandos 1997). In the tropical Cape York peninsula located in the northeast, shifts to more regionalized patterns of painted rock art occur during the last 2,000 years or so, suggesting more territorially based societies (David and Lourandos 1998, 1999). In arid Australia during the same period, a shift occurs towards more intensive seed-based (including grass seed) economies. The ethnographic descriptions of seed use (including grass seeds) by Australian Aborigines indicated they were managed via a wide range of practices including firing, irrigation, and the planting and broadcasting of seeds (Smith 1989, Veth 1989). As in all world regions studied, climatic change—in this case towards drier climates—accompanies many of these trends, but cannot on its own explain them.

2. Discussion

Trends can be observed, therefore, in many areas of the world which incorporate features of broader societal variation among nonagricultural peoples. These have included: increased population sizes and densities; sedentism storage and surplus; intensified and specialized economic practices; the suggestion of land and resource management; and broader social, including more hierarchical, formations. To what extent these prehistoric societies reflect ranking, including chiefdoms and the like, is more difficult to discern clearly. However, aspects of this, and the social context in which these systems are embedded, has been established in a number of case studies. The trends themselves took place over huge spans of time covering, in some cases, thousands of years.

Explanations of the trends in the development of hunter–gatherer society are many but tend to be somewhat polarized. As seen in the above case studies, climate, among other things, strongly influenced many of the general patterns and trends. But the dynamics within hunter–gatherer society itself also need to be considered. For example, incentives to intensify production (economy) may be embedded within the competitive social arena itself. In all, however, such

large-scale processes must have involved a complex set of factors—among them, ecological, demographic, and sociocultural.

Methodological problems also limit our investigations. Difficulties lie in gaining access to finer-grained, middle-range archaeological details. Issues of scale, for example, tend to blur distinctions between macro and micro issues in both time and space. Enormous spans of time and vast regions have been investigated in the general models offered. Access to archaeological data is a slow, meticulous process and answers to many of the questions raised here will take time to resolve.

In all, future directions lie with a much wider range of questions and approaches than were posed in more traditional times. The history of our hunter–gatherer past, quite clearly, has begun to be written anew.

Hunting and Gathering Societies in Anthropology

'Hunting and gathering' is a conventional term for subsisting on the 'natural produce' of the earth by hunting and trapping wild animals, gathering wild roots, fruits, and berries, fishing, and collecting honey of wild bees, as opposed to producing food by agriculture and herding. By hunting and gathering societies (HGS) ethnographers mean contemporary indigenous people who fully or partly engage in these activities, now or formerly, or who see themselves as hunters. (For brevity, the terms 'hunter-gatherers,' 'hunters,' and 'foragers' are sometimes used synonymously.) The term is also used in general reference to prehistoric populations, living before the agricultural revolution (around 10,000 years BC). In common usage, it also stands for an alien 'Other,' diversely constructed by modernity in order to define itself. In this article, the primary focus is placed on the first meaning, while note is taken of its brush with the other two. The term is first examined historically, with an outline of its origins and changes of usage over time. Next, several clusters of features that are partially shared by these societies are presented in model terms, after which the diverse populations concerned are described by region, with the focus on their historical circumstances.

1. *Contested Meanings*

An understanding of the expanding meanings of HGS necessitates a return to the origin of the field and perusal of its historical development. In the seventeenth century, writers invoked 'primitive peoples,' who hunt and gather for their subsistence, in discussing the 'natural state' of humankind. By the eighteenth century these were typed 'hunter-gatherers,' in distinction from 'herders,' within a broad 'savage' class, in writings on the origins of property relations. In the nineteenth century evolutionist work continued to draw on these specific peoples, often without referring to the class as a whole, in studies of the origins of a variety of other social institutions, from kinship through politics to religion.

The notion consolidated as a central term in early twentieth-century cultural-ecology theory, most influentially in Julian Steward's work (1936). Concerned with the relation between society and environment, Steward argued that for any given mode of subsistence, successful adaptation determines a certain level of socio-cultural integration. In the case of hunting-gathering, he argued, this is a 'band,' which is universally patrilineal, exogamous, and territorial. HGS was associated with bands, and hunting peoples were comparatively studied as band-societies (see, for example, Damas 1969), until the 1966 symposium 'Man the Hunter' (Lee and DeVore 1968). This interdisciplinary symposium is commonly considered the beginning of modern hunter-gatherer studies.

The symposium was inspired by the assertion that human beings had subsisted by hunting for over 99 percent of the time of human life on earth. Linking cultural-ecological and (neo)behavioral-evolutionary perspectives, its major objective was to learn about human origins and nature by comparing 'living hunters.' Uniform patterns found among them, it was posited, can be regarded as hunter-gatherers' successful adaptations, present and past.

Serious reservations were raised about its agenda. One objection, for example, was that no contemporary group could be seen as 'living relics,' or as direct descendants, of the Pleistocene. Even if a group had been found to subsist purely on hunting, its people would have had a history as long as any other, and they would not have lived any longer in a world populated by hunters as in the Pleistocene. Another objection was that over the span of 2,000,000 years humans had changed considerably, biologically, and psychologically, enough to render homogenizing them inappropiate.

The ethnographic comparison, at the same time, shook accepted wisdom to the core. Contrary to Steward's persistent thesis, research revealed that most bands are actually socially fluid and nomadic. In many cases, gathering makes no less important a contribution to subsistence than hunting. In contrast to contemporary stereotypes and bourgeois intuition, the comparison showed that these peoples meet their needs with surprisingly little labor. (Marshall Sahlins provocatively dubbed them 'the original affluent society.')

Outweighing the reservations, this successful outcome entangled HGS with the 'Man the Hunter' project. HGS came to mean a type of people, rather than diverse peoples engaged in a type of action, encompassing populations over a vast evolutionary span of time. The term now embodied the hypothesis that, at their core, these populations have similar socio-cultural forms, determined by adaptation to the environment. From a vague term of reference to 'very simple' peoples, and then to 'band societies,' it connoted a firm, homogeneous, and exclusive social category, a category of humanity defined techno-economically.

Subsequent ethnography research, which burgeoned in the wake of 'Man the Hunter,' grew diverse in focus and approach, as seen for example in the series of International Conferences on Hunting and Gathering Societies (1978 to the present, e.g., Ingold et al.

1988, Vols. 1–2, Burch and Ellana 1994). Issues arising from late twentieth-century indigenous circumstances and cultures were addressed, including political struggles and self-administration in modern states, and indigenous peoples' own perceptions of their environment, economy, and self. Historical, interpretative, regional, and applied perspectives commanded attention; evolutionary-ecological studies of foraging behavior increasingly took a separate course. Indigenous people started contributing to academic research, as anthropologists and interested parties. This growing ethnography showed a diversity of social forms among hunting-gathering peoples, from egalitarian to hierarchical, and even slave-owning societies. The 1970s meaning of HGS, as a firm, homogeneous, and exclusive social category, was increasingly challenged. In an attempt to save it, the category was diversely divided into subtypes (e.g., see Woodburn 1982); or it was recharacterized, for example, by a collective appropriation of nature (see Ingold 1987) or by a distinct cultural perception of the environment (see Bird-David 1990).

The 1980s and early 1990s saw many controversies (see review by Myers 1988), sparked partially by inflexible readings of the term HGS. Scholars disputed the category as pertaining to a class of societies that are both singularized by hunting-gathering and distinguished from agricultural and pastoral peoples, because the ethnography revealed continuities between hunter-gatherers and other societies, as well as great diversity among the hunter-gatherers themselves. Other scholars questioned the categorization of societies by mode of subsistence, as research showed heterogeneous and changing economies. Hunting-gathering was found to be articulated with other pursuits, going back in some cases centuries and even millennia, and, at any rate, undergoing rapid changes since the mid-twentieth century. Students debated whether any living group sufficiently complies with the subsistence criterion and whether this criterion generates a meaningful category, one whose members share more than the selecting mode of subsistence. Even the field at large was critiqued as spurious, by researchers seeing it in terms of the 1960s objective to learn about prehistory and evolution. Their criticism drew on ethno-historical and archaeological work suggesting arguably that these societies have not escaped world and regional forces. HGS is sometimes used nowadays simply to denote the assemblage of indigenous peoples discussed by practitioners within the field of hunter-gatherer studies (see Kelly 1995).

HGS has acquired multiple layers of meanings. It is a circumlocution for a historically-situated field of research that provides a stimulating comparative context and a scholarly communal framework within which to explore a broad array of distinctive issues. Ethnographers construct 'partial connections' (in Strathern's (1991) sense) between these societies by studying their respective groups while keeping the others 'in mind.' They call to attention partially shared features, which determine common issues in the field, and contribute distinctive perspectives to anthropology generally. Hunting and gathering activities are a focus of attention, rather than a criterion of demarcation, for scholars as for the indigenous peoples themselves.

2. *Issues*

This section presents in model terms some of the partially shared features that came to light in the course of ethnographers' comparative discussion of their field experiences and material.

2.1 *Hunting and Gathering*

In many of these societies, people combine these activities with other economic pursuits (e.g., trade in minor forest produce, horticulture, work for neighbors, wage-labor, social benefits, etc.). However, hunting and gathering themselves carry special significance; they are a total phenomenon encompassing economic, social, and symbolic aspects. Hunting–gathering, moreover, often influences the way in which people carry out such other activities. They often return to hunt and gather at least periodically, when not prevented from doing so. They regard what they collect as 'real food,' and while they do pursue other activities, in some cases hunting–gathering still provides a major part of their diet.

2.2 *Band Society*

In many of these societies people live in small groups (bands) consisting of several families; the groups are flexible. Making visits, and even shifting residence, from place to place, are common. The total population numbers a few thousand, and may be as low as several hundred. Men and women often know each other personally: they all are (or at least are classified as) family and relatives. Their sense of themselves as family often survives growing integration into nation-states.

2.3 *Sharing*

The land and its resources in many of these societies are often collectively appropriated (see Ingold 1987). Game is publicly shared; other resources, whether procured from the environment or purchased, are shared in response to requests directed by those who lack something to those whom they perceive have it ('demand-sharing': Peterson 1993). Sharing and the expectation of it is part of broader nonaggrandizing

economic reasoning and conduct. While hard to express in modern urbanite language, sharing extends not only to distributive but also to social experience. People in the group share 'each other' (Ingold 1987): company, dwelling spaces and work, stories, memories, and personal histories. They experience their selves as coalescent, rather than as a group of separate individuals. Relationships between people, rather than being regenerated by coercing external structures, spring from the vivid experience of sharing. Sharing, which is normatively promoted, fosters an egalitarian society in many cases (see Woodburn 1982). While closely connected, people usually enjoy considerable personal autonomy.

2.4 Giving Environment

Nature is locally experienced neither as a mechanical system nor as objects for human use and ownership, but as an assembly of sentient beings related to and shared with (Bird-David 1990). These beings (animals, forest, winds, hills, etc.) frequently are approached as relatives, often as grandparents. People care for them, and this helps sustain their collective identity. People engage with these beings through Shamanistic practices and by pursuing hunting–gathering. To hunt and to gather are perceived not just as subsistence pursuits but also as means of communication with the 'natural' relatives. Even when forced to reside away, and to adopt modern life-styles, people commonly practice their rituals, and return to their places to hunt-gather and 'keep in touch' with these relatives. This animistic perception is integrated with deep ecological understanding of their neighborhood. It often propagates responsiveness to and sometimes responsibility for the environment, along with its utilization.

3. Populations

The indigenous populations considered as hunter-gatherers are described in this section, by geographical cluster, in keeping with the *Cambridge Encyclopaedia of Hunters and Gatherers* (Lee and Daly 1999). The figures provided should be regarded as suggestive, as politics of identity, especially in First World situations, and dispersal and inaccessibility, especially in Third World countries, severely limit enumeration.

3.1 Australia

About 266,000 people identify themselves as of Aboriginal or Torres Strait Islander descent, constituting 1.6 percent of the national population (1991 census). This is the case on a continent inhabited solely by hunter-gatherers until the arrival of Europeans in 1788. Compared with an estimated 200 languages and 600 dialects in that year, they now divide into groups speaking about 50 languages. Among the best known are Aranda, the nineteenth-century study of whom was pivotal in anthropology, and Walripi- and Pintupi-speakers, desert-dwellers and the last to make contact with Europeans. A disproportionate number of Aboriginal people are now largely dependent on social security payments, and do poorly by any standard social indicator. At the same time, a revival of tradition is on the increase, in part due to the growing national and international markets for Aboriginal art (especially the desert 'dot-painting'). Politically, significant advances have been recently made. First was the establishment in 1990 of the Aboriginal and Torres Strait Islander Commission (an indigenous body formed to make policy and distribute federal funding for Aboriginal people). This was followed by the High Court recognition in 1992 of native land title (the 'Mabo case').

3.2 North America

Commonly called American Indian Nations in the US, and First Nations in Canada, there are about 500 indigenous groups in this subcontinent. The stratified Tlingit and Haida of the northwest coast, and the egalitarian Arctic Eskimo–Aleut speakers, are renowned for their role in early anthropology. The sub-Arctic Innu, Cree, and Dene are known for their opposition to contemporary environment-threatening development schemes. Prior to European colonization, two-thirds of the subcontinent had been occupied by hunting and gathering people. Devastated by the colonization, some groups perished, and some survived in fragmented forms in reservations. To date, a disproportionate number experience severe social problems. However, recent decades have seen expansions of indigenous organizations, rapid growth of arts, and revival of traditional spirituality (attracting New Age followers). Hunting and gathering economies are being renewed, especially on the north and the northwest coast, as a result of some judicial breakthroughs that brought a degree of recognition of aboriginal and treaty rights. A major landmark was the 1999 establishment of Nunavut, an Inuit majority territory within Canada's federal structure.

3.3 South America

Foraging people in the subcontinent's southern cone were almost extinct by the 1920s, and only a handful of each group remains today, assimilated into other communities. A wide spectrum of forest communities, cultivators and hunters by trade, live scattered in the Amazonian hinterlands. In the 1960s they were viewed predominantly as devolved agriculturists, and only later did their egalitarian and nomadic life-styles earn them the attention of the discipline. The Paraguayan Ache is one of the best known groups. Most of these indigenous people have been converted and restricted to reservations; since the 1960s large-scale economic

development has threatened their environment and life-ways even more. As a result of joint campaigns by indigenous activists and international conservation and human rights movements, a slow but significant movement towards recognition of indigenous territories has been taking place since the 1980s.

3.4 North Eurasia

Latecomers into the hunter-gatherer discourse, there are 26 Arctic and sub-Arctic groups in the Russian north. They are divided into at least six language families, and number approximately 184,500, constituting 0.06 percent of the entire Russian Federation population (in 1990). In the seventeenth and eighteenth centuries the majority moved to reindeer pastoralism as their main subsistence occupation, supplementing it by hunting and fishing. Autonomous districts were established for some of them in the 1930s, although political and economic decisions were still made in Moscow. A substantial majority is now modernized, urbanized, and Russified, but activists (mainly writers) campaign for cultural renewal. Under the mounting economic difficulties in Russia, many are attempting to restore some traditional practices.

3.5 Africa

Bushmen (San) and Pygmy groups caught the 1960s' imagination, not least as their habitat was regarded the 'cradle of humankind.' They number 100,000 and 285,000 respectively; each comprises diverse linguistic groups spread across more than half a dozen countries. A further 55,000 people, largely in East Africa, bring the total number of African foragers, part-foragers, and former-foragers to 440,000. Only a tiny fraction of them subsist intensively on foraging. Most keep close ties with cultivators and pastoralists; the Pygmy groups are known for what is described as symbiotic relationships with their neighbors. With worsening circumstances, some groups sought help from development agencies and church groups and some joined environmental activists in protest against ill-advised large development schemes. The Ju/'hoansi (alias !Kung), the best known hunter-gatherer group owing to Lee's extensive work (e.g., 1979), have initiated self-help schemes intended to develop awareness of nation-politics, and leadership and management styles adapted to it.

3.6 South Asia

Less than two dozen indigenous groups live in the South Asian subcontinent. These total less than 20,000 out of over 1,000,000,000 people (wider estimates, including former foragers, put their number at 1,300,000). They include the exceptional Jarwas and Sentinelese of the Andaman Islands, who by hostile behavior have warded off outside contact up to the present, and South Indian forest-groups who, going back 2,000 years, have played an important part in the economies of the subcontinent's ancient civilizations. The latter groups have provided the main society with exotic spices, medicinal herbs, honey, and meat, occasionally guiding Hindu pilgrims and officiating in their forest temples. Some groups are being pressed to 'develop' into settled agriculturalists by a national modernist policy that sees them as 'backward people' whose existence shames the country; some combine hunting–gathering with trade in minor forest produce and wage-work. Sri Lanka's Wanniyala-aetto (formerly Veddahs) raised strong opposition to their forced relocation, going as far as the United Nations.

3.7 Southeast Asia

Foraging and swidden farming are closely linked in this region, with historical shifts back and forth between them, frequent combinations, and close trade-links between foragers and farmers. In the Philippines there are about 25 distinct linguistic groups, totaling 15,000; in Malaysia, eight linguistic groups total 2,500 people; in Indonesia the total is 15,000, in Borneo it is 12,000, in China it is 4,500, and in Sumatra and Thailand it is 800 and a few hundred, respectively. Governments in this region encourage commercial exploitation of these people's forest habitat, and they rapidly become poor farmers and laborers.

4. Conclusions

Stimulated by the hope to learn about human evolution and prehistory, the study of 'living hunters' has developed into a fruitful area of study in and for itself. These living peoples still afford a study of behavioral-ecological parameters of hunting–gathering, which are important for them, and which they pursue when they can. Over and above this, however, they open a window to socioenvironmental ethics and praxis, conceptions of society and nature, human relationships and economy, which are markedly different from familiar models. In broadening scholars' imagination, that cannot but be biased by urban life-experiences and intuitions, hunting and gathering peoples can help scholars think about other forms of life: human life in the past as well as possible futures. Indigenous peoples for their part increasingly explore new modernities that integrate their traditional practices with life in twenty-first-century nation-states.

N. Bird-David

Hurst, James Willard (1910–97)

It is hardly controversial that J. Willard Hurst of the University of Wisconsin was the most influential scholar ever within the realm of US legal history. By emphasizing factors beyond legal doctrine and by altering the way people think about time, place, and change itself, Hurst enlivened and transformed an entire academic field. As leading legal historian Lawrence Friedman said: 'Willard Hurst, as a scholar, did what few scholars have ever succeeded in doing: he created a whole new field of study, and virtually out of nothing.'

1. *Biographical Background*

James Willard Hurst was born on October 6, 1910 in Rockford, Illinois, where his father ran a movie theater and had other business interests. When Hurst attended Williams College from 1928 to 1932, he majored in economics, became editor in chief of the student newspaper, and president of the International Affairs Club. He also wrote a prize-winning student essay on international implications of the English Gold Clause crisis of 1931, published in the *Journal of Political Economy* the year he graduated. Hurst then attended Harvard Law School, and reported that he was disgruntled about the emphasis on abstractions and the failure to pay attention to the Depression and to the ideas of the legal realists. A note editor of the *Harvard Law Review*, Hurst graduated in 1934 and spent the 1935 to 1936 academic year as a research fellow for Felix Frankfurter, working primarily on a lecture series which Frankfurter published as *The Commerce Clause under Marshall, Taney, and Waite* (1937).

Hurst next served as law clerk for 80-year-old US Supreme Court Justice Louis D. Brandeis during the 1936 term, one of the court's most contentious ever. Frankfurter reported that Brandeis said that Hurst ranked as his best clerk ever, 'professionally speaking.' Brandeis thought the states to be invaluable laboratories for progressive regulation and lawmaking, and he urged young men who worked for him to return to their home regions. Hurst became one of the very few to heed Brandeis's advice. He began his lifetime association with the University of Wisconsin in 1937, when he joined the law faculty in Madison, only a short drive north of Hurst's hometown.

By 1941, Hurst had compiled several books of teaching materials and had coauthored *Law in Society* with his dean, Lloyd Garrison. This pioneering casebook focused on the myriad ways that the plight of a widow—whose husband, a carnival worker, was crushed under a company tractor—intersected with legal institutions beyond the courts. After Pearl Harbor, Hurst and his wife, Frances Wilson, moved to Washington, DC. Hurst first worked for the general counsel of the Board of Economic Warfare and then joined the navy, where his assignments included work on a highly publicized treason case, leading eventually to his *The Law of Treason in the United States* (1971).

Even before returning to the Wisconsin law faculty after World War II, Hurst began to articulate in print the crucial link he perceived between legal history, done in a new way, and 'opportunities to apply informed, humane reason to influence the course of events.' The 'Wisconsin idea' of enlightened political leadership had lasting appeal for Hurst—and he repeatedly rejected job offers to teach at other prestigious institutions. In the course of rejecting an offer from Yale Law School in 1938, for example, Hurst wrote to his mentor Felix Frankfurter that Wisconsin afforded 'just about an ideal "laboratory" situation.' Despite Yale's offer of higher rank and twice the salary, Hurst advised Frankfurter that he preferred Madison 'particularly because of this extraordinarily interesting state government machinery here on the doorstep.' Although Hurst was extremely reluctant to travel from his Wisconsin base throughout his life, he nonetheless was directly involved in launching the

international Law and Society movement, as well as in pioneering a new approach to legal history that has had worldwide impact. He taught full time at Wisconsin until 1980 and continued to publish after retiring from teaching. Hurst died in Madison on June 18, 1997.

2. *Hurst's Scholarship*

Hurst's scholarly career repeatedly underscored a core idea. In 1971, he summarized the enormous project he had undertaken: 'A realistic history of law in the United States will be a social history of law, taking law as man-made, and as the product of both deliberation and drift, but not of any immanent superior order of reality.' Doing legal history from the outside—from the perspective of sociological jurisprudence—led Hurst to turn his back on the 'great man' tradition and to reject the previously dominant focus on formal judicial opinions. He firmly opposed teleological accounts that tended to celebrate the gradual improvement of law over time. Instead, Hurst focused on economic matters—as shaped by the general culture—and on the ordinary processes of statutes, administrators, low-level cases, and the everyday work of lawyers.

In particular, Hurst concentrated on analyzing what he termed 'our prime inheritance,' which he defined as 'middle-class ways of thinking.' With exceptional tenacity, he set about tracking 'the expansion of middle-class energy.' He sought to describe and to analyze how most people in the USA responded to a central problem. That basic issue, according to Hurst, confronts 'whether men will be able to use the power of the politically organized community to secure the basic conditions of a decent life for the individual, without thereby destroying the very values they are trying to realize.'

Throughout his decades of scholarship and teaching, Hurst combined unremitting and careful attention to massive low-level details with sweeping descriptions of general patterns. He sought to develop a new integration of the social-science ideas of his era with careful historical consideration of the largely unexamined mass of law as it functioned on the ground, far removed from the doctrines promulgated by selected appellate judges that dominated—and still dominate—US legal education.

Robert Gordon described the great reach of Hurst's innovative academic project as follows:

> After expanding the relevant record beyond prior appellate cases and their facts to all prior legal acts and the social influences on them, and the pending proceedings to the overall task of designing workable legal-regulatory arrangements for the present age, Hurst wrote his books as background briefs for present-day lawmakers.

To Hurst, social patterns mattered greatly. But he perceived that generalized thoughtlessness and a strong tendency to accept inertia and drift often served to counterbalance, or even to disable, other strong, competing US commitments.

Through his prodigious output of scholarship on markets, legislation, monetary policy, and administrative actions large and small, Hurst pointedly emphasized the frequent unthinking clash between core US values. He seemed to delight in clearly describing basic and sobering paradoxes. Thus, for example, Hurst observed: 'Individuals realize their humanity only in society, but they realize their individuality only in self-awareness, which consists in some sense of separateness.' Moreover, he noted that such tensions afford protective coloration for 'shrewd men' who 'warp individualistic symbols of the constitutional ideal to sanction unchecked organized power.'

As Hurst challenged traditional legal distinctions between public and private activity, he pushed himself and those who followed him to develop both extensive local data and expansive theories to capture and explain overarching patterns. In *The Growth of American Law* (1950), Hurst argued that 'law has been more the creature than the creator of events.' This famous book emphasized the impact of physical, technological, and social facts on nineteenth-century law and paid particular attention to the often inglorious role of the legal profession. Some have criticized Hurst for being too much a functionalist, and for inadequately attending to issues of power. Yet Hurst's 946-page *Law and Economic Growth: The Legal History of the Lumber Industry in Wisconsin, 1836–1915* (1964), for example, highlighted the failures of laissez-faire. It also extensively documented Wisconsin's broad and detailed state regulation of a single industry—during a period generally thought to have been at or near the apex of free-market ideology.

3. *Hurst's Impact*

William Novak asserted in 2000 that Hurst surely ranks as 'a broad-gauged socio-legal thinker of the first order, writing in the tradition of Tocqueville, Weber, Holmes, and Pound.' Hurst was original in his particular emphasis on place and time, particularly through his focus on his native Midwest. He also innovated through his unusual illustration of the difficulty in discerning any clear patterns of progress in US legal developments. Indeed, Hurst concentrated on exploring the intricate network of constraints—some perceived, some never understood, some formally legal, some not legal at all—that repeatedly confined and constrained the freedom of everyone.

In Hurst's view, Americans competed fervently, if often blindly, to manipulate whatever system they found in place in their particular context. He generally found it necessary to bemoan the power of deep habits that often produced irrational development and sub-

stantial depredations over time. Yet Hurst also provided crisp accounts of the constitutional impulse among Pike Creek squatters, for example, as well as broad studies of such issues as the fierce, largely irrational conflict over gold and silver currency in the late nineteenth century.

Hurst sometimes has been inaccurately caricatured as part of the celebratory framework of some forms of 'consensus history.' Yet the very broad-gauged quality of his work (an ongoing quest, in Novak's words, 'to try to twist the tail of the cosmos') emphasized the mainstream at the cost of excluding, or at least understating, the importance of minorities and of dissenting viewpoints throughout US legal history. Hurst's faith in fact-gathering led him to produce not merely a new way of looking at law, but also an extended historical critique of what he called 'bastard pragmatism'—the propensity of people throughout US history to allow themselves to be dominated by the short term and the bottom line.

Through his entire career, Hurst emphasized the difficult, if not impossible, goal of increasing both public and private accountability. In *Law and the Conditions of Freedom* (1956) he noted a clear historic preference among Americans for 'the promise of the future over commitments to the past, but also for the ambitions of the present over the claims of the future.' Somewhat ironically, Hurst nevertheless remained deeply committed to the progressive 'Wisconsin idea.' To Hurst facts were crucial. Only through facts could a doubting optimist, such as Hurst himself, imagine enlightened leaders actually enhancing the general pursuit of 'lives of good conscience and fulfillment.' If Hurst sometimes seemed unabashed in adopting what Daniel Ernst called 'a presentist approach to the past,' he remained first and foremost an innovative, exceptionally influential historian.

The unusual number and breadth of symposia about Hurst's work only begin to suggest how significantly his emphasis on the impact of markets, legislation, monetary policy, social habits, and administrative actions transcended earlier boundaries. Through his enormous output of scholarship, his legendary generosity in giving scholarly assistance to others, and his decades of noteworthy teaching, Willard Hurst changed the way US legal history is written and taught. By now, as Lawrence Friedman put it, 'You're either a Hurstian or a reviser of Hurst.' Hurst not only redefined an entire academic field, but he did much to open the borders of legal history to other disciplines. Hurst's career challenges his successors to consider carefully the intricate, crucial, often paradoxical intertwining of legal ideas and social realities within the many realms in which people actually live.

A. Soifer

Husserl, Edmund (1859–1938)

Edmund Husserl was one of the most influential philosophers of the twentieth century. Inventor of the 'phenomenological method' for the analysis of physical and mental phenomena, initiator of the 'phenomenological movement' of contemporary human sciences, he became the great critic of naive naturalism in philosophy and psychology ('psychologism'), and of what he regarded as the loss of orientation, certainty, and thereby of credibility, of modern science. His appeal for 'going back to the things themselves,' and for a foundation of all science and philosophy in a clearly understood 'life-world' (*Lebenswelt*), inspired the work of a great number of philosophers (e.g., Gadamer, Heidegger, Ingarden, Levinas, Merleau-Ponty, Ricoeur, Sartre) and social scientists (e.g., Buytendijk, Lewin, Schütz).

1. Life and Academic Career

Edmund Gustav Albrecht Husserl was born in Prossnitz, Moravia, on April 8, 1859. He studied mathematics, physics, astronomy and philosophy at the universities of Leipzig (1876–1878), Berlin (1878–1881), and Vienna (1881–1882), where he obtained his Dr.Phil degree in mathematics with Leo Königsberger in 1883. After a short period as assistant

to the mathematician Karl Weierstrass in Berlin, and a year of military service, Husserl continued his philosophical studies with Franz Brentano in Vienna from 1884 to 1886, and with Carl Stumpf in Halle between 1886 and 1887, where he qualified as lecturer in 1887 with a postdoctoral thesis entitled 'Ueber den Begriff der Zahl. Psychologische Analysen' ('On the Concept of Number. Psychological Analyses').

Husserl became a professor in 1894, and moved to Göttingen in 1901. In 1916, he accepted a call to Freiburg to succeed Heinrich Rickert in the chair of philosophy there. Husserl retired in 1929. After the seizure of power in Germany by the National Socialists in 1933, his status of emeritus professor was suspended because of his Jewish descent, and, after a short reinstatement, definitively revoked in 1936 after the Nuremberg race laws. Husserl died in Freiburg on April 27, 1938.

2. *Writings, Subjects, Approaches, and Contexts*

Husserl's significance for philosophy, which is certainly greater than that for the social and behavioral sciences, rests on his establishment of a new way of dealing with philosophical problems, which he called 'phenomenology,' turning this expression into a 'technical' term by giving it a clearer delimitation and a weightier role than it had enjoyed with earlier philosophers such as Lambert or Hegel. The methods and content of Husserl's phenomenology, however, changed considerably during their development, which may be summarized in terms of three 'turns' of direction and aims: (a) the turn from early foundational work to anti-psychologism, (b) the shift from descriptive to 'constitutive' phenomenology, and (c) coping with the 'crisis' of modern science by a new focus on the life-world.

2.1 *From Early Foundational Work to Anti-psychologism*

In *Philosophie der Arithmetik* (*Philosophy of Arithmetic*, 1891, Husserl 1950, Vol. XII, pp. 1–283), Husserl made an attempt at a descriptive—psychological foundation of arithmetic, presumably having in mind an extension of Weierstrass's program of basing the vast number of mathematical concepts on a small number of fundamental ones, by providing an even deeper foundation for the latter by grounding them in the psychical acts underlying the mathematician's work. In the course of these investigations, Husserl introduced (independently of C. von Ehrenfels, who is normally credited with this discovery) 'gestalt qualities,' which he treated under the name *figurale Momente*.

Less successful (with hindsight) was Husserl's criticism of G. Frege's definition of number. It invoked an objective but sharp counter-critique by Frege, which seems to have persuaded Husserl of the impossibility of taking the special science of psychology (which proceeds inductively, falling short of universally valid statements), as a foundation for mathematics or even for all special sciences ('psychologism'). Therefore, in *Logische Untersuchungen* (1901), aiming at a foundation of logic which at that time was usually set up on a psychological basis, Husserl advocated a consequent anti-psychologism which influenced contemporary philosophy profoundly. This concept was extended in his work 'Philosophie als strenge Wissenschaft' ('Philosophy as a Rigorous Science') (Husserl 1950, Vol. XXV, pp. 3–62) to a critique of historicism and (under the label of 'naturalism') scientism (1910–1911).

The positive foundation of logic was to be laid by a new foundational discipline to which Husserl, oddly enough, gave the name 'descriptive psychology,' despite his claim that it differed from empirical psychology as well as from Brentano's descriptive classification of psychical (mental) phenomena; it was to be 'descriptive' in the sense of presenting the immediately given mental facts without presuppositions (*voraussetzungslos*). According to this earliest form of phenomenology, that which is intended in a mental act (perception, judgment, idea, etc.) is transcendent to the act itself and given only in 'adumbrated' (*abgeschattet*) manner, through changing phenomena, and therefore inadequately. By contrast, everything immanent to the act is free of adumbration and can therefore be regarded as given in an absolutely adequate manner. Moreover, intuition of what is immanently given appears as free of structural complications like those attributed to judgment in contradistinction to sensation. The contents of the sphere of immediate experience (*Erlebnisse*) are beyond every doubt; with 'intentionality' at its center, it is the secure ground of a foundational discipline which is capable of justifying statements about essences (*Wesen*) and their relations, by a method which Husserl first called 'eidetics,' but later called 'intuition of essences' (*Wesensschau*).

Particular relevance to a philosophy of the sciences may be claimed for Husserl's remarks on 'pure logic.' Pure logic is an *a priori* theory of science dealing with two kinds of fundamental categories: categories of meaning (concept, proposition, truth, inference, etc.) on the one hand, and categories of objects (object, state of affairs, connection, number, etc.) on the other. Husserl takes the unity of the propositions of a science (or a discipline) to consist in the unity of its explanatory principles, and finds his next task in the uncovering of the conditions of the very possibility of theories. The route is to proceed from preliminary studies, e.g., a 'purely logical grammar' investigating the components and connections of propositions, via the statement of laws obtaining between such categories, to an *a priori* 'theory of possible theory forms.'

These investigations, continued only in *Formale und transzendentale Logik* (*Formal and Transcendental Logic*, 1929) and in *Erfahrung und Urteil* (Husserl 1939), share a methodical aim: the 'fixation of unambiguous, sharply distinct verbal meanings' (Husserl 1901, Vol. I, p. 244; Husserl 1973 (English translation 1973), Vol. I, p. 238).

This search for 'verbal meanings' is also one of the foremost goals of contemporary methodical philosophy and philosophy of science. Husserl, however, did not approach the joint methodical aim by actually constructing a language of science, but recommended an 'intuitive presentation (*Vergegenwärtigung*) of essence in adequate ideation,' obviously conceived as independent of and antecedent to any linguistic construction.The ideation to be performed is not an idealization (as in geometry), but pure description, aiming at the elevation of that which is inexact and essentially vague to something typical, a 'type.' By setting out in this way, phenomenology increasingly moved away from the other methodical currents of modern philosophy and came closer to the philosophy of life (*Lebensphilosophie*), from which, however, Husserl differs sharply methodically by ascribing a foundational value to experience, after its precise rendering as 'pure experience' (*reines Erlebnis*) in which meaning, anterior to everything real, is believed to constitute itself (philosophical intuitionism).

2.2 The Step from Descriptive to 'Constitutive' Phenomenology

Object and method of phenomenology were extended and partly revised in *Ideen zu einer reinen Phänomenologie und phänomenologischen Philosophie* Husserl (1913), and pure logic was also characterized in a new way. In Husserl 1901, the predicate 'ontological' had been restricted (diverging from tradition) to sciences such as geography, astronomy, and anatomy, which deal with concrete objects, and not with abstract objects (like the theoretical or nomological sciences). Now, the old term 'ontology' is taken up again in a new sense. Husserl takes being to be subdivided into highest kinds or 'regions,' so the sciences which deal with them yield 'regional ontologies.' Above these (material) ontologies we find the formal sciences, mathematics and logic, which are aimed at 'form essences' (*Formwesen*) and give rise to a *mathesis universalis*. Treating the 'empty forms of region' as such, they comprise the forms of all possible material ontologies, and are nothing else but a 'formal ontology.'

In *Formale und transzendentale Logik*, formal logic was subdivided into (a) a pure doctrine of forms of meaning, or logical grammar, (b) the logic of consequence, or logic of non-contradiction, and (c) the logic of truth. The purely formal ontology was characterized more clearly as the logic of objects by severing it from the 'apophantic' logic of judgment, while the nomological sciences are deductive, formal–analytic sciences describing 'definite manifolds.' Fundamentally new is Husserl's assessment of ontology as a naive–dogmatic discipline that is turned into a science only by its founding on a 'transcendental logic.' The term 'transcendental,' as explained in 1936, refers to 'the motif of inquiring back into the ultimate source of all the formations of knowledge, the motif of the knower's reflecting upon himself and his knowing life' (Husserl 1954, p. 100). Husserl's reflective 'pure consciousness' of 1913 is now determined further by its function as the 'transcendental ego,' having everything as its object, while never becoming an object itself, and granting access only through 'eidetic intuition.'

The absolute sphere, which is the foundation of ontology and may be distinguished from the ontological sphere as 'semasiological' (R. Zocher), is the object of a 'critical' transcendental philosophy, which Husserl can only conceive of as a fully developed phenomenology. It makes use of the grasping of essences as a tool for analyses which approach the problem of foundation not as a methodological task, but as a problem of constitution in the classical sense: in this sphere, according to Husserl, valid statements may be obtained only by a sequence of increasingly radical reduction steps, each of which is to consist in a certain 'abstention' (*epoché*). The first two steps, i.e., 'phenomenological reduction,' leading to the phenomena, and 'eidetic reduction,' leading to the essential structure of consciousness, carry us on to the transcendental sphere. Access to it, however, is only given by 'transcendental reduction,' which is the 'absolutely universal reduction,' opening up the transcendental subjectivity which constitutes the meaning of the world and its contents, and thereby all objecthood.

2.3 The Crisis of European Science and the Lifeworld

The period between World War I and the seizure of power by National Socialism in Germany abounds with diagnoses of crises, from the foundational crises in most sciences (claimed for psychology, sociology, economics, etc., following the foundational crisis of classical mathematics so dramatically exposed by H. Weyl in the 1920s) to a general crisis of the times, of intellectual and moral orientation, and of European ('rational') culture generally.

Husserl gave much thought to this phenomenon and made out a growing loss of confidence in the sciences hitherto regarded as the firm foundation of Europe's rational culture. He analyzed this situation comprehensively in an article 'Die Krisis der europäischen Wissenschaften und die transzendentale Phänomenologie' published in 1936 in a new and little-

known Serbian journal and later forming the first two parts of the monograph bearing the same title (Husserl 1954). The sciences, it seemed to him, while 'functioning' as well as ever technically, had lost sight of their origin as well as of their aims, and thereby lost their former role and status as a guide and a standard of reliable knowledge and moral responsibility. Husserl hoped for a renewal by recognition of the fact that all scientific knowledge and activity is grounded in and grows out of everyday life. This is a realm usually not reflected upon but capable of thorough analysis as our 'life-world,' the domain not only of the physically 'given,' but primarily of our social life. Our immediate experience is not that of objects given to our consciousness, but that of situations in which we find ourselves with other people, in social groups and institutions, participating in common meaningful action, handling (linguistic and other) symbols, and approaching with understanding even 'the great symbolic systems such as language, myth, religion, art, etc.; all of which are essential elements of the *Lebenswelt* and therewith of highest interest to the social sciences' (Schütz 1959, p. 96). The phenomenological analysis of these largely 'pre-predicative' constituents of the life-world was envisaged by Husserl in the *Crisis* treatise and begun in his late and posthumously published work *Erfahrung und Urteil* (1939), where he has recourse to the life-world and to the primacy of praxis over mere contemplation. But in front of them, he places the 'pre-predicative' evidence of perception and of judgment based on perception, and thereby once more a prelinguistic foundational domain. The new approach remained to be developed by others.

3. *Contexts of Discussion and of Influence*

Notwithstanding the fact that 'Husserl literally "thought through his pen"' (Embree et al. 1997, p. 327), entrusting an incredibly large part of his ideas to shorthand memos that remained unpublished during his lifetime (and part of them until now), his thinking did not develop monologically, without context. During Husserl's student years, the careful study of Descartes, Leibniz, the British empiricists and Brentano was recommended to him by T. Masaryk (today less famous for his *Versuch einer concreten Logik* of 1887 than for his later career as the first president of Czechoslovakia), and Husserl himself testifies to the influence of William James's *Principles of Psychology* of 1890 on the shaping of his phenomenological thought. Having acquired some fame as a creative philosopher, Husserl corresponded with many experts in science and philosophy, and discussed his ideas at invited lectures at other German universities, and abroad in Vienna, Prague, Paris, Amsterdam, London and elsewhere—events certainly prepared by the translation of the *Logische Untersuchungen* and the *Ideen* into several foreign languages.

The beginning of the 'phenomenological movement' may be seen in the exchange of ideas with students and collaborators of T. Lipps in Munich, who learned about Husserl's investigations through their fellow student J. Daubert after he met Husserl in Göttingen in 1902. In spite of having nothing in print, Daubert had considerable influence on the 'Munich phenomenologists' (among them M. Geiger, A. Pfänder, and A. Reinach), some of whom (like H. Conrad-Martius, A. Koyré, and E. Stein, later one of Husserl's private assistants) came to Göttingen to work with Husserl. They became the leading members of the 'Göttinger philosophische Gesellschaft' and main authors of the *Jahrbuch für Philosophie und phänomenologische Forschung*, founded in 1913, which published some of the great contributions (phenomenological and other) to contemporary philosophy, such as Husserl's *Ideen* in 1913, M. Scheler's *Der Formalismus in der Ethik und die materiale Wertethik* (*Formalism in Ethics and the Material Ethics of Value*) in 1913–16, and M. Heidegger's *Sein und Zeit* and O. Becker's *Mathematische Existenz* (*Mathematical Existence*), both in 1927. After its discontinuation in 1930, the publications' goals and role were taken up by the American journal *Philosophy and Phenomenological Research*, founded in 1940.

In Husserl's most active period, private assistants helped organize his literary production, defended his positions (e.g. E. Fink against neo-Kantian critics), and prepared lectures and notes for publication (e.g., the *Zur Phänomenologie des inneren Zeitbewußtseins*, prepared by E. Stein and edited by M. Heidegger in 1928, and, posthumously in 1939, *Erfahrung und Urteil* by L. Landgrebe). In 1940, H. L. Van Breda saved most of Husserl's *Nachlass* (including 40,000 pages of manuscripts, Husserl's private library and much of his correspondence), which today forms the core of the Husserl Archives at the Catholic University at Louvain, Belgium. Philosophical and related work in the phenomenological spirit is, beyond this, upheld by 'Phenomenological Societies' in several countries.

4. *Impact on the Social and Behavioral Sciences*

Husserl's own writings did not take up any topics directly relevant to the social and behavioral sciences and therefore had little influence on them during his lifetime. Yet, they greatly stimulated interest in the phenomenological method in other authors, who explored its applicability and fruitfulness within the social sciences, broadening and strengthening the phenomenological movement. Whereas the investigations of A. Reinach into the *a priori* foundations of civil law, and of M. Scheler into the origins of cultural development, are contributions to the philosophy of

the social sciences rather than to social sciences proper, the potentiality of a phenomenological approach was recognized early in the psychology of personality (especially in the psychology of the subconscious and in psychiatry), and in experimental psychology, where it opened up new vistas for social psychology and the psychology of perception (D. Katz, A. Metzger, M. Wertheimer): the development of gestalt psychology (K. Köhler, K. Koffka) and of K. Lewin's field theory are unthinkable without the impact of Husserl's phenomenology (see also MacLeod 1947). In the field of sociology, the *formal sociology* (or sociological formalism) of A. Vierkandt and G. Gurvitch have drawn explicitly on phenomenological ideas, and more recently, sociological systems theory, social constructionism and ethnomethodology have been clearly influenced by phenomenological thought (P. Berger, H. Garfinkel, E. Goffman, T. Luckmann, Niklas Luhmann, I. Srubar).

According to A. Schütz, 'Husserl's signal contribution to the social sciences consists ... in the wealth of his analyses pertinent to problems of the *Lebenswelt* and designed to be developed into a philosophical anthropology' (Schütz 1959, p. 97). This development was brought about by Schütz himself, who met Husserl personally only in 1932, after publication of his own pioneering work *Der sinnhafte Aufbau der sozialen Welt* (*The Phenomenology of the Social World*, 1972), but established close intellectual contacts for the six remaining years of Husserl's life. Schütz became the towering figure of phenomenological sociology, and it is due to the considerable impact of his work that Husserl's phenomenology, beyond its historical merit of exhibiting the limits of naturalistic and atomistic thinking, has gained a lasting influence on the social and behavioral sciences of today.

Hutterite Demography

The unique demography of the Hutterites—a contemporary Mennonite sect of Germanic origin who live in the Great Plains of the USA and Canada—has played an important role in the development of demographic theory and methods. They practice no birth control for religious reasons and their high fertility levels give reason to believe they do not intentionally control their fertility (Eaton and Mayer 1953). Their communally shared life-style, including the sharing of material resources, is also presumed to limit social or cultural variations in Hutterite fertility (Larsen and Vaupel 1993). Because of their uniformly high and apparently uncontrolled fertility, studies of the patterns and determinants of fertility among the Hutterites have helped to shape our theoretical expectations for populations that do not make any conscious efforts to limit childbearing. And, as a result,

the Hutterites have also been widely used in demographic methods as a fertility standard to which other populations are compared.

1. Hutterite Fertility

Many different estimates of fertility and fertility determinants among the Hutterites have been published in different studies (see Larsen and Vaupel 1993). All of these studies agree, however, that Hutterite fertility is exceptionally high. Eaton and Mayer (1953) reported a median completed family size of 10.4 children among married women over the age of 45 in 1950. Recalculations using the data published by Eaton and Mayer report a lower completed family size with a median of 9.4 children, and a mean of 8.97 among the same women (Lang and Göhlen 1985). These estimates are consistent with the modal completed family size of 10 children, and the maximum of 15 children, reported for the Hutterite sample analyzed by Larsen and Vaupel (1993). Even in this very high fertility population, however, fecundability and the probability of conception decline substantially with age. The monthly probability of conception is estimated to decline by about two-thirds between ages 20 and 35 (Larsen and Vaupel 1993), likely reflecting age-related influences such as higher probabilities of fetal loss, lower coital frequency, longer postpartum amenorrhea, etc., among older age women. Nonetheless, the age-specific influences on Hutterite fertility resulting in a decline of fecundability across ages appear to be largely biological in nature. Compared with other populations, the Hutterite population has exceptionally high fertility levels and the age-related decline in fecundability offers no apparent evidence of intentional fertility limitation.

2. The Hutterites as a Natural Fertility Standard

Because of their doctrines and behavior, the Hutterites are presumed to represent a *natural fertility* population. That is, as Henri (1961) argued, their childbearing patterns reflect no efforts to limit fertility bound to the number of children already born, i.e., parity-*specific* fertility limitation. In fact, the Hutterites were one of the populations Henri (1961) used to define and illustrate the concept of natural fertility. He also ensured a special standing for the Hutterites as a high fertility standard when he found that they had the highest age-specific fertility levels of 13 historical populations he studied, all of which appeared to be natural fertility populations.

2.1 The Hutterites as a 'Standard Natural Fertility Population'—Coale's 'I' Indices

Hutterite fertility levels and age-specific fertility patterns have been used as standards in some of the most widely used fertility measures of recent years. The Princeton European Fertility Project (Coale and Watkins 1986) popularized the use of Coale's (1969) 'I' indices which compare fertility in a population with that of the Hutterites through indirect standardization. Coale's index of overall fertility (I_f) compares the number of births to women in a population with the number of births these women would have had if they had experienced the same high age-specific fertility rates as married Hutterite women (i.e., 0.550 births per year among women aged 20–24, 0.502 to those aged 25–39, 0.447 to those aged 30–34, 0.406 to those aged 35–39, 0.222 to those aged 40–44 and 0.061 to those aged 45–59, see Henri 1961). Coale's index of marital fertility (I_g) similarly compares births to married women with the fertility they would have had if they had experienced the Hutterite age-specific marital fertility rates. And, Coale's index of illegitimate fertility (I_h) draws the same comparison for nonmarried women, again using Hutterite age-specific marital fertility rates as a standard. A final fourth index is intended to capture effects of the proportion married upon fertility (I_m) through comparing the fertility married women would have with that which all women would have, if both experienced Hutterite age-specific marital fertility rates.

2.2 Age Patterns of Hutterite Fertility as a Standard—Coale and Trussell's 'M' and 'm' Indices

Coale and Trussell's (1978) more formal mathematical modeling of age-specific marital fertility control also incorporates the fertility pattern of the Hutterites and Henri's (1961) other natural fertility populations as a standard for comparison. Coale and Trussell used 10 of Henri's natural fertility populations, including the Hutterites, to specify a standard age-specific pattern for natural fertility (see *Demographic Models*). The Coale–Trussell model attempts to parameterize the differences in overall levels and age patterns of fertility from these natural fertility expectations in populations with varying levels of fertility control. The level of fertility is then captured by two parameters of the model, Coale and Trussell's '*M*' index of fertility levels and their '*m*' index indicating departures from a natural fertility age pattern (1978).

2.3 Hutterite Fertility Determinants in Micro- and Macrosimulations

Not surprisingly, demographic simulation models have also made use of Hutterite fertility standards. Ridley and Sheps' (1966) initial (i.e., Cohort A) microsimulation of fertility, for example, used values of fecundability and postpartum nonsusceptibility which were derived from the Hutterite population. Bongaarts' more recent (1976) macrosimulation of fertility also incorporated Henri's (1961) natural fertility estimates as standards for age-specific patterns of

fecundity and for infecundity associated with sterility. In these simulations the Hutterite fertility standards are used to represent biological fertility parameters in the absence of fertility control.

3. Limitations of the Hutterite Fertility Standard

As the theoretical definition of natural fertility has been challenged, so have the measures of fertility control which have utilized the Hutterite fertility standard. Comparisons with a Hutterite standard population, such as Coale's I_g index, may reflect differences in fertility which do not arise from parity specific control (Santow 1995). And, as in the case of Coale's '*M*' and '*m*' indices, such comparisons may also fail to capture the heterogeneity of fertility behavior in populations being compared with the natural fertility standards (Okun 1994), including the possibility of fertility control which is not closely tied to parity such as birth spacing. Although comparative indices and methods face many of the same limitations as any indirect standardization, incorporating the Hutterites as a constant standard population for empirically-based comparisons has nonetheless been of considerable advantage to demographers. Use of the Hutterite standard has allowed meaningful comparisons of fertility levels and patterns across widely different historical populations. The Hutterite standard has also provided indices with a clearly interpretable and unambiguous reference to an empirically observed high fertility standard. And most criticisms of the measures incorporating the Hutterite standard concern their interpretation in terms of underlying fertility behavior (e.g., diffuse birth spacing or parity-specific stopping) rather than their ability to index the levels and patterns of age-specific fertility across populations.

4. The Hutterites and Bio-demography

Underlying their use as a high-fertility standard in many different methods, the Hutterites in and of themselves offer a unique opportunity for demographers to explore biological aspects of fertility and fecundity. An absence of any evident parity-specific fertility control, along with very high fertility levels, makes the Hutterite population one which may be used to study biological determinants of fertility without the confounding influence of fertility limiting behaviors. However, a troubling concern in the study of historical populations that lack widespread evidence of fertility control is the extent to which there may be many subgroups within the population with different fertility levels and patterns arising from different behavior and sociocultural circumstances. The Hutterites' communal lifestyle and uniformly high fertility give no reason to suspect wide differences in fecundability and fertility from social or cultural forces. And the uniformity of the population in many demographic behaviors (e.g., universal marriage and early ages at marriage, short durations of breast-feeding and early weaning, short birth intervals, absence of induced abortion, and low levels of premarital conception, etc.) is likely to minimize many sources of variation in fertility compared with other populations. This relative homogeneity, or absence of subgroup variation, is especially important to the recent use (and assumptions) of event history methods to estimate the underlying biological patterns of fecundability among the Hutterites. This allows researchers estimating fecundability with Hutterite data to assume the underlying patterns and variations they discover arise from biological variation (see Larsen and Vaupel 1993 for a review and example of such studies).

As further studies provide more refined estimates of Hutterite fertility and fecundity, these will likely continue to serve as empirically grounded standards for our demographic expectations in the absence of intentional fertility limitation. The theoretical importance of these expectations to demography is evident in the significant role which studies of the Hutterites have had in shaping the concept of natural fertility and debates over the nature of fertility limitation. Their methodological import is clear in the wide variety of methods already grounded in the Hutterite fertility standard.

Hybridity

'Hybridity,' originally a biological term, has been used by authors in the social sciences, literary, artistic, and cultural studies to designate processes in which discrete social practices or structures, that existed in separate ways, combine to generate new structures, objects, and practices in which the preceding elements mix. During the 1980s and 1990s its use has increased, particularly in English and Spanish, whereas in other languages, such as French, the term coexists with adjacent concepts like *mestizaje* and syncretism, favored in French literature. Some authors include these classic terms in 'hybridization,' conveying greater flexibility to the term to include processes of intercultural confluence.

1. *The Term Hybridity in Biology and in Social Sciences*

The use of hybridity in humanistic and social science studies has been questioned due to the biological origin of the concept. The risk of transferring the sterility commonly associated with the term to society and culture is put forth. Even though this criticism can still be found in recent writings, it is the extension of a nineteenth-century belief, when hybridization was looked upon with suspicion because it was believed to harm social development. However, this opinion has changed since 1870 with Mendel's theory of the enhancement produced by genetic mixing and its twentieth-century examination (Olby 1984). Strictly considered, biology, particularly botany, teems with fertile hybridizations which take advantage of characteristics of cells from different plants to enrich the growth, resistance, quality, and economic and nutritional worth of food stuffs made from these combinations (Callender 1988). Hybridization of human DNA with bacteria to produce protein is also common; this is, in fact, the main means to generate insulin.

Adoption of the term by the social sciences is not legitimized by its biological background. Similarly to other concepts taken from biology, for example, *reproduction*, for which a new elaboration had to take place in order to talk about social, economic, and cultural reproduction, the theoretical solidity and explanatory power of hybridity in social sciences depends upon the manner in which the term is relocated within networks of specific concepts referring to society and culture.

On the one hand, hybridity is linked with more or less classical notions of social thought that allude to the separation and mix among cultures and strata: race, ethnicity, *mestizaje*, miscegenation, syncretism, identity, multiculturalism, heterogeneity, creolization, transculturation, bricolage. On the other, its treatment and epistemological consistency depends upon the manner in which different authors link the concept with terms and theories, such as tradition, modernity, postmodernity, border, contradiction, globalization, that condition the understanding of hybridity.

The sociocultural construction of hybridity has taken place in several disciplines. As a linguistic process it was elaborated, among others, by Mikhail Baktin, who used the term to characterize the coexistence of learned and popular speech in the same goup, or even in a single speaker, and by Homi Bhabha, who defines hybridity as a metonymy of presence and places it amidst power relations, noting differences between colonial and resistance hybridization, depending on whether the linguistic and literary mixes serve domination or subversion (Bhabha 1994). Some historians of the Americas speak of hybridity to explain the interweaving of pre-Columbian imagery with the colonizers' Spanish one and with the culture developed later, during modernity (Gruzinski 1999).

2. Mestizaje, *Syncretism, Transculturation, Creolization, and Hybridization*

Mestizaje and hybridization are as old as exchanges among peoples, migrations, and wars of conquest wars. The Tower of Babel is a story of *mestizaje*. Pliny the Elder spoke of hybridization when referring to the migrants that arrived in Rome in his day. Several historians and anthropologists have illustrated the decisive role of *mestizaje* in certain areas, such as the Mediterranean, since the days of Classical Greece (Laplantine and Nouss 1997). But the more intense—or researched—periods of interethnic and intercultural mixing happened with Europe's expansion into America.

The mix of Spanish and Portuguese colonizers first, then of English and French, with American Indians, to which the African slaves were added, made *mestizaje* the prevailing process within the societies of the so-called New World. Nowadays, less than 10 per cent of the population of Latin America is descended from

indigenous peoples alone (this percentage decreases in the US and Canada). Communities of European descent that have not mixed with native peoples are also a minority. Thus, the makeup of all of the Americas requires the notion of *mestizaje*, both biologically—production of phenotypes from genetic crossbreeding—and culturally: blending of European and native American habits, beliefs, and ways of thinking.

For a very long time, studies on physiognomic and chromatic aspects of *mestizaje* were privileged. Skin color and physical features are still critical in the ideological construction of subordination and discrimination; however, in the social sciences and in more democratic political thought, *mestizaje* presently centers on the cultural dimension of the combination of identities. In anthropology, cultural studies, and cultural policy making, the issue is presented as devising ways to share multicultural life styles (Kymlicka 1995).

Of the diverse crossings that take place among cultures, the religious ones have received the most attention. They are usually referred to by a specialized term: syncretism. European expansion in Africa, Latin America, and Asia gave way to multiple mixed forms where heterogeneous beliefs fused and new divinities emerged (the Virgin of Guadalupe in Mexico; the combination of African ancestors, indigenous figures, and Catholic saints in Brazilian Umbanda). Practically every religion has fundamentalist currents that seek to defend pure forms, but the magnitude of migration and the transcontinental spread of rituals and beliefs during the eighteenth and nineteenth centuries stressed these hybridizations and increased tolerance towards them to such a point that in countries such as Brazil, Cuba, Haiti, and the US, it was frequent to find a double or triple religious affiliation. An example may be a Catholic person participating in an Afro-American ritual or in a New Age ceremony. If we consider syncretism in a wider sense, such as the simultaneous adhesion to several belief systems, not only religious ones, the phenomenon grows remarkably, particularly among the many people who resort to indigenous or Asian medicine for certain ailments, to allopathic medicine for others, and even to Catholic or Pentecostal rituals. The syncretistic use of these health resources usually is combined with musical fusion and multicultural social organization systems, as is the case in Cuban *Santeria*, Haitian Voodoo, and Brazilian *Candomblé* (Rowe and Schelling 1991).

Some of these phenomena were what Fernando Ortiz, Cuban historian and anthropologist, thought about when he proposed the term *transculturation* (Ortiz 1995/1947) to designate 'processes in which features are not mechanically aggregated, but give way to a new phenomenon, independent and original.' Bronislav Malinowski's endorsement of that utterance in an introduction to Ortiz's book, and its future development by literary critics Angel Rama and Mary Pratt in their study of travel writing, are still appealing; particularly in literature and in Anglo-Saxon and Latin-American cultural studies.

The word creolization has also been used to refer to intercultural combinations, especially in anthropology and linguistics. Rigourously, it designates the language and culture created by variations of the basic tongue with other languages in the context of the slave trade. It includes the mixtures French has undergone in America and the Caribbean (Louisiana, Haiti, Guadeloupe, Martinique) and in the Indian Ocean (Reunion, Mauritius), or Portuguese in Africa (Guinea, Cape Verde), in the Caribbean (Curaçao) and Asia (India, Sri Lanka). But whereas it presents paradigmatic tensions between orality and writing, learned and popular sectors, center and periphery, in a diversity *continuum*, Hannerz suggests its usage could be extended to the transnational field to name 'processes of cultural confluence' characterized 'by power, prestige, and material resources inequality' (Hannerz 1997). Even though he is not the only author to stress the inequality and discontinuity present in hybridizations, the emphasis he places on examining increasing flows between center and periphery, together with the asymmetries among markets, states, and educational levels, helps avoid considering *mestizaje* as simple intercultural homogenization and reconciliation (Hannerz 1996).

3. *Hybridization, Modernity, and Globalization*

3.1 *Hybridization*

Whereas the terms mentioned above are nearly used as synonyms by several authors, *mestizaje* takes precedence in studies devoted to the mix of races or ethnic groups, and syncretism to refer to religious fusion or traditional symbolic movements. Besides the fact that *mestizo* has no English equivalent (some authors include the Spanish word in their English writing), research carried out during the 1980s in Spanish, English, and occasionally in French and Portuguese adopted 'hybridity' to include diverse intercultural mixes: ethnic *mestizaje*, syncretism regarding beliefs, and other modern fusion in which arts and crafts integrate with industry, the cultured with the popular and traditional and with mass media messages (Bhabha 1994, García-Canclini 1995, Bernd and de Grandis 1995, Papastergiadis 1997, Webner and Modood 1997).

3.2 *Modernity*

Modernity, an expression of which are nation states, has coherently organized—sometimes in reality, others in appearance—the diversity of cultures. There

are fewer than 200 nation states which comprise more than 600 languages and some 5,000 ethnic groups. These states have had to organize multiculturality through diverse policies, at the same time that they facilitated communication among ethnic groups and the different languages included in their territory. Even in the cases in which a single language was imposed over the 20, 50, or 100 groups that formed the nation, that common language adopts diverse modulations in the same English- or Spanish-speaking country when they combine or hybridize with the words, syntactic structures, and semantic references of the speakers of other tongues.

In the meantime, two other characteristics of modern development, transnational expansion of capitalism and of mass communication technologies, advance relationships and exchanges between local traditions and cultures of modernity. The crafts and celebrations of peasant groups travel, together with their producers, to cities and often to other countries, or they enter into contact with foreign tourists. Ethnic music, linked to specific rituals of a certain group, is not only taped in CDs, movies, and videos to be distributed worldwide; it is also mixed with classical and contemporary music, with jazz, rock, salsa, and other local and regional kinds of music. This is how the chicha, a mix of Andean and Caribbean rhythms was produced. Other examples include the jazzy reinterpretation of Mozart by the Afro-Cuban group Irakere, the re-creation of English, Indian, and other music by the Beatles, Peter Gabriel, and many other musicians.

The rigid borders established by nation states became porous. Few cultures can be defined today as stable units, with precise boundaries based on the occupation of a confined territory. But the multiple opportunities to hybridize neither imply indetermination nor unrestricted freedom. Hybridization happens under specific historical and social conditions, in the midst of production and consumption systems that sometimes operate as constraints, as can be witnessed by the lives of many migrants. One of the social entities that support but also condition hybridization are the cities. The multilingual, multicultural megalopolis, for example, Paris in the nineteenth and twentieth centuries, Vienna at the beginning of the twentieth century, London, Berlin, New York, Los Angeles, Buenos Aires, Sao Paulo, Mexico, and Hong Kong are studied as centers where hybridization fosters greater conflict as well as greater cultural creativity (Appadurai 1996, Hannerz 1996).

3.3 Globalization

Globalization stresses these trends of modernity by creating world markets of material goods and money, messages, and migrants (workers, tourists, exiles). These constant streams and interactions have weakened borders and frontier posts; also the autonomy of local traditions. At the same time, they foster many more forms of hybridization than they ever did in the past: productive, commercial, communicational, and in consumption habits. To the characteristic modalities of hybridization, which came into existence due to migrations and trips, as well as to the educational integration policies by nation states, the mixtures generated by cultural industries have to be added. Industrialization encompasses not only the mass media (radio, movies, television, video), but also industrial production for massive audiences in international exhibitions, folkloric groups' tours, and globalized theme parks such as Disney's (Harvey 1996).

However, the main globalization analysts note that it not only integrates and generates *mestizajes*; it also segregates, produces new inequalities, and stimulates differentialist reactions. Identity alliances emerge (Latins or Arabs in the US or in Europe) as do organizations of regional integration (European Union, NAFTA, Mercosur), which in part aim at strengthening partial groupings to counteract the indiscriminate interaction of globalism (Beck 2000). Some of the actors find resources to resist both globalization and hybridization at once in these alliances.

3.4 The Future

Several anthropologists and cultural studies specialists maintain that the generalized relevance of hybridization requires changes in the ways social sciences are formulated. It is impossible to analyze large units, that is, nations, states, transnational enterprises, without noticing their internal diversities and modulations, as often happens in disciplines devoted to analyzing at the macro level, such as sociology and economics. It is not acceptable either that anthropology, traditionally dedicated to small communities, continues to see solely their homogeneity, and overlooks the heterogeneity and hybridization caused by the transnational goods and messages that intersect these communities. To be able to politically negotiate diversity and hybridizations, we need a '*mestizo* way of thinking' (Laplantine and Nouss 1997, Gruzinski 1999).

Fundamentalisms are not the only opposition to religious syncretism and intercultural *mestizaje*. There is an extended resistance to accepting hybridization because it generates insecurities within cultures and conspires against their ethnocentric self-esteem. It also presents a challenge for modern analytical thought, used to the binary separation: civilized, wild; national, foreign. This schematism leaves aside frequent ways in which culture is shared nowadays, for example, take

someone who is Brazilian by nationality, Portuguese by tongue, Russian or Japanese by origin, and Catholic or related to Afro-American religions.

Hybrid thought will not look forward to working with radically different, homogenous, compact units as much as with intersections, transitions, and transactions; less with identity than with heterogeneity and multiple senses of belonging. To understand the contemporary world it is indispensable to study how cultures mix, to what rhythms and modalities, what they lose and gain in the process, how they agree to cohabit, and how they negotiate to keep the difference alive. To comprehend hybridity and to learn to be cosmopolitan, 'multicultural gourmets', capable of traveling in diverse cultures and savoring the differences, has become necessary to fathom globalization and the ethnic and national societies' crisis. In brief, to understand society.

Hypertension: Psychosocial Aspects

Hypertension is a complex disorder of physiological regulation involving many interacting biological and environmental factors. Although the prevalence of hypertension has decreased over recent years, the latest US survey placed the age-adjusted prevalence ($> 140/90$ mmHg) at 20.4 percent. Interest in the role of psychosocial factors in hypertension has a long history beginning with theories about social stress, affective processes, and individual behavioral dispositions in its etiology. Noteworthy are the early psychosomatic writings about the significance of anger expression and suppression for high blood pressure.

1. Direct and Indirect Evidence

Numerous studies provide evidence of a definite role for psychosocial factors in hypertension. Direct evidence is derived from cross-sectional studies of individuals with hypertension compared to control samples and longitudinal studies to determine what factors are associated with the development of hypertension. Indirect evidence comes primarily from studies of psychosocial factors affecting blood pressure in healthy individuals with or without various predisposing characteristics. Psychosocial factors are also relevant to the degree of adherence to medications, engagement in health-related behaviors affecting risk for hypertension, effectiveness of antihypertensive medications, and nondrug methods of managing hypertension based on psychosocial concepts and methods.

2. Blood Pressure Reactivity and the Sympathetic Nervous System

Elevations in blood pressure can be elicited by many different stimuli and circumstances involving psychological and social factors. Examples are exposure to noxious, painful, threatening, or otherwise stressful

stimuli and events, participation in demanding tasks requiring repeated behavioral and/or mental adjustments, continuous striving and active coping, frustration in achieving goals, mental effort especially in solving difficult problems, momentary moods and behaviors involving fear, anger, and other emotional states, inhibition or suppression of emotional states and reactions, conflicts about the expression of angry feelings or other emotions, and interpersonal and group conflict. Socialcultural norms define what are appropriate and desired reactions and behaviors. The extent to which blood pressure is affected is determined by the balance between demands placed and the individual's resources and ability to cope with the demands.

A common theme in the literature is that individual differences in cardiovascular reactivity to various stimuli and events serve as a risk factor for hypertension and cardiovascular disorders in general. Increased sympathetic nervous system activity and associated hormonal changes is considered the neural source of excessive cardiovascular reactivity (Folkow 1989). In established hypertension, sympathetic activity is increased, particularly in individuals in whom the elevated blood pressure appears to have a basis in the nervous system ('neurogenic' hypertension) (Esler et al. 1977). Moreover, most antihypertensive medications appear to regulate blood pressure by interfering with mechanisms of sympathetic activation. Low parasympathetic activity (vagal tone) may also be a factor in hypertension and may contribute by slowing cardiovascular recovery from stress.

The large body of experimental evidence linking excessive cardiovascular reactivity in humans to established hypertension is compelling on empirical as well as theoretical grounds (Light 1987). Moreover, psychosocial factors are also associated with higher casual or ambulatory levels of blood pressure, suggesting that the transformation from excessive reactivity to a chronic elevation may take place with repeated instances of blood pressure increases. Thus, in some samples of subjects, during waking hours and even during sleep, average levels of blood pressure have been found positively associated with such personality traits as hostility and defensiveness (Shapiro et al. 1993). Physiological models have been developed to describe the cardiovascular dynamics underlying the transformation from early heightened reactivity to later established higher levels of blood pressure.

3. *Methodological Complications in Human Studies*

Despite the vast literature, debates continue about the conclusiveness of the evidence supporting the cardiovascular reactivity hypothesis based on responses to laboratory stressors. The findings are not always consistent or easily integrated. Individuals vary widely in their blood pressure responses to various circumstances. Variations in the kinds of individuals and methods chosen for study may result in different findings and conclusions. Laboratory settings may impose constraints on the participants so that they may not respond to challenges and threats with their preferred method of coping. Individuals also vary in the degree to which their responses persist over time for any one provocation or generalize across provocations. The association between perceptions of stress and the blood pressure response to such stress is not consistent because some individuals tend to report not feeling stressed, anxious, or angry while at the same time showing increased physiological reactivity to provocations or elevated blood pressure levels in general. These individuals either generally do not feel negative emotions or wish to make a good impression on other people. This characteristic has been labeled 'defensiveness.' Finally, many individuals learn to cope effectively with stress or to keep their emotional responses under control. For example, experienced air traffic controllers or other professionals dealing with emergencies do not necessarily show elevated levels of blood pressure (Sega et al. 1998). By taking these various factors into account, further sense may be made out of some of the apparently inconsistent findings, thus adding to confidence in the soundness of the reactivity model.

Thus, the ability to predict individual differences in reactivity and in the development of sustained high levels of blood pressure and established hypertension has been improved by considering other psychological factors such as various personality traits and coping styles (anger/hostility, defensiveness and emotional suppression, denial and repression, anxiety, lack of control and helplessness, Type A behavior pattern, depression, pessimism) (Johnson et al. 1992, Jorgensen et al. 1996, Suls et al. 1995). In the social domain, contributing factors are low socioeconomic status, social disintegration and family disruption (poverty, high crime rates, high divorce rates), occupational stress (job strain, job dissatisfaction, high job demands, little independence in one's work duties or latitude in the ability to make decisions), low levels of family and social support, social isolation, taxing responsibilities such as providing care to disabled family members, marital conflict, minority social status, certain ethnicities, and certain gender roles (Colhoun et al. 1998, Pickering et al. 1998). For example, anger and hostility do not necessarily have the same implications for men and women.

4. *Psychobiological Models*

The ability to predict whether repeated elicitations of increases in blood pressure will lead eventually to chronically elevated blood pressure and to cardiovascular disease is probably best improved when

certain biological factors are included in the test models, such as obesity, physical inactivity, poor physical conditioning, salt sensitivity, excitable autonomic nervous system, deficiencies in certain vitamins and minerals, intake of sodium and potassium, presence of other disorders such as diabetes, high glucose, insulin, or lipid levels, certain racial characteristics, and other genetic or constitutional predispositions such as family history of hypertension and cardiovascular disease. For example, in a study of occupational stress in nurses, those nurses for whom both parents had hypertension and who were hostile, defensive, or anxious had elevated ambulatory blood pressure, which was highest during work days (Goldstein and Shapiro 2000). Other psychosocial, life style, and habitual behavior patterns need to be considered as they are relevant to one's diet, activity level, and intake of caffeine, alcohol, and other substances. For example, high levels of social stress or certain personality traits like a high level of trait hostility may be associated with unhealthy health habits such as smoking, low levels of exercise, poor physical conditioning, and poor nutrition.

5. *Diagnostic Issues*

Psychological factors are relevant to the diagnosis of hypertension. Some patients may show elevations in blood pressure during a doctor's visit and evaluation but not at other times ('white coat effect'). This effect has been related to an alerting response to the examination or anxiety about one's health. In one study, trait hostility was found relevant to this effect. Those individuals who were highly hostile were consistently high in blood pressure during the examination and over the course of the day, whereas low hostile individuals were more likely to show elevated pressure only during the evaluation and not during the day (Jamner et al. 1993). By having the patient record blood pressure at home, useful information is obtained on blood pressure variability at different times and occasions that may guide decisions about treatment and increase the patient's adherence to medications or otherwise facilitate pressure reduction. Reliable devices are now available for this purpose.

6. *The Problem of Blood Pressure Variability*

Blood pressure can be quite variable both in the short term with a range of 5 mmHg or more over the course of a min and 30–40 mmHg or more over the course of waking hours during the day. These facts provided the impetus for the development of portable automatic 24-hour blood pressure recorders, initially used in the diagnosis of hypertension and the evaluation of drug effects and more recently in the investigation of blood pressure in different settings (Shapiro et al. 1993). Ambulatory blood pressure recording methods buttressed by information obtained from diaries of self reports of moods and the situations encountered in everyday life offer many advantages, including a large number of blood pressure measurements under different conditions (work vs. nonwork or off days, sleep vs. waking periods) and in a variety of repeatedly occurring situations, locations, and activities. Valuable data have been obtained from studies of special populations: paramedics, traffic control agents, secretaries, laboratory technicians, emergency dispatchers, nurses, bus drivers, college students. The research is challenging because of the complexities and uncontrolled nature of the observations, but novel analytical tools show great promise.

7. *Psychosocial Factors Affecting Treatment*

Psychosocial factors play a role in the treatment and management of hypertension. The response to antihypertensive drugs may partly depend on psychosocial factors, although research is sparse on this topic and these factors are not usually considered in the choice of medications used to treat patients. In one example, individuals with high levels of hostility were found less responsive to diuretics than nonhostile individuals, suggesting that the former might be more responsive to agents directly affecting the sympathetic nervous system. Ethnicity can affect the response to drug and non-pharmacologic treatments of hypertension (Brownley et al. 1999). Psychological factors influence degree of adherence to medications and may affect the degree to which side effects of medications occur and affect quality of life.

A great deal of research has been devoted to the evaluation of nondrug treatments of hypertension derived from psychological principles (Silverberg 1990). These procedures seem most suitable as alternatives in patients with mild hypertension, especially those who are free of significant cardiovascular disease risk factors (family history, high cholesterol level, smoking) and in other patients as a means of reducing the amount of medication needed for blood pressure control or completely eliminating the need for such medication. Reducing drug requirements may be of special value in dealing with undesired side effects of medications in some patients. The methods include progressive relaxation, simple relaxation, biofeedback-guided relaxation, biofeedback training involving blood pressure, heart rate, and other cardiovascular measures, biofeedback training using measures associated with sympathetic nervous system functioning, cognitive behavioral methods of facilitating coping with stress and dealing with anger ('stress management training'), hypnosis, and autogenic training. As yet there is no consensus about the effectiveness of these procedures, and major trials remain to be done. Other traditional methods such as yoga and meditation may be useful as a means of increasing awareness and control of mental and bodily functioning. Regular physical exercise can

facilitate blood pressure reduction and improve the coronary circulation. Whether or not people exercise, avoid or take medications, or use herbal, homeopathic, or various nondrug methods is determined by many different psychological, social, and cultural factors.

8. Summary and Conclusions

From the standpoint of the social and behavioral sciences, hypertension has attracted a great deal of attention. It forms the backbone of the growing fields of health psychology and behavioral medicine, and benefits greatly from the integration of methods, concepts, and findings of psychology, psychophysiology, social psychology, physiology, and biological and medical sciences. The evidence is supportive of the role and significance of psychosocial factors in the etiology, course, and treatment of hypertension. These factors include personality and coping styles, social and occupational stress, social status, family and social support, ethnicity, and gender roles. This knowledge has the potential for deepening our understanding of the mechanisms involved in hypertension, improving the effectiveness of both drug and non-drug approaches to treatment, and facilitating efforts to prevent the disorder. There is great need for further systematic research and especially for theoretical and empirical integration of psychosocial and biological knowledge of the disorder.

Hypnosis, Neural Basis of

Modern conceptions of hypnosis can be traced directly to the work of Franz Anton Mesmer, a Viennese physician working in Paris just prior to the French Revolution. Within 30 years of Mesmer's work, most of the basic hypnotic phenomena from amnesia to pain control to hallucinations had been reported (see Ellenberger 1970). James Braid, a Scottish surgeon, coined the term hypnosis in the 1840s. Nowadays, hypnosis refers to the acceptance of a social role, usually involving deep relaxation, and engagement in fantasy. During hypnosis a lowering of critical judgment permits a wide range of behavioral, cognitive, and affective responses to suggestion (see, for example, Orne 1970). This article addresses the question of whether response to hypnosis can be related to specific neural mechanisms or events.

During the last two hundred years, a variety of exaggerated and mistaken claims have been made for hypnosis. Claims have ranged from enhanced psychic abilities to past life regression, to revived memories of alien abduction. In the past, such claims have resulted in periods of scientific disrepute for hypnosis. Nevertheless, during the last century fine scientists (e.g., Hull, Hilgard, Orne, Barber, Sarbin and their students) have been drawn to study hypnosis (see Sheehan and Perry 1976). As well as elucidating the domain of hypnosis, their careful investigations have increased understanding of the potential pitfalls that appear in

experimentation with human research participants (see Orne 1959, 1970).

An observer, watching a demonstration of hypnosis with a highly hypnotizable research participant, sees a series of simple verbal suggestions that result in relatively spectacular alterations of behavior, thought, emotion, and perception. For example, the hypnotized burn patient lies quietly and reports no pain, seemingly relaxing while his dressings are changed: a highly painful procedure (Hilgard and Hilgard 1975). The laboratory research participant asked to re-experience the distant past seems to become childlike, entirely captured by the delusion that he or she is many years earlier. Asked to hallucinate the absence of an obstacle between where the participant sits and some other place, the participant claims to see nothing in the intervening space. But when asked to walk to that place (and thus, through the obstacle whose absence is being hallucinated), the participant walks around the obstacle without seeming to notice doing so. Asked to look back and see that there is nothing there, there is easy agreement with no seeming sense that walking around the obstacle has just contradicted this statement. Asked to forget all that has happened until a pencil is tapped twice, the participant will later 'awaken' with amnesia that is (almost always) temporary and reversible.

Thus, in response to brief verbal suggestions, the hypnotized individual seems to see, hear, feel, smell, and taste in apparent contradiction to the stimuli actually present (see Orne and Hammer 1974). Memory, the sense of volition, mood, and even awareness of self may be altered. With appropriate suggestions, such effects may be extended into the posthypnotic period.

Hypnotic phenomena are easy to elicit and robust. A graduate student, given two or three hours training and a standardized script, such as one of the *Stanford Hypnotic Susceptibility Scales*, can elicit all the major hypnotic phenomena in a psychology laboratory (Weitzenhoffer 1959, 1963; see also Shor and Orne 1962). There they can be studied under controlled conditions. Note that for all practical purposes, hypnotic suggestions are likely to be carried out only in settings seen as culturally appropriate. These include therapeutic, classroom, entertainment, research, and forensic settings (Orne 1970).

1. Problems with Seeking Psychophysiological Concomitants of Hypnosis

People commonly speak of being 'hypnotized' or in a hypnotic 'trance.' The underlying assumption is that hypnosis is a distinct, altered state of consciousness. Most early theorizing (and much current clinical thought) about the hypnotic state employed circular reasoning that goes something like this: Q: Why do you say that person is hypnotized? A: Because she is responding to hypnotic suggestions. Q: Why does she respond to hypnotic suggestions? A: Because she is hypnotized.

As Orne (1959) showed us, the hypnotized participant acts as shared cultural expectations suggest. In fact, the deeply relaxed hypnotic participant lying or sitting quietly while listening attentively to the hypnotist's voice manifests only one of many forms hypnosis has assumed. For example, in the late eighteenth century, Mesmer's Parisian patients sometimes had pseudo-epileptic seizures during hypnosis. In the late nineteenth century, Charcot's Parisian patients demonstrated first catalepsy, then lethargy, and finally somnambulism (but generally did not have seizures) when deeply hypnotized. At the same time in the south of France, Bernheim's hypnotized patients simply restfully reclined (see Ellenberger 1970). Most modern research participants and patients sit quietly and look very relaxed during hypnosis, although they may also be hypnotized with an 'active-alert' induction, involving, for example, pedaling a stationary bicycle vigorously (see Banyai and Hilgard 1976).

Obviously, peripheral neural activity during these varying hypnotic activities differs widely, reflecting the activity, not hypnosis. Nor has there been any evidence of brain activity unique to hypnosis *per se*. Nor is there evidence of specific brain activity that accompanies the entire hypnotic experience. After 50 years of modern research, the lack of evidence for any unique psychophysiological marker of a hypnotic trance state is one of the factors that have led researchers largely to abandon the concept of a hypnotic trance as a causal explanation for response to hypnotic suggestions (see Kirsch and Lynn 1995).

Concepts such as response expectancies, role involvement, self-delusion, and cognitive abilities are currently used to explain hypnotic responses. This does not mean that hypnotizing people does not have specifiable effects or that the experiences of highly hypnotizable subjects are consciously faked or otherwise theoretically unimportant. Rather, hypnotic effects result from making suggestions to willing participants of differing abilities and from the expectations and cognitive models that a hypnotic induction engenders both for the hypnotist and the participant (see Sheehan and Perry 1976).

At present, it is clear that the ability to respond to hypnotic suggestions lies largely in the subject (and not in the skill of the hypnotist as was previously held). Reports of being hypnotized or in a trance are seen as reflecting a subjective experience that is one of the many effects of cognitive and emotional set, social and historical setting, and suggestion (see Kirsch and Lynn 1995). And while all subjective experiences must have some neurophysiological substrate, psychology as a field of study has not reached the point where many can be pinpointed. Nonetheless, if phrased properly, reasonable questions about the psychophysiologic concomitants of hypnosis can be asked.

2. *Psychophysiological Differences in Response to Hypnotic Induction*

A discussion of the neural basis of hypnosis may be phrased in terms of answers to three questions. First, are there measurable differences in brain activity in response to hypnotic induction among those who subsequently respond strongly to hypnosis in comparison to those who do not? Second, when measured outside hypnosis, are there overall psychophysiologic differences between participants who usually respond to hypnotic suggestions for major changes in perception, memory, and/or cognition and those who do not? Third, are there patterns of brain activity associated with response (vs. lack of response) to specific hypnotic suggestions? While there are interrelated issues among these three questions, it is probably least confusing to look at these questions sequentially.

First, does hypnotic induction result in measurably different neural patterns among those who subsequently respond to the more spectacular hypnotic suggestions (those calling for hallucinatory or major cognitive changes) and those who do not? The evidence, while mixed, favors a tentative 'Yes, but for reasons that render the difference unimportant.' Brain function studies are divided between those that find highly hypnotizable, well lateralized, right-handed research participants shifting to greater relative right-hemisphere activation after hypnotic induction and studies that find no differences. The lack of consistent findings may be methodological: studies finding differences tend to use ratio measures that are meant to be sensitive to small differences (see, for example, LaBriola et al. 1987). Studies that do not find differences after induction tend to look at absolute values of measures of brain activation, a less sensitive measure (Graffin 1995). So there is some evidence that successful induction of hypnosis often involves a 'shift to the right' a finding in line with task performance measures of the effects of induction.

Why is this unimportant? Activation changes in response to induction are relatively small and disappear once other suggestions are made or tasks required. Relative hemispheric activation, with or without hypnosis, depends on the mental task participants are asked to perform. So the 'shift to the right' seemingly reflects a response specific to the 'task' of induction. And that response might well change were a different type of induction used (see Crawford and Gruzelier 1992).

3. *Psychophysiological Differences between Highly Hypnotizable Participants and their Less Hypnotizable Counterparts?*

Many studies distinguish between highly hypnotizable subjects and their less hypnotizable peers. Most modern scales of hypnotic responsiveness comprise standardized, relaxation oriented inductions followed by 5 to 12 hypnotic suggestions that are each scored pass/fail based on an objective criterion. Entire hypnotic scales are often administered by tape recorder and both experimenter-scored individual formats and self-scored group formats are available. Total score, the measure of each participant's hypnotizability, is simply number of suggestions passed (see Kihlstrom 1985).

All social scientists use Pearson's reliability coefficient, a coefficient that varies from $+1.00$ (relative scores on two measures are identical) to 0.00 (no linear relationship between two sets of scores) to -1.00 (relative scores are identical in size but opposite in sign). Hilgard and his colleagues have found that test-retest reliability of hypnotizability scales usually averages about $+.90$ over periods of one week and about $+.70$ over periods from 10 to 25 years (Piccione et al. 1989). These data indicate that hypnotizability is a highly stable difference among individuals. Among personality traits, the reliability of hypnotizability measurement is equaled or exceeded only by multi-task measures of intelligence.

Hypnotizability is not easily modifiable and governs the large majority of the variance in most experimental studies of hypnotic phenomena. Moreover, what has come to be called 'hypnotizability' is observable in response to suggested alterations in perception, memory, and/or cognition with or without formal hypnosis (see Kihlstrom 1985).

There are two fairly well established psychophysiologic correlates of hypnotizability. First, highly hypnotizable research participants (highs) show higher levels of resting theta activity than their less hypnotizable counterparts. Spontaneous EEG activity may be viewed as constituted of waveforms of different frequencies (delta -0 to 3 Hz, theta -4 to 7 Hz, alpha -8 to13 Hz, beta -14 to 30 Hz). Waking EEG records are largely made up of alpha and beta activity, with a small percentage of theta activity. When measured during rest, this small proportion of theta activity is slightly higher among the more highly hypnotizable participants, especially in recordings from the more anterior brain regions. While no convincing explanations for this phenomenon have yet been advanced, the notion that the theta differences between highly hypnotizable participants and their less hypnotizable counterparts are related to attentional abilities is the most popular hypothesis (see Graffin et al. 1995, Sabourin et al. 1990).

Second, if a variety of other factors are controlled (e.g., task difficulty, familial history of right handedness), well lateralized, right-handed research participants will show greater relative left cerebral hemispheric activation during verbal and mathematical tasks and greater right hemisphere activation during mental imagery. This pattern of task specific hemispheric asymmetry is seen more clearly among highly hypnotizable participants than among their less

hypnotizable counterparts. Highs show greater relative left cerebral hemisphere activation during verbal and mathematical tasks than do less hypnotizable participants. Similarly, highs show greater relative right hemisphere activation during imagery than do low or moderately hypnotizable participants. (The inclusion of moderately hypnotizable subjects provides some control for compliance. Moderates show the same level of compliance to behavioral suggestions as the highs, but are largely unresponsive to hallucinatory suggestions.) These findings have been interpreted as showing greater cognitive flexibility for highs and are in line with some findings in studies using task performance measures (see Crawford and Gruzelier 1992).

4. Psychophysiological Correlates of Response to Specific Hypnotic Suggestions

The third question is whether psychophysiologic differences can be found between those responding to specific hypnotic suggestions and those who fail to respond. This question can be asked in respect to hypnotic phenomena of central interest to experimental psychologists (e.g., hypnotic hallucinations), clinicians (e.g., healing of skin and immune system related disorders), or both (e.g., hypnotic analgesia).

Until the recent advent of functional magnetic resonance imaging (fMRI), activity in the normal waking human brain has been studied, for the most part, using measures of spontaneous and evoked electrical activity in the brain. Researchers usually utilize one of three electroencephalographic (EEG) technologies in which brain activity is recorded from the surface of the skull using standardized electrode placements. Obtaining EEG signals is similar to making an electrocardiogram except that EEG signals are measured in microvolts rather than millivolts signals studied with an EKG. (Since much greater amplification is required, EEG recording requires great care in avoiding electrical, movement, and other artifacts.)

Once having obtained an artifact free EEG signal, researchers digitize and transform it. Most frequently they use signal processing, mathematical (Fourier) transformations to determine the proportion of time in which alpha, beta, and theta activity occur. Alternatively, one may integrate the total area under the curve of an EEG record and compare total area at various sites in the brain during different tasks. In both methods one examines the signals from many recording periods (usually of 1 second to 10 minute duration) over minutes or hours of total recording time (see Karlin et al. 1980, Perlini and Spanos 1991, Sabourin et al. 1990). Almost all the research underlying the conclusions in the earlier sections of this essay has used one of these two techniques.

A third EEG procedure involves the presentation of brief, repeated auditory, visual, or tactile stimuli to elicit acute changes in electrical brain activity called event-related evoked potentials. Evoked potentials can be seen when the spontaneous EEG, used as data in the first two methods, is mathematically removed and only short-term changes in EEG signals remain. The precise shape of evoked potentials differs in relationship to a variety of factors including the duration, intensity, predictability, meaning, and sensory modality of the stimulus. However, when such factors are controlled, one expects a sequence of alternating positive and negative potentials during the second or so after stimulus presentation.

Several studies seemingly indicate that hypnotic suggestions to hallucinate alter evoked potentials among highly hypnotizable participants in ways consistent with their reported hallucinatory experiences. In these studies, highly hypnotizable participants who claim to experience either a particular hallucination or amnesia are compared to less hypnotizable counterparts who do not report similar experiences. Across visual and auditory stimuli and across experiments, highly hypnotizable participants seem to show augmented or faster positive evoked potentials and/or decreased or delayed negative potentials when asked to hallucinate the presence of stimuli that are not there. Again consistent with suggested hallucinations, when asked to hallucinate the absence of stimuli that are present, highly hypnotizable subjects show decreased or delayed positive evoked potentials, and/or augmented or faster negative evoked potentials compared to their less hypnotizable counterparts. Parallel findings to those found in negative hallucinations have emerged after amnesia instructions. In sum, highly hypnotizable participants show brain activity consistent with their reports of hypnotic hallucinations (see Crawford 2001).

Perhaps because it is the most clinically relevant negative hallucination, the effects of hypnotic analgesia instructions, instructions not to experience pain when exposed to a painful stimulus, have been studied with a variety of measures of brain activity. These have included fMRI, cerebral blood flow using 133-xenon, SPECT, and integrated EEG. Such studies confirm the pattern seen in the evoked potential studies: instructions to experience analgesia leads to measurable changes in brain function indicating central amelioration of the painful stimuli among highly hypnotizable participants, but not in lows or moderates (see Crawford 2001, Karlin et al. 1980). It is also noteworthy that other studies indicate that hypnotic analgesia is not mediated by endogenous opiate systems (Hilgard and Hilgard 1975).

As to immune system and skin disorders, the positive data remain largely anecdotal. There is a long history of treating skin disorders with hypnosis. (For example, hypnosis is still treatment of choice for warts that do not respond to conventional treatment.)

Similarly, asthma may be treated with hypnosis (although there is some evidence that hypnotic effects are limited to relaxation of the upper airways, rather than changes at the level of the lung where oxygen exchange occurs). Finally, there have been a number of studies on the ability of suggestion and imagery to alter immune responding directly. However, findings have been mixed and no clear conclusions can yet be drawn other than that large, robust effects seem unlikely (see Rhue et al. 1993).

5. Conclusions

Hypnotic responses remain intriguing, somewhat spectacular effects produced by simple verbal suggestion. Since the 1950s, careful rigorous work has been done to elucidate underlying mechanisms and any psychophysiologic concomitants of these phenomena. Inducing hypnosis *per se* has no clear physiologic effects. However, when compared to their less hypnotizable counterparts, highly hypnotizable subjects show slightly higher levels of theta activity during rest and greater task consistent asymmetry on strongly lateralized cognitive tasks. This is consistent with the notion that highs are capable of more flexible attention than are their less hypnotizable counterparts. Moreover, when successfully engaged in positive and negative hallucinations, including hypnotic analgesia and amnesia, highly hypnotizable subjects show cortical activity consistent with their reported subjective experiences across a number of measures of brain function.

Hypnosis, Psychiatry of

1. Definition

This treatment technique is thought to have received its name from the English surgeon James Braid (1795–1860) whose clinical observations likened the physiological condition of those who were responsive to the intervention to the state of sleep. It is the direct descendent of the seventeenth and eighteenth century

practices then called 'Magnetism,' 'Somnambulism' and 'Mesmerism,' although its roots can be traced to the religious and healing arts of antiquity. Today practitioners of hypnosis would subscribe to the American Psychological Association's (1993) definition of hypnosis as a 'procedure wherein changes in sensations, perceptions, thoughts, feelings or behaviors are suggested.'

2. Relevant History

Chroniclers of hypnosis (see Ellenberger 1970, Gauld 1992) point to the work of Franz Anton Mesmer (1734–1815) as the cornerstone for the establishment of this technique in modern medicine. Mesmer's belief that an imbalance in magnetic fluid led to disease states in humans gave rise to the ritualized application of magnets to individuals with a variety of medical and psychological problems. Not only the metal apparatus, but also certain people were thought to possess the 'animal magnetism' to restore the magnetic equilibrium and health. French government and scientific investigators who tested his work were able to dispute Mesmer's disease theory, but not the results. People continued to recover from a variety of ailments by means of suggestions (i.e., ideas) provided by charismatic individuals, and the technique soon spread throughout Europe and the USA.

Sigmund Freud (1856–1939) made his living as a young psychiatrist by treating patients, almost exclusively, with hypnosis. As a student of the famous neurologist Jean Martin Charcot (1825–1893) and the physician Hippolyte Bernheim (1840–1919), he learned about the efficacy of an idea to facilitate an action or symptom relief. His early technique employed suggestions to deny his patients' complaints energetically and to provide assurance and motivation for the performance of more adaptive behaviors. Freud also observed hypnotized subjects seeming to possess knowledge without realization, carrying out post-hypnotic suggestions without awareness of the source, and blindly following the commands of the hypnotist. From this clinical data and as a translator of Charcot's and Bernheim's writings on suggestion, hysteria and hypnosis, he became convinced that there were powerful, unconscious mental forces extant in humans that influenced behavior.

In Charcot's Salpetriere, Freud learned that traumatic events create trance states in hysterics, similar to hypnosis, wherein individuals are vulnerable to autosuggestion, and painful emotions become pathologically trapped in the nervous system. Hysterics, then, suffered painful reminiscences of these traumata that became expressed cognitively, affectively, somatically and/or behaviorally. Since they possessed similar characteristics, hypnotic trance was employed to assist the individual to revisit the scene of the original trauma, re-experience the original affects for cathartic discharge and recover from their symptoms through catharsis and insight. This technique was the basis for Freud's uncovering treatment in the *Studies on Hysteria* (Breuer and Freud 1893–1895) and hypnosis became one of the underpinnings of psychoanalytic theory and technique.

The power of suggestion, the influence of unconscious mental processes in humans and the use of hypnosis to access memories were not the only contributions of hypnosis to psychoanalysis. Freud was fascinated by the question of 'influence' and what led people to follow the directions of others. He reasoned that group activity and hypnotic treatments encourage people to minimize individual interests, personal control, discernment, personality style, etc., and to develop intense emotional relationships with people for reasons that are difficult to account for objectively. Freud saw the rapport created between doctor and patient in hypnosis to be comparable to that of tribal members for the chief and used it as a paradigm for his understanding of therapeutic influence and transference.

Where Mesmer might be credited with taking hypnosis away from the exorcists and placing it at least on the fringe of traditional medicine, Freud clearly explored hypnosis for what it could offer as a psychotherapeutic technique, and for what it might contribute to his model of the mind. It is clear from a close reading of his work that Freud continued throughout his career to use hypnosis as an archetype with which to compare and study his incipient psychoanalytic theory. However, his report that psychoanalysis began with his rejection of hypnosis relegated this technique to an inferior place among methods for mental health treatment. Very few of his followers would risk alloying the 'copper of suggestion' with the 'pure gold of psychoanalysis.' Freud's efforts to distance himself and psychoanalysis from hypnosis had something of the same dampening effect as Mesmer's failure to validate magnetic theory scientifically.

The birth of psychology and social science research techniques during the twentieth century brought new methods of inquiry into the essence and effects of hypnosis. The rise of interest in mind–body medicine also fueled clinical interest and investment in this area. Both of these developments, along with the creation of several professional journals and international societies for the study and practice of hypnosis, contributed to the continued development of this field.

3. Therapeutic Applications

3.1 Medicine

A technique that can alter sensations, perceptions, thoughts, feelings and/or behavior can be especially helpful in today's medical setting (Covino and Frankel 1999). Patients and practitioners have long experi-

enced anecdotal reports of symptom relief from something that a physician said, did or provided. Researchers in the laboratory and clinical setting have been laboring to establish empirical support for the use of hypnosis with a variety of symptomatic complaints and to manage common emotions in the medical setting to facilitate treatment.

Most clinicians have witnessed the influence of a patient's perception on the subjective experience of pain. Where an objective physiological event almost always serves as the cause of an injury, the meaning that the person makes of the event determines the amount of suffering. In experimental laboratories, hypnotized subjects have demonstrated an ability to tolerate electric shock, ischemic and cold pressor pain better than their nonhypnotized peers or when they employed other pain management strategies. Hypnotic suggestions for analgesia, distraction, and dissociation have been found to be superior to placebo, relaxation, and cognitive interventions in the management of a variety of painful conditions. Clinical research finds success for hypnosis in the management of pain associated with surgery, cancer, reflex sympathetic dystrophy, burns, interventional radiology, angioplasty, bone marrow transplant, and colonoscopy.

A number of experimenters have been successful at producing raucous breathing and decreased pulmonary function among a subset of asthma patients by means of suggestion alone. Whether these patients were invited to believe erroneously that they were encountering an allergen or breathing a bronchoconstricting drug, the idea alone was enough to affect their breathing adversely. Several well-designed studies have found that hypnosis training has a better impact on asthma symptoms, 'as needed' (p.r.n.) medication use, and pulmonary function tests than education, relaxation, guided imagery, and placebo inhalers. Furthermore, asthma patients who were trained to use hypnosis to manage their breathing have demonstrated a superior ability to tolerate methacholine challenge testing.

Allergists, dermatologists, and others have reported successful treatment of warts, eczema, psoriasis and other skin conditions with hypnosis. In clinical studies, suggestions to imagine bathing in salty water, increasing warm and tingling feelings on the skin, reducing blood flow to infected areas and general healing have assisted patients to relieve itchiness, reduce inflammation and decrease the number and size of warts. Likewise, patients with severe burns have been able to refrain from scratching, tolerate dressing changes and reduce their use of pain medications with the help of hypnosis.

Many patients with irritable bowel syndrome experience emotional distress in the form of anxiety and anger that adversely impacts gastric secretion, motility, and pain. A considerable number of these patients find relief from placebo interventions and several studies report alterations in gut physiology with hypnosis. Gastric acid secretion, gut motility, bowel habits, abdominal distention and abdominal pain have been reported to improve with very brief hypnotic interventions aimed at increasing relaxation, controlling smooth muscle and gut activity and bowel function.

Hypnotic training has been found to diminish the severity and frequency of bleeding episodes among patients with hemophilia. Training a small sample of patients to use hypnosis for relaxation and anxiety reduction has controlled factor usage, spontaneous bleeding and the need for transfusion. In addition, preoperative training in self-hypnosis for the control of anxiety and bleeding has been found to reduce the number of blood transfusions required by surgical patients.

One of the most common causes of noncompliance with chemotherapy among cancer patients is the significant distress that they experience from the associated nausea and vomiting. Anti-emetic drugs often have their own side effects and are typically ineffective with the anticipatory emesis that is often a conditioned response. General anesthesia, also, commonly causes postoperative nausea and vomiting among surgical patients. Well-designed clinical interventions have found support for hypnosis training over relaxation techniques, distraction or individual counseling in the management of nausea and the frequency and intensity of emesis. This has been the case for pediatric as well as adult cancer patients.

Although a number of factors including maternal age, number of previous deliveries and medication use can influence the duration of labor, women trained in hypnosis have experienced speedier and more satisfactory deliveries. Suggestions for relaxation, analgesia and comfort have been successful in influencing analgesic medication use and pain ratings as well as the length of time spent in the first and second stages of labor. Hypnosis trained primigravid women performed more like parous mothers than first time mothers without hypnosis on the above variables.

Numerous methodological difficulties limit confidence and widespread application of hypnotic techniques in medicine. As with most clinical research, the heterogeneity of the patients in terms of illness onset, type, course, previous treatments, co-morbidity etc., limits what can be said with confidence regarding the use of hypnosis in medicine. Also, many experimenters fail to include an adequate description of hypnosis, or might include hypnotic interventions as a component of a more complex psychosocial interventions, or fail to ascertain whether the subject was indeed hypnotized during the test. Nonetheless, qualified empirical evidence exists to support the efficacy of hypnotic techniques in the treatment of pain, asthma, dermatological disorders, irritable bowel syndrome, hemophilia, hyperemesis and obstetrics (Pinnell and Covino 2000).

3.2 Psychotherapy

The addition of hypnosis to cognitive–behavioral treatments for anxiety and habit disorders (smoking, weight control) improves the effect of traditional psychotherapeutic interventions. The ability to alter perception, adjust expectations, increase motivation and imagine more adaptive behaviors facilitates change, especially among those suffering from anxiety disorders.

Where it was once thought that autonomic nervous system hyperarousal was the result of so called stressful life events, recent research highlights the importance of cognitive processes such as perception. One person's strain might well be another's relief, depending upon the meaning that is made of the situation. An invitation from the hypnotist to perceive an event in a more benign fashion creates the opportunity for emotional relief and more adaptive behavior. Imaginative individuals can, also, use their capacity to picture frightening situations vividly to expose themselves to feared stimuli successfully. These patients are able to achieve some of the same mastery as '*in vivo* exposure' without the time and travel. Behaviors can be mentally rehearsed, problems anticipated and resolved with the help of suggestion, focused concentration and imagery. Likewise, unique motivational ideas can be the object of attention without distraction or criticism, and used to provide significant force for behavioral change.

Most efforts to use hypnosis for smoking cessation and weight control have seen modest results. Patients often report achieving relaxation and satisfaction with the technique, but pounds lost have been few and smoking abstinence is rarely achieved by more than 20 percent of program participants. This might well be due to the manner in which suggestions are employed to motivate patients and reduce appetite and desire. Anxiety symptoms related to surgeries and phobias have been especially responsive to hypnotic training, especially when combined with other psychological techniques. Much more is known these days about the complex manner in which patients cycle through processes of habit change as well as the benefits of medication support. Further work in this area would do well to integrate differing hypnotic approaches into the diverse phases and processes that people use in making habit change happen.

A number of clinicians have advocated the use of hypnosis for patients in psychotherapy. The hope in this area is to assist people to recover memories of difficult experiences as well as to teach a coping mechanism for managing extreme anxiety and dissociative symptoms. These therapists propose that the absorption, dissociation and intensity of emotions that often accompanies hypnotic trance are similar to the experiences of many victims of trauma. In a manner similar to state-dependent learning, and in much the same way that Charcot and Freud employed this technique, patients are invited to experience hypnosis, revisit the initial trauma and have an opportunity to express, integrate and control their associated emotions. In addition, those who spontaneously experience dissociative states are taught to enter into a hypnotic trance to reduce anxiety and to achieve some ability to terminate or control hyperarousal.

In a fashion that mirrors Freud's later work, the use of hypnosis as a psychotherapeutic technique is the focus of considerable controversy at the moment. In general, as was the case with Freud, the main idea of memory recovery sits in the context of credibility and veridicality. For some patients and practitioners it is painful and angering to raise the issue of truth in memory, since so many of those who were physically and sexually abused in their youth were frightened into secrecy. Yet, Freud seemed to see the inevitable intertwining of suggestion with dissociation in hypnosis as limiting the utility of this technique in psychotherapy.

Laboratory research finds that some modest gains in memory can be achieved from efforts to recall, especially when these are made proximate to the experience. Cues, reviews, relaxation, and other motivational techniques also seem to aid the recovery of memory. Nonetheless, hypnotic techniques have generally failed to improve recall of word lists and eyewitness reports. On the other hand, considerable evidence is mounting to suggest that people in clinical and experimental situations can be lead to the erroneous belief that an event or experience did indeed occur. The fact that these circumstances are more likely to take place in situations of heightened emotionality, uncertainty and unfamiliarity makes many clinicians cautious about using hypnosis as an 'uncovering' technique.

4. Essential Elements and Putative Mechanisms

At the end of such a review, it would be nice to be able to say clearly how and why hypnosis is and has been so helpful to patients in a variety of circumstances. Despite its age as a psychological intervention, this is not yet possible. A good deal of research has, thus far, failed to identify a specific neurological marker or neurophysiological substrate for hypnosis. There are, however, several ways that the beneficial effects of hypnosis have been understood.

Suggestions are ideas presented to a subject for uncritical acceptance. In hypnosis, the subject is asked to concentrate on these ideas in a manner that diminishes distraction, lessens logical analysis and maximizes acceptance and acquiesce. Suggestions are not commands, but invitations that can be rejected or accepted. However, like the response of patients to placebo medications, there is often a sense of

involuntariness to hypnotic responses and an attribution of causation to the hypnotist. The physical context, psychological expectations or the pressure to fit in well with a group can also provide direction for a person's thoughts, feelings or behaviors. Some theorists maintain that these psychosocial factors alone or in combination result in successful hypnotic response.

The ability to become absorbed in an idea as if it is real and to use fantasy and imagery to alter cognition and/or behavior is also seen as a determinant of successful hypnotic response. Such special concentration is thought to invite a state of dissociation where consciousness is divided. The ability to separate awareness of sensation, memory, time, behavior etc., is not only part of daily experience (e.g., shifting the gears of a car without awareness, daydreaming), but it can be created by hypnotists and imaginative patients. Such an ability is thought to facilitate the use of hypnosis in management of painful conditions and anxiety. Since the higher cognitive faculties are blocked from elaborating pain or anxiety signals, emotional or behavioral responses are muted or stopped.

There are a number of clinical, and perhaps nonspecific, factors that facilitate or hinder the response of patients to hypnosis. Patients must be motivated to follow the suggestions of the hypnotist. A fearful, overly defensive, unwilling person will rarely succeed with hypnosis and one who feels safe, valued, and cared for by an 'expert' most likely will. Research indicates that hypnotizability appears to be a rather normally distributed, stable, trait. Although there are some that claim that anyone can achieve some benefit from hypnotic interventions, many hypnosis experts find that those with heightened ability are the most helped. Certain conditions favor suggestion such as ambiguity, uncertainty, novelty and hyperemotionality. Good hypnotic technique endeavors to recruit or develop some of these elements.

Hypothalamic–Pituitary–Adrenal Axis, Psychobiology of

This article will examine the role of psychological factors on the regulation of the hypothalamic–pituitary–adrenal (HPA) axis. The HPA axis regulates the primary endocrine responses to stress, which in turn regulate major metabolic and neural processes. The major principle that will be elaborated is that both activation and inhibition of the HPA axis are in part modulated by psychological factors. We will examine first specific interventions that occur during development that permanently alters the responses to stress. Second, we will discuss some of the mechanisms whereby responses to stress can be modulated behaviorally.

1. The HPA Axis

The secretion of glucocorticoids (GC) by the adrenal cortex under conditions of stress is an important mammalian mechanism of adaptation. The response to stress involves complex interactions between the neurosecretory hypothalamic neurons, the corticotrophs of the anterior pituitary, and the adrenal glands. Various neural afferents mediating the stress response converge at the parvocellular neurons of the hypothalamic parvocellular nucleus (PVN). The cell bodies of the PVN neurons are one of the primary sites of the synthesis of corticotropin-releasing factor (CRF) and project to the median eminence. Activation of the PVN neurons by a variety of different stimuli induces release of CRF into the portal capillaries through which CRF is transported to the anterior pituitary.

The binding of CRF to receptors in the anterior pituitary in turn induces the release of adrenocorticotropin (ACTH). Subsequently, ACTH in the general circulation stimulates the secretion of GC, primarily corticosterone in the rodent and cortisol in primates and humans. GC secreted by the adrenal serve a variety of regulatory and permissive functions which recruit the organism's endocrine, metabolic, immune, and behavioral responses to stress (Munck et al. 1984). Further circulating GCs participate in their own regulation by exerting a negative feedback on stress-induced activity. There are numerous negative feedback sites, which include the PVN, anterior pituitary, and possibly the hippocampus.

The HPA axis is highly responsive to changes in both the interior and exterior environment. One of the more interesting developments in this field is that there appear to be different neural pathways that respond to different stimuli that activate the PVN neurons. Currently, five different pathways have been described (Sawchenko 1991). Certain pathways are activated when visceral and interoceptive signals are involved in the activation of the HPA axis. One of the major pathways involves the structures of the principle components of the limbic region of the telencephalon, which includes the hippocampal formation, the septal, and the amygdaloid nuclear complexes.

Not only have the limbic structure been implicated as possible sites for GC feedback but they are also implicated in the processing of emotional responses (LeDoux et al. 1988). The amygdala plays a pivotal role in the 'fear circuit' described by Davis (1992). The hippocampus also appears to play an important role in the processing of affective information. Given the importance of affective stimuli in the activation of the HPA axis it is not surprising that there should exist neural pathways responsible for processing this class of stimuli.

2. *Early Experience*

After more than four decades of research using a variety of animal species it has been well established that the effects of early experience are diverse and pervasive. One early experience manipulation, early handling, modifies the HPA axis so as to permanently alter the endocrine (ACTH and GC) response to stress and to modify the neural components of the HPA axis that are involved in regulating the stress response. The early handling paradigm involves an apparently innocuous manipulation in which the experimenter removes the rat pup from its mother once daily, placing it either alone or as a group in a novel container for a few minutes and then reuniting it with the dam in the home cage. Early handling is most effective if initiated between birth and 14 days postnatally.

The early studies demonstrated that early handling profoundly altered the GC response to several different challenges. In general, as adults, the magnitude of the GC response was reduced and further, the GC response in the early handled rats returned to basal levels more rapidly indicating a more efficient negative feedback mechanism (Batnagar et al. 1996). The initial studies were limited by the technologies available at that time. With technological advances it became possible to study other components of the HPA axis. Thus, early handled animals showed a reduction in ACTH secretion following stress when compared to non-handled rats. Early handled rats also have significantly lower basal levels of CRH gene expression (Plotsky and Meaney 1993).

Another well-documented effect of early handling is to permanently modify the GC receptors in the hippocampus. In the central nervous system (CNS), two types of GC receptors are found and each functions to regulate different aspects of HPA activity (DeKloet 1991). The mineralocorticoids (MR) are involved in the tonic regulation of the HPA axis, that is, circadian rhythms. In contrast, the glucocorticoid receptor (GR) appears to be an important extrahypothalamic site of an inhibitory feedback effect on HPA activity although it is not clear that the hippocampus is a negative feedback site for GC. Occupancy of available GRs seems to be required to restrain stress induced ACTH secretion.

In an extensive series of studies Meaney and coworkers (see Batnagar et al. 1996) have established that early handled animals have an increase in hippocampal GR sites as well as increased GR mRNA. Early handling has little effect on the MRs. It has been postulated that the increase in GR density increases the sensitivity of the hippocampus to circulating GCs, enhancing the efficiency of the negative feedback inhibition of HPA activity, thus permitting early handled animals to reduce the poststress levels of ACTH and GC.

All the current information on the effects of early handling on the HPA axis indicates that manipulation permanently modifies several of the important components of neural circuitry that regulate the HPA axis. Thus, the effects of early handling can be attributed largely to alterations in the CNS mechanisms that regulate ACTH and GC secretion.

One hypothesis proposed to account for the effects of early handling is that handling affects the pup indirectly by producing changes in the behavior of the dam (the maternal mediation hypothesis). Maternal behavior parallels and compliments the need of the developing organism and the parent–offspring relationship is most intense during the preweaning period when the dam's role in regulating vital neonatal functions is fundamental. Disturbances of mother–infant relationships by brief periods of maternal separation alters the pup's behavior in a manner that would elicit increased pup-directed behavior by the dam, such as licking, grooming, retrieving, etc. This increase in pup-directed behavior could bring about pervasive changes in regulation of the HPA axis. Using a more naturalistic approach (Caldji et al. 1998) demonstrated that pups who received high levels of licking and arched-back nursing from their dams showed the characteristic pattern of HPA activity that closely resembled the early handled pups.

Plotsky and Meaney (1993) have used relatively long postnatal maternal separations as a model of adverse early experience. Thus, pups were separated from the dams for 3 hours daily beginning on day 2 and continuing through day 14. When compared to pups that had experienced short periods on maternal separation GC levels were significantly higher fol-

lowing restraint and further, basal levels of CRH gene expression in the PVN were elevated. Other investigators have used more extended periods of separation, that is, 8 hours every other day, and have also found that HPA activity is altered in the direction of a more exaggerated response.

Thus, it appears as though the HPA axis can be modified bidirectionally depending upon the length of the separation. It is possible that the signals emitted by the pup are different following brief vs. a more prolonged separation and that the effects on maternal behavior are manifested in very different ways resulting in seemingly paradoxical outcomes. The data do clearly indicate that early experiences do result in a permanent and apparently irreversible influence on the adult HPA axis regardless of the direction of these changes.

3. *Coping*

Based primarily on the initial observations of Selye (1956), it became clear that the endocrine system and more specifically increased secretion of the so-called stress hormones ACTH and GC was a critical component of the response to stress. Selye also described these responses as nonspecific. Thus, regardless of the stimulus that provoked these responses they were general and occurred nonspecifically to any or all challenges.

Mason (1968) presented a point of view which differed radically from the widely-held beliefs of the time. Mason emphasized a crucial role for 'the psychological approaches involved in the emotional or arousal reactions to threatening or unpleasant factors in the life situation as a whole.' He argued that the nonspecific response to stress is primarily behavioral or psychological in nature. However, although Mason recognized the importance of psychological factors associated with the endocrine activation following stress he did not elaborate on what some of these dimensions could be.

In an attempt to further specify the psychological aspects of the endocrine stress response Levine and Ursin (1990) invoked a cognitive approach in which the lack of information (uncertainty) resulted in the activation of the HPA axis. Uncertainty could be a function of the absence of information and/or the failure to fulfill an expected outcome or to avoid a negative one. The absence or loss of control and the lack of predictability also creates uncertainty which when processed by the brain activates the neurobiological events that result in increased HPA activation.

3.1 *Control*

One of the most critical psychological dimensions that contribute to the regulation of the HPA axis is control. In a remarkable series of experiments Weiss (1972) convincingly demonstrated the importance of control in reducing the physiological consequences of exposure to stress. Using gastric ulceration as the measure of stress it was shown that rats that could make a response that terminated an electric shock showed a marked reduction in the number of gastric ulcers when compared to a 'yoked' group that received identical shocks but were not permitted to respond. This initial experiment clearly demonstrated the importance of control. In further studies two other psychological operations also ameliorated the extent of gastric ulceration. These were predictability and feedback. These three elements, control, predictability, and feedback, all serve to reduce arousal and thus HPA activity and are postulated to contribute to the process of coping.

There are many examples of the importance of control in modifying the response of the HPA axis. Rats permitted to escape from shock showed a reduction in GC levels although they received shock on every trial (Davis 1977). In contrast repeated exposure to inescapable shock resulted in increased secretion of GC (sensitization). Hanson et al. (1976) exposed Rhesus monkeys to a loud noxious noise. One group of monkeys was allowed to control the duration of the noxious stimulus by making a lever press response to terminate the noise. A comparable group of monkeys were exposed to the identical duration of the noise, but were not permitted to regulate the duration. The monkeys that exercised control showed levels of GC that were similar to nonnoise exposed monkeys. In contrast, the 'yoked' control animals exhibited extremely high levels of GC. In this experiment the monkeys that could control the duration of the noise were re-exposed to the noise on a subsequent day but on this occasion they were not permitted to exercise control. Their GC levels were now elevated and exceeded those of the noise alone group. This finding represents an example of yet another psychological dimension involved in the regulation of HPA activity, the failure of expectancies.

3.2 *Expectancies*

Physiological activation in response to uncertainty is a central component of the model presented by Sokolov (1963). Although this model was an attempt to account for the neural mechanisms involved in the process of habituation, a broader interpretation of this model could also account for why uncertainty would result in the activation of the HPA axis. When a subject is presented with a stimulus that not been previously experienced or is unexpected an orienting response occurs. Both behavior and physiological responses are elicited by the stimulus. Amongst the number of physiological components of the orienting response is HPA activation (Hennessy and Levine 1979).

If the stimulus is repeated frequently the response tends to diminish and eventually disappears. Sokolov's

model is based on a matching system in which new stimuli or situations are compared with a representation in the CNS of prior events. This matching process results in the development of expectancies. Uncertainty can, therefore, be viewed as a violation of expectancies. From this perspective it is the evaluation of the event or events by the individual that is crucial in determining whether that event will elicit a stress response resulting in HPA activation.

(Bolles 1972) identified two distinct types of expectancies, stimulus and response outcome expectancies. Stimulus expectancies refers to the storage of information that one stimulus precedes another (classical conditioning). Response outcome expectancies results from the learning that a particular response results in a positive outcome, that is, obtaining reinforcement or avoiding a negative outcome. The development of positive outcome responses is dependent on some of the coping mechanisms previously described. Thus, if an organism can exercise control by making an active response that leads to a predictable outcome this information will be stored in the CNS as a positive outcome expectancy.

Thus, when rats can obtain reinforcement on a highly predictable schedule removal of the reinforcement (extinction) produces a marked elevation in GC. Further when rats are shifted from a highly predictable schedule to an unpredictable schedule of reinforcement GC are again elevated. In contrast when the shift in reinforcement schedules is from low predictability to high predictability GC levels significantly decrease. More recently a similar outcome has been reported in primates. Squirrel monkeys were required to obtain food in a laboratory model of foraging. When the foraging demand was high and food was available unpredictably cortisol levels were persistently elevated. When these monkeys were shifted to a low demand foraging schedule cortisol levels decreased rapidly. The effects of violations of expectancies are also observed in aversive situations. Rats that successfully learned to avoid shock show a progressive decrease in GC as their performance reached asymptote. However, if the animals are prevented from making the avoidance response, although shock is not administered, GC levels are once again elevated.

3.3 Social Factors

There is a large literature that has documented the importance of social behavior and social relationships on the HPA axis. At first glance these may appear to be a separate class of events. They can be, however, subsumed within the more general theories of stress and coping. An extensive series of studies using nonhuman primates (Levine and Coe 1988) demonstrated that at almost every point in development social variables can modulate the HPA axis, both in terms of increased activity and the inhibition of the response to environmental perturbations. Disruptions of social relationships invariably result in increased HPA activity. Conversely, the presence of familiar social partners can reduce, and at times eliminate, the normal increase in HPA activity in squirrel monkeys. One of the most robust increases in GC levels is observed when infant squirrel monkey are separated from their mothers and other members of their natal social groups. These responses occur even when the infants are separated repeatedly and show no signs of habituation. If the infant is separated from the mother and permitted to remain with their familiar social partners the response is markedly reduced. This occurs only when mother infant dyads are group housed. When the dyad is housed individually the magnitude of the GC response is similar regardless of whether the infant or the mother was removed from the home cage. This phenomenon is often called social buffering, and has been demonstrated in the adult monkeys. Thus, when adult squirrel monkeys were exposed to a natural predator (a live Boa Constrictor) placed in a wire mesh enclosure above their cage, individually housed animals show a striking elevation of plasma cortisol, whereas if the monkeys are exposed to the snake when group housed cortisol levels do not differ from basal levels. Other experiments using different paradigms have demonstrated that the presence of social partners ameliorates the HPA response to stress.

These findings are consistent with the proposed effects of control and feedback on the HPA axis. For the infant, the mother is the primary source of emotional security and serves to reduce the infant's arousal levels. Thus, the infant's capacity to achieve contact and maintain proximity to the mother is perhaps the infant's earliest experience with the use of control. For the adult, the availability of stable and familiar social relationships provides a set of predictable outcomes due, in part, to a prior history of social interactions. Therefore, the predictability of these social interactions would serve to reduce uncertainty.

4. Summary

The contemporary view of stress largely is characterized as an imposition model. The voluminous number of studies in which severely traumatic stimuli were used to elicit HPA activation supports this view. However, there are numerous examples of HPA activation being elicited by the omission of a predictable outcome (frustration) or the absence of a salient feature in the environment such as maternal loss. In both classes of events the common element appears to be the lack of information (uncertainty) related to obtaining positive outcomes or the avoidance of negative outcomes.

The view presented in this article focuses on the capacity of the brain to process information pertaining to obtaining of positive outcomes and/or the avoidance

of negative outcomes. Stimuli that induce HPA activation do so as a consequence of the lack of information (uncertainty) concerning the obtaining of positive outcomes or the avoidance of negative outcomes.

Hypothalamus

1. Introduction

The hypothalamus is a small brain structure (0.4 percent of total brain volume) primarily of gray matter providing important functions which can be summarized to maintain homeostasis. From an evolutionary perspective, the hypothalamus can be considered a very old component of the central nervous system.

Historically, the first observations concerning hypothalamic functions were described for the control of the pituitary gland since endocrinological abnormalities (e.g., due to tumors) were more obvious than disturbances of autonomic functions, which are also under hypothalamic control. In 1930 Ernst and Berta Scharrer developed the concept of 'neurosecretory' hypothalamic cells derived from their morphological structure, and this dramatically stimulated subsequent research. It became obvious that the hypothalamus combines characteristics of glands and neuronal tissue. However, the focus of interest remains in investigations of hypothalamic control via the pituitary gland, which led to the discovery and chemical characterization of vasopressin and oxytocin in the early 1950s. The finding by Schally and Guillemin that the hypothalamus controls the secretion of other fundamentally important hormones such as TSH, FSH, ACTH, and LH was honored by the Nobel prize in 1977.

2. Neuroanatomical Localization and Structure

The hypothalamus is located in the diencephalon. It is laterally bounded by the subthalamus, medially by the third ventricle, rostrally by the lamina terminalis, caudally by the mesencephalon, and dorsally by the thalamus.

Although these boundaries are well defined, the anatomical structure of the hypothalamus is much more complex. From stimulation and lesion studies it is known that the hypothalamus consists of several

Figure 1

neuronal clusters referred to as nuclei (see Fig. 1). Previous attempts at describing the anatomical relationships between these nuclei made use of a hexagon (see Fig. 2).

Based on the systematic topography of the hypothalamus given in Fig. 1, several areas can be distinguished. Most of the nuclei are located in the midline, medial, and lateral areas, which are themselves divided into supraoptic, tuberal, and mammillary sections. The preoptic nuclei are located in the preoptic region of the medial zone. The preoptic region is bounded by the septum in both directions. The anterior (supraoptic) region contains the anterior nucleus, the supraoptic nucleus, and the paraventricular nucleus. The intermediate (tuberal) region consists of the dorsomedial nucleus, the ventromedial nucleus, and the infundibular or arcuate nucleus. In the posterior region of the medial zone, the posterior nucleus and the mammillary nucleus can be identified. Finally, the lateral zone consists of the lateral hypothalamic nucleus. In the area of the periventricular zone many neurons have been identified as having

Figure 2
Schematic diagram showing the anatomical relationships between different nuclei of the hypothalamus as a hexagon (after Sladek and Sladek 1990)

fundamental importance for the secretion of releasing or inhibiting neurohormones. However, a clear distinction of the different nuclei has not been given for this area.

3. *Functions*

Although the hypothalamus can be considered a small brain structure, its functions are widespread and of fundamental importance. It is known that the hypothalamus is responsible for at least seven categories of functions. These are: the regulation of the anterior pituitary; the control of water balance; the regulation of autonomic responses; the regulation of feeding; the regulation of drinking; the regulation of reproductive functions; and the reinforcement and control of circadian functions. For an understanding of these functions, the characterization of hypothalamic inputs from other systems is essential (for a review, see Risold et al. 1997).

Retinal ganglion cell axons project through the retinohypothalamic tracts to the ventral regions of the suprachiasmatic nuclei (SCN). It is known that these nuclei couple the *biological rhythms* to the light/dark cycle. These rhythms can be divided into several categories depending on their frequency. Events repeated nearly every 24 hours are defined as circadian rhythms (e.g., changes in concentration of ACTH and cortisol). Periods with lower frequencies are considered circa-annual or infradian (e.g., season-dependent behavioral or metabolic changes or the menstrual cycle). Those with shorter frequencies (faster occurrence of periods) are defined as ultradian rhythms (e.g., respiration). The hypothalamus controls infradian and circadian rhythms. The important role of the SCN can be demonstrated by lesion studies in

which animals lost rhythmicity. The SCN projects to the paraventricular nucleus, which is connected to the spinal cord by efferent fibers. Noradrenergic fibers project to the pineal gland and affect the production and release of melatonin, concentrations of which markedly depend on the light/dark cycle. Moreover, recent studies have demonstrated that the SCN is involved in the regulation of autonomic responses (changes in heart rate) after brief stimulation by a flash of light.

Interestingly, the lateral hypothalamus seems to be a target for pheromonal stimuli derived from the main olfactory inputs. Moreover, projections from the medial amygdalar nucleus, as well as from the bed nuclei of the stria terminalis, provide accessory olfactory signals to some regions of the medial zone of the hypothalamus. This close connection to the vomeronasal organ is not fully understood with respect to its physiological function. However, two different pathways including amygdalar projections seem to be involved in the modulation of sexual and/or aggressive-defensive behavior.

Another source of 'information' is derived from viscerosensory and somatosensory signals. Most of these projections into the lateral hypothalamus are derived from the solitary tract and the parabrachial nuclei, which both receive visceral information form cranial nerves. However, there is evidence that the periventricular zone is an important target for projections providing 'visceral' signals derived from the brain stem involving catecholaminergic fibers. It is a likely assumption that these projections may provide information inducing the regulation of complex processes such as ingestive behavior. The lateral hypothalamus has been identified as a main target for spinal cord fibers which send information concerning sensations of touch or pain. The presence of fibers presenting auditory information has been demonstrated for the ventromedial nucleus of the hypothalamus. It has been suggested that these projections are important for regulation of lordosis and milk-ejection in lactating females. Somatosensory signals including nociceptive stimuli seem to reach the hypothalamus by activating neurons of the spinohypothalamic tract or involving the catecholamine system located in the brain stem. As a consequence, norepinephrine is released from the paraventricular nucleus (PVN) of the hypothalamus. In general, catecholaminergic projections to the PVN may play a pivotal role in stress responses by activating neurosecretory functions of the hypothalamus, as indicated by a reduced or blocked activation of the hypothalamus–pituitary–adrenal (HPA) axis after lesions of catecholaminergic fibers of the brain stem. There is agreement that the hypothalamus is one of the most important brain structures preparing the individual for appropriate reactions when faced with threat or other types of stress. One set of reactions concerns the cardiovascular system, which is controlled by the hypothalamus via the autonomic nervous system, especially the vagus nerve and/or the initiation of hormone secretion. The fundamental role of the hypothalamus in orchestrating multiple influences on the pituitary will be discussed later.

Hypothalamic control of thermoregulation can be considered an excellent example for maintaining homeostasis. A center responsible for heat dissipation has been identified in the preoptic area and the anterior hypothalamus. The main physiological consequences of an activation of these neurons is suppression of shivering, panting, and vasodilation of cutaneous vessels with the common goal of reducing temperature. On the other hand, conservation of temperature seems to be mediated by the posterior hypothalamic region. Reactions to maintaining or increasing temperature are shivering, vasoconstriction, and suppression of panting. In his early work Bligh (1966) suggested the presence of two regulatory systems. One is mainly responsible for maintaining the normal variation of body temperature, whereas the other becomes activated as a consequence of more serious increases or decreases in body temperature. It is known that the neurons involved are sensitive to higher (37 °C–40 °C) and lower (32 °C–36 °C) than normal temperatures. Afferent pathways transport peripheral information (e.g., cooling or heating of the skin) to these neurons, initiating the regulatory responses. However, one has to realize that the hypothalamus is not the only structure involved in thermoregulatory responses. It is known that in 'spinal' animals (brain disconnected from spinal cord) some basic thermoregulatory responses are still intact, indicating the presence of lower centers for regulation. There is agreement that thermoregulation involves several regulatory circuits acting on different levels, with the hypothalamus the most sensitive one (Satinoff 1978).

Early lesion studies had revealed that the hypothalamus mediates ingestive behavior. Distinct areas responsible for feeding have been identified in the ventromedial nucleus as a kind of satiety center, and in the lateral hypothalamus as a feeding center. Lesion of the ventromedial nucleus results in hyperphagia and polydipsia, whereas stimulation leads to the opposite behavior. There is some evidence that the paraventricular nucleus affects the vagus nerve via its projections to the brain stem, and that the lesions result in a disturbed parasympathetic control of the liver and the pancreas. A closer look reveals that after lesion of the ventromedial nucleus, hyperphagia occurs with temporary dramatic weight gain. However, after a state of obesity has been reached, ingestive behavior becomes normalized and no further weight gain can be observed, although the hypothalamic function is still disturbed. This clearly demonstrates that further brain structures are involved in the regulation of ingestive behavior.

For the lateral hypothalamus, stimulation leads to hyperphagia, and lesions lead to aphagia. However, the mechanisms involved are much more complex

since animals with lesions of the lateral hypothalamus start to eat after an appropriate period of time. Again, other brain areas such as the amygdaloid nuclei, the frontal cortex, and the substantia nigra are involved in regulation of feeding. More recently it became clear that leptin produced by fat cells is important for the regulation of ingestive behavior. Leptin receptors have been identified in the lateral hypothalamus (Hakansson et al. 1998), the supraoptic arcuate, and the paraventricular nuclei. A low quantity of leptin can be considered a signal for increased fat intake. Peripheral (derived from the gut in response to food intake), as well as central (probably produced within the hypothalamus), cholecystokinin seems to play an important role as a satiety hormone. However, neuropeptide Y, known to stimulate appetite, is found in the arcuate nucleus, the medial preoptic area, and the paraventricular nuclei of the hypothalamus. Application of neurotransmitters or neuropeptides into the paraventricular nucleus leads to preferences for different food components. While norepinephrine is accompanied by intake of fat and carbohydrates, galanin stimulates the intake of fat. Leptin suppresses both stimulations of ingestive behavior induced by NPY and by galanin. Orexin has been discovered as a protein that is exclusively produced in the lateral hypothalamus. This neuropeptide markedly increases eating behavior after injection into the hypothalamus.

The most common reason for the induction of thirst is loss of water due to sweating, urination, or respiration. This osmotic thirst, rather than the thirst caused by hypovolemia, is regulated by the hypothalamus. The basis for this is the presence of osmoreceptors in hypothalamic cells. In fact, injection of salty fluid into the hypothalamus induces drinking. Neurons responding to changes in osmotic pressure have been identified in the preoptic area, the anterior hypothalamus, the supraoptic nucleus, and the circumventricular organ. As a consequence of stimulation, AVP (vasopressin, antidiuretic hormone) is released to stop further loss of water. Moreover, increased concentrations of angiotensin II and stimulation of baroreceptors are sensitive signals to the preoptic area resulting in drinking behavior.

Another important function of the hypothalamus is coordination and control of sexual behavior. For female behavior, it is known that estradiol, a sex steroid produced during the ovulatory cycle, specifically stimulates neurons of the ventromedial hypothalamus. These neurons exhibit receptors for estrogen and progesterone, and they are mainly responsible for inducing so-called lordosis behavior. This signals the receptivity of the female to the male population by several postural and physiological signs. It can be concluded that the ventromedial hypothalamus is important for controlling changes in steroid hormone concentrations and, furthermore, that it activates several pathways at the appropriate time during the ovulatory cycle to induce the lordosis response. It is believed that estrogens can activate the hypothalamic receptors for progesterone. During pregnancy, when progesterone levels are very high, a down-regulation of these receptors appears with a decrease in sexual receptivity. The medial preoptic area of the hypothalamus is enriched with steroid-sensitive neurons, and evidence has been published that lesions in this area completely abolish male copulatory behavior in many species. The medial preoptic area is a target for pheromonal stimulation as well. Vomeronasal information reaches the amygdala, which sends signals to the medial preoptic area, indicating that this specific hypothalamic area plays a salient role in coordinating sensory and motor responses important for copulation. Both aspects are initiated by levels of testosterone which, interestingly, affect neuronal targets after aromatization into estrogen. The preoptic area of the hypothalamus is characterized by a sexual dimorphism, which may explain the differences in male vs. female sexual behavior. Taken together, the preoptic area of the hypothalamus is of fundamental importance for controlling sexual behavior, moreover, for sexual orientation as well. Interestingly, a clear-cut sexual dimorphic nucleus of the preoptic area could be identified as being larger in males than in females (Gorski et al. 1978). The reason for this dimorphism is brought about by testicular androgens (testosterone), which obviously influence the development of this specific nucleus within the preoptic area of the hypothalamus.

From animal studies, it is known that the medial preoptic area plays a key role in mediating maternal behavior (Numan 1978). Lesions in that area abolished nest-building and pup care in animals. Important pathways mediating these effects are the connections between the medial preoptic area and the ventral tegmental area. Disruptions of these connections lead to the same effects as described for lesions of the medial preoptic area. Estrogen receptors in this hypothalamic area are of major importance for regulating maternal behavior, as demonstrated by direct injections of estrogen or by suppression of this behavior after treatment with specific antagonists. Moreover, the stimulation of maternal behavior has been demonstrated for other hormones such as progesterone, oxytocin, and prolactin as well. However, more recent reports suggest the involvement of additional hypothalamic areas such as the ventromedial part for mediating maternal behavior.

A last behavioral component mediated in part by the hypothalamus is aggressive behavior. The first reports demonstrating that stimulation of the hypothalamus induces aggressive behavior were published about 70 years ago (Hess 1928). However, the precise mechanisms of these responses are still unknown. There is evidence that the lateral and frontal area of the ventromedial nucleus is of major importance. Hypothalamic aggression can be facilitated by testosterone, which indicates the initiation of offensive

Table 1
Hypothalamic-releasing hormones stimulating tropic hormones of the pituitary

Hypothalamus	Pituitary
Gonadotropin-releasing hormone (GnRH)	Follicle-stimulating hormone Luteinizing hormone
Thyrotropin-releasing hormone (TRH)	Thyroid-stimulating hormone (TSH)
Corticotropin-releasing hormone (CRH)	Adrenocorticotropic hormone (ACTH)
Somatocrinin Somatostatin	Growth hormone (GH)
Prolactin-releasing peptide Prolactin-inhibiting factor	Prolactin

rather than defensive behavioral patterns, since androgens are ineffective in defensive behavior. Other data from the literature support the view that the hypothalamic type of aggression is offensive because behavior is not suppressed by benzodiazepines or alcohol (which is not true for defensive aggression) but by serotonin agonists, which are more potent in reducing offensive behavior. Interestingly, many peripheral hormones seem to stimulate offensive aggression by affecting hypothalamic neurons. Of special interest is the finding that injections of cortisol into the hypothalamus of golden hamsters induce aggressive behavior. This may explain why stress, which activates the HPA-axis, resulting in increased levels of glucocorticoids, is frequently associated with aggression.

One of the most important functions of the hypothalamus is the orchestration of hormone regulation. Nuclei from the hypothalamus, such as the supraoptic nucleus and the paraventricular nucleus, are sources for the two hormones oxytocin and arginine-vasopressin (often called antidiuretic hormone, ADH). These hypothalamic areas elicit nerval impulses to the posterior pituitary in order to release the hormones into the circulation. The important function of vasopressin for water balance has already been discussed. Oxytocin has several functions concerning reproductive and parental behavior (see above). Furthermore, oxytocin stimulates contractions of the uterus and is involved in the milk ejection reflex. However, this hormone is present in males as well, and it has been suggested that oxytocin is of importance for social contacts and attachment.

Another fundamental influence on hormone secretion can be seen in the hypothalamic control of the anterior pituitary. The mechanism of regulating anterior pituitary hormone release is quite different from the hypothalamic influence on the posterior pituitary. While neurons from various hypothalamic nuclei transport the hormones along the axons into the posterior pituitary and release them after specific stimulation, neuroendocrine or neurosecretory cells of the hypothalamus influence the anterior pituitary. They release hormones and transport them into the medium eminence; after stimulation by action potentials, these hormones are transported into the hypothalamic pituitary portal system. These releasing hormones reach the anterior pituitary and stimulate other cells to release tropic hormones into the blood stream; these are different from the releasing hormones provided by the hypothalamus. Table 1 shows the releasing hormones from the hypothalamus, and corresponding tropic hormones derived from the pituitary.

The stimulating effects of releasing hormones derived from the hypothalamus on secretory cells of the pituitary are of fundamental importance since they regulate energy metabolism (e.g., TRH), sexual and reproductive functions (e.g., GnRH), and growth, as well as behaviors related to adaptation (e.g., CRH) and homeostasis. The precise functions of these tropic hormones secreted in the pituitary, as well as their endocrine effects at the levels of target organs, are not within the scope of this entry. However, it should be noted, as described above, that the hypothalamus is the target for many of these peripheral hormones, leading to the modulation of behavior on the one hand and providing complex negative feedback loops for controlling further secretion of hormones on the other.

4. *Summary*

The hypothalamus can be considered to be a brain structure which integrates the complex interactions between hormonal and behavioral processes with the purpose of maintaining homeostasis and survival of the individual and the species (Freeman 1995). It is involved in many different fundamental processes—not only in the regulation of metabolism and hormones, but also in feeding, drinking, reproductive, maternal, and aggressive behavior. It has therefore been suggested that one of its major functions is organization of behavior.

Hypothesis Testing in Statistics

A *statistical hypothesis* is a statement about a population parameter, and the two complementary hypotheses in a hypothesis testing problem are called the *null hypothesis* and the *alternative hypothesis*. They are denoted by H_0 and H_1, respectively.

If θ denotes a population parameter, the general format of the null and alternative hypotheses is $H_0{:}\,\theta \in \Theta_0$ and $H_1{:}\,\theta \in \Theta_0^c$ where Θ_0 is some subset of the parameter space and Θ_0^c is its complement. Typically, a hypothesis test is specified in terms of a test statistic $W(X_1, \ldots, X_n) = W(\mathbf{X})$, a function of the sample. The sample space for W is partitioned into the *rejection region*, R, and its complement, the acceptance region. If $W \in R$ is observed, the null hypothesis H_0 is rejected and the decision is made that H_1 is true. If $W \notin R$, H_0 is accepted as true.

For example, in a study to examine the factors that influence a student's success at completing a four-year college, one factor of interest might be socioeconomic status (SES). If, for simplicity, we just have two groups (high SES and low SES), and the success probabilities of the respective groups are p_h and p_l, then a hypothesis test of interest may be $H_0{:}\,p_h = p_l$ vs. $H_1{:}\,p_h > p_l$.

This is an example of a one-sided test, in which the alternative hypothesis specifies a direction. In contrast, we may consider the two-sided test $H_0{:}\,p_h = p_l$ vs. $H_1{:}\,p_h \neq p_l$ in which no direction is specified in the alternative. If we let $\hat{p}_h$ and $\hat{p}_l$ denote the observed success rates in the two SES classes, the one-sided test would reject the null hypothesis if $\hat{p}_h - \hat{p}_l$ is big, while the two-sided test would reject the null hypothesis if $\hat{p}_h - \hat{p}_l$ is either big or small.

A hypothesis test of $H_0{:}\,\theta \in \Theta_0$ versus $H_1{:}\,\theta \in \Theta_0^c$ might make one of two types of errors. If $\theta \in \Theta_0$ but the hypothesis test incorrectly decides to reject H_0, then the test has made a *Type I error*. If, on the other hand, $\theta \in \Theta_0^c$ but the test decides to accept H_0, a *Type II error* has been made. In our example, in testing $H_0{:}\,p_h = p_l$ versus $H_1{:}\,p_h > p_l$, if we conclude that $p_h > p_l$ but, in fact, $p_h \leqslant p_l$ we have made a Type I error.

1. Constructing Tests

There are many methods of deriving test statistics for a hypothesis test, a few of which follow.

1.1 Likelihood Ratio Tests

The likelihood ratio method of hypothesis testing is related to maximum likelihood estimators (MLE) (discussed in *Estimation: Point and Interval*). Suppose that we have a sample $X_1, \ldots, X_n$, where the X_i are independent, each with distribution $f(x \mid \theta)$. The observed values of these random variables are denoted by $\mathbf{x} = (x_1, \ldots, x_n)$, with likelihood function $L(\theta \mid \mathbf{x})$ given by

$$L(\theta \mid \mathbf{x}) = \prod_{i=1}^{n} f(x_i \mid \theta) \tag{1}$$

The *likelihood ratio test statistic* for testing $H_0{:}\,\theta \in \Theta_0$ vs. $H_1{:}\,\theta \in \Theta_0^c$ is

$$\lambda(\mathbf{x}) = \frac{\sup_{\Theta_0} L(\theta \mid \mathbf{x})}{\sup_{\Theta_0} L(\theta \mid \mathbf{x})} \tag{2}$$

A likelihood ratio test (LRT) is any test that has a rejection region of the form $\{\mathbf{x}{:}\,\lambda(\mathbf{x}) \leqslant k\}$, where k is any number satisfying $0 \leqslant k \leqslant 1$.

If we interpret the likelihood function as measuring how likely the values of θ are, then we see that the LRT

is comparing the plausibility of the θ values in the null hypothesis with those in the alternative. Small values of the LRT statistic are then interpreted as being evidence against H_0, and lead to rejection.

If the null hypothesis consists of a single value θ_0, and the alternative is everything else, then the LRT statistic is simply $\lambda = L(\theta_0 | \mathbf{x})/L(\hat{\theta} | \mathbf{x})$, where $\hat{\theta}$ is the MLE of θ.

Example. Let $X_1, \ldots, X_n$ be a random sample from a $\mathrm{n}(\theta, 1)$ population. The LRT statistic for testing H_0: $\theta = \theta_0$ versus $H_1: \theta \neq \theta_0$ is

$$\lambda(\mathbf{x}) = \frac{L(\theta_0 | \mathbf{x})}{L(\bar{x} | \mathbf{x})} = \frac{(2\pi)^{-n/2} \exp[-\sum_{i=1}^{n} (x_i - \theta_0)^2/2]}{(2\pi)^{-n/2} \exp[-\sum_{i=1}^{n} (x_i - \bar{x})^2/2]} \tag{3}$$

If $T(\mathbf{X})$ is a sufficient statistic for θ then, as with maximum likelihood estimators, the LRT statistic is a function of T. That is, $\lambda(\mathbf{x})$ depends on $\mathbf{x}$ only through $T(\mathbf{x})$.

1.2 Bayesian Tests

The Bayesian paradigm prescribes that the sample information be combined with the prior information using Bayes' Theorem to obtain the posterior distribution $\pi(\theta | \mathbf{x})$. All inferences about θ are now based on the posterior distribution. In a hypothesis-testing problem, the posterior distribution may be used to calculate the probabilities that H_0 and H_1 are true.

One way a Bayesian hypothesis tester may choose to use the posterior distribution is to decide to accept H_0 as true if

$$\frac{P(\theta \in \Theta_0 | \mathbf{X})}{P(\theta \in \Theta_0^c | \mathbf{X})} \geqslant k \tag{4}$$

for some constant k, and to reject H_0 otherwise. Equivalently, we can reject H_0 if $P(\theta \in \Theta_0^c | \mathbf{X})$ is greater than a specified number.

Example. Let $X_1, \ldots, X_n$ be independent identically distributed (i.i.d.) $\mathrm{n}(\theta, \sigma^2)$ and let the prior distribution on θ be $\mathrm{n}(\mu, \tau^2)$ where σ^2, μ, and τ^2 are known. Consider testing $H_0: \theta \leqslant \theta_0$ vs. $H_1: \theta > \theta_0$ where we decide to accept H_0 if $P(\theta \in \Theta_0 | \mathbf{X}) \geqslant P(\theta \in \Theta_0^c | \mathbf{X})$. After some calculation, we find that H_0 will be accepted as true if

$$\bar{X} \leqslant \theta_0 + \frac{\sigma^2(\theta_0 - \mu)}{n\tau^2} \tag{5}$$

1.3 Union–Intersection and Intersection–Union Tests

In some situations, tests for complicated null hypotheses can be developed from tests for simpler null hypotheses. The union–intersection method of test construction might be useful when the null hypothesis is conveniently expressed as an intersection, say $H_0: \theta \in \bigcap_{\gamma \in \Gamma} \Theta_\gamma$, where Γ is an arbitrary index set. If tests are available for each of the problems of testing $H_{0\gamma}: \theta \in \Theta_\gamma$ vs. $H_{1\gamma}: \theta \in \Theta_\gamma^c$ where the rejection region for the test of $H_{0\gamma}$ is $\{\mathbf{x}: T_\gamma(\mathbf{x}) \in R_\gamma\}$, then the rejection region for the union–intersection test is

$$\bigcup_{\gamma \in \Gamma} \{\mathbf{x}: T_\gamma(\mathbf{x}) \in R_\gamma\} \tag{6}$$

The rationale is that if any one of the hypotheses $H_{0\gamma}$ is rejected, then H_0 must also be rejected.

A complementary method, the intersection–union method, may be useful if the null hypothesis is conveniently expressed as a union. Suppose we wish to test the null hypothesis $H_0: \theta \in \bigcup_{\gamma \in \Gamma} \Theta_\gamma$, and $\{\mathbf{x}: T_\gamma(\mathbf{x}) \in R_\gamma\}$ is the rejection region for a test of $H_{0\gamma}: \theta \in \Theta_\gamma$ vs. $H_{1\gamma}: \theta \in \Theta_\gamma^c$. Then the rejection region for the intersection–union test of H_0 versus H_1 is

$$\bigcap_{\gamma \in \Gamma} \{\mathbf{x}: T_\gamma(\mathbf{x}) \in R_\gamma\} \tag{7}$$

and H_0 is false if and only if all of the $H_{0\gamma}$ are false, so H_0 can be rejected if and only if each of the individual hypotheses $H_{0\gamma}$ can be rejected.

Example. Returning to our example about success in four-year schools, we might argue that there are measures of success other than finishing. For example, yearly income could be used to measure success, and denoting mean incomes in the high and low SES groups by θ_h and θ_l respectively results in the hypothesis test

$$H_0: \theta_\mathrm{h} \leqslant \theta_\mathrm{l} \text{ or } p_\mathrm{h} \leqslant p_\mathrm{l} \quad \text{vs.} \quad H_1: \theta_\mathrm{h} > \theta_\mathrm{l} \text{ and } p_\mathrm{h} > p_\mathrm{l} \tag{8}$$

where the groups are considered different only if H_1 is accepted.

If we have estimators $\hat{\theta}_\mathrm{h}$, $\hat{\theta}_\mathrm{l}$, $\hat{p}_\mathrm{h}$ and $\hat{p}_\mathrm{l}$, a rejection region for the intersection–union test could be given by

$$\{(\hat{\theta}_\mathrm{h}, \hat{\theta}_\mathrm{l}, \hat{p}_\mathrm{h}, \hat{p}_\mathrm{l}): \hat{\theta}_\mathrm{h} - \hat{\theta}_\mathrm{l} > k_1 \quad \text{and} \quad \hat{p}_\mathrm{h} - \hat{p}_\mathrm{l} > k_2\} \tag{9}$$

Thus the intersection–union test decides that the high and low SES groups have different levels of success, that is, H_1 is true, if and only if it decides that each of the individual parameters are different.

The topic of acceptance sampling, in which one tests whether to accept a product based on a collection of

measurements, provides an extremely useful application of an intersection–union test (see Berger 1982).

There are many other methods available for constructing hypothesis tests, methods based on invariance, pivots, robust, or large sample arguments, to name a few. For more on hypothesis testing see Lehmann (1986).

2. Evaluating Tests

As mentioned previously, a hypothesis test might make one of two different kinds of errors. The probabilities of making these errors can be calculated using the power function. If R denotes the rejection region for a test, the power function is

$$P_\theta(\mathbf{X} \in R) = \begin{cases} \text{probability of a Type I error} & \text{if } \theta \in \Theta_0 \\ 1 - \text{the probability of a Type II error} & \text{if } \theta \in \Theta_0^c \end{cases} \tag{10}$$

A good test has power function near one for most $\theta \in \Theta_0^c$ and near zero for most $\theta \in \Theta_0$.

Example. Let $X_1, \ldots, X_n$ be a random sample from a $\mathrm{n}(\theta, \sigma^2)$ population, σ^2 known. The likelihood ratio test of $H_0: \theta \leqslant \theta_0$ vs. $H_1: \theta > \theta_0$ rejects H_0 if $(\bar{X} - \theta_0)/(\sigma/\sqrt{n}) > k$ and has power function

$$P_\theta(\mathbf{X} \in R) = P\left(Z > k + \frac{\theta_0 - \theta}{\sigma/\sqrt{n}} \right) \tag{11}$$

where Z is a standard normal random variable.

After a hypothesis test is done, the conclusions must be reported in some statistically meaningful way. One method of reporting the results of a hypothesis test is to report the size $(\sup_{\theta \in \Theta_0} P_\theta(X \in R))$, α, of the test used and the decision to reject H_0 or accept H_0. The size of the test carries important information. If α is small, the decision to reject H_0 is fairly convincing, but if α is large, the decision to reject H_0 is not very convincing because the test has a large probability of incorrectly making that decision.

Another way of reporting the results of a hypothesis test, one that is data dependent, is to report the p-value. Typically, not one but an entire class of tests are constructed, a different test being defined for each value of α. The p-value for the sample point $\mathbf{x}$ is the smallest value of α for which this sample point will lead to rejection of H_0 (see *Significance, Tests of*).

Because rejection of H_0 using a test with small size is more convincing evidence that H_1 is true than rejection of H_0 with a test with large size, the interpretation of p-values goes in the same way. The smaller the p-value the stronger the sample evidence that H_1 is true.

Many other types of evaluations of test can be done. The theory of most powerful tests shows how to construct best tests under a variety of conditions (see Lehmann 1986 or Casella and Berger 2001, Chap. 8). Hypothesis tests can also be evaluated using risk functions (see *Decision Theory: Classical*), as in Hwang et al. (1992).

3. Asymptotics

For the likelihood ratio test statistic (2), the following general theorem allow us to construct a large sample test.

Theorem 1. *Let $X_1, \ldots, X_n$ be a random sample from a probability distribution function or probability mean function $f(x \mid \theta)$. Under some regularity conditions on the model $f(x \mid \theta)$, if $\theta \in \Theta_0$ then the distribution of the statistic $-2 \log \lambda(\mathbf{X})$ converges to a chi-squared distribution as the sample size $n \to \infty$. The degrees of freedom of the limiting distribution is the difference between the number of free parameters specified by $\theta \in \Theta_0$ and the number of free parameters specified by $\theta \in \Theta$.*

(The 'regularity conditions' are concerned mainly with the existence and behavior of the derivatives (with respect to the parameter) of the likelihood function, and the support of the distribution (it cannot depend on the parameter). See Casella and Berger (2001, Sect. 10.6) or Lehmann (1986, Sect. 8.8) for precise conditions.)

Rejection of $H_0: \theta \in \Theta_0$ for small values of $\lambda(\mathbf{X})$ is equivalent to rejection for large values of $-2 \log \lambda(\mathbf{X})$. Thus,

$$H_0 \text{ is rejected if and only if } -2 \log \lambda(\mathbf{X}) \geqslant \chi^2_{\nu,\alpha}$$

where ν is the degrees of freedom specified in Theorem 1.

As might be expected, Theorem 1 has wide applicability. In particular, it is extremely useful in categorical data analysis (see *Multivariate Analysis: Discrete Variables (Loglinear Models)*).

Other large-sample test constructions are based on asymptotic normality of a point estimator (see *Estimation: Point and Interval*). Suppose we wish to test a hypothesis about a real-valued parameter θ, and $W_n = W(X_1, \ldots, X_n)$ is a point estimator of θ, based on a sample of size n, that satisfies

$$\frac{W_n - \theta}{\sqrt{\mathrm{Var}\, W_n}} \to Z$$

where Var W_n is the variance of W_n and Z is a standard normal random variable. We now have the basis for an approximate test, for example, we would reject $H_0: \theta \leqslant \theta_0$ at level 0.05 if $(W_n - \theta_0)/\sqrt{\text{Var}\, W_n} > 1.645$. Note that Var W_n could depend on θ_0 and we can still use it in the test statistic. This type of test, where we use the actual variance of W_n, is called a *score test*.

If Var W_n also depends on unknown parameters we could look for an estimate S_n^2 of Var W_n with the property that $(\text{Var}\, W_n)/S_n^2$ converges in probability to one. Then, using Slutsky's Theorem (see Casella and Berger 2001, Sect. 5.5), we can deduce that $(W_n - \theta)/S_n$ also converges in distribution to a standard normal distribution. The large-sample test based on this statistic is called a *Wald test*.

4. Conclusions

Hypothesis testing is one of the most widely used, and some may say abused, methodologies in statistics. Formally, the hypotheses are specified, an α-level is chosen, a test statistic is calculated, and it is reported whether H_0 or H_1 is accepted. In practice, it may happen that hypotheses are suggested by the data, the choice of α-level may be ignored, more than one test statistic is calculated, and many modifications to the formal procedure may be made. Most of these modifications cause bias and can invalidate the method. For example, a hypothesis suggested by the data is likely to be one that has 'stood out' for some reason, and hence H_1 is likely to be accepted unless the bias is corrected for (using something like Scheffe's method—see Hsu 1996).

Perhaps the most serious criticism of hypothesis testing is the fact that, formally, it can only be reported that either H_0 or H_1 is accepted at the prechosen α-level. Thus, the same conclusion is reached if the test statistic only barely rejects H_0 and if it rejects H_0 resoundingly. Many feel that this is important information that should be reported, and thus it is almost required to also report the p-value of the hypothesis test.

For further details on hypothesis testing see the classic book by Lehmann (1986). Introductions are also provided by Casella and Berger (2001) or Schervish (1995), and a good introduction to multiple comparisons is Hsu (1996); see also *Hypothesis Tests, Multiplicity of*.

Hypothesis Testing: Methodology and Limitations

Hypothesis tests are part of the basic methodological toolkit of social and behavioral scientists. The philosophical and practical debates underlying their application are, however, often neglected. The fruitful application of hypothesis testing can benefit from a clear insight into, the underlying concepts and their limitations.

1. The Idea of Hypothesis Testing

A test is a statistical procedure to obtain a statement on the truth of falsity of a proposition, on the basis of empirical evidence. This is done within the context of a model, in which the fallibility or variability of this empirical evidence is represented by probability. In this model, the evidence is summarized in observed data, which is assumed to be the outcome of a stochastic, i.e., probabilistic, process; the tested proposition is represented as a property of the probability distribution of the observed data.

1.1 Some History

The first published statistical test was by John Arbuthnot in 1710, who wondered about the fact that in human births, the fraction of boys born year after year appears to be slightly larger than the fraction of girls (cf. Hacking 1965). He calculated that this empirical fact would be exceedingly unlikely (he obtained a probability of 1/483 600 000 000 000 000 000 000) if the probability of a male birth were exactly 0.5, and argued that this was a proof of divine providence, since boys—some of whom will be soldiers—have a higher risk of an early death, so that a higher ratio of male births is needed to obtain an equal ratio of males among young adults. We see here the basic elements of a test: the proposition

that the male birth ratio is 0.5, related to data by regarding these as outcomes of stochastic variables, the calculation that the data would be unlikely if the proposition were true, and a further conclusion interpreting the falsity of the proposition.

One of the first statistical procedures that comes close to a test in the modern sense was proposed by Karl Pearson in 1900. This was the famous chi-squared test for comparing an observed frequency distribution to a theoretically assumed distribution. Pearson derived the now well-known statistic to test the proposition, or *hypothesis*, that the probabilities of the various possible (finitely many) outcomes of some random variable are given by certain preassigned numbers. Pearson proved that this statistic has (in a large-sample approximation) the chi-squared distribution; this distribution can therefore be used to calculate the probability that, if the hypothesis holds, the test statistic will assume a value equal to or larger than the value actually observed.

The idea of testing was further codified and elaborated in the first decades of the twentieth century, mainly by R. A. Fisher (e.g., 1925). In his significance tests the data are regarded as the outcome of a random variable X (usually a vector or matrix), which has a probability distribution which is a member of some family of distributions; the tested hypothesis, also called the null hypothesis, is an assertion which defines a subset of this family; a test statistic $T = t(X)$, which is a function of X, is used to indicate the degree to which the data deviate from the null hypothesis; and the significance of the given outcome of the test statistic is calculated as the probability, if the null hypothesis is true, to obtain a value of T which is at least as high as the given outcome. If the probability distribution of T is not uniquely determined by the null hypothesis, then the significance is the maximal value of this probability, for all distributions of T compatible with the null hypothesis. The significance probability is now often called the p-value (the letter p referring to probability). With Fisher originates the convention to consider a statistical testing result as 'significant' if the significance probability is 0.05 or less—but Fisher was the first to recognize the arbitrary nature of this threshold.

A competing approach was proposed in 1928 by J. Neyman and Egon Pearson (the son of Karl). They criticized the arbitrariness in Fisher's choice of the test statistic and asserted that for a rational choice of test statistic one needs not only a null hypothesis but also an alternative hypothesis, which embodies a proposition that competes with the proposition represented by the null hypothesis. They formalized the testing problem as a two decision problem. Denoting the null hypothesis by H_0 and the alternative H_1, the two decisions were represented as 'reject H_0' and 'do not reject H_0.' (The second decision was also called 'accept H_0,' but it will be discussed below that this is an unfortunate term.) Two errors are possible: rejecting a true H_0, and failing to reject a false H_0. Neyman and Pearson conceived of the null hypothesis as a standard situation, the burden of proof residing with the researcher to demonstrate (if possible) the untenability of this proposition.

Correspondingly, they called the error of rejecting a true H_0 an error of the first kind and the error of failing to reject a false H_0 an error of the second kind. Errors of the first kind are considered more serious than errors of the second kind. The probability of—correctly—rejecting H_0 if H_1 is true, which is 1 minus the probability of an error of the second kind, given that the alternative hypothesis is true, they called the power of the test. Neyman and Pearson proposed the requirement that the probability of an error of the first kind, given that the null hypothesis is indeed true, do not exceed some threshold value called the significance level usually denoted by α. Further they proposed to determine the test so that, under this essential condition, the power will be maximal.

In the Neyman–Pearson formulation, we obtain richer results (namely, specific precepts for constructing good tests) at the cost of a more demanding model. In addition to Fisher's null hypothesis, we also need to specify an alternative hypothesis; and we must conceive the testing problem as a two-decision situation. This led to vehement debate between Fisher on the one hand, and Neyman and E. Pearson on the other. This debate and the different philosophical positions are summarized by Hacking (1965) and Gigerenzer et al. (1989), who also give a further historical account. The latter study also discusses how this controversy was resolved in the teaching and practice of statistics in the social sciences by a hybrid theory which combines elements of both approaches to testing, and which has been treated often as an objective precept for the scientific method, glossing over the philosophical controversies.

Examples of this hybrid character are that, in accordance with the Neyman–Pearson approach, the theory is explained by making references to both the null and the alternative hypotheses, and to errors of the first and second kind (although power tends to be treated in a limited and often merely theoretical way), whereas—in the spirit of Fisher—statistical tests are regarded as procedures to give evidence about the particular hypothesis tested and not merely as rules of behavior that will in the long run have certain (perhaps optimal) error rates when applied to large numbers of hypotheses and data sets. Lehmann (1993) argues that indeed a unified formulation is possible, combining the best features of both approaches.

Instead of implementing the hypothesis test as a 'reject/don't reject' decision with a predetermined significance level, another approach often is followed: to report the p-value or significance probability, defined as the smallest value of the significance level at which the observed outcome would lead to rejection of the null hypothesis. Equivalently, this can be defined

as the probability, calculated under the null hypothesis, of observing a result deviating from the null hypothesis at least as much as the actually observed result. This deviation is measured by the test statistic, and the p-value is just the tail probability of the test statistic. For a given significance level α, the null hypothesis is rejected if and only if $p \leqslant \alpha$.

2. Hypothesis Tests in Empirical Research

2.1 The Role of the Null Hypothesis

In the social and behavioral sciences, the standard use of hypothesis testing is directed at single research questions, practically always fragments of larger investigations, about the existence of some or other effect. This effect could be a difference between two group means, the effect of some explanatory variable on some dependent variable as expressed by a regression coefficient in multiple linear regression analysis, etc. Expressed schematically, the researcher would like to demonstrate a research hypothesis which states that the effect in question, indeed, exists. The negation of this hypothesis, then, is understood as the proposition that the effect is absent, and this proposition is put up as the null hypothesis. The research hypothesis, stating that the effect exists, is the alternative hypothesis. Rejecting the null hypothesis is interpreted as support for the existence of the hypothesized effect. In this way, the burden of proof rests with the researcher in the sense that an error of the first kind is to state that there is evidence supporting the existence of the effect if, in reality, the effect is absent. The usual welcoming phrase for the rejection of the null hypothesis is the statement that a significant result has been obtained.

2.2 Example: The t-test

Consider, as a major example, the proposition that two groups, arbitrarily labeled A and B, are different with respect to some numerical characteristic X. Available data are measurements X_{Ai} of this characteristic for some individuals i in group A and measurements X_{Bi} of the characteristics for other individuals i in group B. The first step in modeling this is to consider the observed values X as outcomes of random variables, usually with the assumption that they are stochastically independent and have a probability distribution not depending on the individual i. The next step is, usually, to focus on the expected values, i.e., population means in the two groups, denoted here by μ_A and μ_B. The tested proposition is formalized as the statement that μ_A and μ_B are different (two-sided alternative hypothesis) or as the statement that one (e.g., μ_A) is bigger than the other (e.g., μ_B) (one-sided alternative hypothesis). The null hypothesis H_0 is defined as the statement that μ_A and μ_B are equal.

The most commonly used test for this testing problem is *Student's t-test*, called after the pseudonym of W. Gosset, who laid the mathematical basis for this test in 1908. The test statistic is

$$T = \frac{M_A - M_B}{\sqrt{\left(\frac{1}{n_A} + \frac{1}{n_B}\right) S^2}}$$

where M_A and M_B are the two sample means, S^2 is the pooled within-group variance, and n_A and n_B are the two sample sizes. (Definitions of these quantities can be found in any statistics textbook.) This formula illustrates the property of many test statistics that an observed effect (here the difference between the two sample means) is compared to a measure of variability (based here on the within-group variance). Student/Gosset showed that, if the variable X has a normal distribution with the same variance in the two groups, then T has, if the null hypothesis is true, the so-called t distribution on $df = n_A + n_B - 2$ degrees of freedom. For the two-sided alternative hypothesis, H_0 is rejected for large values of the absolute value of T, for the one-sided hypothesis H_0 is rejected for large values of T itself. The threshold beyond which H_0 is rejected is called critical value, and is determined from the t-distribution in such a way that the significance level has the pre-assigned value. The one-sided threshold at significance level α is denoted $t_{df;\alpha}$, so that the 'rejection region' for the one-sided t-test is given by $\{T > t_{df;\alpha}\}$. The power of the one-sided test is larger than that of the two-sided test for $\mu_A > \mu_B$ (corresponding to the one-sided alternative hypothesis) and smaller for $\mu_A < \mu_B$. This is, in the Neyman–Pearson formulation, the reason for using the one-sided test if the alternative hypothesis is one-sided (in which case parameter values $\mu_A < \mu_B$ are not taken into consideration).

The conventional value of the significance level in the social and behavioral sciences is 0.05. For large values of the combined sample size $n_A + n_B$, the critical value of the t-test approximates the critical value that can be computed from the standard normal distribution. This is because the fact that the variance is estimated and not known beforehand becomes less and less important as the combined sample size gets larger; if the population variance was known beforehand and substituted for S^2, the test statistic would have the standard normal distribution, and the test would be the so-called z-test. For this test, the critical value is 1.645 for the one-sided test and 1.960 for the two-sided test. The power depends on many quantities: the sample sizes, the population means and variances, and the significance level. As examples, the power of the one-sided z-test for $\alpha = 0.05$ is equal to 0.50 for

$$\frac{\mu_A - \mu_B}{\sigma} = 1.645\sqrt{\left(\frac{1}{n_A} + \frac{1}{n_B}\right)}$$

where σ is the within-group standard deviation. The power is equal to 0.95 if $(\mu_A - \mu_B)/\sigma$ is equal to twice this value.

2.3 The Role of Assumptions

The probability statements that are required for statistical tests do not come for free, but are based on certain assumptions about the observations used for the test. In the two-sample t-test, the assumptions are that the observations of different individuals are outcomes of statistically independent, normally distributed, random variables, with the same expected value for all individuals within the same group, and the same variance for all individuals in both groups. Such assumptions are not automatically satisfied, and for some assumptions it may be doubted whether they are ever satisfied exactly. The null hypothesis H_0 and alternative hypothesis H_1 are statements which, strictly speaking, imply these assumptions, and which therefore are not each other's complement. There is a third possibility: the assumptions are invalid, and neither H_0 nor H_1 is true. The sensitivity of the probabilistic properties of a test to these assumptions is referred to as the lack of robustness of the test. The focus of robustness studies has been on the assumptions of the null hypothesis and the sensitivity of the probability of an error of the first kind to these assumptions, but studies on robustness for deviations from assumptions of the alternative hypothesis have also been done, cf. Wilcox (1998).

One general conclusion from robustness studies is that tests are extremely sensitive to the independence assumptions made. Fortunately, those assumptions are often under control of the researcher through the choice of the experimental or observational design. Traditional departures from independent observations are multivariate observations and within-subject repeated measures designs, and the statistical literature abounds with methods for such kinds of dependent observations. More recently, methods have been developed for clustered observations (e.g., individual respondents clustered within groups) under the names of multilevel analysis and hierarchical linear modeling.

Another general conclusion is that properties of tests derived under the assumption of normal distributions, such as the t-test, can be quite sensitive to outliers, i.e., single, or a few, observations that deviate strongly from the bulk of the observations. Since the occurrence of outliers has a very low probability under normal distributions, they are 'assumed away' by the normality assumption. The lack of robustness and sensitivity to outliers have led to three main developments.

First, there are non-parametric tests, which do not assume parametric families of distributions (such as the normal). Most of these are based on the ranks of the observations rather than their numerical values. They are standard fare in statistical textbooks. Second, robust tests have been developed, based on numerical values of the observations, which are less sensitive to outliers or heavy-tailed distributions, e.g., by some kind of automatic downweighting of outlying observations (e.g., Wilcox, 1998). The purpose of such tests is to retain a high power as much as possible while decreasing the sensitivity to deviations from the normal distribution or to departures from other assumptions.

Third, diagnostic means have been developed to spot single observations, or groups of observations, with an undue influence on the result of the statistical procedure (e.g., Cook and Weisberg 1999, Fox 1991). The idea behind most of these diagnostics is that most of the observations come from a distribution which corresponds well enough to the assumptions of the statistical model, but that the observations could be contaminated by a small number of poorly fitting observations. Ideally, these observations should also be recognizable by close inspection of the data or data collection process. After deleting such poorly fitting observations one can proceed with the more traditional statistical procedures, assuming that the remaining data do conform to the model assumptions.

3. Confidence Intervals

Confidence intervals are closely related to hypothesis tests. They focus on a parameter in the statistical model. Examples of such parameters are, in the two-sample situation described above, the difference of the two population means, $\mu_A - \mu_B$, or the within-group standard deviation, σ. To frame this in general terms, consider a one-dimensional statistical parameter denoted by θ. A null hypothesis test is about the question whether the data is compatible with the hypothesis that the parameter θ (in this case $\mu_A - \mu_B$) has the particular value 0. Instead, one could put forward the question: what are the values of θ with which the data is compatible? This question can be related to hypothesis testing by considering the auxiliary problem of testing the null hypothesis $H_1: \theta = \theta_0$ against the alternative hypothesis $H_1: \theta \neq \theta_0$, for an arbitrary but fixed value θ_0. The data may be said to be compatible with any value of θ_0 for which this null hypothesis would not be rejected at the given level of significance. Thus, the confidence interval is the interval of non-rejected null hypotheses.

Another way of viewing the confidence interval is as follows. A confidence coefficient $1-\alpha$ is determined by the researcher (a conventional value is 0.95). The confidence interval is an interval with lower boundary L and upper boundary U, calculated from the data and therefore being random variables, with the property that the probability that $L \leqslant \theta \leqslant U$, i.e., the

interval contains the true parameter value, is at least $1-\alpha$. It can be proved mathematically that the interval of non-rejected null hypotheses has precisely this property.

The confidence interval can be inverted to yield a hypothesis test for any null hypothesis of the form H_0: $\theta = \theta_0$ in the following way. For the most usual null hypothesis that $\theta = 0$, the hypothesis is rejected if the value 0 is not included in the confidence interval. More generally, the null hypothesis $H_0: \theta = \theta_0$ is rejected whenever θ_0 is outside the confidence interval. This shows that a confidence interval is strictly more informative than a single hypothesis test.

4. Problems in the Interpretation and Use of Hypothesis Tests

While hypothesis tests have been applied routinely by hosts of social and behavioral scientists, there have been continuing debates, sometimes vehement and polemic, about their use, among those inclined to philosophical or foundational discussion. Many contentious issues can be found in Harlow et al. (1997), Nickerson (2000), and Wilkinson and TFSI (1999). Within the context of the present contribution I can only give a personally colored discussion of some main points which might contribute to a better understanding and a more judicious application of hypothesis tests.

The reason that there has been so much criticism of the nature and use of hypothesis tests, is in my view the difficulty of reasoning with uncertain evidence and the natural human tendency to take recourse to behavioral rules instead of cogitate afresh, again and again, about how to proceed. The empirical researcher would like to conclude unequivocally whether a theory is true or false, whether an effect is present or absent. However, experimental and observational data on human behavior are bound to be so variable that the evidence produced by these data is uncertain. Our human tendency is to reason—if only provisionally—as if our conclusions are certain rather than tentative; to be concise rather than accurate in reporting our arguments and findings; and to use simple rules for steering how we make inference from data to theories. We are tempted to reason as if '$p > \alpha$' implies that the investigated effect is nil, and the presumed theory is false, while '$p \leqslant \alpha$' proves that the effect indeed exists and the theory is true.

However, such cognitive shortcuts amount to serious misuse of hypothesis testing. Much of the criticism of the use of hypothesis testing therefore is well-founded. In my view this implies that better interpretations of hypothesis testing should be promoted, and that tests should be used less mechanically and combined with other argumentations and other statistical procedures. In any case, the user of tests (or other statistical procedures) should realize that these procedures are based on the assumption that there is random variability in the data which cannot be completely filtered out of the results. Whether a test result is significant or not depends partly on chance, and each researcher obtaining a significant result should be aware that this could be an error of the first kind, just as a non-significant result could be an error of the second kind.

4.1 Some Misinterpretations

The following list tries to correct misinterpretations that have haunted applications of statistical tests. A more extensive discussion can be found, e.g., in Nickerson (2000).

(a) A common misinterpretation is that non-rejection implies support for the null hypothesis. Nonrejection should be interpreted, however, as an undecided outcome: there is not enough evidence against the null hypothesis, but this does not imply that there is evidence for the null hypothesis. Maybe the sample size is small, or error variability is large, so that the data does not contain much information anyway. Usually the alternative hypothesis contains probability distributions that approximate the null distribution; e.g. when testing $\mu_A - \mu_B = 0$ against $\mu_A - \mu_B \neq 0$, the difference between the two population means can be tiny, while the alternative hypothesis is still true. In other words, the power of practically all tests is quite low in a sizeable part of the alternative hypothesis, so if one of the distributions in this part would prevail, chances would be low of rejecting the null hypothesis. Therefore, nonrejection provides support for those parts of the alternative practically as strongly as for the null hypothesis itself, and non-rejection may not be interpreted as support for the null hypothesis and against the alternative hypothesis.

(b) If one wishes to get more information about whether a nonsignificant result provides support for the null hypothesis, a power study is not the answer. Statistical power is the probability to reject the null hypothesis, if a given effect size obtains. Its interpretation cannot be inverted as being the degree of support of the null hypothesis in the case of nonsignificance. Power studies are important in the stage of planning a study. Once the study has been conducted, and one wishes to see in more detail to what extent the null and alternative hypotheses are supported, a confidence interval is the appropriate procedure (also see Wilkinson and TFSI, 1999, p. 596).

(c) Test results tell us nothing about the probabilities of null or alternative hypotheses. The probabilities known as the significance level or the power of the test are probabilities of certain sets of outcomes given the condition that the null or, respectively, the alternative hypothesis is true.

(d) A significant result is not necessarily important. Very low p-values do not in themselves imply large effect sizes. A small estimated effect size still can yield a low p-value, e.g., if the corresponding standard error is very small, which can be caused by a large sample or by good experimental control. Investigation of effect sizes is important, and is a different thing than hypothesis testing. The importance of reporting effect sizes is stressed in Schmidt (1996) and Wilkinson and TFSI (1999).

(e) The alternative hypothesis is not the same as a scientific theory. If a researcher is investigating some theory empirically, this can be based on tests of which the alternative hypotheses are deduced from the theory, but always under the assumption that the study was well designed and usually under additional technical assumptions such as, e.g., normality of the distributions. Since the alternative hypothesis is only a consequence and not a sufficient condition for the theory, it is possible that the alternative hypothesis is true but the theory is not. To find support for theories, one has to find corroborations of many consequences of the theory under various circumstances, not just of one of its implications. On the other hand, it is possible that the theory is true but the alternative hypothesis deduced from it is not, e.g., because the experiment or observation was ill-designed or because the auxiliary technical assumptions are not satisfied.

(f) The null hypothesis is just what it says: a hypothesis. The test is not invalidated by the mere fact that there are other reasons for thinking, or knowing, that the null hypothesis is wrong. Even if there may be other reasons for which the null hypothesis is wrong, still it can be sensible to check whether the data at hand are, or are not, compatible with it.

4.2 Limitations of the Neyman–Pearson Approach to Hypothesis Testing

The Neyman–Pearson (1928) formulation changed the concept of hypothesis testing because it provided a rational basis for the choice of a test statistic. This was obtained at the cost of a quite narrow frame for the notion of a hypothesis test: a two-decision problem in which one error ('type I') is considered much more serious than the other error ('type II'). This model for decision-making is often inappropriate and, when it is useful, it is more commonly a useful approximation than a faithful representation of the actual decision situation. Some of its limitations are discussed briefly in this section.

(a) Even when a dichotomous decision must be taken as a result of a scientific investigation, it is possible that both types of error should be considered equally serious. This is the case, e.g., when two therapies are compared and the most promising one must be chosen for further study or for practical application. If the costs of both kinds of error (choose therapy B, while A is better; or choose therapy A, while B is better) are about the same, then there is no asymmetry between the two competing hypotheses, and a significance test is not in order.

(b) Often there are more than two outcomes of the decision situation. For example, in the two-sample situation discussed above, where the population means are μ_A and μ_B, and where the researcher entertains a theory implying that $\mu_A > \mu_B$, it is natural to define three decision outcomes defined as '$\mu_A > \mu_B$ (support for the theory),' 'undecided,' and '$\mu_A < \mu_B$ (evidence against the theory).' Usually, however, such a situation is represented by a Neyman–Pearson testing problem with null hypothesis H_0: '$\mu_A = \mu_B$' and alternative H_1: '$\mu_A > \mu_B$.' If the t-statistic for $\mu_A - \mu_B$ yields a strongly negative outcome ('significance in the wrong direction') then the researcher only concludes that the null hypothesis is not rejected, whereas the data conveys the message that the alternative hypothesis should be rejected. The data then have to be considered as evidence against the theory embodied in H_1. Such a three-decision formulation is closer to the actual purpose of hypothesis tests in many situations where a one-dimensional parameter is being tested, cf. Leventhal (1999).

(c) The Neyman–Pearson approach is formulated as if the data at hand is the only evidence available about the null and alternative hypotheses: it is an *in vacuo* formulation. This is almost never realistic. Often the propositions under study are theoretically plausible or implausible, there is earlier empirical evidence, there may be converging evidence (as in the case of triangulation studies) in the same investigation, and other evidence may become available in the future. In the light of this surrounding evidence, it is unrealistic—perhaps arrogant—to presume that the researcher has to take either of two decisions: 'reject H_0' or 'do not reject H_0.' It is more realistic to see the data at hand as part of the evidence that was and will be accumulated about these hypotheses. This is a major reason why presenting the result of the test as a p-value is more helpful to other researchers than presenting only the 'significant–nonsignificant' dichotomy (also see Wilkinson and TFSI 1999).

There are several ways in which the results obtained from the data at hand, perhaps summarized in the p-value, can be combined with other evidence. In the first place, an informal combination can be and often will be made by a sensible, nonformalized weighing of the various available pieces of evidence. One formal way of combining evidence is provided by the Bayesian paradigm (e.g., Gelman et al. 1995). This paradigm presupposes, however, that the prior and current ideas of the researcher about the plausibility of all possible values of the statistical parameter under study be represented in a probability distribution for this parameter, a very strong requirement indeed. Other formal ways of combining evidence have been developed and are known collectively by the name of

meta-analysis (e.g., Cook et al. 1992, Schmidt 1996). These methods require that the several to-be-combined hypothesis tests address the same substantive hypothesis, or that they can be regarded as tests of the same substantive parameter.

5. Conclusion

The statistical hypothesis test is one of the basic elements of the toolbox of the empirical researcher in the social and behavioral sciences. The difficulty of reasoning on the basis of uncertain data has led, however, to many misunderstandings and unfortunate applications of this tool. The Neyman–Pearson approach is a mathematically elegant formulation of what a hypothesis test could be. Its precise formulation rarely applies literally to the daily work of social and behavioral scientists, very often it is a useful approximation to a part of the research question, sometimes it is inappropriate—but sacrosanct it is not. A hypothesis test evaluates the data using a test statistic set up to contrast the null hypothesis with the alternative hypothesis, and the p-value is the probability to obtain, *if* the null hypothesis is true, outcomes of the test statistic that are at least as high as the outcome actually observed. Low values therefore are evidence against the null hypothesis, contrasted with the alternative hypothesis. It is more conducive to the advance of science to report p-values than merely whether the hypothesis was rejected at the conventional 0.05 level of significance.

In the interpretation of test outcomes one should be aware that these are subject to random variability; and that the probability calculations are based on assumptions which may be in error. Incorrect assumptions can invalidate the conclusions seriously. Nonparametric and robust statistical procedures have been developed which depend less on these kinds of assumption, and diagnostics have been developed for checking some of the assumptions. When reporting empirical results, it is usually helpful to report not only tests but also estimated effect sizes and/or confidence intervals for important parameters. To sum up: 'It seems there is no escaping the use of judgment in the use and interpretation of statistical significance tests' (Nickerson 2000, p. 256).

Hypothesis Tests, Multiplicity of

Standard procedures for controlling the probability of erroneous statistical inferences apply only for a single comparison or determination from a given set of data. Multiplicity is encountered whenever a data analyst draws more than one inference from a data set. With multiplicity, standard procedures must be adjusted for the number of comparisons or determinations that actually or potentially are performed. If some adjustment is not made, the probability of erroneous inferences can be expected to increase with the degree of multiplicity. In other words, the data analyst loses control of a critical feature of the analysis.

Questions arising from problems of multiplicity raise a diversity of issues, issues that are important, difficult, and not fully resolved. This account empha-

sizes the issues, tries to avoid being trapped in undue detail, and provides examples of the application of a recommended procedure.

It is helpful to recognize several general guidelines:

(a) Two approaches to the same data, with different purposes or with different questions being posed, need not yield compatible results.

(b) Exact equality of long-run values is very rare and should not play an appreciable role either in one's thinking or one's practice.

(c) When posing questions about data, greater realism will be very valuable.

(d) The situations faced must not be characterized either as completely 'fixed' or completely 'random.'

(e) In selecting a bouquet of techniques for the next decade or the next millennium, the selection must not be cast in stone; further evolution is to be expected (in later months, years, or centuries).

Issues of multiplicity appear in a wide variety of settings, including

(a) outcomes, each measured with variability, in several situations:

(i) comparison of all pairs of situations ('multiple comparisons'); and

(ii) comparison between each situation and a standard ('multiple determination');

(b) selection of one or more elements from a set of alternatives:

(i) selection of how variables are to be expressed for analysis (i.e., what re-expression, if any, should be used?);

(ii) selection of which of the available variables are to participate in an analysis (subset selection); and

(iii) reduction in size of a set of alternatives in an attempt to reduce their number without losing the best.

1. Illustrative Settings, Error Rates, and Procedures

Some important issues arise for all of these alternatives. These issues are considered and illustrated for one example of multiple determination and one example of multiple comparisons.

Consider k independent estimates $\bar{y}_1, \bar{y}_2, \ldots, \bar{y}_k$ of, respectively, $\mu_1, \mu_2, \ldots, \mu_k$ and an estimate of variability applicable to all these estimates. This is typical enough of multiplicity problems to render conclusions that are broadly helpful.

1.1 Multiple Determination

Defining a standard, λ, and for each μ_i, drawing conclusions about μ_i–λ based on $\bar{y}_i$–λ is, by definition, making a multiple determination. (In some applications, μ_i is a mean change from one time to another. Often in that case, $\lambda = 0$.) Experience and common sense suggest strongly that μ_i and λ are certain to differ in some decimal place, so that a focus on a null hypothesis that $\mu_i = \lambda$ is quite unrealistic and misleading.

With an interest in μ_i–λ for each value of i, it is reasonable to ask for one of these conclusions: (1) to act as if $\mu_i < \lambda$; (2) to act as if the sign of μ_i–λ is not (yet) determined; or (3) to act as if $\mu_i > \lambda$. Here (1) or (3) is a 'definite' result, while (2) is 'indefinite.'

1.2 Multiple Comparisons

Consider the $k(k-1)/2$ individual pair-wise comparisons y_i–y_j. Using these to draw conclusions about the set of μ_i–μ_j is, by definition, making multiple comparisons, although the definition is more general, and applies to any set of linear contrasts among the μ_i. Because μ_i and μ_j are certain to differ in some decimal place, there is no good reason to focus on the null hypothesis that $\mu_i = \mu_j$. Instead, it should be asked, for each (i, j) pair, whether one should (1) act as if $\mu_i < \mu_j$; (2) act as if the sign of μ_i–μ_j were not (yet) determined; or (3) act as if $\mu_i > \mu_j$.

1.3 In General

Notice the use of '$>$' or '$<$' and the avoidance of '$=$' and '$\neq$.' 'Accepting the null hypothesis' is usually at best misleading. Confounding '$>$' and '$<$' as '$\neq$' is unresponsive and confusing. Thus, focusing on direction is important when dealing with only one comparison (or determination), and becomes vital when dealing with several or many comparisons.

In these formulations, an 'error' is asserting one direction when the (unknown) truth is the other direction. (One should forget about the 'null case' of equality.) Asserting that the direction is not yet established may be a wasted opportunity, but is not an 'error.' The task is to control error while minimizing wasted opportunity, i.e., minimizing indefinite results.

Two classical choices for controlling errors consider expected error rates over replications of the study. (See, for example, Hochberg and Tamane 1987, p. 7.) They are:

$$E\left\{\frac{\text{number of errors}}{\text{number of comparisons}}\right\} \leqslant .025$$

('individual,' 'unadjusted,' or 'per comparison')

and

$$E\left\{\frac{\text{number of errors}}{\text{number of families}}\right\} \leqslant .025$$

('simultaneous,' 'Bonferroni,' or 'per family').

Here, 0.025 could easily be replaced by another choice. (For consistency with commonly used notation, the chosen value will be denoted by $\alpha/2$.) 'Family' refers to an identified set of comparisons whose simultaneous error rate is to be controlled. Normally, 'number of families' would be taken equal to unity. These two choices for controlling errors differ by a factor of k for multiple determinations and of $k(k-1)/2$ for multiple comparisons, so the difference between the two can be quite large.

There has been a feeling for decades (e.g., Tukey 1994/1953) that 'individual' or 'unadjusted' is too soft while 'simultaneous' is too severe. More recently, Benjamini and Hochberg (1995) introduced a compromise that is receiving increasing acceptance.

The two parts of their innovation are a definition of an alternative error rate, the false discovery rate (*FDR*), and a moderately simple procedure that, under the simplest circumstances, controls the *FDR*. The definition is the expectation of the ratio of the number of erroneous assertions of direction to the total number of assertions of direction, i.e.,

false discovery rate =

$$FDR = E\left\{\frac{\text{number of errors}}{\max\{1, \text{number of definite results}\}}\right\}$$

Let p_{crit} be the tail area (usually for each of two tails) of the null sampling distribution of the test statistic for any single comparison being judged by a multiplicity-respecting procedure. Each such procedure will stipulate a probability of error or average fraction of error that is bounded by $\alpha/2$ when judging confidence of direction. The value of p_{crit} will depend on the sort of confidence to be attained. Let K be the number of determinations or comparisons in the family under consideration, where $K = k$ for multiple determinations and $K = k(k-1)/2$ for all pair-wise multiple comparisons. Let $h = 1, \ldots, K$ be the rank of the p-value associated with the test statistic for the comparison concerned when ordered from smallest to largest, so that the observed p-values—$p_{(h)}$ for the hth comparison—are weakly increasing from $h = 1$ to $h = K$. Three distinct procedures, two classical choices and one that controls the *FDR*, are defined as follows:

Unadjusted: be confident of the observed direction for comparison h if

$$p_{(h)} \leqslant p_{\text{crit}} = p_{\text{UNA}} = \alpha/2$$

FDR (Benjamini and Hochberg 1995): be confident of the observed direction of the hth comparison when $p_{(h)}$ is the largest p-value such that

$$p_{(h)} \leqslant p_{crit} = p_{B\text{–}H}(h) = (h/K)\alpha/2.$$

Moreover, be confident of the observed direction for all comparisons g with

$$p_{(g)} \leqslant p_{(h)}, \textit{ i.e.}, g = 1, \ldots, h.$$

Bonferroni (per family): be confident of the observed direction for comparison h if

$$p_{(h)} \leqslant p_{\text{crit}} = p_{\text{BON}} = (1/K)\alpha/2.$$

Because

$$(1/K) \leqslant (h/K) \leqslant 1$$

it must be true that

$$p_{\text{BON}} \leqslant p_{\text{B–H}}(h) \leqslant p_{\text{UNA}}$$

Specifically, $p_{\text{B–H}}(h) = (h)p_{\text{BON}}$ and $p_{\text{UNA}} = (K)p_{\text{BON}}$. The three collections of confident directions corresponding to these three approaches are nested, with the collection for the unadjusted procedure the largest and that for the Bonferroni the smallest.

2. *Examples: The NAEP Trial State Assessment*

Data from the National Assessment of Educational Progress (NAEP) Trial State Assessment were subjected to two separate analyses by Williams et al. (1999). The data for the first analysis consist of average eighth-grade mathematics proficiency scores for the 34 states that participated in both the 1990 and 1992 NAEP assessments; data for the second analysis consist of average eighth-grade mathematics proficiency scores for the 41 states that participated in 1992 (Johnson et al. 1993).

2.1 *Multiple Determination*

One way of assessing year-to-year change in state mathematics achievement involves directly testing the significance of change in each of the 34 states. An ordinary Bonferroni adjustment for control of Type I error per family, as was used by NAEP (Johnson et al. 1993), results in an effective critical p-value of $p_{\text{BON}} = 0.000735$ for $\alpha/2 = 0.025$. Table 1 contains the computed difference between 1990 and 1992 mathematics achievement means for each state and the computed pooled standard error. It also includes the statistical decision about confidence in direction (with confident direction indicated by 'b' in each column) for each state under the three multiplicity treatments. For this example, critical p values are used as a basis for comparison of the adjustment procedures. The cutoff

critical t value for each procedure is also displayed in the bottom line of Table 1.

The unadjusted per comparison approach is confident about the direction of 15 differences, whereas the Benjamini–Hochberg (B–H) *FDR* procedure is confident about 11 of these, and the Bonferroni technique is confident about the direction of only four of the differences.

2.2 Multiple Comparisons

All pair-wise mean differences between the states' 1992 eighth-grade mathematics achievement scores were considered. Because 41 states participated in the 1992 assessment, the family size is $K = 41 \times 40/2 = 820$ comparisons. Using the Bonferroni adjustment, there are 480 confident directions between states, and the use of the B–H technique results in an additional 159. The unadjusted analysis increases the number of confident directions beyond the B–H technique by only six.

2.3 For Both Examples

For each example above, the B–H *FDR* procedure has led to a greater number of confident directions than the Bonferroni procedure. For the examples, we may expect that no more than 0.025 of the confident

directions identified by the B–H procedure are in error. (This is what it means to control the *FDR*.) As is generally the case, the relative advantage of the *FDR* procedure becomes greater with increasing numbers of comparisons (Kesselman et al. 1999).

3. General Considerations

3.1 Qualitative Status

In a situation where only a very few of the results are definite, the B–H false discovery procedure performs much like the Bonferroni simultaneous approach. Because these situations include those where 'definite' is purely accidental, as in extreme instances of 'data mining,' it is important that the approach selected resembles a severe procedure, and the *FDR* approach does so.

In a situation where the total number of definite results is a large fraction of the total number of comparisons an algorithm that controls the *FDR* behaves like the unadjusted procedure. If many comparisons deserve a definite result, it is reasonable that the selected approach should not lead to excessively many errors, and again, the *FDR* approach satisfies the criterion.

3.2 Family Size

One of the many problems associated with multiplicity is a frequent strong dependence of result on the number of comparisons in the family. Applying 'simultaneous' to Vermont vs. Maine as New England states can give results fairly different from applying it to Vermont vs. Maine as two of the 'lower 48,' with a family more than 75 times as large in the latter case. Controlling *FDR* turns out to be much less dependent on family size than the use of simultaneous control.

If the individual elements, e.g., the individual determinations, are stochastically independent, then it is known (Benjamini and Hochberg 1995) that using the *FDR* algorithm does control the rate of false discoveries, and may be unnecessarily conservative. It is reasonable to believe that the result of applying the *FDR* algorithm to elements lightly correlated in the sort of way arising from multiple comparisons will be even more conservative.

For making multiple comparisons in the special case where the true values follow an idealized Gaussian distribution, simulations have shown (Lewis and Tukey 2000) that the algorithm can be made less conservative while still protecting the rate of false discoveries, at least when the number of values being compared is no greater than 25. The modified algorithm follows the B–H approach, but uses $(h/K)\sqrt{(h+1)/2}$ in place of (h/K) in the formula for $p_{\text{B–H}}(h)$, with a caveat that enlargement should stop when the raw modification would otherwise be more liberal than the unadjusted analysis. This modification, here denoted by 'TSR,' results in the following expression for the series of critical values:

$$p_{\text{TSR}}(h) = \min\{1, (h/K)\sqrt{(h+1)/2}\}(\alpha/2)$$

Simulations indicate that a substantial improvement in power may be attained with this modification to the B–H procedure in the situations for which it is appropriate.

For additional recent work on procedures that control the *FDR*, see Shaffer (1999) and Benjamini and Hochberg (2000).

3.3 'Fixed' and 'Variable'

A major source of debate associated with multiplicity and factorial design has to do with 'fixed' vs. 'variable,' i.e., fixed versus random. A significant part of the confusion and conflict can be traced to an unwarranted belief, in tests of hypotheses, that mean squares themselves (or what mean squares estimate) are important. With interest just in directionality, each of the individual questions and answers in multiple comparisons involve $\bar{y}_i - \bar{y}_j$, where i and j are specified, and there is *no sense in asking* whether i and j are fixed or variable. (It may make sense, as shown below, to ask if something else is fixed or variable.)

3.4 A Prototype

The simplest multiple-comparison situation that illustrates the issues is a two-way table of responses with some replication in the cells and questions directed to differences between rows. Starting with k rows and m columns, each comparison involves only two rows. Replacing two rows of measurements by one row of estimated differences yields a 1-by-m table with some replication. (Readers may choose their favorite identities for rows and for columns; in particular, columns = blocks and rows = varieties or treatments gives appropriate realizations.)

If the columns and calculations are fixed, then the uncertainty about the answer is a consequence of whatever makes replicates within a cell different. An estimate of the corresponding variance is, say, an f-error term.

If the columns or calculations would be different were the data to be collected again, in particular, if different applications would require different weights, then the uncertainty about the overall results would reflect two sources of variability: whatever makes replicates differ, and the long-run differences (for a selected comparison) between one column and another.

(The second would not appear if the columns, etc., would be the same.) The resulting error term will be larger than the f-error term; just how much larger will depend on the extent to which differences in columns and calculations are reflected in the overall comparison.

In one crisply specified case where the columns are a random sample from a specifiable infinite population of columns, (and the calculations are fixed), there is a well-determined error term, say, the r-error term. Clearly

$$\text{r-error term} > \text{f-error term}$$

In practice, it is not likely to have exactly either columns and calculations fixed, or columns that constitute a simple random sample from a population.

Two alternatives, 'fixed' and 'variable,' are not enough.

A good way to provide a reasonable amount of realism is to define 'c' by

$$\begin{aligned}&\text{appropriate error term}\\&\quad = (c)[\text{r-error term}]\\&\qquad +(1-C)[\text{f-error term}]\end{aligned}$$

so that 'everything fixed' corresponds to $c = 0$ and 'random' is a particular case of $c = 1$. It pays then to learn as much as possible about values of 'c' in the real world.

3.5 Mathematization vs. Realism

Those who believe that data analysis can and should be mathematized are likely to be neither happy about the introduction of 'c' nor highly tolerant of a major role for such a quantity that is not estimable from data. When they recognize, however, that 'c' is about the data analyst or the data analyst's client—about just what question is being asked or about what is the most realistic question that can reasonably be asked—then they may be more willing to think about 'c' and even to work with its default values. Those who recognize the need for more realism today (and even more tomorrow), however, must be prepared for a growing seriousness about 'c' and a growing impact of nonzero values of 'c' on the conclusions to be drawn from the analysis of data. Some may find it useful to give 'c' a Bayesian interpretation, but this is not a necessity.

The only context in which something like being serious about 'c' has passed into a subject-matter field seems to be climatology. The usefulness of a climatological result is clearly measured by its performance over the set of years from its publication until the publication of its next revision. It will be based on what happened, quantitatively, in a set of years before its construction. Weather is a nontrivial time series (surely not a white noise), so neither $c = 0$ nor $c = 1$ can be expected to do well. Empirical study has led to using a base period for climatology of roughly the last 25 years. This is not directly related to a 'c' but is of a similar flavor.

Most data analysis intended to illuminate the real world is rather like climatology. The data, whether experimental or historical, has been collected under some circumstances and in the past, while its analysis has been carried out to estimate what will or what would happen in the future. The strength of the link from past to future is important; judging it effectively is not likely to be easy. Difficult issues need to be faced. If analyses are to be increasingly realistic, decisions about those issues will be required.

3.6 Plausible Defaults for 'c'

To begin to face the tasks, some values of 'c' can be set forth for some crudely described situations. Using such a list as a basis for choosing a 'c' in real data analyses is likely to be better than doing what has become customary, i.e., to assume either that $c = 0$ or $c = 1$. Values on this list will be likely to change over time as more is learned. (Here 'columns' refers to whatever versions are involved.)

$c = 0.0$ fixed columns and calculation

$c = 0.1$ fixed columns and somewhat variable calculation

$c = 0.5$ fixed columns and illustrative weights

$c = 1.0$ random columns and fixed weights

$c = 1.4$ somewhat illustrative columns

$c = 1.6$ illustrative columns

$c = 2.0$ very illustrative columns

For simple random sampling without replacement from a finite population, the value of 'c' is $1-$(sample size)/(population size).

3.7 More Quantitative Conclusions

The focus so far has been on directionality, an appropriate focus when not dealing with crisp measurements, when the hope is to be convinced by the analysis about the definiteness of at least some directions. Especially in some branches of physical science and engineering, the appropriate interest is in the sizes of differences, sizes that may be measured to a small fraction of their nominal value. Instead of directions, the focus will then be upon confidence intervals.

If the concern really is with all the pair-wise differences among k varieties, treatments, or circumstances, or if the pair-wise differences we are concerned about are selected independently of the numbers to be differenced, the Benjamini and Hochberg approach has to regard the results for all differences as definite so that the *FDR* approach could be taken to coincide with the individual unadjusted approach.

If it really is desired to make a simultaneous statement about 'all differences' or to validate a process of focusing on the single difference or the few differences that appear to be most different from a reasonable anticipation, the only viable alternative is

to take a simultaneous approach, presumably using percentage points for a Studentized-range distribution.

These two procedures need not yield compatible results. A difference may have a definite direction by *FDR* but a simultaneous confidence interval that includes long-run differences of both signs. Such incompatibility should be regarded only as evidence that the analyst needs to be clear which question is being asked. Is the analyst looking for a few definite directions (or for all the directions that can reasonably be believed to be definite) or is the interest in providing intervals covering the worst that is likely to have happened for any difference?

3.8 Other Kinds of Multiplicity

The broad issues presented here in discussing multiple determination and multiple comparisons appear in most of the other situations where multiplicity matters. Details may vary, but the broad issues are parallel. For more comprehensive treatments of multiplicity, see, for example, Miller (1981), Hochberg and Tamane (1987), and Hsu (1996).

Hysteria

The concept of hysteria is almost as old as medicine itself. Explanations of the complaints and behavior of the predominantly female patients suffering from this enigmatic condition have changed many times in response to changing ideas about the causes of disease, but none of these explanations has ever been entirely convincing. For at least the last 100 years physicians have been puzzled by the varied manifestations of the condition, dismayed by its ambiguities, and often exasperated by the behavior associated with it. As a result the term is now fading into history, though the various syndromes it embraced still exist and still await a satisfactory explanation.

1. The History of Hysteria

The concept of hysteria (from the Greek word *hystera* for womb) originated in the second millenium BC. Egyptian priest physicians attributed the paroxysmal symptoms of their female patients to wandering of the womb, and treated them either by the local application of fragrant potions to entice the uterus back to its proper station, or by the oral administration of nauseous draughts to drive it back. These assumptions were inherited by Hippocrates and Galen, and so was born the tenacious idea of a disease of women manifested by recurrent fits and other dramatic symptoms of sudden onset.

The European literature of the last 400 years is summarized by Merskey (1979). Thomas Sydenham was probably the first to recognize explicitly the role of emotion in the genesis of hysteria, for in 1697 he said in his *Discourse* that 'The *External Causes* of this Disease are either violent motion of the Body, or more frequently vehement Agitations of the Mind by the Assaults of Grief, Anger, Fear and such like Passions.' Sydenham was, of course, allowing for 'internal causes' as well, but the identification of these remained elusive. Sir Benjamin Brodie established in the 1830s that the muscles and peripheral nerves of patients with hysterical paralyses or anaesthesias appeared quite normal when examined postmortem, and by the 1870s Sir James Paget was convinced that the problem was one of volition rather that of neurological pathology. As he observed succinctly, 'They say "I cannot"; it looks like "I will not"; but it is "I cannot will."' Even

so, the great French neurologists Charcot and Janet still assumed at the end of that century that the fundamental cause of the suggestibility and hypnotizability of hysterics was a hereditary nervous degeneration. The assumption that hysteria occurred only in women also persisted well into that era. Landouzy stated firmly in 1846 that it was '*exclusive au sexe feminin*' and Charcot regarded ovarian tenderness as one of the stigmata of the condition and attached great significance to the precipitation of hysterical symptoms by pressure on the ovary. Only in World War I, when large numbers of soldiers in all the combatant armies developed florid hysterical symptoms in response to the appalling stresses of trench warfare, was the assumption of an exclusively female illness finally abandoned.

The idea that hysteria was a purely psychological disorder was introduced by Breuer and Freud (1896) in their famous *Studies on Hysteria* and contemporary opposition to their views owed almost as much to the abandonment of neurological pathology as it did to their novel and disturbing ideas about infantile sexuality. According to the corpus of psychoanalytic theory that developed from this revolutionary treatise, hysteria was a specific clinical entity arising from sexual conflicts originating in the oedipal phase of psychosexual development. Failure to relinquish the incestuous tie to the opposite sexed parent that develops during infancy leads to sexual conflicts in adult life because the sexual drive, or libido, retains its forbidden incestuous quality. The drive is, therefore, repressed and its energy converted into a hysterical symptom, which not only protects the patient from conscious awareness of the incestuous wishes, and hence from the anxiety that would otherwise result (primary gain), but simultaneously provides a symbolic expression of it (the rhythmic movements of a hysterical convulsion, for example, expressing the patient's coital fears or phantasies). In addition, the symptom itself often provided other benefits (secondary gain) by rendering the subject visibly ill, or making crucial activities impossible.

Despite the lack of supporting empirical evidence, and the wartime evidence that widespread and florid hysterical symptoms were precipitated by overwhelming stress rather than by infantile sexual experiences or phantasies, this psychoanalytic concept of hysteria remained dominant until the 1960s.

2. *Criticisms of the Concept and its Multiple Meanings*

The English physician Skey commented as long ago as 1867 that 'One good reason that may be assigned to the persistent employment of the term Hysteria—a term we all know to be objectionable—is the difficulty of finding a substitute for it.' Those objections and that difficulty have persisted ever since. Indeed, the objections have been expressed forcefully almost continuously from the early years of the twentieth century by German, English, and even French psychiatrists. The most consistent criticisms of hysteria have centered on the multiple meanings of the term and the wide variety of symptoms and behaviors to which it has been applied. At least seven different meanings can be distinguished.

2.1 *Neurological Conversion Symptoms*

Muscular weakness or paralysis, affecting one, two, or all four limbs, or resulting in loss of speech; convulsions simulating epilepsy; or a loss of sensation (commonly blindness or tunnel vision, deafness, or a circumscribed loss of cutaneous sensation) assumed to depend on the psychoanalytic mechanism of conversion. As the extent of the paralysis or sensory loss reflects the patient's ideas rather than anatomical facts, and as it can often be demonstrated neurologically that the relevant motor or sensory pathways are undamaged, the diagnosis of hysteria can usually be made with some confidence.

2.2 *Hysterical Pain and other Psychophysiological Reactions*

Visceral symptoms like vomiting or otherwise unexplained pain assumed to be produced by the same conversion mechanism. Unlike neurological conversion symptoms, there is usually no easy way of demonstrating that such symptoms must be psychogenic and as a result the diagnosis of hysteria remains uncertain.

2.3 *Dissociative Reactions*

Episodes of amnesia, fugue states, and rare cases of multiple personality assumed, after Janet, to be based on a restriction or dissociation of consciousness. Like conversion symptoms, hysterical amnesias and fugues usually develop in highly stressful situations and have the effect of providing at least a temporary respite from that stress.

2.4 *Anxiety Hysteria*

An obsolete psychoanalytic term for phobic anxiety, implying that repressed anxiety is displaced onto a neutral object or situation instead of being converted into a bodily symptom.

2.5 *Epidemic or Mass Hysteria*

Since the 'dancing manias' of fourteenth-century Europe, over 100 outbreaks of mass hysteria have been recorded, usually in schools, convents, or other communities of girls or young women, and usually at times of obvious stress (Sirois 1974). Shared appre-

hensions and suggestion are clearly important as those affected are always in close contact with one another and develop almost identical symptoms. Influential members of the community are generally also the first to be affected.

2.6 Briquet's Syndrome

A well-defined pattern of behavior, first described by the French physician Briquet in 1859 and seen almost exclusively in young women. They repeatedly consult doctors with multiple and constantly changing somatic symptoms for which no adequate cause can be found. They also have unsatisfactory sexual lives and are prone to develop mood disturbances and conversion symptoms. This behavior persists into middle age or beyond, and as a result such women acquire voluminous medical files, have multiple abdominal and pelvic operations, and often become dependent on analgesics or tranquillisers (Guze and Perley 1963).

2.7 The Hysterical Personality

A personality type, first clearly described by Janet at a time when hysteria was still regarded as an almost exclusively feminine condition, which is assumed to be particularly susceptible to develop conversion and other hysterical symptoms. As described, the characteristic features are attention-seeking behavior, shallow, labile emotions, and self-centered, demanding, interpersonal behavior. A variety of tactics are used to attract and retain the attention of others, including striking or sexually provocative clothing, flirtatious behavior, flattery, dramatized accounts of their past lives or current circumstances, and extravagant gestures.

Despite the linkages between these seven meanings the inevitable consequence of this diversity of usage was confusion and serious ambiguity. The situation was summarized trenchantly by the American psychiatrist Chodoff (1974): 'Entities that are clinically quite different are being held together artificially by little more than the authority of an ancient name' he asserted; 'the diagnosis (of hysteria) has become a balloon filled with air rather than substance … it is a fossil encrusted with and obscured by successive layers of meaning.' For good measure he reminded his audience that the term 'hysteric' was used widely by young male psychiatrists to describe almost any attractive female patient.

3. Hysteria Discarded

Although similar criticisms had been voiced many times before, Chodoff's strictures struck home, and when the American Psychiatric Association produced the revolutionary 3rd edition of its *Diagnostic and Statistical Manual* in 1980 the term hysteria had been discarded (see *Nosology in Psychiatry*). Most of its constituent syndromes survived, however, though with revised titles. Conversion symptoms became conversion disorder and anxiety hysteria became phobic disorder, and both were shorn of their original psychodynamic explanations. Dissociative reactions likewise became dissociative disorders. Briquet's syndrome was renamed somatization disorder, and the hysterical personality was renamed histrionic personality disorder. Mass or epidemic hysteria was not mentioned, presumably because it was assumed that each individual would be categorized separately under the appropriate syndrome. When the World Health Organization produced the next (10th) revision of the International Classification in 1992 its treatment of hysteria was almost identical. The only significant difference was that dissociative and conversion disorders were combined in a single category. Quite suddenly, therefore, one of the oldest, most evocative, and most reviled diagnoses in medicine's nomenclature had been expunged, at least for all official purposes.

4. The Limitations of the 'Medical Model'

Discarding the term hysteria has not, of course, solved the underlying problem of why the patients previously so labeled behaved in the way they did. A large part of that problem is that physicians have traditionally been conditioned by a set of mainly unwritten assumptions—what social scientists call the 'medical model'—to assume that every *bona fide* patient must have a disease of some kind. If the patient's complaints can be related to a pathology of some sort no problem arises. But if they cannot, most doctors tend to oscillate uneasily between two alternative attitudes: either there is nothing wrong with them or they are psychiatrically ill; and both alternatives are often unsatisfactory. The former may be true in organic disease model terms, but it provides no explanation for the patient's behavior and no relief of their suffering. The latter is easily taken to imply that the patient must have some kind of mental illness with a discrete cause of its own. Traditionally, hysteria has been one of these mental illnesses, but only one of them. For physicians have also invoked the concepts of hypochondriasis, neurasthenia, psychophysiological reaction, psychosomatic reaction, 'functional overlay,' and malingering in an attempt to explain their patients' behavior, and all these concepts, except possibly the last, are inadequately defined and overlap with one another.

5. The Sick Role and Illness Behavior

It is increasingly well recognized that the question to be asked when patients consult doctors with complaints that appear to be symptoms of bodily illness but in whom no evidence of illness can be found is often not 'What is the matter with them?' but 'Why are

Figure 1
A tentative classification of illness behavior (reproduced by permission of Cambridge University Press from Kendell R E 1983 Hysteria and the hysterical (histrionic) personality. In: Russell G F M, Hersov L A (eds.) *The Neuroses and Personality Disorders*. Cambridge University Press, Cambridge, UK)

they behaving in this way?' If the issue is formulated in this way the concepts of the 'sick role' and 'illness behavior' originally formulated by Parsons (1951) and Mechanic (1962) provide the starting point for a better understanding of the problem (Pilowsky 1969). As such writers have emphasized, the sick role in contemporary society involves many privileges. Invalids are exempted from many normal social obligations; children don't have to go to school and adults don't have to go to work, and often continue to be paid nonetheless. They are also exempted from responsibility for their incapacity, and so cannot simply be told to pull themselves together. Indeed, others are under an obligation to be kind and sympathetic, and sometimes to take over their responsibilities as well. The only reciprocal obligation on the patient is to seek and accept appropriate treatment, so that they utilize the privileges of the sick role for as briefly as possible.

Patterns of behavior that are rewarded tend to increase in frequency at the expense of those that are not, and the rewards of the sick role are so substantial, and are often experienced so frequently in childhood, that it is hardly surprising that not all those who consult doctors with bodily symptoms have objective evidence of disease. Against this conceptual background, Kendell (1983) proposed a tentative classification of invalid behavior in the form of a Venn diagram (Fig. 1). Although reality is undoubtedly more complex, the relationships between the three overlapping populations in this diagram illustrate some basic principles. Most illness behavior is generated by recognized disease (including well-defined psychiatric syndromes like schizophrenia and phobic anxiety). But substantial parts of the whole are generated either by fear of disease or by the 'positive reinforcement' provided by the rewards of the invalid role. There are large and important overlaps between these three populations, and the main recognized disease population is surrounded by a penumbra of unrecognised but genuine disease (mainly people with accepted but so far undiagnosed illnesses, like occult cancers, but perhaps also including subpopulations with as yet unrecognized syndromes, like people with narcolepsy 100 years ago). The management of individual patients depends on which of the 11 populations formed by the intersections of these four circles they come from, rather than on which of a few mutually exclusive diagnostic categories they belong to. Broadly speaking, illness behavior generated by fear of disease corresponds to hypochondriasis and illness behavior motivated by the attractions of the invalid role to what used to be called hysteria.

Essentially, the sick role is attractive, and so liable to be adopted, whenever the balance of its advantages and disadvantages outweighs those of health. To some people the demands of everyday life are so onerous—either because they lack the energy or ability to cope successfully, or because only when ill do they receive sufficient affection, sympathy or attention from other people—that the sick role is preferable most of the time. To many more, the sick role becomes attractive only in situations in which their responsibilities are abnormally heavy (soldiers in battle, for example), or when they are in trouble (impending exams, debt, the threat of blackmail or prosecution, and so on), or when the prospect of financial gain increases the attractions of illness still further (so-called compensation neurosis). The very high incidence of hysterical phenomena in exhausted combat troops suggests that everyone is potentially capable of developing hysterical symptoms, just as they are capable of developing epilepsy, but vary in their liability to do so. This variation presumably depends partly on constitutional variables like suggestibility and capacity to dissociate, partly on past experience, and partly on the subject's current social situation.

6. *Contemporary Understanding of Hysterical Behaviors*

The social and behavioral perspective described above is now accepted widely and implies that hysteria should be regarded not as an illness, or even as a group of related illnesses, but as a set of ways of reacting to stressful situations. It also provides a plausible ex-

planation of what is known of the epidemiology of hysterical symptoms and of the choice and outcome of individual symptoms, and has important implications for diagnosis and treatment.

6.1 Implications for the Epidemiology of Hysteria

Few community surveys of the incidence or prevalence of psychiatric syndromes have generated satisfactory measures of hysteria, because the range of phenomena embraced by the term is so vague and variable, and because most hysterical phenomena are short-lived. Consequently, most of the epidemiological 'facts' referred to below are derived, *faute de mieux*, from the opinions and experience of clinicians. Subject to this proviso, the reason the incidence of conversion hysteria is falling both in the industrial and the developing world (in India there is epidemiological evidence of this) is probably that in both settings levels of education and sophistication are rising and life becoming less stressful. The reason hysterical symptoms are seen mainly in adolescents and young adults is probably because the adoption of a dependent role comes most readily to those who have only recently forgone the privileges of childhood and are least experienced at coping with the demands of the adult world. The predominance of conversion symptoms in women almost certainly has a similar explanation. In most cultures women have always been dependent on their husbands or fathers. As a result, they have been forced to utilize the few opportunities provided by that dependent role to get their own way in a male dominated world. Only in the last two or three generations, and only in industrial countries, has this slowly ceased to be so, which is probably why the number of young women presenting to doctors with conversion symptoms has fallen steadily since Charcot's day and why the female predominance has now fallen below 2:1. The frequent coexistence of hysteria and organic disease is also readily explained, for those who are genuinely ill or handicapped—by epilepsy or multiple sclerosis, for example—are the very people likely to have the most difficulty coping with the demands of everyday life, and with the most vivid and recent awareness of the rewards of the sick role. Finally, the predominance of left-sided limb paralyses and anesthesias, first remarked upon by Briquet, is explained, for in a right-handed person this minimizes the handicap without reducing the social impact.

6.2 Implications for Choice of Symptom and Outcome

According to psychoanalytic theory the choice of symptom is determined by its symbolic meaning for the patient, and doubtless this is sometimes so. Usually, though, it is determined by cultural expectations and the subject's own experience of illness, in themselves or others. The nurse who develops hysterical blindness, for example, had severe conjunctivitis as a child, and the young man who loses the use of his legs had a grandfather who was housebound for years after a stroke.

Just as the development of hysterical symptoms is encouraged strongly by situations in which the balance of the advantages and disadvantages of sickness outweigh those of health, so recovery is encouraged by a reversal of that balance of advantage. This is why the symptom usually fades away if the situation that provoked its appearance resolves itself. If that situation persists, however, or if the inadequacies of the subject are paramount, the advantages and disadvantages of the chosen symptom become important. This is why disabling symptoms, like blindness or inability to stand or walk, have a comparatively good prognosis, whereas those which can be switched on or off as occasion demands, like fits or vomiting, or cause little disability, like tremors, are more intractable.

6.3 Implications for Investigation and Treatment

There are two implications for the investigation of patients with suspected hysterical symptoms, both well known. The first is that medical attention, admission to hospital, and glamorous investigations may easily potentiate the attractions of invalidism. (Indeed, many psychiatrists suspect that the fascinating phenomenon of multiple personality is largely the product of excessive medical interest.) For this reason it is important that the investigations needed to make sure that the patient's symptoms are indeed hysterical are completed as quickly as possible, and not repeated without good reason. The second is that it is immaterial whether or not the patient is aware that he or she is in some sense feigning illness, because the treatment is the same either way. Although the dilemma usually was avoided by assuming unconscious motivation, the traditional medical or psychoanalytic approach should require a distinction between conscious motivation (which is malingering, and so subject to strong disapproval) and unconscious motivation (which is an illness—hysteria—and so worthy of sympathy and treatment) in spite of the fact that it is generally impossible to distinguish the two. Indeed, the patient's degree of awareness often varies from time to time, so that what is initially unconscious becomes conscious, and vice versa.

There are always two components to the management of hysterical symptoms: an attempt to form a psychotherapeutic relationship with the patient, and an assessment of the elements of their social environment which are encouraging or discouraging

invalid behavior. The former is never straightforward, and inexperienced therapists often allow themselves to be manipulated by flattery or coquetry, or end up angrily rejecting the patient because they resent being manipulated, or indeed do both these things in succession. Occasionally it is possible by gentle degrees to lead the patient into a discussion of the emotional predicament from which their symptoms arose, and of the relationship between that predicament and their symptoms. More often there is a sustained denial of emotional difficulties of any kind, and it becomes increasingly clear that the subject is more interested in being a patient than in being cured, and curiously uninterested in the origins of their symptoms.

Arriving at an adequate understanding of the conflicting emotional and social pressures on the patient, both those encouraging and discouraging invalidism, and assessing the possibilities for strengthening the latter, usually involves talking to other key figures in their life as well as the patient. If the patient no longer needs to be ill, they either get better spontaneously, at least in the short term, or do so in response to any treatment that allows them to recover without loss of face. If, on the other hand, there are cogent reasons why invalidism is still more attractive than health, attempts have to be made to modify the attitudes and behavior of those with most influence on the balance of advantage and disadvantage referred to above, and at times this involves devoting more time to a key relative than to the patient. In the past hypnosis was used widely in the treatment of hysteria, and there is no doubt that, thanks to the suggestibility of people with hysterical symptoms, hypnosis is often dramatically successful in the short run. But unless the attractions of invalidism are also tackled, or the underlying predicament has resolved itself, success is usually short-lived.

6.4 The Limitations of Contemporary Understanding

Although this contemporary social and behavioral view of hysterical behaviors explains many otherwise puzzling clinical observations, it provides no explanation of the mechanisms of conversion and dissociation. The explanatory theories proposed originally by Freud and Janet over 100 years ago have been abandoned, but nothing has yet been offered in their place and the neurophysiology of both phenomena remains a mystery. Indeed, shorn of the original psychoanalytic assumption that unconscious anxiety was being converted into a neurological deficit, the term conversion disorder has lost all meaning. And hysteria itself has been discarded. But as Lewis observed a generation ago, 'a tough old word like hysteria dies very hard.' It may yet come back.

I

Ideal Type: Conceptions in the Social Sciences

The term 'ideal type' (*Idealtyp*) was chosen by Max Weber (1864–1920) to denote the methodological status of certain theoretical constructions central to many social sciences, e.g., the economists' 'law of demand' or any of the concepts defined in his *Economy and Society* ('social relationship,' 'sultanism,' etc.). Common to all is their reference to the subjective action-orientations of individuals, for in Weber's opinion, socio-cultural phenomena become objects of social-scientific interest precisely under their description as 'subjectively meaningful' (see *Problem Selection in the Social Sciences: Methodology*). His point in labeling such constructions 'ideal types' is to emphasize that they cannot be rightfully interpreted as 'laws.' This tenet has never ceased to be controversial.

1. The Ideal Type as Summary of Empirical Findings (Weber)

Most of Weber's methodological reflections bear on the defense of historical science against the Positivist doctrine that to be worthy of the name, a science must aim to discover laws. His reasoning follows the philosopher Heinrich Rickert's (1863–1936), who submits that a discipline's scientific legitimacy is a function of the cognitive value of the selective representation of concrete reality constructed by it, and that to qualify as worth knowing, a representation has either to encompass every phenomenon or to accommodate every significant detail of a single properly selected phenomenon. On this view, scientific 'knowledge' is obtained through the methodical application of a suitable principle of abstraction (or 'concept formation'). There are two such principles: generalizing abstraction—defining natural science—proceeds by disregarding all properties that make things dissimilar, so as to arrive at a set of generalizations universal in scope ('laws of nature') under which every phenomenon can be subsumed and in this sense explained. Individualizing concept formation—defining history—singles out a culturally significant social arrangement and aims to depict it as a configuration of component features that make it unlike any other. The explanation of this conjunction can only be historical, as the combined effect of a unique sequence of unique constellations of causal antecedents. The prototypical individual concept, then, consists in an entire causal narrative in which the development of some unique aspect of a people's civilization is traced from its first beginnings to its (temporarily) final condition (see *Narrative, Sociology of*).

As regards its implications for Weber's conception of the ideal type, Rickert's account of abstraction/concept formation has two noteworthy features. First, concepts are viewed as assertions that something is/was empirically the case. Individual concepts (historical narratives) state the occurrence of complex cause-effect sequences. General concepts explicate their claims in their definitions (which are thus interpreted as summations of numerous findings, depicting the common features of the phenomena classed together). Classification and generalization amount to the same thing. Second, since generalizing abstraction aims to encompass ever wider domains of phenomena, it must necessarily discard their subjectively meaningful aspects. A science of socio-cultural phenomena that preserves them as such can therefore only be historical (see *Generalization: Conceptions in the Social Sciences*; *Classification: Conceptions in the Social Sciences*; *Explanation: Conceptions in the Social Sciences*).

Rickert's ideas ground Weber's position in the controversy following Carl Menger's (1840–1921) criticism of the German economists' rejection of 'abstract theory' in favor of economic history. Predisposed to defend the historical approach, yet convinced of the value of theory, Weber seeks to accommodate both within Rickert's framework. His problem is that of squaring the historical narrative's unavoidable reliance on general concepts (including economic ones) with the incongruity of these concepts' general form with their reference to individuals' subjectively meaningful orientations (which is a requirement of their serviceability in historical narratives). The methodologically crucial manifestation of this incongruity is the disparity between the conceptual definitions' claim to the uniform, explicit, and unalloyed presence of these meanings in the minds of the relevant individuals, and the observed variations in clarity and purity. Given his understanding of general concepts as summarizations of singular instances, Weber tries to make methodological sense out of the conceptual representation of empirical spectra of meaning as strictly general uniformities. His solution is straightforward: their general form notwithstanding, these are not truly 'generalizing' concepts, but 'idealizing' ones;

they depict not those aspects with regard to which phenomena are exactly like others (of a class), but those that by degrees render them 'culturally significant' or 'typical.' Hence, their methodological status is that of 'ideal types' (see *Causal Counterfactuals in Social Science Research*).

Weber considered the formulation of ideal types to be the task of a specialized generalizing discipline—sociology—that would supply the individualizing science of history with its apparatus of general concepts. Methodologically speaking, ideal-type formation is therefore constitutive of a Weberian sociology; it also denies it autonomous scientific value (see *Theory: Conceptions in the Social Sciences*). Whatever cognitive value ideal types may have relates to their utility for historical science. This utility is first of all heuristic: As descriptions of characteristic patterns ideal types can furnish initial guiding assumptions for the scrutiny of sources, especially regarding complex and non-obvious causal relationships and the unobtrusive presence of specific meaning elements in the opaque tangle of concrete action-orientations. Second, they can serve as a basis for educated guesses to bridge gaps in the available evidence. Finally, they are irreplaceable as descriptive devices. To historians who desire precision they provide a clear terminology and an efficient way of pinpointing a phenomenon's peculiarity by specifying its deviation from an ideal-typical definition functioning as a benchmark.

2. *The Ideal Type as Mode of Experience (Schutz)*

While Weber's position harnessed theory and history together, its ultimate vindication of the historical approach could hardly satisfy Menger's intellectual heirs. Ludwig von Mises (1881–1973) objected that the most general propositions of social science could not possibly be derived inductively from atheoretical historical data since the sources are incomprehensible unless they are apprehended in terms of 'the principle of action.' The grasp of human life-manifestations as instrumental and preference ordering underwrites all experience of them as 'actions' and therefore has *a priori* status, like the principle of causality. In von Mises' view, the theorems of economics are nothing but logical implications of the axiomatic category of action and therefore are universally valid independent of all empirical evidence, their grasp made possible through (categorical) 'conception' (*Begreifen*), which is the special mode of cognition that reveals the universal aspects of meaningful behavior. For, so von Mises, human conduct is reason in action, and the universality of reason is the basis of the universality of conduct's structures.

Von Mises' critique of Weber on the grounds of an epistemology of comprehension is shared by Alfred Schutz (1899–1959), who also proclaims the universal validity of 'pure' economic theory. That he simultaneously considers its concepts to be ideal types indicates a conception fundamentally different from Weber's; certainly, his analysis of *Verstehen* as the ideal-typifying grasp of subjective meanings is at least in part conceived to offer a phenomenological–empiricist alternative to von Mises' rationalism (see *Phenomenology in Human Science*; *Interpretive Methods: Micromethods*; *Interpretive Methods: Macromethods*). Accordingly, Schutz formulates a theory of the experiencing of meanings, and of the differences between its everyday and scientific versions. His argument proceeds through a discussion of four scenarios:

(a) An agent's (ego's) understanding of his or her own action's subjective meaning is described as his or her direct awareness of its specific identity as the entailment of his or her action's wherefore ('in-order-to motive' or 'project').

(b) Ego's understanding of someone else's (*alter's*) subjective action meaning is analyzed as his or her experience of what alter is/was experiencing, through the medium of *alter's* inner experiences' outward manifestations (such as acts or pronouncements). Manifestations can be perceived 'objectively' as self-contained entities with identities of their own (as specific things, performances, states); they can also be taken as purveyors of information about their producers' 'inner durations.' In 'objectifying' perception, a bundle of experiences is disembedded from its original setting—the cognizing subject's ever-changing stream of consciousness—and, as a unit, held still over and against it so as to appear as a de-subjectified, bounded, and stable entity classifiable in a schema of 'objective' meaning. Any agent's perceptual bestowal of such objectivity, unity, and permanence (with its attendant assimilation into an objective-meaning schema) on elements lifted from the primordial flow of his or her lived experiences, for Schutz constitutes (ideal-)typification. Even after objectification, however, the reference of action-products to the processes in human consciousness underlying their generation is not obliterated, and in subjectifying or symptomatic perception, it can be made topical. Ego's grasp of *alter's* inner life (understanding) is always based on the subjectifying exegesis of his or her own experiences of such manifestations, aiming to recover their constitutive in-order-to motives. Understanding thus presupposes a particular 'intentional' attitude, i.e., the 'directing' of the 'attention' toward the phenomena not as objective entities but as embodiments of their creators' projects.

In everyday face-to-face relationships a most important role is played by the 'signitive' apprehension of *alter's* body as an expressive field. This apprehension—neither inferential nor hypothetical, but a *sui generis* grasp of the other person's lived experiences at the very moment of their occurrence—is of such immediacy that *alter's* consciousness appears to ego

without any opaqueness and as operating in a manner exactly like his or her own. This prereflective conviction supports the procedure by which ego grasps *alter's* inner life through an explication of his or her own experience of its manifestations. Fantasizing them as generated by himself or herself, he or she imagines what for him or her would function as their in-order-to motives, and treats them as *alter's* own.

(c) When *alter* is not physically present, ego must do with a set of manifestations much reduced in number and symptomatic reach. *Alter* loses his or her quality as a palpable, many dimensional, and multilayered dynamic presence and becomes a more or less anonymous and schematic 'contemporary.' As a function of this anonymity, ego's subjectifying intentional attitude—his or her 'Other-orientation'—undergoes a profound change in structure. In the face-to-face situation, the 'Thou-orientation' founding signitive apprehension captures the other person as a concrete, spontaneous, live self. Beyond this sphere, direct apprehension becomes impossible, and ego-*alter* interaction is no longer structured through dynamic mutual attunement; instead, the participants now treat each other as objects of predicative orientation. The corresponding 'They-orientation' directs ego's attention to those of his or her experiences that can function as substitutes for the unavailable direct experience of *alter's* duration. These substitutes are found in ego's store of objectified motivational constellations accumulated in past encounters with numerous individuals' consciousnesses. They can serve this function because, lifted from their original context, they have become de-subjectified and anonymous. The result of their deployment is the experience of *alter* as a type with a typical project, indistinguishable from other individuations of the same type.

(d) Sociologists adopt the same orientation as contemporaries, but use scientifically tenable (clear and precise) ideal-typifications to grasp their subjects' typifying action orientations. Since these structure the interactions sociologists are interested in, sociological ideal types must be compatible with the agents' types. In addition to exhibiting this 'adequacy at the level of meaning,' they must also be 'causally adequate,' singling out the meanings likely to be the operative ones. Both criteria are satisfied through the formulation of types of rational action orientation, as these are clearly understandable and pervasively used by contemporaries.

The ideal-typical character of social-scientific formulations does not preclude their universal validity, as Weber would have it, confounding the types' 'ideality' with their 'anonymity.' As long as the elements synthesized in them have been so abstracted (idealized) as to exhibit affinity to any particular (kinds of) inner durations no longer, they depict totally anonymous, fully generic processes of consciousness. Such are the propositions of theoretical economics, capturing the actions of a faceless 'pure anyone,' of whom nothing is presumed except that he or she is exchanging goods to satisfy preferences.

In making the universal validity of economic theory a function of the empirical vacuousness of the project attributed to the anonymous 'one,' Schütz adopts von Mises' position. Both authors also agree that substantive assumptions about goals of action are properly regarded as a matter of economic history, where Weberian ideal types reign. Schütz's considerations here are articulated by Felix Kaufmann (1895–1949), who charges theory with providing the 'basic concepts' ('forms') that serve as a field's *a priori* foundation by defining its phenomena, and distinguishes this task from empirical 'application,' where questions of empirical evidence become relevant. One must not confuse, *à la* Weber, the universality of a field's categorical forms with the empirical confirmation of generalizations in its domain of application.

3. *The Ideal Type as Definition of a Model*

The more recent proponents of nomological social science do not propose a theory of abstraction but highlight the role of general empirical hypotheses in nomological-deductive explanations; accordingly, they focus on the explanatory potential of ideal-typical generalizations (see *Explanation: Conceptions in the Social Sciences*). Hempel, for instance, regards ideal types as theoretical systems akin to idealizations in natural science (e.g., the theory of ideal gases); these postulate that under 'ideal' conditions the systems' behaviors exhibit specific regularities. Prototypically these conditions describe empirically never encountered extremes of actual system properties or entities, which raises the question of the explanatory value of 'laws' that either have no empirical domain or lead to false predictions when applied to existing nonideal constellations. This problem is resolved when the law can demonstrably be derived from an independently established, more general theory, but Hempel notes the nonavailability of such a theory even in economics, the most advanced social science, and ends up regarding its idealizations as 'intuitive' initial simplifications awaiting further refinement. However, economists have not been moving to improve their central axioms, and Rosenberg considers them essentially unrefinable generalizations of folk psychology: their fundamental categories ('belief,' 'preference,' etc.) fail to classify phenomena in terms of natural kinds and therefore cannot yield genuine laws.

Hausman undertakes to defend the discipline's methodological peculiarities by viewing theories as general hypotheses that predicate the assumptions of specific models of particular portions of the world. In this perspective, models are definitions of more or less complex predicates (concepts, structures, systems), such as 'classical particle system' (defined by Newton's laws of motion and gravitation), 'simple consumption

system' (Hausman 1992, p. 35), or 'exchange' (Weber 1968, p. 72), and are constituted by sets of assumptions which *per se* assert nothing about the world but merely describe a structure. They may, however, be declared true of some empirical domain, as attributes of actual systems, which are thus asserted to exhibit the structure defined by the model. A predication of this sort is a theoretical hypothesis.

The point behind model construction is to simplify reality's complications. In natural science it is often possible to create experimental situations approaching the model's simplifications and thus to test its empirical adequacy as a predicate. The unavailability of this opportunity in economics has led, on the one hand, to a preoccupation with model construction *per se*, disregarding empirical issues, and, on the other hand, to a conception of economics as 'inexact,' only approximately true (see *Systems Modeling*).

Economic models usually are definitions of (hypothetical) economies or markets, suggesting to Hausman that the discipline is less concerned with the establishment of genuine nomological propositions than with the implications of certain behavioral generalizations—presumed to be roughly correct—for the actions of individuals, markets, and institutions operating in particular circumstances. Compared with the corresponding empirical domains, they represent radical simplifications and idealizations, achieved through the deduction of a basic system structure from a set of theoretically favored principles of economic behavior, and by treating whatever is not so deducible as the confounding effects of 'external,' (noneconomic) factors (which for this reason are excluded from the model).

The highly 'abstract' character of economic models may well be unavoidable. Yet in view of the 'inexactness' of the underlying behavioral premises, conjoined to the practical impossibility of empirically controlling for the effects of the 'external' variables, the models' lack of 'realism' raises the question of their usefulness as predicates in assertions about the real world. In Hausman's view, to make scientific sense, statements employing such predicates must be understood as (implicitly) qualified by vague *ceteris paribus* clauses, which make their truth dependent on the satisfaction of a number of unspecified conditions. Ideally, a *ceteris paribus* clause serves as a shorthand for a list of specific and separately analyzable causal factors whose explicit inclusion in a model renders true otherwise false statements predicating it of some empirical structure(s). Economists, however, frequently invoke the clause without having any precise idea of what specifically is covered by it. This sort of employment amounts to the claim that there are some unidentified factors whose inclusion in the model predicated of some empirical system(s) will make the otherwise false assertion true. Hausman is very much aware that the line between an assertion's 'vague qualification' and its permanent immunization against falsification is easy to cross. How much one may want to stake on vaguely qualified assertions will vary with the context and must depend on one's assessment of the extent of the basic behavioral postulates' 'inexactness.' Hausman believes that a case can be made in their favor but also acknowledges economists' anti-sociological commitment to economics as a 'separate' science, whose enduring appeal seems to involve more than matters of scientific fruitfulness.

Idealization, Abstraction, and Ideal Types

1. Abstraction

Abstraction is a psychological action in which usually one, but possibly more, aspects of a thing or process,

or a group of things or processes, are mentally separated out from that thing or process, or group of things or processes. All intelligent thought about the sensible empirical world can be understood as being abstractive. The empirical world throws up an ever-changing melange of details which invades the senses. To render this datum intelligible, inconvenient details and transitory changes need to be abstracted away from and the simple, stable, and general located. The successful identification of natural and social kinds would seem to require the ability to perform abstractions. Individual police officers, who instantiate the social, kind *police officer*, vary considerably in personal appearance and in other forms of possible identification. In order to reliably identify an individual as a police officer, the stable and enduring underlying properties that are common to the kind police officer must be identified.

Because the process of abstraction involves the disregarding of particular features of things or processes in an attempt to develop more general concepts, abstractions are sometimes conflated with universals. However, there is no requirement that a successful abstraction need lead to the development of a concept which identifies a universal. A successful abstraction may lead to the identification of relatively invariant generalizations about a kind of thing or process which fall well short of being universally applicable. Whereas the universal is conventionally contrasted with the particular, the opposite of the abstract is usually held to be the concrete.

Not everyone would accept that abstraction is as pervasive in the mental lives of individuals as has been suggested here. Plato can be interpreted as denying that the intelligibility of the sensible requires abstraction. It may appear that the mind is abstracting from the experience of concrete entities to the identification of underlying general kinds. However, Plato would argue that it is actually noticing resemblances between particular entities and a world of perfect forms, which it was familiar with before this life. Berkeley and Hume also downplay the role of abstractions in everyday thought. They object to an account of abstraction provided by Locke, holding that what cannot be separated in reality cannot be separated in the mind either (Baxter 1997). Berkeley and Hume see no need for abstraction from the empirical, in order to render the world intelligible, because they do not allow that the sensible is distinct from the intelligible.

Whether or not Berkeley and Hume are right to reject portrayals of abstraction as being all pervasive in thought, it is clear that the process of abstraction plays a central role in the mental lives of individuals. The ability to apply the sophisticated apparatus of modern mathematics and logic to actual situations depends, *inter alia*, on the capacity to reason abstractly. Also, the capacity for abstract thinking enables previously unfamiliar experiences to be rendered intelligible, by relating these to the familiar. The nineteenth century empiricist John Stuart Mill presents the example of 'South-Sea islanders,' whose only experience of four-legged animals is of hogs. The islanders are able to make sense of European talk of other four-legged animals by abstracting from the concrete example of hogs to the general concept of the quadruped (Mill 1950, p. 299).

2. *Idealization*

Idealization, which is enabled by abstraction, is also a psychological act which, while not as pervasive as abstraction in everyday thought, has been extremely important in modern scientific thinking. While abstraction only involves the mental separation of aspects of things or processes, from those things and processes, when these may not be so separable in reality, idealization involves the mental rearrangement of features of reality so as to assist the development of explanations. A familiar idealization is the frictionless plane, used to exemplify mechanical explanations. To conceptualize the frictionless plane, real planes which have friction-causing surfaces are abstracted away from. However, frictionless planes are not merely abstractions. It is convenient to imagine things which have surfaces that are frictionless, even though it is generally accepted that all surfaces exert some friction on objects which they come into contact with, however slight. For the purposes of thought experiments, disbelief is suspended and the convenient idealized fiction of a rearranged and simplified reality, which suits explanatory needs, is allowed; a reality in which, for example, a surface can come into contact with an object and exert no force of friction on that object whatsoever.

The application of scientific laws and models to real complex situations often requires considerable idealization. In order to practically apply Newtonian mechanics to predict the trajectory of a driven golf ball, the golf ball is idealized as a perfect sphere which is struck with a constant force in the direction in which it is intended to travel. Details of the shape and surface of the actual ball which, in reality will affect its trajectory, are conveniently ignored. Other, potentially relevant causal factors such as wind resistance and humidity are also ignored. The resulting idealized calculation of the golf ball's trajectory will, at best, be approximately true some of the time. The trajectory of a golf ball which is hooked or sliced will not be accurately predicted, nor will the trajectory of an irregularly shaped golf ball be accurately predicted, and nor will the trajectory of a golf ball which is struck into a strong wind be accurately predicted. The idealizations made are useful ones. The utilization of a simple model which exactly describes the motion of an ideal golf ball enables an approximate description of the motion of actual golf balls in a useful range of cases. An explanation of the golf ball's trajectory which did

not employ idealizations and which involved an attempt to include all causally relevant factors would be horrendously complex, if it was possible to calculate at all.

Galileo initiated the scientific revolution, in part, by legitimizing use of the abstract language of mathematics to enable the application of idealized explanatory laws and models in the natural sciences. Galileo's *Dialogue Concerning Two Chief World Systems, Ptolemaic and Copernican* (Galilei 1953) is a polemical work in which a proponent of the new approach to science, which endorses idealization, argues against an advocate of the Aristotelianism of Galileo's day that was opposed to idealization in the sciences. In response to the major Aristotelian objection to idealization, that the physical world is not a world of perfect geometrical shapes and therefore cannot be accurately described in geometrical terms, Salviati, Galileo's proponent of idealization, draws an analogy between the 'geometrical philosopher' and a merchant who allows for the weight of packaging materials when calculating the weight of his wares.

> … when he wants to recognize in the concrete the effects which he has proved in the abstract, [he] must deduct the material hindrances, and if he is able to do so, I assure you that things are in no less agreement than arithmetical computations. The errors, then, lie not in the abstractness or concreteness, not in geometry or physics, but in a calculator who does not know how to make a true accounting. (Galilei 1953, pp. 207–8)

The recognition that idealization is endemic to scientific explanation is problematic for the confirmation of theories. An empirical test is rarely, if ever, a decisive test of a theory. Instead it is a test of a conjunction of the theory plus a series of idealizing assumptions. A falsification of this conjunction implies that either the theory is false or that one or more of the idealizing assumptions are to be rejected. Unless the magnitude of the combined effect of all of the idealizing assumptions which stand between a theory and empirical reality can be identified, or unless a theory which accurately describes reality without the aid of idealizing assumptions can be constructed, an exact experiment which decisively confirms or disconfirms a theory cannot be performed. This problem is better known in the philosophy of science as the problem of auxiliary hypotheses (Lakatos 1970).

3. *Idealization in Economics*

The social science in which idealization is most obviously employed, and most explicitly defended, is neoclassical economics. This is because neoclassical economists make idealizing assumptions which are plainly false and therefore in need of defense from criticism. Most if not all of the generalizations which form the corpus of neoclassical economics are true only in idealized situations where fully informed, fully rational agents, who are concerned only with maximizing expected utility, trade in conditions of unfettered competition. Economic reality is very different from this idealized situation. The prices of actual goods usually do not vary in the ways in which the neoclassical laws of supply and demand suggest that they should, and real humans do not appear to act so as to always maximize expected utility. Not only do many of their actions have no apparent relation to the maximization of expected utility, they often appear to act in ways which actually result in a decrease in their expected utility.

The most influential justifications of the use of idealization in economics have been conducted on Galilean lines and appear as part of a defense of economics as being methodologically similar to the natural sciences. A historically influential defense of idealization in economics is presented in John Stuart Mill's *On the Definition of Political Economy; and on the Method of Investigation Proper to It*. According to Mill:

> That which is true in the abstract, is always true in the concrete with proper *allowances*. When a certain cause really exists, and if left to itself would infallibly produce a certain effect, that same effect, *modified* by all the other concurrent causes, will correctly correspond to the result really produced (Mill 1967, pp. 326–7).

Mill notes the unreality of Euclidean geometry for '… lines, angles, and figures, as human hands can construct' (Mill 1967, p. 327), and draws an analogy to the situation of the 'political economist':

> No mathematician ever thought that his definition of a line corresponded to an actual line. As little did any political economist ever imagine that real men had no object of desire but wealth, or none which would not give way to the slightest motive of a pecuniary kind. But they were justified in assuming this, for the purposes of their argument; because they had to do only with those parts of human conduct which have pecuniary advantage for their direct and principal object; and because, as no two individual cases are exactly alike, no *general* maxims could ever be laid down unless *some* of the circumstances of the particular case were left out of consideration (Mill 1967, p. 327).

Mill's defense of idealization ties its use to a metaphysical picture of the world as being composed of causal tendencies which continue to be efficacious when they are not being interfered with by the activity of other causal tendencies (Hausman 1992, pp. 33–53). This is a metaphysical picture which has been argued for recently, and for similar reasons, by Cartwright (1989), whose Millian heritage is quite explicit.

While Mill argued for the general legitimacy of idealization, Marx went further and attempted to

demonstrate the ways in which idealizational explanations in the social sciences could be rigorously tested, or at least this is how he has been interpreted by Leszek Nowak. According to Nowak, Marx should be recognized as 'the Galileo of the social sciences' because his application of Galilean idealization to the social sciences is the first instance of the use of rigorous scientific reasoning in the social sciences (Nowak 1980, p. 38). Nowak's Marx relates idealizational generalizations to real situations in which these can be tested, by identifying each interfering cause which affects the expression of an underlying factor represented by an idealizational law, and attempting to calculate the magnitude of the effect of each such interfering cause.

Nowak interprets Marx's presentation of the law of value—a law relating the value of a commodity to the amount of labor devoted to its production—as an attempt to show how this idealized law could be used to explain the actual price of that commodity in particular economic circumstances. Nowak holds that Marx's law of value is strictly true only when adjustments are made for eight factors which can affect actual economic situations. For example, the law of value applies when the supply and demand of a commodity are exactly balanced, but ordinarily this is not the case. If the magnitude of all factors which distort the value of a commodity are identified, then actual market prices can be explained and decisive tests of the idealized law of value produced, or so Nowak's Marx would argue. Marx and Mill are only some of the better known defenders of idealizations in economics. More recent defences have been provided by Lionel Robbins and Milton Friedman, among others (Hamminga and De Marchi 1994).

Opposition to the use of idealized explanatory models and laws, in economics and other social sciences, is often tied to broader concerns. In particular, some opponents of the use of Galilean idealization in the social sciences attempt to draw a sharp distinction between the methods appropriate to the social sciences and those appropriate to the natural sciences. One influential way of characterizing this distinction is to hold that naturalistic explanations are inappropriate in the social sciences where interpretive understanding is the appropriate methodological framework. On some such views, explanatory laws and models are out of place in the social sciences, and the fact that these are idealized only serves to demonstrate how unrealistic and inappropriate they are in the social sciences. The possibility of a sharp methodological divide between the natural and the social sciences has been under attack, in recent times, by methodological pluralists who want to recognize the potential legitimacy of a range of methodologies in both the natural and the social sciences (Bohman 1991, Clarke 1998). If methodological pluralists are right, then there is no reason to think that idealized nomic explanations are generally inappropriate in the social sciences, although they may be inappropriate in some social sciences, or in some aspects of social science. Recently there has been a renewed effort by naturalists to defend the legitimacy of nomic explanations in the social sciences, and this has included explicit defenses of the utility of idealized explanatory laws in the social sciences (Kincaid 1996, McIntyre 1996).

A focused attack on the use of idealized explanations in neoclassical economics has been put forward by Hollis and Nell (1975, pp. 43–6). Hollis and Nell draw a distinction between the practical application of idealizing explanatory assumptions, such as the idealizing assumption of frictionless motion in physics and the practical application of idealizing explanatory assumptions in neoclassical economics, such as the idealizing assumption that adequate information about the market is available to all participants. In the case of frictionless motion, a clearly defined variable, the coefficient of friction, which can be accurately adjusted for, is assumed away. Actual participants in actual market places often have inadequate information about the market and as—in contrast to the case of frictionless motion—the effects of inadequate information are not well understood, it is practically impossible to adjust real data to precisely test explanatory laws and models which make the idealizing assumption of adequate information.

Hollis and Nell are right that the effects of inadequate information cannot be easily measured and adjusted for, whereas the effect of friction on the motion of objects traveling along a plane can. However, the simplicity of the frictionless plane is atypical of idealizations in the natural sciences where approximations and adjustments for factors which are not fully understood are frequently made (Cartwright 1983, 1989, Laymon 1995). If it is accepted that idealizations are being inappropriately used whenever the effect of interfering factors cannot be quantified—an assumption which Hollis and Nell appear to have made—then considerations of consistency suggest that the results of a very large proportion of the natural sciences ought to be rejected on the very same methodological grounds.

4. *Ideal Types*

Although it did not originate with him, the notion of an ideal type has come to be associated closely with Max Weber, and it occupies a central place in his thinking about social scientific methodology (Weber 1949, 1968). There is a large and growing literature devoted to the interpretation and exposition of Weber's methodology, which one of the leading contributors to it describes as being in a 'poor state' (Burger 1987, p. xiv). Unfortunately this is a comment which strikes this author as an accurate assessment. No doubt the poor state of commentary on Weber's

writings on ideal types is due, in part, to the difficulty of combining the skills of a historian of ideas, a sociologist, and a philosopher of science, which are all needed to properly assess Weber's methodological thought.

Weberian ideal types are a form of idealization which Weber thought to be important in, and distinctive to, the social sciences. Ideal types in the social sciences play many of the roles that idealizations in the natural sciences play. They are used to identify and separate underlying causal factors that are obscured by the interplay of causes which contribute to social environments. When messy, complex data about social environments is appropriately simplified by abstraction, they enable explanatory generalizations and models to be developed.

Weber is at pains to ensure that ideal types not be understood as averages, or as direct attempts to form empirical social generalizations:

> It is thus the "idea" of the *historically* given modern society, based on an exchange economy, which is developed for us by quite the same logical principles as are used in constructing the idea of the medieval "city economy" as a "genetic" concept. When we do this, we construct the concept "city economy" not as an average of the economic structures actually existing in all the cities observed but as an *ideal type*. An ideal type is formed by the one-sided *accentuation* of one or more points of view and by the synthesis of a great many diffuse, discrete, more or less present and occasionally absent *concrete individual* phenomena, which are arranged according to those one-sidedly emphasized viewpoints into a unified *analytical* construct. In its conceptual purity, this mental construct cannot be found empirically anywhere in reality (Weber 1949, p. 90).

Like idealizations in the natural sciences, ideal types can perform explanatory work at a number of different levels of generality, and do so in a number of different ways. Weber employs the concept of the ideal type in several different explanatory roles (Burger 1987, pp. 130–5). First there are 'individual ideal types' which can play a role in clarifying conceptions of specific historical phenomena. Even if there is no actual instance of the pure individual ideal type of feudalism, it aids historians in understanding feudal societies, and the era in which feudalism was prevalent, if they can see how and where particular societies approximated to the ideal type feudalism. Second, there are 'generic ideal types' describing the underlying causal factors which influence many or all societies. Here Weber would include the idealizations which constitute the 'fundamental concepts' of economics (Weber 1949, p. 100). A third role for ideal types is to describe developmental sequences relating historical epochs. Marx's postulated historical sequence leading to the development of pure socialist societies is an example of this role. In all of these roles ideal types are not obviously distinct from idealizations in the natural sciences, which can also be specific, generic, or developmental. However, there is a fourth way in which ideal types are used in an explanation which appears to distinguish them from idealizations in the natural sciences, which is when they are used as 'essential' ideal types.

Essential ideal types describe the ideas which are characteristic of the thinking of a particular group of people, and which imbue their thought with meaning. If the pre-Raphaelite art movement of the nineteenth century is to be understood, for example, it will not be enough only to examine actual instances of pre-Raphaelite art. The ideal type of art which the pre-Raphaelites were striving to perfect will have to be understood. It may be that no single pre-Raphaelite artwork completely succeeded in capturing the artistic ideals which the pre-Raphaelites aimed to achieve. Nevertheless, there is no hope of understanding the pre-Raphaelite art movement, and its causal interactions with other art movements and with the wider world, unless the expressive aims of its participants are understood. The same is true of broader and more complicated intellectual movements such as Christianity and Communism.

Because the ideal type is a form of idealization which legitimizes causal explanations in the social sciences and can also be an explanatory form which gives a distinctive place to human meaningfulness, its use by Weber can be understood as a means to find middle ground between methodological dualist interpretivists such as Dilthey, who draw a sharp divide between natural scientific explanation and social scientific understanding, and methodological monist positivists and naturalists, who typically seek to subsume social scientific concepts under natural scientific categories. The actual role that Weber's discussion of ideal types played in the history of the intense and polemical methodological debates in Germany early in the twentieth century—the 'Methodenstreit'—is much more complex than this story allows, however.

Although ideal types continue to be a subject of considerable historical and sociological interest (e.g., Burger 1987, Ringer 1997, Runciman 1972), they have rarely been discussed in recent philosophy of science and social science (exceptions include Papineau 1976 and Weinert 1996). In part this is because philosophical discussion of ideal types has mostly been subsumed into discussion of idealizations and in part it is because idealization has not been a focus of a great deal of discussion in twentieth century philosophy.

5. *Contemporary Problems*

While it will be conceded by most that there are particular situations where idealizations can be useful in the provision of approximately accurate descriptions, there remains much dispute about the range of

the utility of idealizational explanations. If idealized laws and models are to be reliably used in scientific explanation, the ways in which actual situations deviate from ideal ones will have to be accounted for. A temptingly simple way of dealing with this problem, which is explicit in Nowak's Marxist treatment of idealization, is to understand each idealization as a limit of a series of real cases and make adjustments accordingly (Nowak 1980). Sometimes this approach is appropriate. The frictionless plane is a limit case of a series of actual planes which are successively less affected by friction. So it is a simple matter to correct for the effect of friction to precisely explain actual cases. However, scientists often have little idea of how to go about correcting for idealizations in order to accurately describe real situations (Cartwright 1983, 1989, Laymon 1995).

In the experimental sciences, the gap between idealizations and the reality they are intended to help describe can be reduced by designing more complex experiments which involve fewer idealizations. Also, experimental situations which eliminate or minimize the effect of interfering causes can be set up, thereby reducing the need to idealize (Laymon 1995). While these approaches will typically reduce the magnitude of the deviation of idealized explanatory laws and models from reality, there remain a number of problems with their application. First, scientists do not appear to construct complete lists of causal factors which might interfere in experiments. Indeed it is not clear that they could do this. Second, causal factors do not always interact in an additive way, so their combined effect resists simple calculation. A third problem is that there is an explanatory cost involved in the use of highly specific experiments. The explanations arrived at are applicable to a narrower band of cases. The cost of accuracy is the loss of generality.

In the social sciences there are moral and practical barriers to experimentation. However idealizations, especially explanatory appeals to ideal types, remain omnipresent in social science explanations. While the gap between idealized explanations, and the real situations that they can be applied to, can be reduced in the experimental sciences, there is little hope of bridging the gap in the social sciences. Social scientists appear to be stuck with the choice of either admitting that their preferred idealizations may be wrong-headed or insisting, without apparent justification, that these are acceptable *a priori*. But idealizations can go badly wrong (Cartwright 1995) and it seems a mistake to disallow this possibility by appealing to *a priori* justification. Nowak's Marx attempted to abstract from the actual circumstances of nineteenth century capitalist economies to the law of value. Neoclassical economists, who deny that economics should concern itself with the concept of value at all, would say that this is a paradigmatic example of idealization gone wrong. But what guarantee do neoclassical economists have, or could they have, to think that their preferred idealizations stand on a surer footing?

A further subject of dispute centers around a metaphysical consequence of the prevalence of idealization in science which has been raised against scientific realists by Nancy Cartwright (1983, 1989), reviving and developing the antirealist thinking of Pierre Duhem, the French physicist and philosopher who wrote at the end of the nineteenth century. Cartwright (1983) agrees with scientific realists who hold that that the fundamental laws of science are explanatorily powerful generalizations, but denies that this in itself is a good argument for their truth. The fact that fundamental laws are idealized means that they are protected from direct empirical testing by loose approximations, by the use of open-ended *ceteris paribus* clauses, and by the unrealistic assumption that causal factors are straightforwardly additive. Scientific realists generally concede that these problems exist, but argue that nonfundamental laws in science, which are special instances of more fundamental laws, are more amenable to testing and can be better confirmed. However, Cartwright denies that actual nonfundamental laws in the natural sciences are literally to be understood as logical derivations of fundamental laws. In a careful study of the construction of amplifiers, Cartwright (1983, pp. 107–12) demonstrates how engineers approximate away from general theory in *ad hoc* ways so as to find descriptively accurate laws which have only the appearance of being logically derived from general laws.

Scientific realists can accede to all of Cartwright's points and hold out the hope of improving experimental techniques, and thereby improving scientific explanations to the point where there is less room for doubt as to the veracity of fundamental laws. However, because of a lack of experimentation in the social sciences, the social scientist who is a realist about particular grand theories in the social sciences, is faced with the same problem without apparent hope of a solution. No progress is made towards demonstrating that a grand sociological or economic theory is true by showing how it is applied in a particular situation to provide a more specific theory, which is empirically well established, if the application of the grand theory to the particular situation turns out to depend on *ad hoc* modifications, and is not an instance of logical derivation. However few, if any, specific social scientific theories appear to be logically derived from grand theories.

Identity and Identification: Philosophical Aspects

It is doubtful that the concept of identity is susceptible to a substantial philosophical treatment at a high level of generality. This is not so much because there are too many disparate theories of identity, but more because the sort of things of which the identity is taken up by philosophers are too disparate for uniform treatment. Broadly speaking, two conspicuously different sets of interests make such a treatment particularly difficult. The concept of 'identity,' when applied to such very basic categories as objects, properties (or universals), events, and persons, forms a cluster of themes in metaphysics, and these receive a kind of analysis far removed from such themes as national, ethnic, racial, or sexual identity that are usually discussed in political philosophy and moral psychology. No obviously common notion of identity that is either tractable or interesting spans both sets of interests.

One point of intersection between the more metaphysical and the more social themes might be this. The concept of a person has long been thought of as an ethical category, but more recently the most interesting accounts of the metaphysical issue of personal *identity* have begun to stress these normative and ethical considerations in a rigorous way, thereby infusing metaphysics with value. Although this development is often resisted, it should not really come as a surprise since the metaphysical question of personal identity has always been one of the criteria of identity of a person over time, and if that question was answered wholly in non-normative terms, then the answer would be disappointing in having no relevance to evaluative questions such as why a person should accept responsibility for actions of a past self that is identical to them, or why should a person particularly care—as they do—for the wellbeing of a future self that is identical to them. To insist that any answer to the metaphysical question should have such a relevance would be to begin to unify the two sets of disparate interests in the notion of identity mentioned earlier. Having said that, this article will not take up the metaphysical issues surrounding identity any further, but will focus entirely on the concept of identity that is of more direct interest to the social sciences.

Here too the issues are diverse. There is the familiar question as to the identity of collective social phenomena: of classes, of nations, and of society itself, and whether or not their identity is in some sense dependent ('supervenient') on the identity of individual persons who belong to them. Much has been written on this subject but it is less current than another subject, which is: What is it for an individual person to be a social type, a Muslim, say, or a white male, a Quebecois, a gay or lesbian … ? The currency of the subject is a result of the importance it has come to have

in politics. The rest of this article will restrict its focus to this question.

Although the intensity of identity politics in many parts of the globe in the last few decades of the twentieth century has given rise to the constant use of the term 'identity' as well as to a glamorous theoretical interest in the concept it expresses, there has been little clarity or rigor in its theoretical deployment. One initial step towards imposing some theoretical order on the concept is to distinguish at the outset between its subjective and objective aspects. The term 'identification' may be usefully introduced to cover the former aspects. That is, when a person is said to have a certain identity owing to some characteristics they have, and with which they identify, then identity is being thought of in its subjective aspects. If their identity is owed to characteristics they possess but with which they do not necessarily identify, then we are thinking of identity in its objective aspects. This distinction is of the utmost importance, because it eventually reveals the conceptual links that the concept of identity has with a range of other notions in moral and political philosophy, such as autonomy and reason (to mention just two of the most fundamental), and with the significant debates about them.

1. *Subjective Aspects of Identity*

What is meant by identifying with some characteristic, thereby making it an identity-imparting characteristic in the subjective sense? This is actually a more complicated question than it might seem.

A first attempt to answer it might be to say that someone identifies with a certain characteristic, if they value it. Thus one may value the fact that one belongs to a certain nationality or ethnic community or even to a certain profession, if one can be said to have the identity (in the subjective sense) of an Indian or Korean–American, say, or a teacher and writer. This seems to be a minimal initial condition for identifying with it; but it is clearly not sufficient since one may have values from which one is oneself alienated. This can be a fairly common phenomenon. To be alienated from one's values is structurally akin to being alienated from one's desires. Just as an alcoholic may be disgusted with his own addictive desire for alcohol, so also someone may disapprove of his own patriotism, or find his pride in his profession intolerably smug.

A further condition has consequently to be added to our minimal condition before a characteristic imparts subjective identity: one has to endorse one's valuing of that characteristic. That would presumably ensure that one is not alienated from its valuing. There is further reason why endorsement of this kind is necessary apart from the attempt to solve the problem of values one is alienated from: the topic of identity *qua* identification is not merely about what one is but also about what one conceives oneself to be. This idea, therefore, brings with it the reflective endorsement of the relevant valued characteristics.

To endorse a value, it is often said, is to have a second-order value. Someone must value the fact that they value the characteristic of belonging to a certain nationality or profession, before they can be said to have the identity of an Indian or a teacher, in this subjective sense. (We should add that something like a second-order valuing may not be necessary in order to ensure that there is no alienation from one's own first-order values. All that may be needed is something negative: that there is no second-order disapproval of one's first-order value. However, as already noted, the second-order level comes in a more positive form, because identification is unavoidably about reflective matters such as what one takes oneself to be.)

With this second-order valuing in place, have we said something sufficient about identification? Not yet, since one's second-order values can be highly neurotic, and when they are they can be values that one is also alienated from. For example, someone may feel their second-order value which disapproves of their first-order valuing of their role in their profession as being too smug, the profession itself being too prim, too censorious, or too much of a super-ego phenomenon.

What further condition must now be added to give a sufficient account of identification? One possibility is to conceive of identification as requiring a receding hierarchy of orders of value. At each order, one is not alienated from a value if one endorses it at a higher order. So, in our example, any neurosis regarding a person's second-order disapproval of his pride in his profession is ruled out if he has a third-order approval of his second-order disapproval.

This solution, however, raises worries about an infinite regress. In order to avoid such a regress, a second possibility is to conceive of identification as not emerging in a receding hierarchy but as requiring a coherence among one's values, no matter what order of value is being considered. So, in our example, the second-order disapproval is neurotic, not because there is a lack of third-order approval of the second-order disapproval, but rather because the latter does not cohere with one's other values at all levels, including the first-order values. The second-order disapproval is something that one is not alienated from, i.e., something that one identifies with, only if it coheres well with the first-order values and other second-order values one has. Here no infinite regress threatens, but some philosophical account of coherence among values must be worked out to match the coherentist accounts of belief and knowledge that we have already available to some degree of sophistication. It is worth noting that if this coherentist way of thinking of identification is right, identification is very closely tied to rationality in values, since the point of a coherentist account of value is presumably that it is an account of when one's values are rational. In a word, one identifies with one's values to the extent that the

value is rational, in the sense of being fortified by coherence with our other values. The conclusion is attractive, as is any conclusion which allows two seemingly separate themes (rationality and identification) to be united.

The trouble, however, is that if identification is given by a rationality-imparting coherence among our values, then we will be identified with all the values we have which are rational in this sense. But that is of not much help with respect to the idea of identity since it follows from this that our identity (in the subjective sense) is never going to be anything very distinctive. It will pick out nothing very special or identity-imparting among all our coherent values such as the ones we have been discussing, one's valuing the fact that that one is an Indian, a teacher, a writer, a Muslim … no one of these will be more importantly relevant to one's identity than other characteristics of ours which we value coherently, such as one's weight, one's love of cricket or of dessert. Precisely what seemed attractive about this view of identification is what makes it of no particular help on the subject of identity, with which we are concerned. (However, on this point it should be noted that the hierarchical conception does no better since it too gives no indication as to why we should think that higher-order valuings of first-order values regarding such things as one's nationality or profession should be more relevant to one's identity than those which endorse first-order valuings of one's weight or of dessert.)

It is not of much help to say that in a relatively coherent set of values, some will still be more coherent than others, and it is these which are relevant to identity. These will still be far too many to be distinctive in the way we want the values to be which give one one's identity. There will be nothing very interesting about the notion of identity, and no particular reason to take it up as a theme in social and political philosophy, if our identity is always given by a wide range of characteristics which we value and whose valuing we endorse.

Perhaps this difficulty teaches a deflationary lesson. Perhaps it is a sign that there is something inflated about the very idea of identity, that our thinking that there is something specially distinctive about some characteristics is misguided, that it is not something we should expect, and that we have come to expect it only because of the recent rise of identity politics which has elevated some characteristics—nationality, ethnicity, linguistic, and religious allegiances—beyond anything warranted by or echoed in the actual moral–psychological economies of ordinary citizens. There is some point to this qualm, a point that needs much nuanced development in longer discussions of the subject. But it can also be a point that is too glibly made. For it does seem, at first sight anyway, to be quite accurately descriptive of at least a small, vocal, and influential body of citizens in many polities who display a strong identification with these very characteristics. And of them at least, some notion of identification must be given that shows why these characteristics are valued more distinctively than the many others that are also coherently and rationally valued by them.

We therefore still lack a sufficient account of identification which will make the notion relevant to our subject of identity. To repeat: what we need is not merely endorsement (of one's own valuing of some characteristic of oneself) by some higher-order values or by coherence with other values, but some further element that makes the value endorsed more central and distinctive in our psychological economies.

An obvious thought here might be to say that the values which are more central are those that are more intense than other values, especially since it does seem as if Muslims, Quebecois, Serbians, etc., who seem most visible in identity politics, value their Muslimness, etc. very intensely, more intensely than other things they value. It is a question, however, of how theoretically useful it is to assert 'intensity' as a primitive and unanalyzable property that values have; but even apart from this problem, the proposition is wrong, for in some cases of weakness of will we act on values that are very intense but which we do not endorse. Nor does it improve things to make the requirement of intensity move up one level by requiring the endorsement of identity-imparting values at the second-order level to be more intense than the endorsement of other values. This is because the problem created for the requirement of intensity by cases of weakness of will carries upward to higher orders as well.

A better way of getting at the required further element is to say that the endorsement of the value must be such that it makes the value concerned more *unrevisable* (rather than more intense) relative to the other values one holds. For it is surely intuitive that Muslims or Quebecois, whose identity is caught up with their valuing of their characteristics, are less likely to give up valuing them than the other values they hold, or perhaps—a more subtle variation of the intuition, one that will be developed briefly below—are less likely to conceive of themselves as giving up the value.

For this thought to be genuinely promising, we need (a) to show what sort of endorsement of a value makes the value relatively unrevisable, and we need (b) to ground the idea of unrevisability in something which would not show the reluctance to revise to be irrational by the lights of the agent herself (in the way cases of weakness of will show that acting on or even holding some of our most intense values is irrational by the agent's own lights).

The first is the most significant task: which among all the values that equally cohere with one another are the more unrevisable? As we said, it is only if we answer this question that we capture what is distinctively identity-imparting about valuing being a

Muslim or Quebecois for the sort of agent we are concerned with. Here is a way of bringing out why this should be so. Any answer to the question would have an analogous effect to what Quine (1953) and Putnam (1975) intended when they argued that some beliefs or propositions are at the very center rather than further out toward the periphery in our physical theory. The idea behind this metaphor was intended to replace misguided traditional ideas of 'analytic' or 'synthetic' *a priori* propositions. Their point was that for the theory to be the theory it is, is given by the beliefs or propositions which are at the center of our physical theory (e.g., our belief in the transitivity of length), since they are more immune to revision than the ones further out on the periphery which are more exposed to what Quine called the 'tribunal of experience.' If those central beliefs do get revised, then it is not clear whether the theory (the very same theory, that is) has been refuted, or whether we have changed the subject because the meanings have changed. So also, analogously, we might say that a person's identity is given by his or her relatively unrevisable values—however we characterize them—and if those are given up, then it is not clear whether it is a change in the ordinary sense where the overall identity remains constant whilst a change in value has taken place, or whether the overall identity itself is changed. This analogy, though inexact, is all the same roughly intuitive and reflects our ordinary talk, when in a fit of nationalist sentiment, we say things such as 'I will lose my sense of self if I betray my country' (or, as in Forster's British schoolboy morality, 'I will lose my sense of self if I betray my friend'); the sort of thing we are not likely to say of other things we value. Compare 'I will lose my sense of self if I give up my love of dessert,' which shows that these latter first-order values are analogous to beliefs or propositions at the periphery for Quine. (These are mere examples intended to convey the structural point of the analogy intuitively. Of course it is possible, though perhaps not routine, that someone may value his sweet tooth in the way a stereotypical nationalist or British public schoolboy values country or friendship, that is, analogously to Quine's center of the web rather than the periphery. The possibility in no way spoils the analogy, it merely shows that identities might be eccentric or bizarre on occasion.)

So much for the significance of unrevisability. But (a) was the task of defining it; it sought to define a way of endorsing one's valuing of some characteristic one possesses that shows that value to be relatively unrevisable compared to other values one holds. Since we have already seen that coherence cannot provide such a special way of endorsement, let us return to the idea of second-order valuing of a first-order value in order to explore the sort of endorsement needed. What do we need to add to a second-order value to make the first-order value endorsed as (relatively) unrevisable in one's psychological economy? An example may help to make the question and an answer to it less abstract.

Let us take some of the more absolutist Muslims in Iran over the last two decades of the twentieth century. They have often urged something that approximates unrevisability of their Islamic values. One way they have done so is to argue that Iran needs to protect itself; not just others in Iran, but even the absolutists themselves should protect themselves against their own 'moral' weakening and corruption in the face of the inevitable spread of the pernicious values of modernity in general and of the West in particular. And they have argued (like Ulysses did, anticipating the Sirens) that this protection should be ensured by entrenching Islamic values so deeply now that, were Muslims even to be so weakened, the social, political and legal institutions would not make it easy for them to shed their Islamic way of life. Such a form of endorsement of one's Islamic values vividly shows it to be more unrevisable (in a very special sense) than other values one has and endorses having. Consider that the endorsement takes a counterfactual form: we value something in such a way that we want ourselves to be such that we live by the value, even if we (counter to present fact) do not value it, anymore. At the time of valuing it, then, such a value stands out as very distinctive. The sort of unrevisability here is quite special because it is not so much that the value (at the first-order level) itself is permanent or immutable, but even though we may revise things later and cease to value it, the fact is that at the time of valuing it in this way, one (at the second-order level) yearns for the value to be unrevisable and relatively permanent, unlike all the other values which we endorse in the more ordinary way. That surely makes it part of one's deepest self-conception since one would disapprove of oneself if one did not have the value at some other point, enough to now make sure that one's self, at that other point, would live according to the value. 'Identity-imparting,' 'self-constituting,' etc., seem apt descriptions for values held and endorsed in this way.

Task (b) remains. Not all values which are unrevisable in this way are rational. What needs to be added is that these unrevisable values must also cohere with our other values. Coherence of an unrevisable value with one's other values allows for the rationality of the unrevisability since reluctance to revise could only be irrational if the value one does not revise is one that does not have support from one's other values.

Before leaving the subjective aspects of identity and turning to the objective aspects, we should make one important cautionary remark to prevent a misunderstanding of the notion of identity as we have just defined. One should not be put off by the specific example given above, and think that the sort of endorsement that generates identity in this way is a sign of fanaticism or illiberalism, just because we have become used to thinking of Islamic absolutism to be illiberal. That would be to allow substantive opinions to blind us to the merits of the theoretical conclusion we have come to; that is to say, blind us to the

structural feature of the endorsement that generates identity. After all, the special way we value our own basic constitutional rights reflects just such an endorsement of our own identity-generating values as liberals, since all it does is reflect the same structure as the Iranian absolutists in the earlier example: we elevate a very few of the many values we more or less coherently hold to fundamental constitutional 'rights,' for example that of free speech, precisely because we want to protect ourselves from giving in to any weakening of those values, for example in the case of so strong a dislike of another's substantive views, that we might find ourselves wanting to censor him. What our elevation of these values into fundamental rights does is express the fact that what we now want is that we cannot later censor someone we strongly disagree with, if indeed later we have weakened enough to wish to censor him. A liberal's deepest self-conception, i.e., a liberal's identity, and a Muslim's identity, therefore, whatever the differences between them on other matters may be, is given by the same counterfactual structures of endorsing and identifying with their cherished values that our theoretical conclusion rests with. Such a conclusion therefore should be a satisfying point of conclusion for the subjective aspect of identity.

2. *Objective Aspects of Identity*

When we turn to the objective aspects of identity, identification on the part of the subject in question with the identity-imparting characteristic(s) is not a necessary condition. Thus, for instance, identities when they are thought to be given by characteristics of descent, such as race, are objective in this sense. Chromosomatic ways of defining gender identity are similarly objective. But biological criteria are not the only criteria that are routinely invoked. Inter-subjective and social criteria are also much favored. Thus, for instance, Marxists often claim that one's identity is given by one's role in a particular economic formation in a given period of history, that is to say, one's class identity as 'class' is defined by Marx (1978).

Many oppose the purely biological ways of thinking about various kinds of identity, such as racial and gender identity, claiming that these identities are 'socially constructed' by the perceptions and attitudes of one's fellows, by the zeitgeist of a particular period, or by the conceptual categories and social institutions at a given time. Foucault (1972) and those influenced by him have made much of this, and Foucault himself gave detailed historical and social accounts of particular concepts and institutions in Europe as being determining of identities. In fact it is interesting that Foucault and his followers claim that it is not only the biological and other scientific criteria that are caught up in social factors of this kind, but the subjective ones we discussed in the last section as well. These too are shaped by conceptual and institutional formations far removed and hidden from the exercise of our reflective self-understanding, thereby showing the ideals of individual autonomy that we assume to reside in the idea of identification to be illusory. This article will not take up these issues raised by Foucault's influence. It will look instead briefly at the motivations for looking at objective factors of identity at all, over and above the subjective ones.

Many subjects may identify with some characteristic that is not to others what is most salient about them and it is thought important by many political philosophers that it is these latter which may often define their identity, no matter what subjects may conceive themselves to be. A good example of this can be seen in Stalin's (1953) well-known definition of a 'nation,' which stresses the importance of historical and economic criteria for national identity, with a view to providing a corrective to what were seen as somewhat premature and ungrounded subjective identifications of 'nationality' found in many secessionist demands in different parts of the world. Here the motivation for objectivist criteria of identity is (at least implicitly) political.

But underlying this is a more interesting theoretical rationale which points to important issues of a more philosophical nature. The claim that agents may have a certain identity even if they do not consider themselves to do so implies that what one takes oneself to be can be mistaken, a kind of self-deception, or at least a self-myopia (which may not always involve the motivated element often associated with self-deception, but involves at least the idea that one may sometimes simply be too deep for oneself—where 'deep' is not intended as a bit of eulogy).

It would be philosophically clarifying to make a distinction between two different sorts of appeal to objectivist identities which are said to be (possibly) hidden from a subject's own self-conception. One claim—the weaker one—is that subjects often betray signs of a certain identity in much of their behavior, even if they do not endorse and identify with what is reflected in their behavior. The other, stronger, claim does not even require that something in the subjects' behavior reflects the identity given by the unendorsed characteristic; rather that the characteristic and the identity is given by the deliverances of some (social, political, economic, or biological) theory regarding these subjects.

(a) The weaker claim not surprisingly, is less controversial since it requires that the characteristics of a subject which are going to define his identity are something that he at least reveals in his behavior. The subject may not endorse them, he may not even acknowledge them, but if the only good explanation of his behavior is that he has those characteristics, and if those characteristics are salient compared to others, then some claim can be made regarding how they

impart his identity. Within this view, the more extreme cases will be where the subject does not even acknowledge the characteristics as being revealed in their behavior. Many of the identities that surface in Freudian (Freud 1963) and psychoanalytic theories make much of this sort of case (Oedipal, narcissistic identities). The less extreme cases will be those where there is acknowledgement of the characteristics, but no endorsement of them on the part of the subject. These are likely to be more common. What may be called 'silent' identities, as in 'silent majorities' often consist of subjects who are not self-identified with a certain pattern of behavior, but will not be in any particular state of denial (as they are in the more extreme cases) about whether their behavior reveals the characteristics they are seen to have. It is very likely, for example, that many moderate Muslims in Iran and other Islamic countries, who do not identify with absolutist or fundamentalist Islam, may all the same admit that much in their behavior offers mute assent to the Islamist elements in their societies.

(b) The stronger claim very often appeals to biological criteria, but is most interesting when it does not. Since the biological criteria are in any case usually caught up with social factors (see the point made about them above during the brief discussion of 'social construction' of identity), they will be ignored here. Perhaps the most well known, well worked out, and widely discussed of the stronger objectivist version of identity, which is not biologically based, is due to Marx and those influenced by him. What makes for having a class identity, say, a proletarian identity, is not any kind of self-identification with the working class, not even any behaviour that suggests certain unacknowledged or unendorsed allegiances to that class, but simply the objective fact of having a certain place and function in the relations of production during the modern capitalist period of economic history. What is remarkable and controversial about this view, more so than anything found in (a) above, is that something regarding the self and its identity is being attributed, without any basis or manifestation being required in the conscious or unconscious behavior of the selves or agents concerned. A working-class person who exhibits no proletarian consciousness nor any of the solidarity and forms of behavior appropriate to the class, and none of whose behavior reflects an unconscious betrayal of such solidarity or consciousness, is nevertheless said to have proletarian class identity, albeit with a 'false consciousness.' It is only because he has this identity that there can be cause to call such a subject's consciousness 'false.' It is false precisely because he fails to conceive himself aright, fails to see his deepest self as it is determined by objective historical and material relations.

It is such a view of self and identity (where self and self-conception can fall so radically apart) which filled Isaiah Berlin (1969) with anxiety in his discussion of 'positive liberty,' since what it encourages is the idea that the achievement of self-realization of individual citizens, that is, the achievement of their own autonomy and liberty (in the positive sense), is now left to states or to the 'vanguards' of political parties, which lay claim to greater understanding of what some subject's self really and objectively is. In such a view, according to those alarmed by it, there is no paradox in the expression 'forcing someone to be free.' (Lenin's (1975) 'vanguardism' was frank about denying any such paradox.)

Underlying political anxieties of this kind is the more philosophical issue of external as opposed to internal reasons, which is much discussed in contemporary moral psychology. An internal reason is a reason for one to do or believe or value something, which appeals to some other evaluative element in one's moral–psychological economy. An external reason makes no such appeal to an internal element; it requires only some objective fact that need not even be recognized by the subject for whom it provides a reason. Thus in the orthodox Marxist tradition, a proletarian, given his historically determined identity, has (an external) reason to be a revolutionary even if there is no element in his moral–psychological economy which values it. Berlin's (1969) anxieties about statist tyranny, carried out in the name of self-realization, autonomy and positive liberty, were thus implicitly and more deeply about the very idea of external reasons, even though he never quite articulated them as having that underlying target; however, it becomes very explicit in a denial of the cogency of the very idea of external reasons in a brilliant essay by Bernard Williams (1981) (a philosopher much-influenced by Berlin), though the point is marred in that essay by a somewhat confused equation of internal reasons with a Humean notion of value and motivation.

This last set of points provides a good closing point for this article on identity, which has distinguished fundamentally between the subjective and objective aspects of the concept. To a considerable extent, which of these two aspects we emphasize in our study of the concept will be a matter of theoretical decision, a decision which, in turn, depends on non-arbitrary philosophical considerations having to do, as we have just seen, with themes at some distance from identity, such as autonomy and moral reasons. In itself, this is to be expected since self, freedom, and reason have been closely connected themes in philosophy ever since Kant, both in the analytical and the European traditions of the discipline. Though much more needs to be said in detail to make the links between these themes explicit, it is safe to say that that the more inclined we are to be uneasy about the idea of 'external reasons,' the more likely we are to stress the subjective rather than the objective aspects of identity.

Identity in Anthropology

'Identity' is a vexed topic in anthropology. Simply described, a person's identity is his or her psychologically salient individuality, the way he or she feels different from or similar to other people. But what that means to anthropologists has shifted over time.

At one time anthropologists, and perhaps all social scientists, tended to think of identity as a clear and unambiguous assertion of selfhood, which directed behavior and motivated actions. Self, person, and identity were more or less interchangeable. When Erik Homburger Erikson (for many years the central theorist of identity) wrote about identity, he described it as a kind of consolidation of self, so that when someone acquired her identity, the way she interacted with the world—her ability to trust, to work, and to play—was recognized externally by others in a way that was consonant with her own internal understandings. For Erikson, then, 'identity' was something that had to be achieved, and its achievement was a developmental milestone in the human life cycle. The Eriksonian self stood facing the world as the private awareness of that person which, when mutually recognized and consciously accepted, became her identity. 'Identity formation … arises from the selective repudiation and mutual assimilation of childhood identifications and their absorption into a new configuration, which, in turn, is dependent on the process by which a society (often through sub-societies) identifies the young individual, recognizing him as somebody who had to become the way he is and who, being the way he is, is taken for granted' (1963, p. 159). By definition, identity was unitary and more or less coherent.

In the closing decades of the twentieth century, that simplicity has been lost. There are at least three reasons for this: the postmodern turn in anthropology and elsewhere in the social sciences; the recent focus on power and agency; and the emergence of what is called 'identity politics.' Each suggests a somewhat different perspective. Nonetheless, one can say that 'identity' is no longer conceived as necessarily unitary, no longer perceived as a match between inner experience and outer acknowledgment, and no longer understood as a developmental achievement. But before we discuss these changes, some discussion of terms is in order.

1. Definitions

At least four terms are inextricably intertwined in these discussions: identity, self, agency, and person. Were the intellectual world to be sensibly organized, anthropologists would use these four words to refer to different concepts, but that is not always the case. As a result, the discussions can seem a little murky. It is helpful in this context to turn to discussions in the psychological literature that have been read by anthropologists and to use them to clarify the central concepts.

To begin with the self, more complicated psychoanalytic approaches to the self began to emerge with the psychoanalyst Heinz Kohut's work. In a famous article (1959), he pointed out that the tools of psychoanalysis are introspection and empathy, and he

argued that psychological phenomena like the self thus necessarily include introspection and empathy as essential elements. The 'I-experience,' as he called it, captures the way an individual introspects; thus evidence for the self is fundamentally different from evidence for the observable body. Kohut went on to establish his own vocabulary about the 'I-experience,' the most useful phrase probably being the 'self-object,' the other person that an individual may use to soothe himself and restore inner harmony, as a mother can reassure a child that an imagined dragon is not real. His most fundamental contribution, however (at least for the present purpose), was to distinguish between the introspective nature of the self and the differently observable nature of the person.

This is the distinction that the psychoanalyst Roy Schafer later develops as the distinction between the person, as the agent who acts, and the content of the ideas they have about personhood, the person's understanding of his or her 'I.' He calls these 'self-narratives' (but often refers to them as selves). Schafer also argues that from this perspective, there is clearly more than one self, a position that some anthropologists and psychologists also now adopt (Kondo 1990, Gergen 1991). There may be the self who is confident, assertive, and effective and the one who is weak, embarrassed, and reactive (it is that 'second' self which the analysand will present in the analytic hour). There is the self we become when speaking French, freer, more sophisticated, we feel, than our English-speaking self (cf. Kaplan 1993). There is the work self, the play self, the parenting self, the self in different roles, and the self under different circumstances. Schafer (1992, p. 25) quotes a male analysand speaking to his analyst: 'I told my friend that whenever I catch myself exaggerating, I bombard myself with reproaches that I never tell the truth about myself, so that I end up feeling rotten inside, and even though I tell myself to cut it out, that there is more to me than that, that it is important to me to be truthful, I keep dumping on myself.' There are, Schafer suggests, eight selves of five types in that remark. The types are: actual self, ideal self, self as place, self as agent or subject, self as object. The selves are: analysand self, social self (talking to friend), bombarding self, derogated self, exaggerating self, conciliatory advisor self, advisory self, and the defended self with redeeming features. Schafer is perhaps being excessive (it is his exceeding self) but the point is powerful. To call all of what his analysand describes the product of a single self is to lose a good deal of helpful detail.

From this perspective, a self—or more precisely, a self-narrative or self-representation—is a cognitive schema, a bounded collection of conceptions and images that an individual uses to perceive, to categorize, and to experience his world: in short, to think with. Clearly, people are motivated by more than one simple cognitive packet. They are Americans, professionals, parents, neighbors; they are shy in some settings, assertive in others; skilled and aggressive in some games, cautious and awkward in others. Some theorists conceptualize these 'packets' in terms of roles. Mardi Horowitz et al. (1996), more complexly, write of 'role-relationships.' We establish, they argue, particular ways of relating to people that are driven by our concepts of who they are, who we are in relation to them, and how we are to act in that relationship. They see these role relationships as integrated in a sense of personal identity. Claude Steele (1988) provides evidence for that integration in an experiment in which women in Salt Lake City were called by a man posing as a pollster. While the call was ostensibly about conducting a future poll on women's issues, some women were told that it was commonly known that they were uncooperative with community projects. Some were told that it was commonly known that they were cooperative. Some were told that they were bad drivers. Two days later, a woman called them back and asked them to help with a community project. Salt Lake City is a heavily Mormon community, with a strong ethic of community cooperation. Perhaps unsurprisingly, those who were insulted as uncooperative were twice as likely to agree to help out as those who were praised, as if to clear their good names to themselves. What was more remarkable, however, is that those who were called bad drivers were also twice as helpful as those who had been praised. Steele went on to argue that people often respond to damage to one self-representation by affirming success in another. I hang back with embarrassment as a lousy athlete when friends at a beach party decide that we should all play volleyball, but I can make myself feel better by reminding myself, when I drop the ball, that I am competent in the classroom. Those of us who drop volleyballs can enhance our self-esteem by bringing a terrific homemade pie to the next seaside event.

At the same time, the term 'self' seems to imply something more than this tale of loosely integrated but shifting schemas suggests. Cultural psychologists Markus and Kitayama (1994, p. 569) argue that 'the model which underlies virtually all current social science views the self as an entity that a) comprises a unique, bounded configuration of internal attributes (e.g., preferences, traits, abilities, motives, values, and rights) and b) behaves primarily as a consequence of those internal attributes.' They go on to argue that in the West, for the most part people assume that the major normative task of the self is to maintain its independence, and in other, particularly Asian, settings, the normative task becomes maintaining interdependence with others. (This proposition has been a subject of active debate in anthropology.) They use the concept of the 'self,' then, to indicate not only schemas of the 'I,' but processes of acting in the world.

The cognitive psychologist Ulric Neisser (1988) makes sense of this confusion in an article widely read by psychologically-minded anthropologists. He argues

that there are five kinds of self-knowledge, five ways in which we have knowledge of our 'I.' There is the ecological self, the 'I' perceived with respect to the physical environment; the interpersonal self, experienced in emotional communication, the way 'I' behave in a particular human interchange; the extended self, based on memory and anticipation, the 'I' who has done certain things in the past and will likely engage in certain routines in the future; the private self, experienced as the awareness that other people cannot see your thoughts, that (in some ways) only I can know me; and the conceptual self, the wealth of concepts that I believe comprise my self: my roles (professor, friend, dog-owner), my features (I have a liver, a nose, and a mind), and my specific traits (I am tall, short, smart, stupid, brunette, blond). It is important, Neisser argues, to distinguish between kinds of self-knowledge, because otherwise the self is full of apparent contradictions. It is physical yet mental, public yet private, directly perceived yet incorrectly imagined, universal yet culture-specific. 'Although there is nothing with which we are more familiar, we are often enjoined to know ourselves better than we do' (1988, p. 35). He resolves the contradictions, however, by speaking of different 'selves.' 'They differ in their origins and developmental histories, in what we know about them, in the pathologies to which they are subject, and in the manner in which they contribute to human experience' (1988, p. 35).

The major distinction here is between 'self' and 'person.' 'Self' is used to refer to the introspective experience of the 'I,' and while there are at least two dominant ways of theorizing this experience—the first, as a collection of cognitive schemas and the second, as a more complex integration of those schemas with other psychological processes—the term focuses in on a subject-centered internal experience of the subject. 'Person,' by contrast, is an other-centered term. It evokes an individual's understanding of the shared qualities of individuals like him or herself—the common qualities of those who have selves. Most anthropological discussion of the person takes its starting point from Mauss' (1938) famous essay. Mauss pointed out that the concept of the person changed considerably over time and across space. It was only in the Roman Empire, for example, that the concept of the person came to refer to a locus of rights, which has remained the legal meaning of person in English and American law today. As Geertz (1983, p. 59) points out, the Western concept of the person is 'a rather peculiar idea within the context of world cultures.'

The distinction between 'identity' and 'agency' redescribes that internal/external opposition in more specific terms. 'Agency' is the volitional capacity of all persons: their ability to choose, to intend, to act. When anthropologists talk about 'agency,' they contrast it to 'structure,' by which they tend to mean the external constraints on human freedom institutionalized within a society (the kinship structure, political structure, economic structure, and so forth; see Ortner's (1996) useful discussion).

'Identity' tends to be used for a particular kind of self: the internal, subject-centered experience of unique agency. It would (or should) seem strange to say, 'his whole self is wrapped up in being an anthropologist.' That would seem to imply that even the way he located his body in a room and his memories of childhood were somehow centered on being an anthropologist. But to say, 'his whole identity is wrapped up in being an anthropologist' means that he thinks that the way he currently chooses, intends, and acts has a lot to do with the way he conceives of himself as an anthropologist and not as a chemist. The concept 'self' necessarily entails a sense of not being another person. 'Identity' indexes a much sharper, more conscious sense of difference: having a different kind of agency, making different kinds of choices. The term 'identity,' then, should be used for a subject-centered sense of personal agency. It answers the question, 'who am I?' by asking, 'what can I do in the world?' (See Holland et al. 1998 for a detailed discussion of identity and agency through a dialogic, practice theory orientation.)

2. *Contemporary Influences*

There are three dominant influences on contemporary identity theory within anthropology. First is the literary, postmodern turn in the social sciences. This has brought an emphasis on narrative and performance. Identity becomes something which individuals perform, enact, and present; often, the medium of performance is understood as narrative (see Steedly 1993, Stewart 1996). Lavie's *Poetics of Military Occupation* (1990) is a good, relatively early, example of this kind of work. The goal of Lavie's ethnography is to describe the way Bedouin have come to understand themselves as actors in the world. She presents this through presenting the performance of different Bedouin roles—the sheikh, the fool, the old woman—and through the stories Bedouin tell about themselves. And she uses photographs which, unlike the photographs of most ethnographies, enact the thesis of the book.

Second is the emphasis on power and agency. Like the literary, postmodern turn, this influence permeates much of contemporary anthropology. Its relevance to identity theory lies in the way agency is understood to act within the constraints of external power. Ethnographies with these concerns focus on those who would seem deprived of power or importance, and then demonstrate how even within the margins of the nation state, or in the lowest ranks of the factory, people identify themselves as effective actors in the world. For example, Tsing (*In the Realm of the Diamond Queen*, 1993) organizes her ethnography around a woman who is not only marginal in the eyes of most Wester-

ners (she lives in the Indonesian hills) but in the eyes of her own people: she is intermittently psychotic and is the leader of a small, unpopular cult. Tsing uses her speeches as the vehicle to illustrate how those on such margins nevertheless conceive of themselves as effective actors in relationship to the center, and to some extent actually are.

The third and most powerful influence comes from cultural studies, and more specifically from postcolonial studies and identity politics. Postcolonial studies focuses on relationships between the colonizer and the colonized, and identity politics on relationships between different races and/or genders, but for both the central issue is an asymmetrical power relationship and its consequences.

Memmi's *The Colonizer and the Colonized* (1965) is a foundational text in postcolonial studies. Memmi argues that he who is colonized models himself on the colonizer, aping his customs and yearning for his appearance. He loses his past; he learns the history of Cromwell but nothing of his own progenitors. He grows embarrassed by his mother tongue. 'The first ambition of the colonized is to become equal to that splendid model [of the colonizer] and to resemble him to the point of disappearing in him' (1965, p. 120). The colonized agrees, in Memmi's words, to destroy himself and become what he is not. But then he learns that in the end the colonizer will reject him anyway, and he is filled with shame and self-hatred (1965, pp. 121–2). Ultimately, he has no choice but to recognize the anger in his ambivalence and to rebel. 'Revolt is the only way out of the colonial situation, and the colonizer realizes it sooner or later' (1965, p. 127). And yet even if he is successful he remains still tortured, still living in a psyche defined by the colonizer, defined by what he is not. 'So goes the drama of the man who is a product and victim of colonialism. He almost never succeeds in corresponding with himself.'

Frantz Fanon, in *Black Skin, White Masks* (1967) wrote even more starkly about colonialism and race: 'for the black man there is only one destiny. And it is white' (1967, p. 10). The terrible cost of colonialism in Fanon's eyes is that, in yearning to be like the white colonizer, the black colonized man comes to accept the white man's degrading vision of the black man and so to lose himself. He is alienated from himself when he feels most white, and humiliated when he feels most black. And so, perpetually, the black man is torn, rejecting himself to become white, only then to grasp a more terrible vision of his never-to-be-scrubbed-clean skin. 'A Negro is forever in combat with his own image' (1967, p. 194).

Identity politics takes this central relationship between a dominant group and a subordinate group, an us and a them, and makes theories out of the attempts to change it. For those confronted by the inferiority of their skin, gender, or accent, should they adopt the mainstream style and hope to be respected, or reject the mainstream in order to build a world in which its values will not matter? Those who write within this arena tend to see the route to political resolution of their problems through the conceptual deconstruction of this basic opposition. West, for example, writes of the 'double consciousness' of the rejection of the mainstream (and its association of blackness with inferiority) while assimilating into it. He writes admiringly of 'cultural workers who simultaneously position themselves within (or alongside) the mainstream while clearly aligned with groups who vow to keep alive potent traditions of critique and resistance' (1990, p. 33).

Bhabha, another central voice in identity politics, similarly diagnoses the central problems of the colonized subject as ambivalence and hybridity. The colonial subject identifies with the colonizer and yet cannot be the colonizer. If he identifies with his nativeness, he confronts his own condemnation; if he identifies with the Westernization he has adopted, he confronts his own alienation. 'The taking up of any one position, within a specific discursive form in a particular historical conjecture, is then always problematic' (1990, p. 81). Bhabha uses the word 'hybridity' to describe the solution, or condition, of the multiply defined self which both reiterates binary colonial categories and ultimately subverts them, but through echoes and not direct opposition. Bhabha suggests that the postcolonial subject, the marginal subject, is someone who feels that her capacity for self-declaration has been taken from her repeatedly through a long history in which she has been forced to conform to the dominant culture's prejudices and biases.

As a result, the politics in identity politics become fragmented and complex. Another theorist, Lata Mani, argues that to understand these different perspectives as a unity 'sets up problematic chains of equivalences between, say, people of color in the United States, people from the third world, lesbians, gays … It is not as though difference is not acknowledged, for an inventory of difference is crucial to this narrative; rather it is that difference is insufficiently engaged' (1992, p. 393). Political affiliation becomes possible only though acknowledging difference, because these politics are as much about selfhood as about political economy.

Bhabha sees this complexity of identifications as a condition of modernity. This does tend to be a view about elites (or the middle class) by those who are elites (and have money to spend at Tower Records) but, as elites, many theorists agree. The anthropological critic James Clifford (1988, p. 11) diagnoses contemporary identities thus: 'intervening in an interconnected world, one is always, to varying degrees, "inauthentic": caught between cultures, implicated in others. Because discourse in a global system is elaborated vis-à-vis, a sense of difference or distinctness can never be located solely in the continuity of a culture or tradition …'

3. Contemporary Identity

One could argue that the mastery of multiple narratives is the core project of the postmodern politics of identity. This perspective on identity is quite different from Erikson's naturalistic vision of an identity which can be intuited by an objective observer over a limited period of time. The most insistent message of these identity theorists is the refusal to be characterized by someone else's narrative, and to assert their own authority in laying claim to a narrative of agency that ultimately may not be so different from those they have rejected. When Gayatri Spivak (1987), for example, denounces her characterization as a Marxist, a feminist, a deconstructionist (she is famous for being all three), she does so, one suspects, not because she rejects the personal resonance of those categories for her, but because she resists having them imposed. When members of an academic culture are complicit in the dicta that only women can write on feminism, only men may write about the men's movement, only African-Americans can write on black politics, we acknowledge the importance of allowing those who have been disempowered to experience empowerment through the casting of their narratives of self-characterization.

From this perspective on the politics of identity, successful (healthy, appropriate) identity in a modern postcolonial context is less a self-characterizing narrative with a mirroring world than a sense of command over narrative complexity: narratives which one has to some extent chosen, whose mastery gives one a sense of direction, adequacy and goodness. Rather than locating identity in single narratives, or in narratives matched to external approval, we capture more of the emphasis of these accounts in their experience of comfort and control in slipping from one narrative to another (see Luhrmann 1996). This comfort is what Schafer evokes in his account of the freeing of the 'imprisoned' analysand: not that the analysand is unconstrained by narrative, but that the analysand comes to feel that her narratives of personhood, complex and contradictory as they might be, are those that she has chosen—that rather than being controlled by the brute oppression of a narrative externally imposed, she is in mastery of the narratives which structure her presentations of personhood to the world.

But, as the decades pass, that formulation will change again.

Identity in Childhood and Adolescence

Identity will be discussed as an individual psychological characteristic. In its broadest sense, identity refers to a person's sense of continuity with the past that constitutes the foundation for a meaningful personal and social present, which, in turn, suggests directions for their future. The theorist in the latter part of the twentieth century who is most closely associated with the concept of identity is Erik Erikson (1980). In fact, a recent biography of Erikson (Friedman 1999) is entitled *Identity's Architect*. The most widely used research paradigm developed to study Erikson 's ideas empirically is the identity status model developed by Marcia et al. (1993). Both Erikson's psychosocial developmental theory and Marcia's identity statuses are located within the general context of psychodynamic (ego psychoanalytic) theory. This contextual placement is especially useful because it establishes identity as a developmental structural concept having implications for later adult psychosocial development as well as historical roots in earlier psychosocial periods. The theorists, in addition to Erikson, who speak most directly to the childhood conditions necessary to the establishment of a sense of identity are John Bowlby, Heinz Kohut, and Margaret Mahler. This discussion of identity will be presented within the context of these theories as well as the empirical work of Marcia and colleagues.

1. Identity Described from an Eriksonian Position

Erikson's psychosocial developmental theory is based upon the epigenetic principle that certain ego abilities will develop in a predictable stage sequence given an 'average expectable environment.' He views identity as the stage-specific task of adolescence. Although he has offered different definitions of identity at different times, a comprehensive one is:

> The integration now taking place in the form of the ego identity is more than the sum of the childhood identifications. It is the inner capital accrued from all of those experiences of each successive stage, when meaningful identification led to a successful alignment of the individual's *basic drives* with his *endowment* and his *opportunities*. In psychoanalysis we ascribe such successful alignments to 'ego synthesis' … (Erikson 1959, p. 94, italics in original)

and identity refers to 'a conscious *sense of individual identity*; … an unconscious striving for a continuity of personal character; … as a criterion for the silent doings of *ego synthesis*; and, finally, as a maintenance of an inner *solidarity* with a group's ideals and identity (Erikson 1980, p. 109; italics in original).

The period following puberty and before young adulthood is seen as a time when individual needs (e.g., to be independent, to be sexually expressive) and abilities (e.g., physiological maturity, cognitive sophistication) articulate with societal demands (e.g., to begin to put away childhood, to prepare for an occupation), and rewards (e.g., granting of increasing autonomy, offering rewarding occupational niches and relevant education/training). It is at this point in the life cycle that the individual is expected to begin to leave the childhood position of 'one who is given to and who takes' to 'one who is to give to, and be responsible for, others.' A crucial shift in ideological perspective is required to navigate this transition. This is one of the reasons that Erikson emphasized the importance to identity of an ideology, a kind of theory of oneself and one's social outlook: a *weltanschauung*. Childhood worldviews are not serviceable in adult life, and adolescence constitutes the period of transition between the two. Besides ideology, another area of importance in identity formation in adolescence is occupational choice. Making decisions about this area involves adolescents' inner self-examination of their competencies, wishes, and goals and their outer exploration of available rewarding social contexts. Therefore, one might say that an adolescent is constructing an identity when he or she is exploring alternatives and establishing commitments in the life areas of ideology and occupation. Some of the childhood constituents whose development is necessary to identity formation are described next.

2. Childhood Antecedents to Identity

2.1 Eriksonian View

From an Eriksonian psychosocial developmental perspective (Erikson 1980), the childhood precursors to the development of identity are the more or less successful resolution of preceding psychosocial stages. These involve the formation of predominant senses of basic trust (from infancy), autonomy (from early childhood), initiative (from play age), and industry (from school age). Basic trust (vs. mistrust) refers to the infant's sense that the world (and, hence, oneself) is trustworthy and largely benevolent and predictable. A sense of autonomy (vs. shame, doubt) is formed as one modifies one's will (in areas such as toilet-training and locomotion) to coincide with the demands of significant socializing figures in such a way that an eventual feeling of justice is attained. During the

periods of trust and autonomy, a self-structure (described in Sect. 2.2) is also being formed. Initiative involves the harnessing of previously developed autonomy in early childhood to the planning and completion of projects, both physical and interpersonal (viz., oedipal). Initiative is a crucial component in the ability to 'play,' both by oneself and with others. The immediate psychosocial precursor to identity is a sense of industry which springs from the child's experience of self as a competent worker with peers and teachers in school. As each psychosocial stage's challenge is met and resolved in an essentially positive manner, these accrued ego strengths furnish the adolescent with the psychological foundations to resolve successfully the identity issue of adolescence. Failure to optimally resolve earlier stages jeopardizes, but does not obviate, identity development, because every stage is assumed to occur in some form at every other stage. A particular psychosocial stage is not just resolved or unresolved once and for all time. Hence, all of the stage issues preceding identity recur at adolescence and there is an opportunity for their reresolution. However, because the adolescent must now face not only the present issue of identity but past ones as well, it is necessary to provide the person with a better-than-average expectable environment in the form of psychotherapy, counseling, or special programs aimed at enhancing psychosocial development.

2.2 Object Relational Perspective

Object relations theory is that branch of psychodynamic thought that focuses on relationships being more crucial to personality development than are individual drives and abilities (see Greenberg and Mitchell 1983). Here, the important identity-preceding structure is the self, a personality structure formed out of interpersonal interactions. The view of the development of the self presented here combines the thought of Bowlby (1982), Mahler et al. (1975), and Kohut (1977). The self is formed in infancy and early childhood (up to four years of age) out of the internalized and 'metabolized' interactions between the child and significant other persons (sometimes called 'self-objects'). Although the origins of the self lie in self-other interchanges, the self is experienced as one's own, and one comes to sense one's existence as both a separate and interdependent being. The conditions necessary for the establishment of a self include an initial period of undifferentiated symbiosis (Winnicott's 'dual unity') with a mothering/caregiving figure, differentiation from that figure, attachment to the caregiver and other significant objects, exploratory back and forth movements from the attachment figure, and eventual individuation as the self–other interactions become internalized and take the form of a secure self. Concurrent with, and following, the establishment of a self are conditions, described by Kohut (1977), that promote the maintenance and enhancement of that self. These are the presence of several kinds of 'self-objects,' namely 'mirroring' (an object who reflects the infant's ambitious grandiosity), 'idealizing' (an object who can be admired, identified with, and whose strength can be shared), and twinship' (a 'best friend,' a companion of one's heart). These self-objects continue to be important to self-maintenance and enhancement throughout the life cycle.

2.3 Classical Psychoanalytic Approach

The important identity-preceding structure described by classical psychoanalytic theory is the superego (Freud [1933] 1964). This personality structure is assumed to be formed at about five to seven years of age and is based upon internalizing the values of parental figures in order to defend against experiencing negative feelings occasioned by fear of punishment or of loss of love. The conscience aspect of the superego reflects parental prohibitions: what one ought not to feel, be, or do. The ego ideal portion of the superego is composed of parental aspirations: what one should feel, be, or do. Hence, the superego provides an internalized 'parent,' experienced as oneself, that is a source of guilt and shame, as well as a source of self-esteem. It is especially the ego ideal portion of the superego that undergoes modification during the identity formation process of adolescence. During this period, which may be seen as a second differentiation phase (Blos 1967), adolescents may substitute contemporary popular figures (e.g., sports or music stars) or literary or scientific heroes for original ego ideal parental introjects in efforts to become their own persons, rather than, or in addition to, being only their parents' child.

2.4 Summary of Perspectives

In summary, there are three important personality structures posited by different branches of psychodynamic theory, each taking form at different points in the individual life cycle. The self (an object relational concept) is formed in infancy and early childhood out of the internalized and transmuted interactions between the individual and important self-objects. The superego (a classical psychoanalytic concept) is developed during play age and is based upon the internalization of parental prohibitions and aspirations. An identity (an ego psychoanalytic concept) is formed during adolescence and is indicated by self- and environmental exploration and eventual commitment in significant life areas. A self establishes *that* one is; a superego determines *how* one should be; an identity is a statement of *who* one is. A self and a superego are necessary, but not sufficient, conditions for the formation of an identity.

3. Empirical Work: The Identity Statuses

The four identity statuses (Marcia et al. 1993) are ways in which a late adolescent might be found to be dealing with the identity issue. They are intended to reflect, on a behavioral level, the nature of the identity structure described by Erikson. Criteria for determining the identity statuses are the presence or absence of exploration and commitment in the areas of occupation, ideology, and interpersonal values. Identity status is typically assessed by means of a structured interview scored with a standardized manual, although sometimes a questionnaire is used. 'Identity achievement' persons have undergone a period of exploration and have made ideological, occupational, and interpersonal value commitments. 'Moratorium' individuals are currently in the exploration period, actively searching among alternatives. When this exploration process becomes emotionally fraught, these kinds of moratoriums are described as being in an 'identity crisis.' 'Foreclosure' persons are those who are committed in the interview content areas, but who came to those commitments with little or no exploration; usually, they have adopted directions laid down for them by parents or other early authority figures. 'Identity diffusions' persons are uncommitted in important life directions and are not currently engaged in a process leading to commitment (as are the moratoriums).

Over 35 years of research has established empirically some of the following characteristics of the four identity statuses. Identity achievement individuals have been found to be resistant to experimental attempts to raise or lower their self-esteem, to be nonconforming to group pressure, to think effectively under stressful conditions, to employ the higher levels of moral reasoning, to be advanced in intimacy development, to be complex in thought processes, and to come from families where differences among members are acknowledged and accepted. In addition, they appear to have a strong and autonomous sense of self, are capable of secure attachment relationships, and are realistically high in self-esteem and relatively unimpeded by rigid superego strictures.

Moratorium persons, like identity achievements, are relatively stable in self-esteem and not easily moved to conform. Sometimes their level of cognitive performance exceeds that of achievements and they tend to function at the highest levels of moral thought. Occasionally, they vacillate between harsh self-judgment and lax self-permission. They are the lowest among the statuses in their endorsement of authoritarian values, probably reflective of their attempts to differentiate themselves from their parents. Their relationships with their families are ambivalent, and they tend to be somewhat insecure in their attachment, at least for the duration of their moratorium period.

Foreclosure individuals are the least cognitively flexible of the statuses and the most highly endorsing of authoritarian values, suggesting a relatively unmodified ego ideal. They employ conventional reasoning about moral issues and either acquiesce superficially to, or stubbornly resist, positions discrepant from their own. In relationships, they give the appearance, but not the substance, of intimacy. They describe their families in unrealistically ideal terms. In terms of attachment, they are about evenly divided between secure and insecure attachment patterns.

Identity diffusion persons are vulnerable to self-esteem manipulation and become disorganized in their thinking when under stress. They are at the lower levels of both moral reasoning and capacity for intimacy. Diffusions experience a marked distance between themselves and their parents, especially the parent of the same sex, whom they feel that they can neither emulate nor please. It is not surprising, then, that they are the most insecure in attachment among the statuses.

It should be kept in mind that most of the studies that have furnished the above findings have involved the use of the identity status interview, have been done in Western, technologically advanced countries, and most of them have involved college students. However, there have recently been a fairly large number of studies being conducted in developing countries and with other social classes and ethnic group, especially by Jean Phinney and her colleagues (see Roberts et al. 1999). Whether or not the foregoing descriptions of the identity statuses will obtain with these noncollege groups remains to be seen. One might expect, for example, a foreclosure individual to appear differently in a culture that prizes foreclosure than in one valuing exploration and change. In any case, the interview method would provide more flexibility in such investigations than the more static questionnaire measure.

4. Identity Development in Adulthood

While identity is first consolidated at late adolescence, this is only the initial identity. An identity can be expected to undergo successive transformations at least with each life cycle stage (see Kroger 2000). Hence, the identity serviceable to the late adolescent will probably be reformulated in early adulthood when intimacy is the primary psychosocial concern. Another change can be expected in middle adulthood around issues of generativity. Finally, integrity at old age poses perhaps the greatest challenge to the reconstruction and maintenance of an identity in the face of necessary physical, mental, and interpersonal losses. The processes by which identity changes in adulthood appear similar to those described by Piaget (1972) to account for changes in cognitive structure: assimilation, disequilibration, and accommodation (Whitbourne and Connolly 1998). An identity assimilates experiences so long as they are comprehensible within the identity structure. When they can no longer

be sufficiently accounted for by the individual's identity 'theory,' a state of disequilibration exists, and a subsequent accommodation, or change, in identity structure is called for in order to handle the new experiences. In a sense, an achieved identity contains the seeds of its own destruction. Because the identity was formulated to deal with certain experiences, it affords some efficiency in experiential processing and permits one to be aware of new experiences previously not within awareness. The growing awareness of experiences not assimilable in the current identity leads eventually to the disequilibration of that identity (a moratorium period) and to the necessity of formulating a new one (achievement). As life experiences accumulate in adulthood, prior identities are modified and made more serviceable. These achievement-moratorium-achievement (MAMA) cycles (Stephen et al. 1992) are not undertaken by all persons. There are some who foreclose at adolescence and, by means of employing defensive processes, or by remaining in foreclosing settings, never experience disequilibration and identity reformulation. Also, identity diffusions may drift through life taking on, superficially, whatever identities are provided to them by their environments. The assumption in identity theory is that MAMA cycles are probably the most developmentally adaptive trajectories.

Research has shown some relationships between identity development and the resolution of adult psychosocial stages following adolescence. Achievements and moratoriums are more advanced in intimacy than are foreclosures and diffusions (Marcia et. al. 1993). Persons who are resolving positively the generativity issues of middle age look very much like identity achievements; and those who are having difficulty here appear much like foreclosures and diffusions (Bradley and Marcia 1998). Persons characterized as integrated at old age are more likely to be identity achieved than those not so integrated. (Hearn et al.) Thus far, however, all studies involving linkages between identity and preceding or succeeding psychosocial stages have employed simultaneous measurement. Except for research within the identity development period (approximately ages 13–23), there is no longitudinal research linking earlier stages with identity for the same individuals.

5. *Criticism and Suggestions for Further Research*

Both the Eriksonian approach to identity, as an individual personality variable, and the identity status approach to the study of Eriksonian ego identity have not been without their critics. Some theorists see society constructing individuals' identities, rather than individuals' constructing their own identities out of social givens (e.g., Gergen and Gergen 1997). These critics, though, have difficulty in explaining individual differences in identity content and process within the same culture. Some writers have questioned the degree to which the identity statuses fully represent Erikson's ideas (e.g., Cote and Levine 1988, but see also Waterman 1988). However, these critics overlook the substantial nomological network of studies that have actually yielded accrued meaning to both the identity statuses and to Erikson's identity construct. Similar to any scientific construct, the identity status paradigm is a 'work in progress.' Yet, it remains the predominant method for studying the development of ego identity in adolescence.

There is a clear need for longitudinal studies on a developmental theory such as Erikson's. This includes tracing, empirically, the childhood antecedents of adolescent identity as well as the transformations of identity throughout the life cycle. What are the necessary childhood conditions for identity formation at adolescence? What does identity look like at adulthood, at old age? In addition, now that we have some validated measures of the adult psychosocial stages we can be more specific about identity development's impact on their resolution. Is identity formation at adolescence a necessary condition for, say, generativity at middle adulthood? Additional areas of research concern include the impact of social conditions on identity formation. What kinds of social contexts foster or restrict identity development at adolescence? How does identity differ cross-culturally?

Who one is, to oneself and to others, is a lifetime project and a singularly cherished accomplishment and possession. Human history is replete with stories of persons and nations willing to go to any lengths to preserve or establish their own identities. What is significant about Erikson's approach to identity, in addition to the richness of his description, is that he locates its initial formulation within the individual lifecycle as the specific developmental task of adolescence, to be continued by means of successive reformulations throughout adulthood.

Identity Movements

The main objective of social movements is to transform society so as to reflect the social actors' interests and view of the world. Such was the case with the labor movement in the early twentieth century and the decolonization movement in the 1960s (see *Social Movements, History of: General* and *Social Movements: Resource Mobilization Theory*; Chazel 1992, Oberschall 1983). The identity movements that came to the fore in the last third of the twentieth century are of a different nature, because they express two complementary types of collective demands: (a) the defense of interests and the promotion of rights of certain groups of individuals who feel discriminated against, and (b) the search for symbolic recognition by a significant other.

Identity movements defend the interests, world visions, and values of groups of individuals or communities defined by such characteristics as phenotype (or *race*) and ethnicity; sex; language; sexual orientation; mythical origins and ancestral territory, in the case of First Nations in the Americas and the South Pacific; and religion, in the case of certain societies. Melucci (1989) even posits that *all* social movements have an identity dimension (on the link between social movements and identity, see Jasper 1997, Larana et al. 1994).

Identity movements have three main and very distinct objectives. First, they denounce injustice toward minorities. Second, they convey the idea that specific cultures must be taken into consideration when public policies are elaborated so that they meet the specific needs of minorities. Third, they demand greater control of their institutions—a demand that sometimes goes as far as self-government.

Individuals involved in identity movements promote their own interests (Olson 1965) based on their way of seeing things and their personal knowledge and values. Their action is therefore marked by instrumental, cognitive, and axiological rationales. Boudon and Bourricaud (1982/2000) have shown that the two dimensions of collective behavior described by Smelser (1962), relation with norms and relation with values, are so closely linked as to become interdependent. The shared values of the members of a group or community play a central role in emerging identity movements, at least as important as the pursuit of individual interests.

This article will specify what should be understood by identity, define the characteristics of different types of identity movements, and discuss the relationship between the universal and particularistic norms which are specific to each movement.

1. *Identity*

In the early twentieth century, identity was often defined according to 'objective' traits, such as English tenacity, German discipline, and French ingenuity. What we now call identity was then known as the 'soul of peoples' (see Siegfried 1950). Today, the problem of identity is no longer seen in this light (see *Social Identity, Psychology of*).

It is no longer possible to separate personal and collective identities. Individuals now belong to several social networks and groups, which, in turn, shape their identity, and they draw from society the elements that they need for self-definition. Today, they are faced

with a great number of choices, many more than those of preceeding generations. Education, individual and collective fulfillment, social mobility, career mobility, geographical mobility, and lifestyle are some of the social processes that help to build identity.

Individuals play a key role in the building of collective identities especially in countries such as Australia, Canada, and the United States, where the mass arrival of immigrants shapes the basis on which identity is redefined. Canada, for example, which welcomed more than eight million immigrants between 1945 and 2000, defines itself no longer as a binational society but as a bilingual and multicultural one. Australians are questioning the relevance of maintaining the royal symbols that are remnants of their colonial past. The same can be said of older countries such as England or France, whose present collective identity is marked by changes in individual lifestyles and moral values and the intermingling of peoples of diverse ethnic origins. Aspects of Ancien Régime France and Victorian England coexist with their more modern counterparts. Such contrasts can now be found in various degrees in every society. Immigration, urbanization, international trade, unequal regional development, differing interpretations of the past, social conflicts, and social stratification affect the construction of collective identities.

Taylor (1989) defines the concept of identity three ways. First, identity defines the moral outlook of each individual, in the sense that individuals are able to determine what is important to them. This corresponds to Erikson's (1968) conception that individual identity implies self-knowledge and a successful and accepted synthesis of diverse influences, especially those of the individual's family.

The second definition came into being with modernity and has enabled individuals to have a better grip on their own destiny. Theoretically, within the limits of their capacities, people can become what they want to be; the future is no longer dictated solely by ascribed status in society. Political freedom, education, and economic development have enabled individuals to innovate, and, to a certain point, be responsible for their future. Each individual may have diverging or even conflicting interests, but each will eventually define values that will be expressed through various social movements and collective conduct.

Taylor insists that self-affirmation and recognition by a significant other are the two conditions for achieving a successful identity. Social actors involved in identity movements are motivated both by what they see as a deficiency in democracy, and by the search for recognition which involves negotiation and sometimes struggle and which is probably the main feature of such movements.

Because individuals are also part of a people or nation and therefore also define themselves by their collective past, national identity is the third definition that Taylor gives to the concept of identity. A nation or historical community offers people another perspective made up of a shared culture, lifestyle, and language (Todorov 1995). Nations are also imagined communities (Anderson 1991). However, most countries are not homogeneous; in the second half of the twentieth century, they have had to deal with the problem of recognition of various nations within their own midst. One can therefore say that the relationship with the other, which is at the heart of identity assertion, is an internal problem in most countries.

Dumont (1974) distinguishes three types of human communities, each with a particular way of building self-identity: primary groups (small groups based on face-to-face interactions), integrated groupings (in which individuals play interchangeable roles), and reference groups (defined by a sense of belonging, an awareness of forming a community). Diversity, plurality, conflicts, and differences become inevitable as social groups grow in size, and the need to adopt a common reference then becomes essential to ensuring cohesion. Evidence of adhesion must eventually be transposed into a series of collective signs and symbols in order to become conscious references for each member within the grouping. Dumont goes on to describe the constantly repeated mechanisms that contribute to the building of identities: ideologies, literature, and historiography (to which, today, we could add the media) play a key role in the shaping of a common reference. He speaks of conflicting interpretations between various categories of actors involved in the process of building identities, and defines society as a series of interpretive practices.

The Scottish example is relevant here. Language is not a central issue in defining Scottish national identity, despite a recent interest in Gaelic; more important is identification with a mythic territory, a common history, and recollection of ancestral wars (Macdonald 1997). The situation is quite different in Quebec and Catalonia, where promotion of the national language (French and Catalan, respectively) plays a central role in the building of the respective identities.

2. *Identity Movements*

Four types of identity movements will be characterized by the cognitive and axiological systems that determine their action (see Boudon 1999), the means and field in which the action takes place, and the meaningful others involved in the search for recognition.

2.1 *National Identity Movements*

Movements of national affirmation are undoubtedly the best-known types of identity movements. Gellner (1997) estimates that there are 15,000 national cultures demanding recognition in a world where there are only

a few hundred nation-states. These movements challenge the dominant national reference in their respective countries, and they are determined to achieve official recognition. They are composed of national minorities—not to be confused with ethnic minorities resulting from immigration, who make demands of another nature.

National minorities fight social inequalities of which they see themselves as victims, and many demand that official institutions be modified. These types of protests generally give way to a search for a new constitutional framework within a nation-state. Situations and demands, in accordance with the historical and national contexts, are extremely diversified (Calhoun 1994).

2.2 *Aboriginal Identity Movements*

The self-assertion of aboriginal nations in countries shaped by influxes of immigrants must be considered separately. There are approximately 250 million aboriginals living in these immigrant societies throughout the world, mainly in the Americas and the South Pacific. This enormous population (equivalent to half of that of Europe or two-thirds of that of the United States) is divided into several thousand nations or distinct groups. In Canada, for example, there are 633 different bands and aboriginal nations—some groups numbering only a few hundred people—speaking 57 different languages.

Conquest and colonization by Europeans marginalized aboriginal nations, sometimes moving them to reservations, as is still the case in Canada and the United States. These peoples have been the victims of serious historical injustices, and some of them were nearly extinguished by warfare. Today, they are demanding control of a number of institutions that will help them maintain their specific collective identities. Some aboriginal nations in the United States, the Sioux for example, and a large number in Canada and Australia are striving for self-government within their respective countries, but their small populations prevent most of them from claiming complete sovereignty.

Aboriginal communities build their action on three main aspects of their value system. First, there is the feeling of a common mythical origin. Second, and probably at the heart of their culture, is their relationship with nature, the land, and ancestral territory. Third, is the idea of kinship and blood: aboriginal communities generally do not integrate strangers, for one is either born Native or one is not.

The search for symbolic recognition is particularly important to aboriginal communities, since, traditionally, their culture has been denigrated or denied. The leaders of these communities are now striving to build a new sense of identity in order to counteract the feeling of self-contempt. This explains why, for many of them, interpretation and self-definition have become so important.

2.3 *Particularistic Identity Movements*

Other identity movements do not question existing institutions but aim for the rightful participation of specific groups of individuals, sometimes even imposing various modes of participation suited to their particular characteristics. Such is the case with linguistic or ethnic minorities that insist on having better access to important positions in the civil service and business organizations.

This type of movement includes the great majority of the feminist movements that demand an end to sex discrimination in public institutions and private enterprises. Although the feminist movement has very diverse components, it presents itself as an identity movement because it defends the interests of a portion of the population who feel wronged simply because they are women, and because of their opposition to a meaningful other who, in turn, becomes the main point of reference: men. Groups of women now insist on empowerment and their share of all higher appointments in various occupations. The most radical feminist movements go so far as to claim that all social relations are gender relations.

The civil rights movement for black Americans, which climaxed under the leadership of Martin Luther King, is also an identity movement (Morris 1984). Even though this movement is typically American, in the second half of the twentieth century, it has taken on a very important symbolic value in most Western countries; it also gave rise to programs for affirmative action in favor of visible minorities in the United States.

2.4 *Normative Identity Movements*

Other identity movements set out to modify social norms that affect the private, civil, and professional lives of individuals. Actors in these movements aim for symbolic acceptance of their differences and want to change social stereotypes. These differences are of a sexual, intellectual, or physical nature, such as the visible characteristics of certain immigrants (Bauman 1996). Movements based on sexual orientation and in defense of the handicapped are good examples of this type, whose participants feel that they are the victims of prejudice. Their complaints have been legally validated by many countries and have helped to change public attitudes. In most developed countries, homosexuality is no longer seen as a criminal offence and is officially accepted in some institutions such as the armed forces. Today, some countries even acknowledge same-sex unions.

3. *Universalism vs. Particularism*

Identity movements and the associated communitarian philosophy see values as being interwoven with specific cultures (Touraine 1997, Elbaz and Helly 2000).

Some analysts worry about the negative consequences of cultural relativism underlying certain demands put forth by identity movements (see Boudon 1999, Hardin 1995). These critics emphasize that communitarian norms easily converge with the interests of the actors involved in identity movements, whereas universal norms seem to be weaker and take more time to surface because they do not serve the immediate interests of individuals. In this sense, Hardin (1995) has demonstrated that mobilization by spontaneous coordination may even bring about conflicts between different groups.

For other analysts, countries and modern constitutions today have no option but to accept and make the most of cultural diversity (Tully 1995). Multiculturalism—which has three different meanings and refers to a sociological reality, a philosophy, or a state policy—must be held up as an example. Kymlicka (1989) claims that multiculturalism does not split society up into isolated subgroups but, on the contrary, offers a common framework within which differences may blossom in a context that respects diversity.

Identity: Social

Problems of social, group, and collective identity have become a major focus of contemporary research. Such identity supposedly is determined by ethnic or other important characteristics. Interest in these issues presumably has been sparked by two factors. First, there are concerns of and concerns for minority ethnic groups in many nations, either from immigration, as in the US, or from historical intermingling, as in Belgium and most nations of the world. Second, the assertion of ethnic and gender identity has been a central element in recent politics in many nations. Much of the research on social identity has an inescapably normative tone, and much of it is written as though by advocates of particular identities or even, implausibly, by advocates of identity *per se*.

A social scientist must view identity as largely a social construction that is malleable to some degree, especially in younger ages, and as plural rather than singular, at least in advanced societies. People who

declare their identity commonly view it as objective and normatively commanding. Hence, identity and identity politics pose a sharp example of the common phenomenon that social science explanations are rejected by the very people whose behavior they ostensibly explain. This may be part of the reason that, especially, postmodern advocates of the importance of identity reject explanations as ideologically corrupted.

There are three central issues in social identity that will be discussed here. What does it mean? What are its moral implications? And what motivates people to act on their identities? The first question raises the issue of what it means both to a social scientist and also what it means to an individual who has some putative identity. The second involves claims about what actions or policies are justified by aspects of social identity, especially when these characterize substantial groups. The last question shifts the focus from supposedly objective facts of identity to subjective issues of motivation and, hence, as discussed below, from identity to identification. This question arises independently of whether identity is socially constructed or objective. For example, philosophers once supposed the possibility of an ardent Nazi, so ardent in his commitments as even to think it right that, once his Jewish identity was discovered, he should be expelled from Nazi society.

These three questions have answers that are not entirely separable, because they inform each other. The third question involves issues of explanation. How do we explain an individual's identification with a particular group? If meanings are theory-laden, then the first question also involves issues of explanation.

The most common categories of social identity are racial, gender, religious, national, communal, and ethnic, all of which are taken to be chiefly or at least partially ascriptive. We might add familial, professional, and other identities to this list for at least many people, but for many of the theorists of social identity these categories suggest the breakdown of the central idea, as the plural ties of modern societies also commonly do. Indeed, some of the discussions of identity take the form of advocacy of a restoration of some of the earlier forms of social life, without the corrosive effects of modern liberalism and pluralism on community.

There is a long history of the analysis of individual or personal identity by psychological theorists, from James (1981) forward. And there is a rich history of the effort to socialize the idea of a person or the self, from at least Mead (1934; see Joas 1997). An implication of much of the latter literature is that social identity is important in large part because it determines personal identity so heavily. Advocates of social identity sometimes are accused of having an oversocialized conception of the person. Some of the strongest contemporary advocates of social identity share the postmodern and communitarian rejection of any strong notion of individual autonomy, such as has descended from the universalist stances of the utilitarians and Immanuel Kant. They therefore think it makes no sense to speak of your identity without essentially definitive recourse to your social context and background. Bridges between the psychological study of personal identity and the sociological study of social identity are, however, few and often narrow (but see Taylor 1989). Most of the discussion is not empirical and it often has the strong scent of ideological pleading. This is a topic that is sorely in need of explanatory accounts.

One of the great strengths of the psychological approach to personal identity is that it at least struggles with and has some chance of explaining the formation of such identities. For example, Sigmund Freud and many others have argued for the 'narcissism of minor differences' (Blok 1998). Bourdieu (1984) supposes that 'Social identity lies in difference, and difference is asserted against what is closest, which represents the greatest threat.'

If we are to understand social identity, we probably need to have accounts and explanations of its formation (Hardin 1995, Laitin 1998). Commonly, its genesis simply is assumed and accounts start from a present, assumed identity. Indeed, many writers even give credit to some notion of collective memory that connects, say, contemporary Serbs with the dreadfully lost war with Turks in 1389 in the Field of the Blackbirds. Somehow, the English seem to be exempt from the effects of the dreadful memories of Hastings Field and Americans do not even remember, much less resent the burning of the White House by the British. The assertion of historical memory contributes to mystification rather than explanation or understanding. Such mystification is, in a famous remark of Ernest Renan, required for nationalism, because one can be committed to the rightness and purity of a nation only by forgetting its brutal and messy past. Mystification is also required for many claims of group identity.

1. *The Meaning of Social Identity*

Many descriptive accounts of social identity virtually essentialize it to suppose that, if we know relevant descriptive facts about you, we know your social identity. Against any such move, others note that even a descriptive account could conclude that your identity is quite varied. You are an Italian, Catholic, New York accountant with particular social activities in specific groups. There may be no one you know who shares all of these characteristics that are, together, central to your own life. Hence, it would make sense to say that you have multiple identities, which likely are evoked in different contexts or on different issues. But maybe you dislike your Italian neighbors and their vocal style, you have rejected Catholicism and have stopped going to mass, and you wish you could move

out of New York and change your profession. All of the things you now reject might nevertheless have effects on you and might help others to understand parts of your behavior and attitude, so that in some explanatory sense they are part of your identity. Still, in your case, there is an odd difference between the use of your characteristic identity to explain things you do or think and your actual commitments. Much of the literature that explicitly or implicitly justifies actions from identity takes relevant commitments for granted once identity is established. But your case suggests that this correlation of ascriptive characteristics and commitments can be entirely wrong. The idea of social identity in a pluralist world in which individuals themselves have plural commitments seems to break down, and the recent efflorescence of communitarian thought is largely a response to this breakdown (see e.g., Etzioni 1993). In a plural society, the philosophical concern with identity and its fundamental meaning for even a mere physical object becomes acute. The traditional philosophical example is the boat that is rebuilt over many years, one rotted plank at a time. Suppose no piece of the original boat remains but that 'the' boat continues to sail. Is it the same boat? Are you in any meaningful sense the same person who was born and lived for many years in a different society before you migrated, went to university, developed radically different tastes, rejected your prior religious views, and lost contact with virtually everyone you knew earlier, and so forth? And if personal identity is in question, can social identity be any more stable?

Identities that are asserted forcefully are often virtually invented by leaders with agendas (on the deliberate creation and manipulation of national identities, see Anderson 1991, Hardin 1995, Hobsbawm 1990, Lebovics 1992). Many of the communities with which individuals identify are hierarchical or otherwise diverse in ways that suggest there is not a unique identity or kind of person at issue. The ascriptive variables on which identity might be based are, as noted, numerous and varied. It is therefore almost impossible to talk about social identity without making the term denotative, without virtually pointing and saying, '*That* is an identity.' What is missing is some standard set of characteristics that defines a social identity beyond the fact that some significant numbers of people assert that they have such an identity. Social identity theory is woefully undertheorized.

2. *The Ethics of Social Identity*

Much of the contemporary literature on identity is normative, not causal, and is therefore unlike the early Chicago school of sociological work on ethnic minority groups. It is driven partly by the post-modern rejection of explanation and its focus on description and normative judgment that seems to flow merely from description, contrary to the famous principle of David Hume that one cannot deduce a moral conclusion from a mere fact, of an 'ought' from an 'is.' Of course, specific claims of identity in actual contexts typically are normatively loaded. They commonly are claims for political rights or redress of wrongs (Kymlicka 1989).

How should the social theorist or policy maker respond to identity claims? We generally do not honor relativistic moral claims, such as that you or your group has a special status that others must honor. Rather, we expect moral claims to be universalistic in some sense. For you to make a moral claim, you must grant implicitly that all who are in similar circumstances, somehow defined, can make the same moral claim. If you insist that your claim should motivate others, the claims of those in a position analogous to yours should motivate you to some extent. Assertions of the rightness or goodness of one's own group and its claims often are little more than group solipsism. Adding the appellation 'group' to solipsism does not rescue it from the moral opprobrium that solipsism normally has.

When an identity is enforced on an individual (or group) by others, as in contexts of racism, we might agree easily that there is a moral aspect to the individual's claims from identity. Indeed, racist treatment seems to be a simple case of universalistic concern. It is perhaps this quality, when it is present, of much of the assertion of identity by suppressed groups in their own defense that has motivated concern with group identity and that has elevated it to the status of a moral issue.

Actual supporters of group identity in many contexts would blanch at the thought of support for, say, Caucasian American, Anglo-Saxon, or German identity, although each of these historically has been asserted against immigrant groups and, in the US, former slaves. For contemporary identity theorists, the only apparent candidates for claims of rights of identity are minorities, those in secondary status, and third world populations. But these are not moral statuses *per se*. Hence, we would have to be articulate about what characteristics of these groups entitle them to special concern. A particular social identity cannot be good or right except contingently. Otherwise, it would be wrong of me to reject mine—or, more typically, some of mine.

While we could have compelling explanatory discussions of social identity, the contemporary literature to date has few such discussions. Instead, authors commonly take identities for granted and they focus on the normative qualities of social identity and, typically therefore, of communal life. They often pose such life as good and as hostile to traditional liberal principles of universality and autonomy, which would seem to entail opening the doors of community to free entry by outsiders, much to the detriment of the

community's ur-members. To establish that something is good, we might show that it follows from some theory of the good or that it fits human nature or that it was brought about by a relevant procedure. Communitarianism is essentially proceduralist about the good. If the community generates a practice, that practice is good for the community. This is a peculiar move in standard ethics, because proceduralism typically has been the path to the right, not to the good.

The question for a communitarian definition of the good is what the procedure is about and how it works. In law, procedures often are supposed to work for discovery of the truth or for protection of people from particular kinds of official abuse. Hence, they make right. Communal creation of values commonly is supposed by communitarians to make those values good, at least for the community that creates them. Because we assert our identity, that identity has moral weight, it is part of our good. Unfortunately, although practicing communitarians are almost always partial to their own group and hostile and even murderous to certain other groups, this implication has a universal quality that suggests that any group that asserts its identity has thereby defined the content of much of its good and the good of its members. It is partly therefore that communitarianism has taken a dramatically conservative turn and that defenders of the goodness of stultified, narrowly focused communities that often entail severe restrictions on the opportunities of their children have become communitarians. The quasi-universal quality of communitarian thought is about the universality of the way a group's good gets defined, not about the content of that good. Some communitarians seem to espouse a return to religion (for others) not because of the rightness of the content of the beliefs but because of the discipline and control of the self that religiosity brings.

3. *Motivations To Act*

Perhaps the least addressed of the three questions central to understanding social identity is what motivates individuals to act on their identities. In a sense, this question changes our focus from identity to identification, or 'a sense of inner identity,' which was a central concern of Erikson (1964). Such identification has not often been addressed in the contemporary claims for identity. Indeed, there is often not even a clear distinction between personal and social identity. There have been three major approaches to the analysis of identity beyond mere assertion or description of it. These are psychological, moral, and rational choice accounts.

The most influential psychological account has been that of Erikson, although Erikson's focus is not on social identity but rather on the individual's creation of an identity or a self, all, of course, under massive social influence. Despite the initial promise and compelling qualities of Erickson's work on identity, however, psychological accounts have often had an *ad hoc* quality that has perhaps kept them from being followed up extensively by anyone other than their original authors. There is, therefore, not a coherent body of work that gives clear insight into why one's objective circumstances of language, religion, skin color, gender, prior history, and so forth should motivate one to energetic and even risky action on behalf of whatever one might identify with.

It is not difficult to give a moral account of the motivations of many individuals who act on behalf of a group, as, for example, Frederick Douglass did for American blacks or as Mahatma Gandhi did for the lower castes of India. But it is difficult to construct a moral story that justifies Serbian ethnic cleansing or to see scurrilous leaders such as Slobodan Milosevic or Franjo Tudjman as moral. Many members of various ethnic groups do claim that they have been wronged morally and that their actions against others are morally grounded. But it is hard to moralize the ethnic cleansing in Yugoslavia, most of which has been carried out by soldiers under orders, or the spontaneous violence by uncontrolled mobs that have wreaked havoc and death on Sikhs in India after Indira Gandhi's assassination, on blacks during hundreds of lynchings in the US, and on Tutsis in Rwanda during the incomparably bloody rampage of the Hutu extremist *interahamwe*. Interestingly, these are all instances of majority ethnic groups attacking minority groups, and the ethnic groups committing these atrocities were in political power at the time (although the Hutus soon lost power).

One way of ostensibly explaining any specific motivation is to reduce it to other motivations that are well understood and that have much broader application. Some explanations of social identity implicitly posit it as a motivation of its own kind, a kind that has only relatively recently been discovered. This is a very unsatisfactory move because supposed social identities do not correlate with actions following from the motivation. Psychological accounts are relatively fragmented because they do not reduce the relevant motivations to some widely accepted core.

Rational choice explanations gain what power they have from the attempt to reduce particular motivations to some narrower set of motivations, often simply to interests, which can be moderately well defined and measured across a large variety of contexts and actions. In such an account of individual identification with a group, we look to see how certain interests of the individual might be satisfied by participation in the life of the group. And we look to see what interests members of the group might have to impose constraints on each other to enforce their commitments to the group. In essence, groups commonly produce norms of exclusion, whose content is rules for belonging to the group and whose chief means of sanction is the possibility of excluding

miscreants from the group. If membership has its pleasures, the sanction of exclusion has bite. It might be trumped by inducements from outside the group, and therefore many people leave groups with which they have previously been strongly associated. Indeed, they leave nations and home communities, even at great cost, for the benefits they might expect elsewhere. It is a striking feature of norms of exclusion that their sanctions are often easily motivated, while the sanctions against violating universal norms are very hard to motivate unless they can be brought to bear in essentially dyadic or small number contexts (Hardin 1995).

Such an account of their commitments is unlikely to satisfy members of a group, who are more likely, with Renan, to justify their commitments by mystifying the value and reason of the group. Unfortunately, the only account that would not have this problem of rejection by the group is the account the members themselves would give. That account is unlikely to lead to understanding and is typically likely to be almost entirely normative. The social scientist who tries to explain communal commitments and social identities is apt to lead an existence somewhat barren of such community. Gellner (1998) argues that moderns, with their individualistic life and thought, may suffer a romantic wish for, or even insistence on, community and a particular social identity. Wishing will not make it happen, and most moderns will be able to speak of their own social identity only in the plural, often the extremely plural, and, as James argued long ago, in a plural that is in frequent flux. An irony of the lives of the theorists of social identity and community is that they too are inherently plural in their own identities and that they typically lead their lives in the cold comfort of anti-communal, universalistic universities.

Ideology: History of the Concept

The concept of ideology is a highly contested notion and there is no general consensus today about how best to define the term. In the work of some authors, 'ideology' is used in a general way to describe sets of values and beliefs which guide political action; one could describe the values and beliefs which underpin political parties as 'ideologies' in this sense. In the work of other authors, however, 'ideology' is used in a more critical way to refer to ideas or symbolic forms which in some way distort or misrepresent the social world, or which serve the interests of some individuals or groups at the expense of others. Used in this second sense, the concept of ideology is often linked to a type of social or political analysis which adopts a critical stance towards the social world. So to study ideology, in this second sense, is also to look critically at ideology; it is not simply to describe values or beliefs but also to unmask them, to show how they misrepresent the world or how they serve dominant interests.

1. Brief History of the Concept

The term 'ideology' was first used in the late eighteenth century by the French philosopher Destutt de Tracy (1754–1836). An educated nobleman who was strongly

influenced by the European Enlightenment, Destutt de Tracy wanted to develop a new discipline which would be concerned with the systematic analysis of ideas and sensations. He described this proposed discipline as 'ideology'—literally, the science of ideas. Since all scientific knowledge involved the combination of ideas, ideology would be the 'first science'; it would also provide a basis for education, morality, and politics. Ideology would enable us to understand human nature, and hence would enable us to regulate social and political life in accordance with the needs and aspirations of human beings. Destutt de Tracy's vision for this infant discipline was thus a natural development of certain themes of the Enlightenment, such as the emphasis on progress and on the capacity of human beings to understand and control the world through systematic, scientific analysis.

In the early nineteenth century, the meaning of 'ideology' was transformed in various ways. This transformation began when the French emperor, Napoleon Bonaparte, turned against Destutt de Tracy and ridiculed the pretensions of his work. Napoleon described Destutt de Tracy and his associates as 'idéologues,' and he condemned ideology as an abstract, metaphysical doctrine which was divorced from the realities of political power. As his military campaigns ran into difficulties and his position weakened at home and abroad, Napoleon's attacks on the idéologues became more sweeping and vehement; increasingly he viewed ideology as the source of France's difficulties, since it sought to base laws on the abstract analysis of ideas rather than on the lessons of history. The meaning of the term 'ideology' began to shift: it was no longer used primarily to refer to the science of ideas but was used increasingly to refer to the ideas themselves, and especially to ideas which were alleged to be erroneous, misleading, and divorced from the practical realities of social and political life.

The term was taken up and further transformed by Marx and Engels in the 1840s and 1850s. Marx and Engels were familiar with Destutt de Tracy's work and with Napoleon's attack on it, and in some of their early writings they used 'ideology' in a way that was informed by this controversy. In *The German Ideology*, written in 1845–6 but left unpublished, Marx and Engels criticized the views of the so-called 'Young Hegelians' such as Ludwig Feuerbach, Bruno Bauer, and Max Stirner (Marx and Engels 1970). In characterizing the views of these thinkers as 'the German ideology,' Marx and Engels were following, very broadly, Napoleon's use of the term: the work of the Young Hegelians was the equivalent, in the relatively backward social conditions of nineteenth-century Germany, of the doctrines of Destutt de Tracy and his associates. Just as Napoleon had poured scorn on these doctrines, giving the term 'ideology' a negative connotation, so too Marx and Engels derided the views of their compatriots. The views of the Young Hegelians were 'ideological' in the sense that they were abstract and metaphysical; these thinkers were preoccupied with ideas and the analysis of ideas, and they failed to grasp the real material conditions of social and political life.

In later writings, however, Marx laid the foundations for a somewhat different and more innovative account of ideology. He suggested that, in societies divided into classes, ideas may play an important role in articulating the conflicting aims and interests of different social classes. In his 1859 Preface to *A Contribution to the Critique of Political Economy*, Marx distinguished between the material conditions of production, on the one hand, and what he called 'ideological forms,' on the other (Marx 1968). While the material conditions of production were the real basis of social and political life and the driving force of social change, he suggested that it was at the level of ideological forms of consciousness—including legal, political, religious, aesthetic, and philosophical forms—that individuals become aware of the conflicts stemming from the material base and fight them out. Moreover, 'just as our opinion of an individual is not based on what he thinks of himself,' so too we cannot take these ideological forms of consciousness at their face value: we must show that they are rooted in, and shaped by, the material conditions of social life. By explaining ideological forms of consciousness in this way, we can also *unmask* them—that is, we can show that they are expressions of the interests of particular groups and classes. Hence an analysis based on the scientific study of the material conditions of social life can at the same time be developed, Marx suggested, as a critique of ideological forms of consciousness which it both explains and unmasks.

These and other contributions by Marx and Engels provided a rich source of inspiration for subsequent authors, and the concept of ideology became a central topic of debate in Marxist circles in the twentieth century (for a full discussion of ideology in relation to Marxism, see Larrain 1983). But the concept was also taken up by sociologists, political scientists and others who wanted to use 'ideology' in a way that would be more neutral and less concerned with questions of normative judgment and critique. This shift of emphasis was evident in the work of Karl Mannheim, whose *Ideology and Utopia*, first published in 1929, became a key text in the complex history of the concept (Mannheim 1936).

In Mannheim's view, most earlier conceptions of ideology were what he called 'particular' conceptions, by which he meant conceptions which remained at the level of more-or-less conscious disguises, deceptions and lies. When we characterize the ideas and views of our opponents as 'ideological' and regard them as misrepresentations or distortions of the real nature of the situation, we are presupposing the particular conception of ideology in this sense. Mannheim contrasted this with what he called the 'total' conception of ideology. We presuppose the total con-

ception when we try to grasp the modes of thought and experience, the *Weltanschauung* or 'world-view,' of an epoch or group and view it as an outgrowth of a collective life-situation. The particular conception remains at the level of individuals engaged in accusation and deception, whereas the total conception has to do with collective thought systems which are related to social contexts.

In Mannheim's view, Marx was the first thinker to make the transition from the particular to the total conception of ideology, but he did so only in a partial and limited way. Marx moved beyond the particular conception in so far as he sought to trace ideas back to the class positions of their exponents. But Marx's approach retained elements of the particular conception in so far as he sought to discredit bourgeois thought and to criticize the ideas of his adversaries, while refraining from applying the same approach to his own thought. In other words, Marx adopted a rather partial version of the total conception; what is necessary, argued Mannheim, is to make the full transition to the total conception. When one fully adopts the total conception, the analysis of ideology ceases to be the intellectual weapon of a party and becomes instead a method of research in social and intellectual history, a method Mannheim described as 'the sociology of knowledge.' For Mannheim, therefore, 'ideology' in the sense of the total conception could be regarded as the interwoven systems of thought and modes of experience which are conditioned by social circumstances and shared by groups of individuals, and which can be analyzed by means of a discipline—the sociology of knowledge—that moved beyond the partisan character of earlier approaches.

Marx and Mannheim are only two of the many social thinkers who, in the nineteenth and twentieth centuries, used the concept of ideology and tailored it to their own specific concerns (for accounts of the contributions of other thinkers, see Lichtheim 1967, Barth 1976, Larrain 1979, Thompson 1984, Eagleton 1991). The literature abounds with different conceptions of ideology; it also abounds with differing assessments of the significance of ideology (or ideologies) and the role it plays in modern societies. One assessment of the significance of ideology which was influential in the 1950s and 1960s was the so-called 'end of ideology' thesis.

2. *The End of Ideology Thesis*

The end of ideology thesis was originally put forward by a number of liberal and conservative thinkers in Europe and the United States in the 1950s, including Raymond Aron, Edward Shils, and Daniel Bell (see Aron 1957, Shils 1958, Bell 1960, Waxman 1968). In its original formulation, the end of ideology thesis was an argument about the alleged decline of radical and revolutionary political doctrines in developed industrial societies. It was argued that in the wake of World War II, the defeat of Nazism and Fascism, the Moscow trials, and the denunciation of Stalinism among other things, the old ideologies stemming from the eighteenth and nineteenth centuries had lost much of their persuasive power. These ideologies had taken hold primarily among groups of intellectuals who had become disaffected with existing social and political institutions, and who had expressed their disaffection by calling for radical change. But the political events of the early twentieth century had exposed the naivety and danger of such calls. It was becoming increasingly clear that the problems confronting developed industrial societies could not be solved by the kind of radical social change espoused by Marxism and communism, since this kind of change gave rise to its own problems and to new forms of violence and repression.

The end of ideology theorists argued that the old 'ideological politics' were a spent force, and were giving way to a new sense of pragmatism in developed industrial societies. Revolutionary passion was waning and was being replaced—in the West at least—by a pragmatic, piecemeal approach to social change within the framework of a mixed economy and a redistributive welfare state. The end of ideology theorists generally recognized that ideologies would continue to flourish in less developed societies, and they did not altogether rule out the possibility that revolutionary passions might occasionally reappear as isolated outbursts in the developed industrial societies. But they maintained that, as a general situation in which the political arena is animated by radical and revolutionary doctrines, which arouse passion and heated conflict, the age of ideologies is over and ideology has ceased to be a significant feature of modern industrial societies.

Of course, the end of ideology theorists were using 'ideology' in a very special sense. Ideologies, in their view, were a particular kind of secular belief system: they were comprehensive, totalizing doctrines which offer a coherent vision of the social-historical world and which demand a high degree of emotional attachment. For most of these theorists, Marxism was the epitome of ideology in this sense. Marxism offered a systematic, totalizing vision of the social-historical world; it predicted a future which would be radically different from the present, and which could only be realized through the dedicated action of individuals who believed unflinchingly in their cause. These were the characteristics of ideology: totalizing, utopian, impassioned, dogmatic. The end of ideology in this sense was not the end of political debate and conflict, but these debates and conflicts would no longer be animated by totalizing, utopian visions which incited individuals to revolutionary action. Political processes would be increasingly institutionalized within a pluralistic framework in which political parties or

groups competed for power and implemented pragmatic policies of social reform.

The end of ideology thesis was put forward at a time—the late 1950s—when economic growth in many Western countries had helped to create conditions of relative stability, and when the idea of combining a mixed economy with a welfare state had been accepted by many intellectuals and politicians as a viable institutional framework for developed industrial societies. The political turmoil of the late 1960s and the economic recessions of the 1970s and 1980s undermined these conditions to some extent, and it could be argued that, contrary to the expectations of the end of ideology theorists, ideology has remained an important aspect of politics and political struggle in Western industrial societies. One could plausibly argue, for example, that Margaret Thatcher's reorientation of the Conservative Party in Britain in the 1980s, and the rise of neoliberalism in many Western countries in the 1980s and early 1990s, were instances when ideology had a significant impact in the political realm. Part of the difficulty with the end of ideology thesis is that it used the term 'ideology' in a very special sense (with Marxism as the prime example), and this undoubtedly limited the usefulness of the thesis as a way of understanding the changing character of politics.

With the benefit of hindsight, the end of ideology thesis in its original form may well appear to be a product of its time. Nevertheless, there may be some substance in the view that ideological differences between the major political parties in many Western countries have declined to some extent since the 1960s, partly as a result of broader changes in social structure. During the second half of the twentieth century, the changing character of work in Western industrial societies has transformed the social context of politics. Parties could no longer rely on the old social classes which once provided the core of their support. Traditional doctrinal divisions were attenuated, and increasingly parties and their leaders had to struggle to win the support of a growing pool of uncommitted voters. The traditional class-based party politics, with its strongly opposed belief systems and its strong contrast between left and right, has not disappeared, but it has been weakened by these social transformations. Ideology has not been eliminated from party politics but its role has undoubtedly changed, as parties and their leaders know that they can no longer count on a stable and committed electoral base and must try to win support by means of specific policy pledges and carefully devised electoral campaigns.

3. *The Concept of Ideology Today*

Given its long and complex history, there are some social scientists today who believe that it would be best to dispense altogether with the concept of ideology. They argue that the concept is simply too ambiguous, too controversial and contested, to be retained as a useful tool for social and political analysis. But this view is not universally shared. There are others who believe that the concept of ideology still has a useful role to play, although differences remain in terms of how best to define the concept. While the term 'ideology' is still used in a variety of different ways, one can distinguish between two broad conceptions of ideology which are prevalent in the literature today.

Many social and political analysts today use the term 'ideology' in a largely descriptive way to refer to any system of thought or belief which animates social or political action: this is what could be described as a *neutral conception* of ideology. Thus ideologies can be thought of as discrete and relatively coherent systems of thought or belief which inform social and political action, and the task confronting the analyst of ideology is to delineate these systems and describe their main features. (This is the view adopted, for example, by Martin Seliger; see Seliger 1976.) This conception is exemplified by the tendency to think of ideologies in terms of 'isms'—Marxism, communism, socialism, Fascism, Nazism, liberalism, conservatism, etc. Most modern political parties, as well as social and political movements like the women's movement and the environmental movement, have ideologies in this sense. The capacity of such organizations or movements to mobilize support depends on their ability to produce and diffuse belief systems which have some degree of appeal among activists and followers.

Other social and political analysts use the term 'ideology' in a more normative way to refer to ideas, beliefs or symbolic forms which are in some way misleading, illusory, or one-sided, or which serve the interests of powerful groups. We can describe these uses as variants of a critical conception of ideology. The analysts who adhere to this conception argue that the very characterization of something as 'ideological' unavoidably conveys a negative connotation: it implies that the ideas or symbolic forms are partial or are harnessed to particular interests. There are differing views in the literature about how exactly this critical conception of ideology should be understood. Some theorists regard ideologies as sets of ideas about the social world which are in some sense 'false' or illusory, whereas other theorists prefer to think in terms of the inter-relations between symbolism and power. An example of the latter approach is the view that ideology should be conceptualized in terms of the ways in which symbolic forms serve, in specific circumstances, to establish and sustain relations of domination (see Thompson 1990). If one adopts a critical conception, then the analysis of ideology is not simply a matter of describing values and beliefs: it also has a normative dimension. In other words, the analysis of ideology is linked to questions of social and political criticism. Another implication is that the study of ideology has to be extended beyond the sphere of organized

politics. While the institutions of political power are clearly an important site of ideology, it is also important to consider the ways in which meaning is mobilized by other institutions, such as the media and the educational system.

While there may be no consensus about how best to use the term 'ideology,' many commentators would agree that the study of ideology is an indispensable part of social and political analysis. Political systems, social and political movements, and relations of power and domination are always interwoven with ideas, beliefs, and symbolic forms of various kinds; power is rarely exercised without some kind of symbolic basis or support. It is this aspect of power, and the ways in which relations of power are interwoven with ideas, beliefs, and symbolic forms, which define the domain of study for those who are concerned with problems of ideology.

Ideology: Political Aspects

A political ideology is a set of ideas, beliefs, values, and opinions, exhibiting a recurring pattern, that competes deliberately as well as unintentionally over providing plans of action for public policy making, in an attempt to justify, explain, contest, or change the social and political arrangements and processes of a political community.

The concept of ideology is subject to a range of different, partly incompatible, interpretations. In the Marxist tradition it relates to an illusory distortion of material reality, supported by exploitative power relations, and it is employed critically to unmask those dissimulations and to eliminate ideological thinking as false consciousness. In non-Marxist approaches it is split among three trends. The first is a largely pejorative reference to abstract and closed idea systems, of a totalitarian or doctrinaire nature, which are contrasted with looser belief systems or with pragmatism. The second is an ostensibly value-free perspective in which ideologies are empirically ascertainable attitudes towards political issues to be explored using behavioral methods. The third recognizes the inevitability of ideologies as ubiquitous mapping devices of cultural symbols and political concepts that constitute a crucial resource for understanding sociopolitical life and enable collective choices to be made concerning the shaping of that life. Thus, what constitutes a political ideology, and describes its main features, is partly influenced by the conception utilized.

1. Genesis of Modern Ideologies and their Study

Although ideologies are as old as human thought and organization themselves, they emerged in a differentiated political form in the nineteenth century. This reflected the Enlightenment-inspired exploration of new thinking, the gradual spread of education and broader political articulateness, and the rise of mass politics, within which context ideologies served as important mobilizing tools for wider bands of active citizenry. Initially the term 'ideology' was coined by Antoine Destutt de Tracy to refer to the scientific study of ideas. Soon, however, the term was diverted to address some of the mounting epistemological and political concerns of the age. In particular, the search for social truths became a central bequest of the positivist tradition, and the discovery of power relationships among groups engendered innovative social theorizing. Ideology was now employed by Karl

Marx and Friedrich Engels to signify two main features. The one was the absence of true consciousness, replaced by imagined and metaphysical phantoms of the human mind. The ending of alienation through scientific socialism would rectify this defect and eradicate ideology. The other was to characterize ideology as an instrument of oppression by the ruling class in order to establish its dominance over the dehumanized majority. Ideology was located firmly within a set of socioeconomic capitalist practices and interests. It reflected in an inverted form the social contradictions of material conditions, so that repressive practices—such as the 'free' market—appeared as liberating ones.

Within the Marxist tradition Antonio Gramsci (1971) strengthened the notion of ideology-cum-power through his theory of the hegemony of a consensual historical bloc, but he also detached ideology from its ephemeral and dogmatic nature. He acknowledged the role of mass political activity in shaping popular culture through secular faiths, and recognized ideology in its highest sense as a conception of the world consolidated by intellectuals, directing social and political practices, and present in all manifestations of collective life, including art, religion, literature and law. Louis Athusser (1984) continued this reconciliation with ideology by emphasizing its integrative, 'interpellating' function. Ideology was both an imaginary representation of the real and a permanent lived relation between individuals and their conditions of existence. He too, though, still saw the role of central political institutions as producing 'ideological state apparatuses' that ensured their control over the established order.

From the late nineteenth century onwards, the European political arena became increasingly dominated by a struggle among competing political ideologies, in particular varieties of conservatism, liberalism, and socialism, all undergoing considerable growth. While Marxists could dismiss most of these as bourgeois illusions, the power of ideas as a means to organize political action, through political parties and their programs, as well as in extraparliamentary forms, became evident. The family of socialisms was subject to multifold internal divisions which underscored the subtlety of ideological argument. Attack and counterattack assisted in raising the profiles of the major ideologies and in accepting them as instruments of political conflict as well as transformation. To begin with, studies of ideology were mainly of historical and concrete ideologies, expository and frequently exhortatory. The threat of the totalitarian ideologies of communism and fascism changed that outlook, and a different pejorative connotation from the Marxist one imbued both popular and scholarly understandings. Ideology as a phenomenon was now characterized not only by its dogmatism, but by the superimposition of alien thought systems on a subjugated population, as part of a struggle for world domination. By contrast, liberalism and conservatism presented themselves as respectively open and flexible, or concrete and empirically based, sets of political ideas. Their claims to universalism were packaged in turn as rationally persuasive or invisibly natural, rather than manipulative.

Karl Mannheim (1936) assisted in changing the conceptual interpretation of ideology and alerted observers of politics to its ubiquity. Mannheim accepted the Marxist focus on the historical and social genesis of thought, but expanded ideology to cover the multiple social understandings of diverse social groups, each undergoing a common experience. Ideology was thus subject to a new epistemology that regarded all historical knowledge as relative to the thinker's sociohistorical location. Mannheim applied the term ideology solely to the interests of ruling groups intent on conserving existing social arrangements. It was divided between a particular conception of ideology as a lie or error and hence a function of individual psychology; and a total conception that referred to the entire *Weltanschauung* of a group. Ideology was contrasted with utopia, which on Mannheim's understanding was a transformative set of ideas, though more akin to what would now be termed a progressive ideology. Mannheim proffered ideology as a normal feature of sociopolitical thinking, and Marxism was itself unmasked as ideological. However, his attempt to transcend relativism through a sociology of knowledge was less convincing. He accorded free-floating intellectuals the capacity to incorporate the perspectives of different groups into a holistic relationism and to attain a critical approximation of truth. This tortuous quest only served to underline the problem of attaining objectivity in the social sciences.

2. *Analytical Perspectives*

2.1 *Empirical Approaches*

After World War II, US political scientists injected an empiricist dimension into identifying ideology. Employing behaviorist procedures to explore political attitudes, opinions, and evaluations, they concentrated on mass publics in democratic regimes. This method has applied interviewing and statistical techniques to aggregating and analyzing research findings. The regularities and constraints in the belief systems of social groups are related to the political thinking of elites and to public policy. These broadly functionalist approaches are innovative in their social-psychological focus on integration, and in recognizing ideology as unreflective and semiarticulate as well as reasoned and coherent. But they have also assimilated the study of ideology into a methodological individualism and a predilection for cognitive expression. Political ideology was now far removed from Marxist under-

standings: the question of its truth was bypassed in favor of regarding it as a scientifically neutral input into political systems. However, a reaction to that neutrality has been proffered by those who see ideology as possessed of a monolithic logic, closed to information that might challenge its coherence. Such interpretations have supported the contentions of many ethicists who consider ideology to be a betrayal of the moral expectations attached to political philosophy, rather than a different, but equivalently significant, form of political thought. Ideology may thus be relegated again to the category of bad theory.

2.2 Interpretation and Mapping

Anthropological and linguistic insights radically transformed interpretations of the functions and forms of ideology. Clifford Geertz (1964) portrayed ideology not as a mask, a weapon, or an expression of material interests, but as an ordered system of interdependent cultural symbols that imparted meaning to political systems. Ideologies provided patterned and holistic maps that both reflected and shaped a problematic social and political reality, and without which individuals would be unavoidably disorientated. This shift to the semantics of ideology was also evident in linguistics, with its emphasis on the interconnectedness of words as the basis of grammar and meaning. The inevitability of ideology had become ever more salient. If concepts were signified by words, then polysemic political concepts—the building blocks of ideologies—could form disparate semantic fields. Moreover, symbols and practices also combined to form systems of meaning. These theories allowed for an interpretation of ideology not only as sets of ideas having an impact on political action, but as pervading patterned social practices, often bereft of social transparency, yet decodable as unconscious incarnations of ideological stances.

2.3 The Unconscious, Emotion, and Reason

The introduction of the unconscious as a valid source of ideological data has itself been a site of scholarly dissent. The nonreflective manifestations of ideology may also be conflated with irrationality. Some political scientists asserted that ideologies were not only total but infused with passion: as Daniel Bell (1962) put it, secular religions. This led to the conclusion that, as extreme ideologies were apparently burning themselves out, the end of ideologies was in sight. Such views underestimated the emotive power of political ideas. They also incorporated a definitional constraint that ignored additional features of ideology that render the political 'center' just as ideological as the 'right' and the 'left,' or that cannot account for the rise of social movements such as feminism and environmentalism—political and ideational expressions of new social concerns. An alternative perspective identifies all political thought as proffering a mixture of rational and arational argument—both being a legitimate part of the ideological arsenal. All ideologies require some, albeit variable, degree of coherence, but they also incorporate emotion in the shape of fervor and rhetoric, vital to the recruiting of political support, and in the shape of commitment to non-negotiable core values. That, it is claimed, distinguishes them from 'best practice' political philosophy, where logic, consistency, intentionality and moral persuasiveness constitute the criteria by which political ideas are assessed. More recent hermeneutical arguments recast the role of the unconscious, as in Paul Ricoeur's notion of 'surplus of meaning' beyond the intentions of the agent. Here unlimited readings of the same texts and ideas account for differentiated ideological interpretations. Ideologies are diversely consumed, as well as produced, by groups. This offers one reason for the indeterminacy of ideological meaning and for the richness of idea resources they supply. The range of social understandings can never be captured by any political utterance and the study of ideology needs to incorporate this inescapable multiplicity. Among others this has led to a break with a sole focus on the great 'isms' and to developing more subtle microanalyses of ideological variability.

2.4 Poststructuralism and Microstructuralism

At the beginning of the twenty-first century, developments in the analysis of ideology display two tendencies. Post-Marxist and poststructuralist theory regard ideology as a modernist construct through which narratives necessary to maintaining the social order are produced, or that paper over the void that renders the social order itself a fiction. Ideology therefore assumes the features of permanence, while remaining nebulous and 'unreal.' These standpoints have also expanded the source material for political ideology to include cultural goods, literary and visual. The second tendency builds on semantics and hermeneutics in order to present ideologies as differing configurations of the major political concepts they contain. For instance, the concept of liberty may be present in most ideologies, but its meaning is determined from case to case by the proximate concepts that surround it, private property or social welfare pulling it in different directions. Ideologies are hence forcefully assertive, as well as unwitting, competition over the 'correct' and legitimate meanings of political words and ideas, and by means of that control, over the high ground of politics. The essential contestability of concepts requires that the 'decontestations' that ideologies offer are logically arbitrary but culturally significant, and reflect fundamental, if diverse, social understandings. Liberalism or conservatism have so far displayed stable, though moderately varying, conceptual patterns; totalitarian ideologies exhibit greater inflexibility in their

internal configurations; and other ideological clusters, such as the New Right, may exhibit fleeting or hybrid structures, or be less comprehensively systemic, as in nationalism. Political ideologies possess loose family resemblances and vary by dint of the different internal conceptual morphology each family exhibits. Continuities of time, space, political reasoning, and psychological dispositions hold together what could otherwise be, from a postmodernist viewpoint, a fragmentary and elusive form. In parallel, discourse analysis has located political ideology in ordinary language and communication—text and conversation—illuminating forms of human interaction. Such approaches have partly replaced the classification of political ideologies on a left–right continuum, which is too simplistically based on dichotomies such as individualism versus collectivism. They regard ideology not as coterminous with political thought, but as one of its dimensions.

Ideology, Sociology of

The concept of ideology constitutes a significant chapter of social sciences in general and sociology in particular. The exact localization of this chapter remains, however, uncertain. Linked from the point of view of its emergence and its development to the Marxist tradition, the analysis of ideological phenomena overflows very quickly and very largely this tradition. Producing, under certain conditions, positive knowledge about the social order, the analysis of ideologies intends sometimes to fulfill a 'performative' function, i.e., contribute to the transformation of this social order. Finally, constitutive of various considerations concerning the social determinants of beliefs, the sociology of the ideologies is quickly led to define its own condition and, through this reflexive movement, to appear on a level quite as empirical as epistemological.

This pluridimensionality of the sociological analysis generates the feeling of confusion characteristic of many debates relating to ideology, its causes and consequences. This feeling is reinforced since more than 15 possible definitions of the very concept of ideology correspond to the diversity of the manifestations of the ideological phenomena through contemporary sociological writings (Eagleton 1991). After having briefly made sensitive the nature of this diversity, we will approach the way in which sociologists have tried to characterize and to explain the ideological phenomena. Three interdependent aspects will be successively considered: the referent, the structure, and the value of truth of ideologies. We will be interested finally in revival of the sociological analysis on the relationship between science and ideology.

1. The Diversity of Ideological Phenomenon

The origin of the sociological use of the concept of ideology can be found in Marx's writings. Admittedly, as reminded by many commentators, the concept of ideology existed before Marx. One thus finds a particular form of this concept at the end of the eighteenth century with the French tradition of the *idéologues* who, led by Destutt de Tracy, saw in the *Ideologie* a new discipline: the science of the ideas. Further still the theory of the *idola* developed by the English philosopher Francis Bacon in his *Novum Organum* anticipates certain aspects of both science of the ideas of the French *idéologues* and the modern theory of the ideologies. But it is with Marx that a certain use of this concept appears. Its well-known analysis of the *coup d'etat* of Louis Bonaparte is from this point of view very instructive (Marx 1852). The important part of its argument consists of showing how, once the riots of June 1848 were over, dissensions within the *aparti de l'ordre*—the right wing of the French parliament—helped make this *coup d'etat* unavoidable. This party was composed of many fractions which all, Marx affirms, have a 'superstructure of impressions, illusions, ways of thinking, and some philosophical conceptions.' To understand the origin of these 'ways of thinking' it is essential to identify the 'competition of interest,' the will of each fraction 'to restore its own supremacy.' The land aristocracy and the industrial bourgeoisie

develop different political representations thus: the former theorizes the benefits of the absolute monarchy, the latter those of parliamentary monarchy. In both cases, Marx suggests, they tend to give a general value to 'ways of thinking' which actually constitute only the formulation of objective conditions which ensure the domination of a social group over another. The analysis of Marx does not end with this comparison between particular 'interests' and 'ways of thinking,' it also underlines the way in which certain individuals embody ideologies. Describing the 'ideologists' consists mainly for Marx of studying the 'writers,' the 'press,' and more largely 'representatives' of the *bourgeoisie*. In the present case, the inability of these ideologists to express the real opinion of those they should represent: little before the *coup d'etat*, Marx points out, 'the representatives and represented had become strangers to each other.'

The argument is simple and easily acceptable: when an institution—here a political mode—appears in conformity with the particular interest of a social actor, individual, or collective, this actor generates, directly or indirectly, a whole set of ideas, representations, and theories intended to make the value of this institution acceptable by the greatest number. Also, even if the value objectively makes real sense only for the social actor considered. When K. Mannheim looks back to this argument in *Ideology and Utopia* (1929/1991), he presents it as a fundamental stage towards the formation of the sociology of knowledge: the first attempt to stress 'the role of the position of class and the interests of class in the thought.' This attempt rests, however, on a confusion between two conceptions of the ideology which is necessary to identify. In the first—particular conception—the 'ways of thinking' are 'mystification more or less conscious of the real nature of a situation whose exact recognition would not be in agreement with the interests of the ideologist'; they are reducible to a psychology of the interests, concern primarily the individuals, and are connected with lies on the moral level or errors on the epistemological level. In the second—total conception—the same 'ways of thinking' are not 'illusions' deliberately maintained by the individuals according to their more or less immediate interests, but elements of a total 'system of significance,' 'knowledge grown out of our experience in the real situations of the life.' One of the rare examples of ideological 'knowledge' in this 'total' conception suggested by Mannheim is the moral judgement related to the loan of money with interest. Formulated and assimilated by the Church like an ethical standard, the morally reprehensible character of the loan with interest becomes ideological, affirms Mannheim, since the social actors try to maintain it out of the social framework to which it is 'adapted': a precapitalist society based, economically and socially, on personal relations of intimacy. Through its attachment to this judgement, the Church expresses its difficulty in thinking of social reality independently of a 'system of significances' adapted to a disappeared social framework from now on.

This total character of the ideology described by Mannheim acquires a new meaning with the compared analysis by Raymond Aron (1964) devoted to the contemporary political modes. In its *nouvelles leçons sur les sociétés industrielles*, Aron identifies in an ideal typical way each political mode by an 'official ideology,' i.e. a 'complex doctrinal system,' made up on the one hand of general principles resulting 'from theoretical analysis of what really occurs' and on the other hand of proposals qualified as 'misleading,' 'distorted,' or even 'absurd.' More than the simple critical census of these proposals, Aron underlines the specificity of all 'official ideology': the will of its promoters to withdraw it from any critical discussion. Why, Aron asks, do the partisans of the socialist ideology generally refuse to talk on a reasonable basis about the advantages and disadvantages of their conception of the individual and society? The answer is to be found in the 'universal' vocation of the studied ideology: it is given for its partisans as for its detractors as a global system of interpretation of the historico-political world.

2. *Sociological Characterization of Ideologies*

As suggested by these examples, the sociologists use the concept of ideology to describe a phenomenon of 'belief': belief in the value of the absolute monarchy for the land aristocracy (Marx), belief in the morally reprehensible character of the loan with interest for the Church (Mannheim), belief in the universal vocation of the collectivist mode for the Socialists (Aron). To speak about belief is to describe an ethical or cognitive reality—principle, idea, theory, doctrines, etc.—which not only makes 'sense' for an individual or collective actor, but a reality about which this actor may develop a deep feeling of conviction. It also describes a factor likely to influence the behavior of this actor. Innumerable sociological and anthropological work made it possible to identify the diversity of the beliefs and their consequences according to the social systems considered. *The difficulty which arises consequently is that of the specificity of the ideological phenomenon as belief compared to the various possible registers of the general phenomenon of the belief.* Sociologists generally approach this specificity in terms of degree and not of nature under three interdependent aspects: (a) referent of the belief, (b) forms of the belief, and (c) value of truth of the belief.

2.1 *Referent*

The ideology as belief is singular by the centrality which it accords to the nature and becoming of

politico-social organization. The referent is actually double. The ideologist aims by his discourse not only at describing the legitimate social order but also and especially at directing the consequently collective action. He proposes more than one simple explanation of observable social reality: a program to transform it. The direction of this transformation can be multiple. When Mannheim defines the ideology in opposition to utopia, by making the former an exclusive vector of conservatism (a barrier to the rise of capitalism in the case of the taboo of the loan with interest) where the latter would be progressist, he only preserves the initial views of Marx. This vision of the ideology is, however, too restrictive. Not only are the ideologies not the prerogative of the conservatives—T. Parsons (1959) distinguishes four types of ideologies: conservative, counter-, reform, and revolutionary—but one ideology can, according to social and historical circumstances, serve various social purposes. Liberalism, Socialism, or various contemporary forms of Nationalism (E. Gellner 1983, P. Birnbaum 1997) appear, at a given time of their history, as vectors of social emancipation as well as general principles of immobilism or conservatism.

This double referent—sociopolitical and practical—makes it possible to differentiate ideology from other types of beliefs, religious ones in particular. If the majority of the religions contain a representation of the social organization, they define only rarely a collective action plan. This representation is generally the consequence of a reality considered to be more central: a transcendent realm revealed by the faith. *The ideologist speaks in the name of reason*. Its truth claims positive values of science and is diffused by suggestion, persuasion, but much more rarely by revelation. Many sociologists (R. Bendix 1964, A. Gouldner 1976) thus establish a strong parallelism between the development of the ideologies at the end of the eighteenth century and the emergence of Modernity defined as a 'rational' social order in opposition to a 'traditional' social order. This by no means implies that the religious, mythical, or more largely traditional elements disappear from the ideological discourse, but that these elements occupy a peripheral place in this discourse.

2.2 Forms

When Aron analyzes the contemporary political modes, he considers ideology as an explicit system of beliefs developed around a core of descriptive and prescriptive proposals. The dominant features of the system are unity, coherence, and totalizing character—the capacity to potentially bring a response to any interrogation.

This traditional representation of ideology as a 'monolithic' block needs to be tempered: all ideologies contain irreducible tensions and contradictions. On the one hand, because any ideology contains irreducible tensions and contradictions. The goal of any ideologist is certainly to give an overall coherence to what he perceives as real and necessary, but one cannot judge the nature of a system of beliefs only on the base of how it wishes to appear. Sociologists insist thus on the 'compromises' and the 'adjustments' necessary to hold in the same unit theoretical logic and the principle of action (M. Seliger 1976). Other sociologists proposed to consider the production of ideology as a 'tinkering' process during which the ideologist tries to satisfy the demand of meaning of his public without ever being able to exert a true control on his resources (F. Bourricaud 1980).

Moreover, the contemporary ideologies no longer have the width of the all-encompassing ideological systems of the end of the nineteenth and the beginning of the twentieth centuries. If it still appears illusory to regularly announce the 'end of the ideologies' (D. Bell 1960, M. Lipset Seymour 1960), it is undeniable that the form under which they appear evolves. For R. Boudon (1999), modern ideologies evoke the image of archipelago, while the old ideologies evoked rather the idea of a continent. 'We have ideologies,' writes Boudon, 'as to what should be done about unemployment, educational opportunities, fighting against crime or drug addiction and on a myriad of subjects, as well as how it should be done. But these theories are weakly related to one another. We have ceased to believe that they could be derived from an all-encompassing theory. We have all kinds of local ideologies; we no longer believe in general ideologies.'

2.3 Value of Truth

The link established by the Marxist tradition between the concepts of ideology, alienation, and 'false conscience' led many sociologists, Marxist and non-Marxist, to identify the ideological phenomenon with false beliefs. The ideologist produces a representation of the social order he wishes to be socially considered as the unique depository of a true meaning, but both representation and meaning are mainly illusory. The ideology, according to the formula of T. Parsons, should be regarded as a 'deviation compared to scientific objectivity.' The relative disaffection of the category of ideology in the poststructuralist and postmodernist currents of thought is thus principally due to the fact that this category seems to imply a naive conception of truth as correspondence, but also a rigid demarcation between the science and the other discursive registers.

The reality of the ideological phenomenon is, however, more complex. From a theoretical point of view, some sociologists propose to define it inde-

pendently of any reference to science and objective knowledge. C. Geertz (1964) for example conceives the discourse of the ideologist as a 'symbolic act' intended to produce an effect of mobilization: the 'cognitive' function of ideology is consequently second behind its 'pratico-social' function. This approach is not however without difficulties: it gives of ideology a hypertrophied representation, and especially misses the fact that even when conceived as a symbolic act, ideology remains open to judgements of truth and falsehood. From a more empirical point of view, many studies show that ideologies grant a universal validity to proposals whose validity is only limited; or more simply that they mix doubtful or fragile proposals with more solid, quasiscientific proposals. General ideologies as Marxism, liberalism, or certain forms of conservatism or developmentalism are based explicitly on scientific argumentations. More local ideologies such as the widespread belief that mechanization or globalization are the main cause of unemployment can be seen as grounded on factual evidence, but evidence of limited validity. If ideology cannot be conceived as a delirious thought, it appears from now on quite as imprudent to accept it in block as to reject it in block.

3. *Sociological Explanation of Ideologies as Collective Beliefs*

Ideology being only one particular case of the general phenomenon of belief, its sociological explanation relies on the same principals as the explanation of other beliefs. When a sociologist explains an enigmatic phenomenon, he tries not only to infer the existence of relations between a whole set of variables (dependent an independent) but also to test, according to multiple modalities, the validity of his inference. There is not, however, a single way to conceive the factors to consider nor even the type of relations likely to be tested. Sociologists considered the production and the diffusion of the ideological phenomenon in three different ways: first as the consequence of a 'causal' process; second as a response to a 'functional' requirement, and finally as the product of a 'subjective rationality.'

The first general type of explanation considers the production and diffusion of ideological belief as the consequence of 'forces' on which the social actor has no control. These forces can be of various types. The Marxist tradition closely associates the production of ideology with the existence of class 'interests' which dominates the conscience. According to this tradition, the fact for an individual of belonging to a class is enough to mechanically impose a set of collective beliefs on his conscience. The general thesis is that if the dominated class accepts blindly social representations which contribute to reproduce its subordination, the dominant class generates social representations which maintain its domination. The example of the study of the 18 brumaire shows, however, that Marx develops, in certain empirical writings, a less simplistic vision of the production process of ideologies. Those ideologies are described as more than strategical theories imposed on social actors: representations of limited validity inspired by reality such as can be observed from a given social position. From a different point of view, the forces which drive the actors to produce or adhere to ideologies are also sometimes conceived as 'passions.' In its classical *Traité de sociologie générale*, Pareto considers thus that the ideologies—he speaks of 'derivations'—are primarily the effect of feelings remaining inaccessible to the conscience. More precisely, Pareto affirms that the social actor wants to be convinced of the value of his passion, and produces derivations for this purpose only. The ideologies would thus be the epiphenomenal expression of dominant passions. Such a representation, however, remains not easily generalizable insofar as on the one hand the ideologies are seldom lived by those which produce them or diffuse them like simple feelings, and on the other hand the rationalization process that characterizes ideologies is hardly reducible to a simple 'logical varnish.'

The second general type of sociological explanation considers the production of ideologies as a response to a double demand: demand for 'security at an individual level, demand for 'equilibrium at a more general level. The insecurity is regularly described by sociologists as a permanent aspect of the social systems. The individuals continuously feel the need to be able to think that 'everything will be all right.' Precisely, observes Parsons (1964), 'the strains involved in such expectations may be lessened by displacing the fulfillment outside the immediate field of action, either into the future as in the case of the leader of a movement for reform, or into a transcendental sphere (…).' At a collective level, the absence of integration is considered a permanent risk for the reproduction of the social system: principles, standards, goals differ according to the social sector considered (political, family, economical, etc.). Ideological belief is considered, from a functional point of view, as an ambivalent phenomenon: it produces disintegration because any ideological expression is generally directed against a pre-existent belief system, but it can also produce 'solidarity' insofar as the ideological orientation makes it possible to maintain the collective identity of a given group. The functional approach shows thus how a belief makes it possible to solve an individual and collective problem. Interpreted however in too extensive a manner, this approach generates a certain number of skids, among which are the identification of the society to an 'organism' and of ideology to a 'disease.' Another contemporary skid of the functional approach consists of seeing behind any ideology a social function, but moreover to define this function as

exclusively directed towards the maintenance of the domination of a social group on another.

The third general type of sociological explanation consists mainly of adopting a similar attitude as M. Weber towards the ideological beliefs for the magic beliefs or, to a certain extent, Durkheim for the religious beliefs: reconstruct the 'meaning' of the ideological belief for the social actor by seeking the system of reasons or preferences which this actor produces to justify to himself his adhesion. The rationality considered by the sociologist is not reducible to an instrumental one but is also quite different from the 'derivations' described by Pareto. The sociological analysis opens on a set of 'subjective reasons' that represents the necessary conditions of the ordinary thought. These reasons are of general but nonuniversal validity and manifest themselves on different levels: utilitarian, axiological, traditional, or epistemic. Inspired by studies of A. Downs (1957) and H. Simon (1982), the restricted theory of the ideology elaborated by R. Boudon (1989) thus stresses the necessary 'comprehensive' dimension of the sociological analysis. When some people adopt statements or ideas that appear to the sociologist as false or doubtful, the sociologist has to consider that this may derive from the fact that, given the situation, these beliefs are to them the conclusions of reason they perceive as 'strong.' This explicative strategy is directly linked to an active theory of ordinary knowledge: the social actor produces knowledge, not simply by contemplating reality, but by interpreting it from its social position, and more generally from questions which are only seldom directly provided by reality itself. This last approach has a certain number of objective advantages. In particular, it makes it possible to give an account of an important subjective data: the feeling of conviction and not of interiorization which generally characterizes the relation of any individual to his own ideological beliefs.

4. Science and Ideology: Extrascientific 'Interest' and Relativism

The analysis of the relationship between science and ideology is traditionally focused on the ideological dimension of social sciences and sociology in particular. The ideologist shares in fact with the sociologist the will to produce a discourse on society. It is not rare that certain sociologists consider their analysis as the methodical prolongation of a preexistent ideological point of view. The historical examples are numerous and well known: openly conservative, Frédéric Le Play theorizes the traditional form of family—*famille souche*—as 'the social unit per excellence'; convinced liberal, Herbert Spencer proposes an evolutionary model closely associated with the diffusion of 'social Darwinism,' etc. Inversely a sociological theory or paradigm conceived independently of any ideological commitment can, when it is exploited out of its immediate context of validity, generate an ideological skid. The mechanism is once again well known: it consists mainly of projecting on the theory or sociological paradigm the totalizing character of ideologies and by doing so asking those theories and paradigms to answer any possible interrogation.

The significant development since the beginning of the 1970s of the social studies of natural science made it possible to highlight the importance of economic, cultural, and political factors on the course of scientific research. These studies show on the one hand how the scientific institutions satisfy a social demand, and on the other hand how the scientists integrate in the course of their practices different cultural elements, in particular extrascientific 'interests' (Barnes 1974). The reality of these facts should not however be misinterpreted. It leads certain radical sociologists to affirm the ideological character of all sciences and to consequently develop a relativistic conception for which the superiority of the scientific approach of reality compared to other 'representations of the world' is nothing but an occidental myth.

This extreme relativism rests on confusion between the intrinsic quality of a knowledge (objectivity or absence of objectivity) and its referential dimension (the focus of science). Nobody rejects the fact that the scientific practice cannot develop without a certain number of resources. The unequal allocation of these resources exerts a considerable influence on the choice of the research topics, on the level of development of the disciplines, sometimes even indirectly on the degree of requirement of the experimental control. This social conditioning of science does not however invalidate the fact that a scientific knowledge has an intrinsic validity, independent of its immediate context of production. The sociocultural determination and the rational determination of scientific knowledge are by no means necessarily mutually exclusive.

Illiteracy, Sociology of

Between complete *illiteracy* and good *literacy*, different levels of abilities may be distinguished, including *quasi-illiteracy*. Research from the last decades shows that the majority of adults in highly developed countries, as well as many men and women in the Third World, rank somewhere among these in-between levels. This situation seems to depend mainly on the fact that the way of life and work for large numbers of the population, in both less developed and, paradoxically, developed countries, does not require more than rudimentary or mediocre literacy skills.

1. *A Look at Illiteracy Statistics*

In most Western and Eastern European countries including Russia, as well as in Australia, Canada, Israel, New Zealand, the USA or, for instance, Argentina, Cuba, Mongolia, the Philippines, Puerto Rico, South Korea and Tajikistan, official statistics show that adult complete illiteracy is practically non-existent or very rare. Almost every other country lags somewhat or further behind these.

Table 1
Percentage of illiterate adults from 1900 to 1995 in six countries (UNESCO estimates and national statistics)

	1900	1950	1970	1995
USA	11	3	1	—
Italy	50	14	6	1.8
Mexico	78	43	25	11
Brazil	65	51	32	17
India	94	81	66	48
Mali	—	—	94	68

During the twentieth century, the absolute number of completely illiterate adults increased in the Third World due to population growth. In terms of percentages, however, adult illiteracy declined everywhere. Table 1 illustrates this point as regards six countries typical of different degrees of economic development.

The official statistics of illiteracy among adults in many countries are notoriously imprecise. They have another great deficiency, which is that they give no information about the real literacy capacities of the adults who are not counted as completely illiterate.

2. *Functional Illiteracy*

Third World countries are well aware of the extent of functional illiteracy, that is, of the gravely insufficient literacy level of many adults who are not completely illiterate. On the other hand, in developed countries, significantly high rates of functional illiteracy were almost unimaginable up until recent times, following decades of universal compulsory free education and, in particular, since the development of postcompulsory schools following World War II. This conviction has been steadily waning after converging results of various research showing that functional illiteracy was frequent in modern societies. The first international survey was conducted in 1994–5 under the auspices of the Organization of Economic Co-operation and Development (OECD 1995). The reports published by the OECD in 1995 and 1997 covered 12 countries, seven in Western Europe, plus Australia, Canada, New Zealand, Poland and the USA. The same, extensive battery of reading, writing, and arithmetic exercises typical of current tasks of daily life and work was used in evaluating the literacy level of adults aged 16 to 65. This international survey gave an interesting picture of the distribution of the adult population of typical developed countries by literacy levels at the end of the twentieth century.

Table 2
Percentages of adult population aged 16–65 (born in the country) by literary levels. Three examples: Germany, Sweden and the USA in 1994 (OECD 1995)

Literacy levels	Germany	Sweden	USA
Good	19	36	23
Mediocre	41	40	34
Low	31	19	27
Quasi-illiteracy	9	5	16
Total (percent)	100	100	100

The four categories of Table 2, which excludes immigrants, correspond to the following levels of literacy.

(a) Good: ability to at least understand newspapers and nontechnical articles written for the general public, write a simple letter, perform elementary arithmetic, read a road map, etc. These skills correspond roughly to the kind of reading, writing, and arithmetic abilities that compulsory schooling tries to instill.

(b) Mediocre: Between nearly good and nearly low levels.

(c) Low: at most can understand parts of short, very easy articles, complete a basic application for employment, interpret a pay stub, etc.

(d) Quasi-illiteracy: at most can understand or write isolated phrases, add or subtract small numbers; often can only understand or write isolated words and numbers. Exceptionally, complete illiteracy.

Sweden was the top-ranked country of the OECD survey. Yet even in Sweden, the adults found to have good levels of literacy did not make up the majority, but rather only one-third of the total adult population. In every other country surveyed by the OECD, the percentage of cases of good levels of literacy is lower. In Sweden, approximately one-quarter of the adults are clearly functionally illiterate (categories c and d). In the 11 other countries, the rate of functional illiteracy is even higher.

Landmarks of change are extremely scarce. A good short-term comparison of the literacy levels of younger Americans aged 21–5 is possible. Their average literacy abilities in 1992 were even more mediocre than in 1985 (Kirsch et al. 1993).

In Switzerland, from 1879 to 1913, the literacy skills of all young men aged 19–20 years old were evaluated each year by means of military reading, writing, and arithmetic exercises which were conducted at a level as constant as possible from year to year. Great progress was made. The exams ceased to be carried out after 1913. Some literacy evaluations of recruits were again conducted during the last quarter of the twentieth century, particularly in 1984. The results suggested a decline compared to pre-World War I statistics. This decline has since been confirmed by the results of young Swiss respondents aged 16–25 in the 1994–5 OECD survey.

3. *Social Contexts and Illiteracy*

The reasons for the extent of complete or functional adult illiteracy in less developed countries are well known. First, a fraction of the children do not attend primary school at all. The proportion of such cases is decreasing due to the increase in the number of schools and also, probably, because more families are becoming interested in the possibility of sending their children to school. Often, however, this interest is weak, as is the motivation of the children. Dropping out of school before the end of the first year of primary school is frequent. In sub-Saharan African countries, as well as in Latin America and Southeast Asia, approximately one-fifth of the children on average drop out of the first year of primary school and still many before the end of the fourth year. This high precocious dropout rate is generally attributed to the dissatisfaction of rural and urban poor families, who do not see the connection between the skills necessary for their milieu and what the school is teaching. These families tend to think that their children are wasting time at school. In many instances, they prefer to have the children around for helping with their own job or working outside of the family. One

> should also note the importance of the considerable increase in the number of persons who have not only attended primary school but have also taken more advanced courses … which enables employers to require higher levels of education than formerly, whether in the sectors of production, services or the civil service. For some families, whose incomes do not enable them to educate their children beyond the primary level, the later loses the importance it used to have as a certain means for social advancement and for improving their material situation. (Tanguiane 1990)

Many Third World adults live and work in social strata where illiteracy is the rule and almost all communication is oral. In such cases, the skills acquired at school or through adult education courses and alphabetization campaigns are never or rarely used. Generally, they deteriorate or disappear altogether. Thus, people in such situations tend to return to complete illiteracy or close to it. During the nineteenth century in Europe, the culture and economic conditions of large numbers of the traditional rural classes and the proletariat had similar effects (Weber 1976). How is functional illiteracy possible today, in the Netherlands, Australia and other highly developed countries? In Sweden, where there are slightly more than five million Swedish-born adults aged 16–65, the percentages of Table 2 correspond roughly to 268,000 quasi-illiterates and one million with low literacy levels. In Germany, according to the same table, there would be about five million native-born illiterate

adults and more than 10 million with low literacy levels. In the USA, the corresponding numbers would be 26 and 44 million, respectively. Yet the presence of so many quasi and semi-illiterates went unnoticed until the revelations of the surveys at the end of the twentieth century. The strong shock produced by the results of these surveys underscores the invisibility of functional illiteracy in most modern nations.

The quasi-illiterate and low-literate adults living and working in these societies are generally not even aware of having reading, writing, and computing problems themselves. Less than 10 percent to one-third of the quasi-illiterates (depending on the criteria and country), admit to having poor literacy levels. As for adults with low literacy, the percentage of respondents who consider themselves as having poor literacy skills is insignificant, ranging from less than 1 percent up to 5 percent.

The public's long-held unawareness and the previously mentioned self-evaluations may help to move forward in clarifying the problem of widespread quasi-illiteracy and low literacy in the adult populations of developed countries.

If the limited literacy abilities of a significant portion of the adult population of such countries would prevent them from coping normally at work, home, in stores, on the road, etc., then they would constantly make mistakes and have difficulties in the world around them. Yet this is not the case for several reasons.

(a) Except for a small percentage of the lower levels of the group, quasi-illiterate adults are not completely incapable of reading, writing, recognizing numbers, making out fragments of sentences, and performing very simple arithmetic problems. The literacy skills of low-literate adults are even a little less limited. In other words, quasi-illiterates and low-literates are capable of performing very simple or at least rudimentary literacy tasks.

(b) It is true that advanced societies depend more and more on the variety and quality of highly specialized knowledge. However, that does not mean that every member of society needs to possess sophisticated reading, writing, and arithmetic skills. As with housework, many jobs and leisure activities do not require literacy skills more advanced than those of quasi-illiterates or low-literates. Technical advances have led to an explosion of push-button and similar devices, from remote controls to bar codes. In advanced countries, about one-half of the jobs—many highly skilled in other respects—can be done with basic abilities: read road signs, enter numerical codes, read or write routine sentences or computer messages with the same few words, etc.

(c) Reading for pleasure is by no means commonplace for most adults, and writing even less so. A large percentage of adults never or almost never read books. Television and radio furnish an abundance of their information and entertainment. Paper and pencil computation has practically become a lost art form due to the availability of all sorts of electronic calculators.

(d) When faced with a situation where reading, writing, or computing would be useful, it is relatively easy for people to find a way out. The most common solution is to communicate orally with family members, colleagues, friends, employees of shops and public services, etc. Personal and administrative documents can usually be filled in by one, more or less designated member of the family. In the workplace, there are usually one or two employees of the group who handle most of the reading and writing tasks, if any. These ways of getting out are used to a great extent by people of all social classes and literacy levels and do not attract much attention or ridicule.

(e) At the turn of the nineteenth and twentieth centuries, and during some decades thereafter, literacy among children was highly prized, particularly for parts of the peasantry and working classes. It was regarded as a sign of personal dignity, autonomous judgment, and as a factor of material improvement and social mobility. Today, literacy skills have lost most of their prestige.

Insofar as home and neighborhood life influences children, these circumstances often contribute to the insufficiencies and fragility of the literacy abilities acquired at school. These same circumstances tend to cause adults with limited literacy to stay at poor levels, and the literacy skills of many others to deteriorate. The most deprived and other lower social classes are highly susceptible to the risk of quasi-illiteracy or low literacy. But the other social strata are not completely immune to this risk either. As they constitute the large majority of the population, they account for an important proportion of the quasi- and low-literate adults. In the USA, three-quarters of the adults living below the poverty level were either quasi-illiterate or low-literate in 1992. Yet 57 percent of the quasi-illiterate adults, as well as more than three-quarters of the low-literates belonged to the vast and heterogeneous nonpoor classes.

In spite of the great differences that separate the less and most developed worlds, the same basic mechanisms are at work in both with respect to literacy and illiteracy. They dominate the action of the multiple, more contingent factors influencing individual motivations and achievements at a young age and later in life. These mechanisms on the whole form rather clear tendencies towards an approximate equilibrium between, on the one hand, the common subjective and objective needs of the individual's social and occupational milieu and, on the other hand, their reading, writing, and computing capacities. Similar equilibrating tendencies develop with all other kinds of practical knowledge, from occupational and computer skills to foreign languages.

As long as they cope with the limited demands inherent in their roles at work and in society, with

respect to reading, writing, and computing, functional illiterates are generally not inclined to improve their literacy skills. Therein lies the greatest obstacle to the success of basic adult education programs.

Illness Behavior and Care Seeking

1. *What is Illness Behavior?*

The phrase 'illness behavior' conveys two, important, meanings. It differentiates disease, a biological phenomenon, e.g., cancer, congestive heart failure, diabetes, etc., from the behaviors associated with disease. These 'behaviors' range from the private experiences of disease symptoms through the subjective meaning of the disease and the emotions accompanying it, to the overt expression of 'sickness' such as seeking medical care, being excused from work and household duties, and other behaviors or 'privileges' involved in the sick role (Charmaz 1999). Investigators have also differentiated between illness behaviors and 'health behaviors,' the latter referring to actions taken in the absence of symptoms of physical illness (Kasl and Cobb 1966). This second differentiation is based on the assumption that it is important to identify whether behavior is instigated and sustained by the presence of symptoms and disease, or motivated either by concerns about the possibility of illness, or by motives totally unrelated to health and illness, e.g., physical appearance and social conformity.

The distinction is of questionable value, however, since behaviors to avoid and control illness can be performed in the presence of disease and the absence of symptoms as not all disease is symptomatic; and in the absence of disease and the presence of symptoms, as symptoms are experienced in the absence of detectable disease. It seems more reasonable to define 'illness behavior' as any action taken to cope with and manage the experience of symptoms and the presence of disease, or the anticipated occurrence or threat of symptoms and disease. A behavior that effects health, positively or negatively, but it is not seen to be health relevant, would not be regarded as a health behavior.

2. *Why is Illness Behavior Important?*

The use of health care resources is an important aspect of illness behavior. Using care has monetary and nonmonetary (mortality; poor quality of life) costs for the health care user, the user's immediate social network—family—and to the social institutions sharing the costs. Reducing monetary costs is cited frequently as a reason for reducing overuse, i.e., the use of care in the absence of diagnosable disease. The conditions or syndromes generating these 'unnecessary financial costs' include: somatization, chemical sensitivity, chronic fatigue syndrome, and most recently, Gulf War syndrome. Each involves the use of care, the absence of diagnosable disease, symptoms that the 'sick' person attributes to underlying disease, and each is presumed to be produced by the interplay of severe life stresses and personal vulnerabilities. The 'worried

well,' a label often applied to elderly women who are frequent participants in blood pressure screening programs, form another class of resource user, whose worrying drives behavior in the absence of disease and symptoms. The magnitude of the costs generated by these behaviors has been exaggerated, however, as they mainly involve the use of primary care services, which consume little more than 20 percent of the total health care budget, including both visits for unverifiable as well as verifiable conditions.

Life threatening conditions, e.g., coronary disease and cancers, and end-of-life treatments are the major source of financial costs to the health care system. Illness behaviors associated with the underuse of diagnostic and treatment regimens can add to their already considerable financial expense, and add to what may be more important costs of mortality, morbidity and reductions in quality of life. For example, risks to life, extensive morbidity, and the need for more invasive treatments, e.g., complex surgery and extended rehabilitative services, may result from delay in seeking care for cancers and coronary disease, as well as for less dramatic life threatening conditions such as appendicitis and ectopic pregnancies. These delays may be due to incorrect self or medical diagnosis, the absence of symptoms, and/or denial. Morbidity and social dysfunction can result from resistance to participation in post-treatment rehabilitative regimens following episodes of myocardial infarction, stroke and cancer. Resistance may emerge due to individual, socially supported but mistaken beliefs such as 'complete rest is essential to avoid death from heart attacks,' or to misinterpretation of the pain from the healing of the surgical wounds as pain from failure to repair the underlying disease, e.g., the pain attributed to the effect of physical activity on a damaged heart.

3. *Determinants of Illness Behavior and Care Seeking*

Given the number of syndromes used to describe illness behavior and the many ways in which it can inhibit effective self management, it appears wise to focus on those features of illness behavior that are common to multiple conditions. Describing just a few syndromes, e.g., somatization, hypochondriasis, or body dsymorphic disorder, would be of less interest and would overlap with their description in other entries in this volume. We will begin, therefore, by focusing on the factors affecting care seeking, and then address the effects of these factors on self-management during chronic illness.

3.1 *Symptoms and Care Seeing*

Each of us knows that changes in somatic experience, or symptoms, are powerful stimuli for seeking medical care. But symptoms alone are clearly not sufficient to motivate care seeking. Survey respondents have reported experiencing at least one new symptom each week of the year (Demers et al. 1980), but it is the rare individual indeed who seeks medical care 52 times a year, after excluding medical visits demanded for employment or insurance. Thus, symptoms are clearly a necessary but not sufficient condition for care seeking (Cameron et al. 1995). Somatic changes become symptoms when they are elaborated upon or represented by the individual as indicators of underlying illness. They may be represented as indicators of minor, self-limited and self-treatable events, of possibly serious disease in need of further evaluation, or as distinctive signs of disease threat that can be painful and which demand immediate attention from a qualified practitioner (Chrisman and Kleinman 1983, Levenhthal et al. 1980). Care seeking follows the interpretation that one is 'ill,' unable to manage the condition on one's own, and therefore, in need of medical attention.

3.2 *Symptom Interpretation: A Social-psychological Process*

Psychological theories model the cognitive and emotional processes that are internal to the person experiencing symptoms (see *Symptom Awareness and Interpretation*). When somatic sensations are given meaning, they are represented as symptoms of a suspected, specific disease, with a perceived cause (virus; stress), time-frame (to develop, to resolve, etc.), consequences (missed work, hospitalization, etc.), and responsiveness to treatment (control). As the individual lives in a social environment, these processes are sensitive to and affected by context. Chrisman and Kleinman (1983) posit three contexts that are involved in the interpretation of somatic changes: the popular sector, which comprises the individual's immediate social contacts, family and community, who interpret the person's somatic changes in light of a shared belief system; the folk sector, consisting of nonprofessional specialists, ethnic healers, religious or faith healers; and the professional sector, or culturally defined specialists such as physicians, osteopaths, chiropractors, etc., in Western countries such as Europe and the USA. The initial hypotheses respecting the meaning of the change is usually supplied by the individual experiencing the change, and members of the popular sector. The professional and folk sectors come into play when the initial popular evaluations suggest a need for additional expert help.

Participation by these three levels of social influence occurs in at least two different ways. First, the symptomatic individual, i.e., the prospective care-seeker, has internalized schemata or expectations as to what his or her symptoms represent, and how others

would interpret them. These expectations give meaning to what would otherwise be unelaborated sensations and signs. Second, when others in the popular sector are told about or observe these somatic changes, they will suggest interpretations of them and may also recommend specific ways of managing them. Studies show that great majority of symptomatic adults—often 90 percent or more—will talk to someone, usually a family member, about their symptoms. The response may be supportive ('What can I do to help?'), directive ('You should see your doctor right away!'), or simply grant permission to seek medical care ('I think it's something most anyone would get checked over').

3.3 Factors Affecting the Interpretive Process

Painful and disabling symptoms call for expert assistance as they are perceived as being beyond individual control. But symptom severity, e.g., excruciating pain, is not the factor most often associated with care seeking. Factors that appear to predict care seeking in the majority of illness episodes include variables such as duration (symptoms exceeding the expected time-line for minor and ignorable events), familiarity (do not fit into the pattern of familiar, manageable illnesses), and worry (worry about the symptoms). The properties of symptoms that are critical for care seeking are those that imply specific meanings or hypotheses regarding their identity; that is, whether the symptoms are signs of a common chest or head cold, temporary gastric upset, or indicators of a possibly serious illness such as a stroke, stomach ulcer or cancer (Bishop 1991). Thus, symptoms which last longer than expected, and symptoms that are unfamiliar, may be interpreted as a sign of a serious, life-threatening event. Once individuals believe they are indeed sick, they are more likely to be fearful and worried if they are uncertain about the meaning of the symptoms, and believe they may indicate a serious threat. The consequences of fear and worry, i.e., whether they provoke or delay care seeking, appears to depend upon their perceived source. Thus, worry that a disease is a threat to life is likely to encourage care-seeking, but worry or fear about treatment will delay it.

A variety of contextual factors also affect care seeking. For example, it is often proposed that life stresses increase the likelihood of care seeking (Mechanic 1979). Though some studies support their proposition, many others are inconsistent with it. Simple, main effect hypotheses, i.e., that an increase in a single factor such as stress is related to an increase in a behavior such as care seeking, fail to capture the complexities of decision making. An example of these complexities can be seen in a study of mothers' use of medical care for their sick children. Stressful life events pose barriers to seeking care on the day these events occur. A day later, when the event is resolved and the barrier it created is removed, there is an increase in care seeking above the level that would be seen had the event not occurred (Gortmaker et al. 1982). Personal interpretations as to how life stresses affect health further complicate the process of decisions to seek care. For example, if ambiguous symptoms such as fatigue and muscle aches appear in the context of a recent life stressor, i.e., a stressor that has lasted for but a few days, the symptoms are likely to be evaluated as signs of stress rather than as signs of illness. Symptoms of stress in this case are not seen as meriting medical care, and do not increase the level of care seeking. But if ambiguous symptoms appear in the context of prolonged life stress, i.e., stresses that have lasted four or more weeks, these symptoms are more likely to be interpreted as signs of stress-induced illness (Cameron et al. 1995). Adults will seek medical care under these conditions with the same frequency as for symptoms that are distinct signs of non-stress related illness.

It is worth noting that the duration required for a stressor to influence a change in decision from not seeking care to seeking care for ambiguous symptoms is roughly the same duration of life stresses that Cohen and colleagues (Cohen et al. 1998) discovered to be needed for stress to increase susceptibility to cold viruses. They assessed the presence and duration of life stress in participants, who were then randomized into five groups, all of whom live in an experimental unit. The members of four of these groups were subjected to controlled exposure to different cold viruses; the members of the fifth were exposed to neutral material. The persons who became sick after exposure to the viruses had been under stress for four or more weeks: shorter stressors did not increase susceptibility to colds. Thus, in at least this instance, people's appraisals of ambiguous symptoms, in combination with their life situations, correspond with data on actual effects of stress on susceptibility to colds.

A wide range of procedures are used in the evaluative processes underlying self-diagnosis. These include social comparison, e.g., if many other persons have the same symptoms it is likely not serious (Croyle and Jemmott 1991), or if we shared exposure to a particular pathogen, e.g., tainted food, we are likely to have the same illness; and historical self-comparisons, e.g., is this a new symptom or one experienced before, or if it is a change in function, is the trajectory of change worsening or improving. Symptom response to treatment, e.g., to home remedies, are also diagnostic. The headache that is cleared by aspirin is less likely to be seen to indicate serious, underlying disease than the headache that is recalcitrant to self-management. Treatments that control symptoms are valued over those that do not, though the evidence for efficacy may be based on little more than strongly held subjective convictions arising from a placebo effect that is

unrelated to any direct physiological benefit from treatment.

3.4 The Interpretive Process in Abnormal Illness Behavior

'Somatoform disorders' is the overarching label encompassing those syndromes defined by the reporting of symptoms and the conviction that one is ill in the absence of medically definable disease, e.g., somatization, hypochondriasis, etc. The process underlying this 'disorder' involves the amplification and conversion of benign somatic sensations into symptoms attributed to illness (Kellner 1990, Kirmayer and Robbins 1991). Repeated care seeking, doctor shopping, etc., are the consequences of this cognitive process. Many investigators have concluded that neurotic tendencies or trait negative affect, may underlie excessive care seeking in the absence of verifiable disease (Watson and Pennebaker 1989). Trait negative affect refers to a relatively stable feature of personality characterized by self reports that one's mood or emotional state is usually worried, anxious, blue or depressed; individuals with high scores on scales measuring this trait report a larger number of somatic complaints than individuals with low scores. There is little evidence, however, that persons high on trait negative affect make greater use of health care (Watson and Pennebakar 1989), as it is unlikely that many of these individuals have the additional cognitions that are necessary for such overuse, i.e., the beliefs that they are sick and that their somatic sensations are symptoms of illness. These beliefs distinguish those who suffer from somatoform disorders, less than 1 percent of the population, from the substantial number of persons who score high on trait negative affect (Robins et al. 1984). Thus, while individuals in both categories may report worry about health, worry is not equivalent to or sufficient for interpreting and attributing sensations to illness. Individuals with relatively high scores on trait negative affect appear able to distinguish between their life-long symptoms of emotional distress and symptoms of illness.

4. Chronic Illness, the Self and Illness Behavior

Analyses of illness behavior and care seeking often ignore the difference between acute and chronic illness. A focus on chronic disease raises at least two additional sets of questions for the study of illness behavior: those concerning adaptation to or living with illness, and those concerning changes in the self system. Chronic illnesses such as osteoarthritis, adult onset (type 2) diabetes, cancers (e.g., breast, prostate, colon), hypertension and cardiovascular disease, appear with increasing frequency in the later years of life. The average 70-year-old may have four or more such illnesses. These diseases bring reduction in physical function that restrict participation in daily activities, and these in turn are associated with increases in negative, i.e., depressed, affect, and declines in positive affect (Benyamini et al. 2000, Zeiss et al. 1996). They also lower people's assessments of their health, and these reductions are associated with reduced expectations respecting functional ability and life expectancy (Idler and Benyamini 1997). Managing unfamiliar disease can contribute to the sense of hopelessness that is an integral component of depression, and lower quality of life. The evidence indicates, therefore, that functional decline associated with both advanced age and chronic illness carries additional, psychological hazards, and these psychological changes reinforce the very functional deficits that initiated them (see *Chronic Illness, Psychosocial Coping with*).

4.1 Illness Behavior and the Management of Chronic Disease

Both cognitive and affective processes can be identified as sources of illness behaviors that are inappropriate for disease management. Cognitive factors are visible in individuals with congestive heart failure, i.e., their hearts ejecting less than 40 percent of the blood in the left ventricle to the rest of the body. These patients face episodes of heart failure and death due to the gradual decompensation of heart muscle and accumulation of fluid in the lungs and throughout the body. As their symptoms (fatigue, swollen legs, etc.) are slow to change and are omnipresent, they do not recognize them as indicators of their underlying heart condition. They fail to monitor changes in their symptoms and do not make effective use of available treatments in response to change: they act when facing crises, e.g., inability to breathe.

Another cognitive factor, conservation of resources (Leventhal and Crouch 1997), a strategy that encourages inactivity, appears to be maladaptive for living with many chronic illness. For example, it is associated with increases in pain over a three-year time span in rheumatoid arthritis patients (van Lankveld et al. 2000), and among coronary patients, it encourages inactivity and avoidance of exercise needed for improved cardiac function. A contrasting cognitive factor, belief that a strategy of vigorous engagement is necessary for good health, can lead cardiac and cancer patients to adopt behaviors such as jogging and the use of herbal supplements in order to strengthen the disease fighting capacity of their immune system. Although exercise is effective in reducing risk of mortality (Bijnen et al. 1999) few herbals deliver on their promises for health gains and some generate risk as they may interact adversely with chemotherapies of proven value, and many patients using supplements fail to communicate their use to their physicians.

A wide range of illness behaviors can be instigated by the emotional reactions elicited by the dysfunction and dysphoria of chronic illness. Depression is associated with nonadherence to medical treatment for angina, end-stage renal disease and cancer (DiMatteo et al. 2000), and both high and low levels of anxiety are related to inadequate self-management in patients with severe asthma. Asthmatics low on anxiety fail to take protective action (use of inhalers) to early signs of asthmatic attacks, and asthmatics high on anxiety over-use protective measures and need hospitalization due to the exacerbation of symptoms by fear.

4.2 Illness Behavior and the Changing Self

Chronic illness can change how individuals define themselves, and how they act in relation to others, to work and to the tasks of daily life. The functional and emotional impact of chronic illness and its permanence, presents a challenge to the very definition of the self. Thus, chronic illness represents a challenge both from the bottom up—its symptoms, signs, dysfunctions and effects—and from the top-down—the meaning of these signs and symptoms (Leventhal et al. 1999). Prior self identities and competencies and the social context (the popular (family), folk, and professional sectors), both directly influence and moderate these changes in self. Intellectual, emotional and social resources can support illness behaviors which are effective for the management of disease even when disease is not curable. Successful illness behaviors and effective disease management can strengthen the individual's sense of competence, create new and strengthen existent identities, and enhance the individual's ability to participate in life despite the drastic impact of illness on the physical self. Illness behavior at its best, i.e., the performance of new actions in managing the self with disease, can be the source of new, stable identities that define the value of life.

Illness: Dyadic and Collective Coping

Within the last few decades, the individual perspective of viewing illness as a personal issue has been enlarged to include the social context (e.g., social support, family resources, marital functioning).

In regard to coping with illness in marriages, this enlarged perspective has been suggested by a number of theorists and researchers who have proposed different conceptualizations of dyadic coping, such as (a) an effort to establish and maintain close relationships, (b) a congruence of individual coping efforts by both partners, and (c) an interpersonal coping process involving both partners in order to reduce problem- and emotion-focused stress (see *Stress and Coping Theories*).

1. Dyadic Coping

1.1 Dyadic Coping as Relationship-focused Coping

The theorists of the first approach assume that partners must not only engage in problem- or emotion-focused coping when facing an important chronic or life-threatening illness, but also have to address the emotional needs of both partners and attempt to deal with the impact of the illness on the relationship. Consequently, Coyne and Smith (1991) have proposed relationship-focused coping as a third coping category, which includes one partner's efforts to reduce stress in the other partner and to guarantee his or her physical and psychological wellbeing. The authors suggest two main strategies: (a) active engagement (involving the partner in constructive problem-solving, problem-oriented discussions, and helping to explore the feelings of the partner) and (b) protective buffering (hiding concerns, denying worries, avoiding disagreements). DeLongis and O'Brien (1990) and O'Brien and DeLongis (1997) describe a similar aspect, namely focusing on dyadic efforts in order to maintain the quality of a relationship in situations of high stress (e.g., the dementia of one partner). They assume that relationship-focused coping preserves and enhances social relationships (or disrupts dysfunctional relationships). Thus, they emphasize the importance of empathic coping (affective awareness of the partner's problem and the ability to communicate this understanding to them in an appropriate manner) (see *Social Support and Stress*).

1.2 Dyadic Coping as Coping Congruence between Partners

Theorists referring to dyadic coping in terms of congruence or discrepancy between partners argue that the compatibility of problem- and emotion-focused coping strategies by both partners may be predictive of marital adjustment. This approach emphasizes (a) the usefulness of similar (congruent) or complementary coping strategies by partners facing a common stress event (Revenson 1994), (b) the assumption that it is optimal for couples to have similar emotion-focused coping strategies but dissimilar problem-focused coping strategies (Barbarin et al. 1985), or (c) that it is the average level of coping among partners that may be what is of particular importance (Pakenham 1998, Terry 1989)

1.3 Dyadic Coping as an Interpersonal Process

In the conceptualization of dyadic coping as an interpersonal process (Bodenmann 1995, 1997), a systemic-process oriented view of stress and coping in close relationships is suggested. Here, dyadic coping is understood as the interplay between the stress signals of one partner and the (dyadic) coping reactions of the other partner to these signals. Depending upon the stress event at stake, in dyadic coping the stress management resources of both partners are activated in order to maintain or restore a state of homeostasis among both partners as individuals, within the couple as a unit and in regard to other social partners, since it is assumed that one partner's wellbeing and satisfaction depend highly upon the other's wellbeing and satisfaction as well as social integration of both partners. According to the profile of the stressful situation and the individual and dyadic appraisals and goals, common (e.g., joint problem solving, mutual solidarity), supportive (e.g., practical advice, emotional comfort, belief in partner), or delegated dyadic coping (e.g., one partner takes over duties and tasks of

the other) are differentiated in this approach. These different forms of dyadic coping can be problem-centered or emotion-centered and may be either positive or negative (hostile, ambivalent, superficial) in nature.

1.4 Dyadic Coping and Physical Illness

A number of studies have investigated stress and dyadic coping in physical illness, such as cancer (Baider et al. 1995, Barbarin et al. 1985, Hannum et al. 1991, Kayser and Barbarin 1992), myocardial infarction (Coyne and Smith 1991, 1994, Suls et al. 1997), multiple sclerosis (Pakenham 1998), rheumatoid arthritis (Manne and Zautra 1990, Revenson and Majerowitz 1991), and physical disabilities among the elderly (Wright and Aquilino 1998) (see *Coronary Heart Disease (CHD), Coping with*).

Researchers using the congruence concept of dyadic coping predominantly reported that a high degree of similarity or high mean scores (average of the coping skills by both partners) were associated positively with marital adjustment, reduced burden for the spouse, and overall improved functioning in couples coping with severe illness (e.g., Pakenham 1998, Revenson 1994).

Others, such as Barbarin et al. (1985), have found that congruence between the wife and the husband is advantageous with regard to emotion-focused coping, whereas complementarity in problem-focused coping is correlated with better marital functioning. Kayser and Barbarin (1992), on the other hand, reported higher marital satisfaction and dyadic cohesion when both partners were congruent in problem-focused coping. They found lower satisfaction scores among wives when the husband practiced more emotion-focused coping strategies (independent of the wife's use of coping) in dealing with the cancer of the child.

A study by Baider et al. (1995) examining couples coping with the malignant melanoma of one partner suggested that dyadic coping (support by the spouse) has a different meaning for husbands and wives. Whereas husbands refer primarily to the dyadic coping of their spouse, wives tend to mobilize their extra-marital support network as well. In addition, Wright and Aquilino (1998) have pointed out that reciprocity in emotional support between the caregiving partner and the impaired spouse plays a crucial role in regard to marital adjustment and to the perception of the situation as burdensome.

Researchers referring to the relationship-focused coping construct reported no consistent findings concerning the usefulness of the protective buffering strategy. Coyne and Smith (1991) and Suls et al. (1997) found higher distress scores in wives and husbands as a function of the use of this strategy by the husband, the wife, or both. Thus far, relationship-focused coping proved to have little impact on illness recovery. However, Coyne and Smith (1994) showed that the patient's self-efficacy depended upon their spouse's practice of active engagement. Further research is necessary in order to highlight the usefulness of relationship-focused coping.

2. Dyadic Coping and Mental Disorders

2.1 Dyadic Coping in Depressed Couples

Mitchell et al. (1983) were among the first researchers to present a study integrating social aspects into the framework of stress regulation in depressed couples (see also *Depression, Hopelessness, Optimism, and Health*). They illustrated that clinically depressed persons coped less efficiently than their partner or controls, and that they experienced less social support from significant others. Partners of depressed individuals taken from a community sample, however, fell between the scores of depressed and nondepressed participants. The important role of support from the partner was also pointed out by Moos et al. (1998). A study by Gotlib and Whiffen (1989) assessing stress and coping in couples in which the wife was depressed revealed that depressed persons and their partner displayed more often congruent dysfunctional coping (confrontation, self-control, and escape-avoidance).

In a study conducted with couples where one partner was depressed ($N = 42$ couples), it was found that depressed couples, when compared with nonclinical controls, communicated their emotional stress less often and practiced dyadic coping (emotion-focused supportive and common dyadic coping) significantly less. On the other hand, both the depressed individual and their partner displayed ambivalent dyadic coping more frequently (Bodenmann 2000).

2.2 Dyadic Coping in Couples with an Anxiety Disorder

Studies concerning dyadic coping in couples in which one partner suffers from an anxiety disorder are rare (see *Anxiety and Anxiety Disorders*). In a study ($N = 70$ couples), it was found that there are significant differences between those couples suffering from anxiety disorder and control couples from a community sample. Both the patient with the anxiety disorder and their partner reported less problem- and emotion-focused stress communication and a higher rate of ambivalent and hostile dyadic coping. The partners of the patients, however, displayed more problem- and emotion-focused supportive dyadic coping (Bodenmann 2000).

2.3 Dyadic Coping in Couples with Sexual Dysfunction

In a study conducted with couples suffering from a sexual dysfunction disorder ($N = 120$ couples), empirical evidence was found indicating that those couples in which both partners experienced the sexual dysfunction disorder relied more heavily on ambivalent dyadic coping (see *Sexual Attitudes and Behavior*). Husbands suffering from a sexual dysfunction disorder perceived less emotion-focused supportive dyadic coping and less delegated dyadic coping from their spouse and a higher rate of ambivalent dyadic coping. It is interesting to note that in women, disorders of sexual desire and sexual aversion were associated with lower dyadic coping, whereas in men lower dyadic coping scores were related to sexual aversion and anorgasmy.

2.4 Dyadic Coping of Partners of Patients with Dementia

A study conducted by Tuor and Stadler (1999) using our concept of dyadic coping revealed that partners of AD patients ($N = 65$ couples) reported significantly less problem- and emotion-focused stress communication and less problem- and emotion-focused supportive dyadic coping from their partner, whereas their own problem- and emotion-focused dyadic coping scores were elevated (see *Dementia: Overview*). When the severity of the illness was included, all dyadic coping scales were reduced in the caregiving partner. It was interesting to note that negative dyadic coping (hostile, ambivalent) was not higher than among control persons. However, the partners of dementia patients seemed to practice their supportive dyadic coping much more superficially.

3. Discussion

The integration of dyadic coping in the study of coping with severe and chronic illness seems to call for attention. However, as this article suggests, there is currently still a lack of broad research activity including dyadic coping. Whereas social support from network partners outside the marriage are often examined, the relevance of the partner's support or dyadic coping are mostly ignored. As the first section has shown, there are several interesting approaches defining dyadic coping which have already proven their usefulness and clinical significance. The assumption that couples in which both partners contribute to dyadic coping and in which the partner is a substantial source of support in cases of illness-related needs has been supported by a number of studies. However, broader research activity is necessary in order to highlight the direct and moderating effects of dyadic coping in addition to individual coping efforts. It is a field that represents a promising challenge for new and innovative studies.

Imagery versus Propositional Reasoning

1. Introduction

Probably the first theories of thinking, developed by the ancient Greeks, relied on the idea that thought relies on series of mental images. However, as Berkeley (1710) pointed out, images cannot represent categories easily and are inherently ambiguous—and yet our thoughts often rely on categories and are rarely (if ever) ambiguous. Thus, thinking must rely, at least in part, on some other type of mental representation. The obvious alternative candidate is language, but words are often ambiguous. Frege (1879) argued that thought relies on internal representations that are more abstract than language. These representations have come to be known as 'propositional representations,' and are like unambiguous statements of the gist of an idea (e.g., see Anderson and Bower 1973). Sachs (1967) provided empirical evidence for such representations in her demonstration that people remember not the specific words in a sentence but rather the idea expressed by it (see also Bransford and Franks 1971). Most cognitive scientists concur that propositional representations require an abstract and unambiguous syntax, but there is debate about the precise structure of this syntax, its similarity to natural language, and how this code is translated into natural language (Stillings et al. 1987).

Some cognitive scientists maintain that all thought relies solely on propositional representations, to the exclusion of other possible forms of internal representation (e.g., Pylyshyn 1973). In contrast, other theorists have maintained that the mind makes use of multiple forms of internal representation. These theorists have collected much evidence that mental imagery is a separate medium of thought, which preserves the spatial structure of pictures (e.g., Kosslyn 1980, 1994, Shepard and Cooper 1982). Although thought does not rely exclusively on imagery, imagery does play a role. In this article we consider the interplay between propositional representations and mental images during reasoning.

2. Propositional Reasoning

2.1 The Structure of Propositions

Propositions capture relations between concepts or objects. Propositions are characterized by a syntax that includes both (a) elementary symbols and (b) formal rules specifying how the distinct symbols may be combined. The meaning of a proposition depends upon the content, that is, the meaning each symbol and combination of symbols conveys. For example, the proposition 'Hans likes Maria' represents a belief a person may hold. This belief might be coded as the proposition '$x(h, m)$,' where x represents being in the state of 'liking,' and h and m represent Hans and Maria, respectively.

2.2 Reasoning with Propositions

Consider the following conditional syllogism:

If Hans likes Maria, then Hans also likes Susie.
Hans does not like Susie.
∴ Hans does not like Maria.

Does this conclusion follow from the premises? Most people find this problem easy, but psychologists have not yet determined how people reach the proper conclusion in even simple situations like this. Aristotle considered syllogistic reasoning to be the highest form of human thought, and William James (1890) dedicated nearly an entire chapter to the topic in his *Principles of Psychology*.

Until the late twentieth century, the dominant psychological view of reasoning was that people are naturally endowed with (or somehow acquire) the formal rules of logic. For example, the logical rule of *modus tollens* will always apply when terms are substituted for these variables:

If p, then q,
not q,
∴ not p.

These theorists maintain that people reason by constructing propositional representations of each of

the premises. They then apply formal rules of inference one by one to these representations, in steps that lead from the first premise to the final conclusion (e.g., see Braine et al. 1984, Rips 1994). The main rules are based on each of the logical connectives, such as *if*, *and*, *or*, and *not*.

2.3 Reasoning Errors

If the second premise above is changed to 'Hans does not like Maria', how will the conclusion change? Marcus and Rips (1979) report that 21 percent of respondents concluded that 'Hans does not like Susie.' This is a possible answer according to the rules of formal logic, but not a necessary one; Hans could like Susie even if he does not like Maria. Marcus and Rips provide support that an error in *encoding* produced this outcome. Specifically, that people encode the first premise as a biconditional, 'If p, then q' equals 'If q, then p,' instead of, as the laws of logic dictate, as a unidirectional.

Errors are very common in reasoning about such categorical syllogisms. Using the quantifiers *all*, *some*, and *no*, Mayer (1992) counted 64 possible pairs of premises, which in turn imply only 19 necessary, unambiguous conclusions. This leaves plenty of room to generate false conclusions or mistake possible conclusions for necessary ones. Can formal rules theories continue to account for these mistakes? Two common errors are as follows:
Undistributed middle:

All A are B; all C are B; therefore, all C are A.
Bostonians like cream pie.
Jack likes cream pie.
∴ Jack is a Bostonian.

Premise errors:

Some A are C; some C are A; therefore, some C are B.
Some Bostonians are college educated.
Some mechanics are Bostonians.
∴ Some mechanics are college educated.

According to formal rule theories, the contents of a syllogism should have no bearing on whether the conclusion follows from the premises. Nevertheless, several lines of research have shown that one's beliefs about and the contents of the premises can bias one's conclusion, that syllogisms with false premises and/or abstract symbols are more difficult than syllogisms with true premises and concrete symbols, and that people are more likely to come to a valid conclusion if they tend to agree with the premise's conclusion (Janis and Frick 1943, Evans et al. 1983).

2.4 Accounting for the Errors

Psychological theories of reasoning should be able to account for human reasoning errors and predict under what circumstances they will occur. There are currently several psychological theories that hold promise of satisfying these requirements (Begg and Denny 1969, Johnson-Laird 1998, Cheng and Holyoak 1985). These theories are based on semantic rules of reasoning instead of the syntactic method of formal rules (see Mayer 1992 for a good review). Formal rules are, by definition, independent of context or knowledge. However, our capacity to evaluate the various instantiations of formal rules and contrast the truth value of every possible conclusion based on the rules of formal logic is constrained by our limited working-memory capacity. It also seems that formal rules are not very useful for solving the practical reasoning problems that humans face. Semantic rules are derived from situation-specific (context-dependent) heuristic processes and the pre-existing knowledge they activate. For this reason, semantic theories postulate that the most optimal reasoning strategies select only highly relevant (and available) information for retrieval from long-term memory (Stillings et al. 1987). In other words, in everyday reasoning people tend to employ reasoning strategies that usually work effectively, even if they at times cause errors.

3. Imagery in Reasoning

The revival of interest in imagery representation was bolstered by anecdotal accounts of how visual mental imagery has facilitated understanding of scientific problems. For example, Albert Einstein reported visualizing himself traveling at the speed of light alongside a beam of light, and observing the appearance of the beam. This 'thought experiment' helped him to see that light is not an electromagnet field with no velocity, and to realize that such a thing did not exist. Nikola Tesla reported using visual mental imagery when working on his inventions. He used a visual image to conceive the details of the machine he was working on, and noted that his 'mental pictures' were more vivid than any blueprint. He also would run mental 'dry runs' to examine the machine for wear and tear over weeks of time (see Kosslyn 1983).

3.1 The Structure of Images

Experiments that have investigated image transformation (Shepard and Cooper 1982), and image zooming and scanning (Kosslyn 1980) have provided empirical support for the claim that mental imagery is a distinct type of internal representation. In these studies, subjects' response times increase as a function of the amount that an object must be transformed, zoomed in on, or scanned. Such evidence led Kosslyn (1975) to propose a distinct analogue subsystem, the visual

buffer, as the repository of internal representations that do not describe shape (as do propositional representations), but rather depict shape. That is, each part of a depictive representation corresponds to part of the object or scene being depicted, and the distances between the representations of the parts preserve the corresponding distances between the parts themselves. The visual buffer is a spatial structure that supports such representations. Various processes access perceptual memory and reconstruct the appearance of an object in the visual buffer; once reconstructed, the shape can be reinterpreted and manipulated in various ways. These depictive representations, unlike propositional representations, do not have an inherent truth content, are modality specific (propositions are amodal), are not formed according to a syntax, and are inherently ambiguous.

3.2 Reasoning with Images

Visual reasoning has two major components: first, a particular image must be formed in the service of solving a particular problem; second, once formed, the image must be manipulated and interpreted appropriately. Imagery can be used in two distinct types of visual reasoning, symbolically or as a type of 'mental simulation.'

3.2.1 Symbolic reasoning with images. Some types of imagery use relatively abstract images to stand in for concepts. For example, Huttenlocher (1968) provided empirical support that depictive representations can help people to reason about ordinal relations. She presented people with problems such as the following.

> John is taller than Sam, and Rick is shorter than Sam, who is tallest?

Subjects report visualizing a vertical axis to represent height, and visualizing a dot for each person—with each dot's height representing the relative height of the corresponding person. The same type of representation can be used even with abstract relations, such as 'smarter than.' Shaver et al. (1974) provide evidence that spatial arrangements (e.g., above–below) or metaphors for spatial arrangements (e.g., better–worse) are processed easiest when people construct such images, and that subjects make fewer errors when they use images. They also report that a subject's spatial ability predicts how well a person can use imagery to aid such reasoning (see also Hegarty and Sims 1994). Kosslyn and James (summarized in Kosslyn 1983) had subjects memorize the relative beauty of five people. They asked their subjects to visualize either five dots (one standing for each person) on a vertical axis that was positioned in the center of their visual field, or that was positioned off to one side. The subjects required less time to use the image in reasoning about the relative relations between pairs of people when they visualized the five-dot pattern in the center, which has higher resolution than the periphery (Finke and Kosslyn 1980). Furthermore, when a different group of subjects overlearned the relations (i.e., memorized them extremely well), this effect disappeared. It seems that overlearning fostered propositional coding of the relations so that imagery no longer was helpful for performing the task.

All students of logic quickly learn how imaging Venn diagrams helps one to avoid making the syllogistic fallacies mentioned above. However, it is not always clear how to form a model of abstract relations, and some types of problems that involve negation (see Johnson-Laird 1998) and contradiction (see Schwartz and Black 1996) cannot be visualized without propositional support.

3.2.2 Simulation reasoning. Many studies have shown that mental images can serve as a surrogate for perception (e.g., for reviews see Kosslyn 1980, 1994, Shepard and Cooper 1982). Thus, images can allow one to reason about the physical properties of objects in their absence, as was evident in the anecdotes we related about Einstein and Tesla. Instead of lugging furniture around, one can simply visualize the multiple ways of arranging furniture in one's living room. Such visualized patterns do not *arbitrarily* stand for objects or concepts as in symbolic imagery, but instead represent objects as they might actually appear. When using such an image in reasoning, one may let go of those features that are not relevant to the problem at hand, while honing in on pertinent ones. Hegarty (1992) showed that the static depiction of a pulley system can be mentally 'animated' using a piecemeal imagery strategy. That is, subjects animate local chunks stepwise (usually in the direction of causality) followed by other local chunks in order to infer something about the entire system.

There is good evidence that imagery simulations draw on some of the same mechanisms used in actual perception. For example, concurrent visuospatial tasks interfere more with mental simulation than with concurrent verbal tasks (Sims and Hegarty 1997). Moreover, spatial ability is correlated with a subject's accuracy in such tasks (Hegarty and Sims 1994), and hand gestures assist and promote spatial thinking (Athavankar 1999). Indeed, the time to infer the motion of interlocking gears is proportional to the angle through which the gears must move (Schwartz and Black 1996). When Schwartz and Black (1999) asked subjects which of two glasses (of equal height, but different diameter) almost full of water would pour at the shallower tilt, subjects believed the glass

with the smaller diameter would pour first. When then asked to simulate mentally using their hand and an empty glass (while marking the imagined water level with their thumb), however, they correctly changed their answers. Such findings suggest not only that imagery is dissociated from our descriptive beliefs (propositions), but also that there might be a haptic component of mental imagery that is distinct from the visual component.

4. Conclusion

The human information processing system is remarkably flexible, which is one source of its enormous power; indeed, no machine yet approaches the problem-solving prowess of a human being. Such flexibility arises in part because we not only can make use of different types of representations, but also can use them in different ways. Some reasoning may be most effectively accomplished using only propositional representations, and other reasoning may be most effective using a combination of types of representations. Images play a key role in some forms of reasoning, if only as 'mental notepads,' helping one to keep track of the things being reasoned about and the relations among them. However, it is clear that images alone cannot support reasoning. Images must be 'under description': any given image could have an infinite number of meanings (e.g., an apple could stand for an apple, fruit, food for worms, motherhood, etc.), and yet we are not confused about what we are thinking about when we have an image. The image must be interpreted by processes that themselves are not ambiguous. Hence, the role of imagery in reasoning must be understood within the context of a larger processing system, which also makes use of propositional representations.

Imagination: History of the Concept

In the course of the recent emergence of constructivism, which regards the world less as objectively given than as constructed and reproduced through (symbolic) practices as a web of social representations, and after the so-called 'linguistic turn' (see *Linguistic Turn*), the discursive construction and narrative constitution of the social and historical world has been in the center of interest in social theory and research. Despite their variety, reaching from semiological to analytical to hermeneutic accounts, these 'linguistic' approaches share a common perspective: social life and its history is seen as representations of the structure of its textualization and/or narration (White 1973, Clifford 1988, Ricoeur 1983). History and society, however, do not constitute themselves merely by narration, but also—and significantly—by nonlinguistic practices and images. Most recently, Castoriadis (1998) has underlined the 'imaginary institution of society' as the basic component of a comprehensive social theory. As a starting point to overcome both narrow textualism as well as the older neopositivism, the role of images and the imagination (*Einbildungskraft*) in social practices, which is at the core of any representation, be it narrative, iconographic, or aesthetic, has been focused upon. By this move, one has had to return to the classical philosophical topic—reaching from Plato and Aristotle to Kant and Husserl—of the imagination as the source and foundation of thought. Cognition is unthinkable without imagination. Even if one argues that cognition unfolds through the analytical operations that make phenomena distinguishable, these phenomena are shaped in and by imagination.

The semantic reach of the term 'imagination' includes as various connotations as mental imaginery (*Abbild*), invention of the mind (*Einbildung*, *Erfindung*) or illusion, which links imagination to fantasy. The substantive meaning of imagination or *Einbildungskraft* is rather similar to the Latin *imaginatio* and is distinguished—as in Kant—from fantasy, invention, and chimera. The semantic reach of the term fantasy, however, was clearly moved to the realm of the unreal during the eighteenth and nineteenth centuries. Although the term imagination had long been linked to various doctrines about what could be considered as 'true,' it is only from then onwards that the various connotations of different traditions collapsed into the one major distinction between the true and the untrue—for Ludwig Feuerbach, for instance, imagination is a key concept of the critique of religion, since religion presents imagined beings as real beings.

Across all varieties of meanings, however, there is a common reference of the term to the human ability to form—more or less intentionally—images of phenomena, be these absent or present. This faculty of mental imagery has been given central place in philosophical discourse with regard to (a) knowledge, concept formation, and language, (b) trace and memory, and (c) aesthetics.

1. *Knowledge, Concept Formation, and Language*

Within the philosophical legacy, 'the image' has been conceptualized as that which connects cognition to perception, the subject to the object. With the onset of modern times, empirical verification becomes the cornerstone of all knowledge. *Empería*, as that which the senses take note of, includes not only that which appears to the senses, but also the preservation of a sense impression in memory as well as the logical connection between such sense impressions in judgment (cf. Bohn 1990, p. 7).

The conjunction between thought (knowledge), image (as original image, *Urbild* or *eidos*) and memory goes back, in intricate ways, to Greek reason. In the ancient Greek tradition—and with Kant as well—the faculty of imagination is the source and foundation of thinking (to be distinguished, however, from both concepts and fantasy). For Aristotle, thinking occurs through mental images. Thinking is possible because we can place the things 'in front of our eyes'; then, the imaginative faculty can work upon the perception by the senses. Without the faculty of imagination, thinking would not be possible. Imagination is either a function of memory, of the retention of that which has made an imprint on memory, or it is productive, namely when it belabors the *phantasmata* that present themselves—that is why in ancient terminology imagination was called fantasy.

The Platonic term *phantasia* refers to both the truthful representation and the illusory appearance. *Phantasis*, vision, and *phantasma* are not linked primarily to the treacherous appearance, but they are true and untrue at the same time. *Phantasma* is that 'which appears,' thus not a representation. It is not primarily an intentional image, but that which appears in dream or when awake. For Aristotle, *imaginatio* is the faculty to receive the sense impressions, whereas *phantasia* is the faculty that bundles the *phantasmata* of the *imaginatio*. Thus, for Aristotle (*De memoria*),

every image becomes *theorema* or *mnemoneuma*, that is, the realistic representation of a thing or the reference towards another thing that shows no connection to the former one.

These constellations of thinking, which bring knowledge, image, and memory together, link imagination to sense perception. In one version, imagination reproduces—passively—the perceptions of the senses, whereas fantasy creates them—actively. In another, Kant's version, imagination is seen as twofold. It is passive as the receiver of sense perceptions, but it is active by idealizing them, that is, by holding them in an immaterial way.

For Kant, human cognitive capacity, on the one hand, is subdivided into two separate faculties, sensibility (*Sinnlichkeit*) and understanding (*Verstand*), to which imagination is then added as a third faculty. In analogy to this triple distinction, on the other hand, understanding is also distinguished from reason (*Vernunft*), a distinction to which the faculty of judgment is added. Every intuition (*Anschauung*) contains within itself a manifoldness that would be represented as unity, if 'the mind (*Gemüt*) did not distinguish time in the sequence of impressions' (Kant 1974, A 98). To turn the manifold into the unity of intuition, what is necessary is 'to run through this multiplicity and to hold it together' (A 98). Kant calls this operation the 'action of synthesis of apprehension.' It is followed by the synthesis of reproduction in imagination, that is, the connection of the representations according to a constant rule (to which the appearances are subjected as well). The final operation is the synthesis of the recognition in the concept, in which that which was gradually seen and that which was reproduced are united. 'There is therefore present in us an active capacity for synthesis of the manifold, a capacity which we call imagination and whose direct action on perceptions I call apprehension. For the imagination serves to bring the manifold of intuition onto an image, hence it must, prior to this, gather up impressions into its activity, that is to say it must apprehend them' (Kant 1974, A 119). The productive synthesis of imagination is—in contrast to the reproductive faculty of imagination, which rests on experience—thus the condition of possibility of knowledge. Imagination mediates between understanding and sensibility, by presenting the concept with the perception to which it corresponds. This operation of presentation is a scheme, in which the making of an image is no simple copying or reproducing, but a process of bringing into relation. Imagination here is linked simultaneously to intuition, image, and concept, in a way which is not only reproductive, but active. In *Anthropologie in pragmatischer Hinsicht*, imagination then is conceived as the faculty of perceiving an object 'even without its presence,' and a distinction between 'poetic' and productive or 'merely recalling and reproductive' aspects of imagination is introduced (1977, § 25, p. 466).

Hegel (1986, § 452–5) similarly brought memory in conceptual proximity to imagination by developing a three-stage model of recollection, imagination, and memory (*Zusatz*, § 451). He, too, made a distinction between reproductive and productive imagination. In this model, imagination is the faculty that determines the images, since imagination moves them into their being. Images that are no longer determined by the perception are, without consciousness (*bewußtlos*), stored independently of time and space; as infinite arrays of images, slumbering in the inner being, in the 'simple night,' (§ 454) they are unthought and not yet brought into the 'form of reason' and therefore belong only formally to the human being. To turn into conceptions (*Vorstellungen*) such abstractly stored images require the synthesis of the interior image with the remembered being; thus they will be brought to intelligence. Hegel calls *reproductive imagination* the intelligence that is active in this faculty and ties it to the associating relation of images. Imagination then is, first, the activity of associating images and subsuming them under general conceptions. In a second step, intelligence identifies its general conceptions with the particularities of the image and gives them existence as images. This image assumes the double form of symbol and of sign; such symbolizing an sign-creating fantasy forms the point of transition to memory (*Zusatz*, § 455). This sign-creating fantasy is—as symbolizing, allegorizing and poetic imagination—linked to language. As *productive* imagination, the formal aspect of art, the imagining activity arrives at its point of completion in itself and forms the general or the idea in the form of sensible being, of the image. Recollection, thus, turns a perception into an image that will be stored as something general in intelligence. As a reproductive faculty, imagination can repeat conceptions and connect them in new ways, but even though this connecting occurs rather freely, it is still linked to perception. As sign-creating fantasy, in contrast, it endows a sign with meaning in a sovereign way—such theory of signs forms the basis of Hegel's theory of language (Homann 1970, p. 273).

For Kant, consciousness is constituted in the moment of intuition in a movement in which activity and passivity join together. And for Husserl, consciousness is intentional, thus not restricted to the image as a phenomenon, but moving towards that which is represented in the image. Even though Husserl, thus, sees the object as always transcending consciousness, he nevertheless remains close to Kant's thinking, aiming to think inscription as that which constitutes sense impression as well as intellect. For Sartre (1986, 1994) similarly, following Husserl, the image is not the contents of consciousness, but consciousness itself and thus the possibility of knowledge.

Heidegger (1951) shows how Kant arrives at the concept of transcendental imagination, uniting sensibility and understanding and being rooted in time determined as pure self-affection—time and ima-

gination thus belong together. It was also Heidegger who directed the attention to a further connection between image and cognition. The modern era is characterized by its conquest of the *world as image*. It thus brings something into being that it puts in front of the 'presenting-producing' subject (*vorstellend-herstellend*; Heidegger 1980, p. 92). In precisely this sense, the experiment becomes this mode of producing by presenting (*vorstellendes Herstellen*) that characterizes modern science (see Shapin and Schaffer 1985). That which is to be researched is constituted as an object; the results of research are considered as a representation of reality; the world becomes readable like a book, and philosophy turns into 'the mirror of nature' (Blumenberg 1981, Rorty 1979, see *Representation: History of the Problem*). With the entry of a modern scientific conception into the historical and social sciences, subjective and objective accounts of the social and historical world are separated from each other and different genres and modes of writing established. By this move, however, the affinities between literary writing and scientific formation of concepts and knowledge, affinities that reside in their common ground in the power of imagination, are denied.

Even the words that are to provide evidence of thinking in concepts, namely, are always already connected to innumerable metaphors and figurative word-images (Blumenberg 1960). As Nietzsche remarks: 'We have not seen anything but the pictures of "causes and effects"! And it is precisely this pictoriality that makes the insight into the connection that is more essential than the sequence impossible' (1993, 2nd book, § 121). Human beings do not encounter the truth of the things and of the causal relations in these images, but only ever themselves: 'How is explanation to be possible if we turn everything into a picture, into our picture!' (Nietzsche 1988a, § 112, 1910, pp. 157–8). Word and image form an infinite movement that cannot be interrupted or destroyed: 'When I understand the pictoriality in language, then I do not transcend the picture-world in which we live. The images have not been removed when we have recognized that they are images. Truth and reality are grasped in the image. Reason that no longer wants the image retains only nothingness' (Jaspers 1990, p. 19). The figurative character of concepts cannot be dissolved, since even in the process of destruction only one thing happens, changes, and is created: images. Concepts are unable to provide any absolute notion, any real word of truth or any thinking that is purified of images, but they always speak of the forgetting of this notion and this word. As Nietzsche remarks 'truths are illusions about which it has been forgotten that they are illusions, worn-out metaphors without sensory impact, coins that have lost their image and now can be used only as metal, and no longer as coins' (Nietzsche, 1988b, pp. 880–1). There are no 'proper' words, they emerge by forgetting the word to which always already image on image have attached themselves, the one 'continuing the other, elucidating, modifying, correcting, effacing it' (Jaspers 1990, p. 19).

2. *Trace and Memory*

The relation between knowledge, image, and memory, thus, has a long intellectual tradition with a variety of different constellations. Already in the ancient 'art of memory' of Simonides or Cicero, remembrances of things as well as of words and concepts are seen as being inscribed in memory through sites and images (*notae*) (Yates 1966). Kant revives this connection when he links cognition to the *notae*, and relates intuition (*Anschauung*) and knowledge to such inscription and annotation in the memory. Freud (2000) similarly conceptualizes the psychical apparatus as a mystic writing-pad which—like a *tabula rasa* (which can be seen as passive as in Locke, or as active as in Hegel)—receives impressions and perceptions as well as stores them like memory.

This long, often rewritten and interrupted tradition reaches from Plato's 'wax tablets,' into which the things we remember imprint themselves (*Theiatet*), to Freud's 'magic pad' and to Derrida's concept of the trace: imprints, traces left in memory by the things and images released into narration by language. Remembrance and trace, concept and knowledge form the key components of this long and familiar story. St Augustine already referred to the pictoriality of this constellation, since for him the representing—in the sense of 'making present'—of the past occurs when the remembrance that is stored in memory appears to view, and—as he adds—if these images were missing, nothing could be named at all (Saint Augustine 1912). Obviously, it is not the things themselves that have made their imprint on memory, but their traces. When things past are remembered, what is retrieved from memory are not things themselves, but only words, which represent the images of these things which are imprinted on the mind like traces. It was already Aristotle who noted that it is not the thing which is imprinted into the *anima* to be conserved in the archive of memory, but its *trace*. Traces mark the *possibility* of remembrance of the disparate connections between them and, thus, of cognition and knowledge (Gawoll 1986/87, 1989).

Those traces are neither image nor absence of image, they are the possibility of image. Ferraris (1996) develops—with the concept of trace—a perspective that undermines the conventional dualism of aesthetics and image, on the one hand, and logos and concept, on the other, while maintaining the possibility of thinking their difference. Imagination touches upon remembrance and temporality through retention and protention, but it does so not as the product of time, but as its possibility instead. This view implies that perception and reception become the same: They open

towards the senses and to the intellect in a single, though divided moment. The opposition between intuition, image, logos, and concept is thus dissolved without denying the differences between these aspects.

3. Aesthetics

Christian Wolff and Gottlieb Baumgarten had already pointed to the connection between sensation, aesthetics, and knowledge. With the turn away from the principle of mimesis, of the imitation of nature, and with the radicalization of the principle of autonomy of the arts during the eighteenth century, then, the role of (productive) imagination for knowledge and for aesthetics is being revaluated.

Imagination—which Kant cast as the faculty of perception even without the presence of the object—is, when it is productive, a faculty of original representation. Aesthetic judgment judges in the presence of the object as much as under the condition of the absence of its objectness. The work of imagination when enjoying the beautiful shows itself independently of interest or cognition. Aesthetic grasping is not possible by mere conceptual framing and synthesis; aesthetic judgment, though, is nevertheless a judgment of reflection and not of the senses—otherwise it would merge with mere pleasure. Kant's third critique—complementing Kant's overall system—establishes the specificity of aesthetic judgment, or of the judgment of taste.

While the philosophical tradition assumed the intelligibility of the world by philosophical means, and thus saw philosophy as providing the arts with the means of interpreting the world, romantic thought, in particular early romanticism, reverts this relation and denies the primacy of philosophy for knowledge. It is precisely imagination that is to guarantee the autonomy of the aesthetic sphere, since imagination goes beyond sense perception. 'Imagination is this wonderful sense that can *replace* all senses for us—and that stands that much already under the power of our will. The outward-oriented senses appear to be entirely governed by mechanical laws—imagination, in contrast, is evidently not tied to the presence of, and touch by, external stimuli' (Novalis 1977, II, p. 650). On the basis of Kant's critique, the task of the arts is reformulated such that aesthetic imagination and aesthetic communication can bring together that which had been separated. At the same time, the active pole of imagination is emphasized, its faculty to create images independent of empirical perception.

Fichte's theory of productive imagination (*Grundlage der gesamten Wissenschaftslehre*, 1794), in particular, had a strong impact on the aesthetic conceptions of romanticism. Fichte understands by imagination a faculty that is suspended in between determination and non-determination, between the finite and the infinite, a suspending, and back and forward movement, of transcendental imagination however, refers to transitions between opposites and not their mediation and 'sublation' (*Aufhebung*) in a Hegelian dialectics. Schlegel 1988 draws upon such idea of a movement of productive imagination in his concept of 'progressive universal poetics' and in his view of infinite irony as poetic reflection, which explicates and presents the hidden transcendental mobility of self-consciousness (1988, II, pp. 114–6, see *Romanticism: Impact on Social Thought*). The conception of infinite irony resorts to the idea of an infinite reflexivity, which is not limited by any kind of fixation, and thus also rejects the rhetoric distinction between that which is meant and inauthentic utterances. In infinite irony, poetics is not only seen as the 'image of an era' (1988, p. 114), but imagery is also linked to ever-incomplete becoming and, thus, to time. The opposition between concept and image, between aesthetics and logic, between the sensible and the intelligible can no longer be upheld in such nondialectical indecidability.

According to Schlegel, imagination, always striving towards the pictorial, receives its highest form of freedom by free invention, thought, and poetics. For Schlegel, the image is the counter-thing that has been liberated of the domination by the thing when the spectator's faculty of imagination meets with the one of the artist. It is linked to a kind of love that is inclined towards the 'counter-I,' aiming at the overcoming of the separation of theoretical and practical philosophy and having to achieve the anticipation, 'in a leap,' of a concept that yet remains to be formed (see Homann 1970, p. 282).

Even though the concept of imagination appears no longer to hold a central place in philosophical discourse as a category of artistic activity and as an instance of mediation, it has remained vibrant as a liberating power that restores the lost human freedom against technology and reification—such as, for instance, in Herbert Marcuse (1964) (or similarly in Castoriadis, see above), who thinks freedom in aesthetic categories and demands the liberation of fantasy through political praxis.

Immigrant Fertility

The phrase immigrant fertility is fraught with ambiguity. Does it refer only to the fertility of immigrants? Does it also refer to the fertility of international migrants who are not immigrants in the technical sense of the term? Does it refer to the fertility of minority group members who are descendants of immigrants? In its legal sense, the term immigrant refers only to persons who, with the authorization of their countries of destination if not always their countries of origin, cross international borders in order to establish residences in new countries. Immigrants include neither unauthorized international migrants nor authorized nonimmigrant crossers (tourists, students, and business travelers). Whether or not to include unauthorized migrants in research on immigrant fertility depends on the purpose of the study. Such decisions will not only be the subject of debate, they may also affect the results of research. In countries with birthright citizenship, such as the United States, the offspring of unauthorized migrants are citizens perforce and may constitute a nontrivial component of the fertility of a given birth cohort or time period. Because of space restrictions, the present discussion cannot address or resolve all such definitional issues. So we simply note here that by immigrant fertility we mean the fertility behavior in a given country of destination of immigrants, unauthorized international migrants, and their relatively recent descendants (the second and third-or-later generations).

Fertility refers to the childbearing patterns of women or couples in their new countries of residence. Because the levels and patterns of immigrant fertility hold significant demographic, sociological, political, and economic implications for destination societies, they are of considerable practical as well as theoretical interest. Analyses of factors affecting fertility levels and trends among immigrants and nonimmigrants may involve a focus on the number of births, the timing of these births, and associated reproductive behavior such as union formation (including marriage

and co-habitation) and contraceptive behavior. Among the most important factors affecting the levels and trends in the fertility behavior of immigrant groups are variables relating to the processes of incorporation, disruption, selectivity, and ethnic and minority group formation that may be experienced by the members of immigrant groups.

1. Major Substantive Domains

Demographically, the childbearing patterns of immigrants directly affect the future size and composition of the overall population. Thus, any distinctive levels or patterns of childbearing among immigrants should be factored into the production of population estimates and projections (Edmonston and Passel 1992, Smith and Edmonston 1997). These effects are most consequential in situations where immigration streams substantially increment the size of socially demarcated ethnic (minority) groups, return migration is comparatively low, and the childbearing schedules of the immigrant women are distinct from those of the native-born (majority group). Such circumstances have recently characterized the demographic regimes in many countries (e.g., the United States, Israel, Australia, Belgium). The demographic impact of immigrant fertility may be especially pronounced at the subnational level when immigrant populations are heavily concentrated in certain regional locations.

At various times and places, the dynamics of intergroup relations have been influenced by a politicization of immigrant family formation patterns. Members of majority groups may see higher immigrant fertility, real or perceived, as threatening to the majority group and as reinforcing ethnic or racial stereotypes of associated immigrant groups. The history of the United States reveals a recurring interest in the relative reproductive levels of the latest round of immigrants (and their children) vis-à-vis those of the native-born population. King and Ruggles (1990), for example, point to the inclusion of natality stereotypes into turn-of-the-century nativist ideology, including predictions of 'racial suicide,' even though the *actual* fertility of immigrants and their offspring was on par with or below that of third-generation Americans. A century later, unflattering stereotypes of large immigrant family sizes remain alive in the political discourse of many countries.

Sociological concerns, however, dominate social science research on immigrant fertility. Such research often focuses on the extent to which the childbearing patterns of immigrants vary from those of natives and on the pace with which convergence between the two groups occurs. Such convergence is what we mean when we refer to incorporation. We do not use the term assimilation here because we wish to emphasize that convergence can involve the movement of two groups toward a single point, rather than merely the movement of immigrants toward the level of the native-born group. The persistent and pervasive influence of incorporation perspectives in the sociological literature on immigration has led to the general hypothesis that with the passage of time (either individual or generational), immigrant groups and their descendants will become increasingly less and less dissimilar from natives along a variety of social and economic dimensions. As a consequence, such perspectives predict immigrant and native childbearing patterns will come to resemble those of one another (Bean and Swicegood 1985). The extent of convergence of fertility behavior has often been viewed as a measure of social integration between immigrants and natives (e.g., Coleman 1994).

2. Incorporation Processes

The preponderance of research on immigrant fertility has focused on the childbearing patterns of women who have migrated from less-developed countries with relatively higher fertility levels to more developed countries where demographic transitions to lower mortality and fertility are further advanced. Historically, empirical research has concentrated on assessing levels and changes in the gap between the fertility levels of immigrant and native-born women. Theories of incorporation processes have provided the theoretical backdrop for such investigations. Incorporation perspectives on immigrant childbearing implicitly if not explicitly invoke the operation of social influences that are grounded in both origin and destination societies. Because acculturation, or the process of cultural incorporation, has been assumed not to occur quickly, the hypothesis has often been advanced that childbearing norms acquired prior to immigration (or from immigrant parents) will for some period of time continue to influence fertility after migrants arrive in the destination society. The significance of cultural norms will depend on the degree of difference between reproductive norms at origin and destination and the strength with which they continue to be salient for immigrants in their new homes. Little research has attempted directly to assess the influence of fertility norms. Instead, most research has focused on structural incorporation by examining key elements of the structural position of immigrants in destination societies, such as education and labor market position, and how these affect immigrant and native fertility behavior.

Both conceptually and empirically, incorporation may be viewed as occurring among individual immigrants and across generations. In a given destination, either or both of these may be in operation. However, empirical research has tended to address one or the other. In the first case, which involves only the examination of immigrant women, the term adap-

tation is sometimes used to refer to changes in the fertility behavior of immigrant women that occur with increasing time in the destination country. Studies of adaptation are likely to focus on correlations between measures of length of time spent at destination and changes in the gap between immigrant and native-born fertility. In the second case, which involves the examination of both immigrants and their descendants, the fertility of immigrant women is compared to that of the second and subsequent generations. This approach is frequently confined to a single country of origin group compared to later generational co-ethnics and natives. The existing literature has not yielded empirical generalizations about the factors conditioning the pace of either of these kinds of incorporation.

3. *Disruption Processes*

Over the period when international migration occurs, the complex interplay of forces deriving from planning and carrying out the move, changing living arrangements, undergoing spousal and family separations, and experiencing unanticipated crises may result in the disruption of childbearing schedules. The reallocation of resources may be required to finance the move, spouses may undergo lengthy periods of separation, and relocation into a new society can invoke a variety of stresses both economic and cultural. Empirical analyses provide indirect evidence of the operation of disruption effects on the fertility of immigrants to the United States (Blau 1992, Kahn 1994, Stephen and Bean 1992). However, the absence of longitudinal fertility data makes these effects difficult to detect, in part because some or all of the fertility postponed by disruption may be compensated for later by accelerated childbearing during the postmigration years. Kahn's (1994) analysis of US data produced patterns consistent with general disruption effects, but the degree of compensation varied by national origin group. Among women who were recent immigrants in 1980, Mexican-born women increased fertility relative to the native-born population over the remainder of the decade, thus indicating substantial compensation, whereas the fertility of Asian-born women fell further behind that of the native born. In another case, Aussiedler immigrants to Germany from the former Soviet Union showed fertility levels prior to settlement in Germany that were 50 percent greater than those of comparable German women. In the several years following immigration, their fertility dropped to only 40 percent of that of native German women, whose fertility rates are comparatively low by international standards (Dinkel and Lebok 1997). In another case, Indochinese refugees to the United States in the 1980s exhibited very high fertility during the period immediately following their resettlement (Weeks et al. 1989), demonstrating that disruption can sometimes be so short-lived as to be almost nonexistent.

4. *Selectivity Processes*

On average, immigrants are seldom representative of the general populations in their former countries of residence. Moreover, the characteristic profile of recent immigrants tends to change over time. Immigrant streams can differ with respect to factors like the percentage of risk takers, the level and distribution of human capital resources, and the percentage married or already having children at the time of migration. The selectivity of the immigrant streams with respect to such fertility-related characteristics must be considered when examining (a) variation in fertility patterns across immigrant groups from different origins or (b) the change in fertility patterns across successive immigration cohorts. Several studies have provided indirect evidence of selection effects. In the United States, postwar changes in the selectivity of immigrants both within and across origin countries have resulted in relatively higher fertility among the immigrant population than would otherwise have been the case (Blau 1992). Selectivity effects are also important because they can condition the strength and duration with which factors in the country of origin continue to influence childbearing in destination societies. For example, Kahn (1988) found that childbearing patterns more typical of the country of origin are most pronounced among the least educated, least incorporated immigrant women in the United States.

5. *Analytical Design and Methodological Issues*

Research on incorporation has clearly shaped the analytical design of immigrant fertility studies. A common feature is the comparison of the behaviors of immigrant women with those of some reference group. The appropriate referent group is defined by the substantive focus of the study (see Singley and Landale 1998). Measures of fertility behavior are modeled as a function of immigrant status and demographic factors such as age and marital or union status. Fertility differences between immigrants and the reference group are determined and then statistical controls for other factors such as female education, labor force participation, income, and individual and household characteristics are included in the models. The specific set of control variables is dictated by what aspect of fertility behavior is under consideration and by the theoretical and disciplinary orientations of researchers.

In most places immigrants are a relatively small portion of the population. Thus, large sample sizes are necessary for sufficient numbers of immigrants to allow for generalization. This problem is exacerbated in situations where the immigrant population is spread across multiple national origins. Information on date of immigration is not always collected and in some countries immigrant status is not included in official

statistics once naturalization has occurred. When only cross-sectional data on number of children are available, researchers cannot distinguish between *exposure effects*, or the amount of time spent at destination, and *cohort effects*, which pertain to the group of immigrants arriving at their new country at a particular time. Exposure effects provide evidence on incorporation processes, while cohort effects may be grounded in changing selectivity of the immigrant stream. Similar confounding of conceptually distinct influences may occur when examining a time series of period fertility rates for evidence of immigrant/native-born convergence. Coleman (1994) for example, reports that since the 1960s the annual birth rates for immigrants in many European countries have moved closer to those of the native-born population. This convergence, while consistent with the idea of behavior change within the life course of immigrant women, could also reflect different childbearing patterns among more recent immigrants compared to those migrating in earlier periods. Again processes of incorporation cannot be clearly distinguished from cohort change. Processes of adaptation similarly may be empirically confounded with disruption effects. A pattern of lowered fertility around the time of immigration is consistent with either type of effect.

The simultaneous and most complete assessment of all of the factors involved in differential immigrant fertility would require detailed longitudinal fertility data for (a) immigrant women and their descendants in countries of destination, (b) native-born women in countries of destination, and (c) nonmigrant women in countries of origin. For destination countries with multiple-origin streams, the data would need to be collected for women in each country of origin. Questions regarding the aggregate effects of selectivity over time would further require data from multiple age cohorts. Data limitations have hindered the possibility of directly addressing intergenerational changes in childbearing. Analyses that examine differences across generation groups typically compare immigrant women with second or later-generational women, all of whom are the same age. Data have not been available to compare the fertility of immigrant women directly with that of their daughters.

6. *Current Approaches and Emerging Lines of Inquiry*

Recent research reflects a trend toward more direct measurement of factors associated with incorporation. Okun (1997) finds, for example, that national military service is strongly associated with adoption of modern forms of birth control among North African and Middle Eastern Jewish immigrants to Israel. Military service is argued to rapidly break down traditional fertility norms prevailing in the country of origin. Other current research more explicitly considers discontinuities between the social context of origin and destination societies. Hwang and Saenz (1997) compare the fertility levels of immigrant women from the People's Republic of China with those of foreign-born Chinese women from other source countries. The immigrant women from the People's Republic reveal lower cumulative fertility overall, but higher levels of childbearing once in the United States. This heightened fertility increases with each additional year within the childbearing ages spent in the United States. The authors' view this as consistent with an 'emancipation' hypothesis whereby freedom from the restrictions of the Chinese one-child population policy allow pronatalist and son preference values to be realized. Still other current work involves an effort to anchor the study of immigrant fertility more squarely into a life course perspective. Singley and Landale's (1998) research on migration and fertility among Puerto Rican women illustrates the unfolding relationships between the timing of migration, marriage, and childbearing, viewing migration more as a series of events, each of which may reciprocally interact with decisions related to other life course transitions. Such frameworks are very worthwhile but demand detailed longitudinal data to implement, a luxury unavailable in the case of many countries, especially less developed countries.

The amount of immigration and the nature of immigrant settlement patterns are both factors that contribute to establishing the social and economic contexts in which immigrants live, work, and make decisions relating to reproductive behavior. These contexts may shape the extent to which old norms are reinforced or new ones encountered, and they condition the way in which personal characteristics such as education or language proficiencies end up influencing family-building strategies of individuals or couples. The new patterns of international migration to the United States offer a challenge to the incorporation perspective that is anchored in a focus on the context of the immigrant experience. Massey (1995) argues that the new immigration will have a different meaning for ethnicity and race in American life than early European waves because it is grounded in fundamentally different structural circumstances. Flows of new immigrants are expected to be more continuous across a longer duration of time, creating a state of more or less 'permanent immigration.' Geographic concentration of the new immigration creates and sustains distinctive language and cultural communities on an unprecedented scale.

To the extent that sustained streams of new immigrants reinforce ethnicity, distinctive norms about childbearing may also be strengthened within the entire ethnic community, including native-born generations. This may be especially true for a group like Mexican Americans in the United States. Their immigration occurred from a higher fertility context.

Areas of residential concentration in the United States are relatively close to Mexico, their migration patterns frequently involve return episodes, and numerous large Spanish-language communities are available as destination points. Evidence of fundamental shifts in fertility regime has been found in a recent study of Mexican origin generational differences (Bean et al. 2000). The fertility of Mexican-born women was observed to substantially exceed that of non-Hispanic white women both before and after the introduction of standard sociodemographic controls. In accordance with the predictions of incorporation perspectives, the fertility of the second generation was considerably lower than that of immigrants. However, third- and later generation women showed levels of childbearing that were not only higher than those of non-Hispanic white women but also higher than those of second-generation women. Such higher fertility suggests that incorporation perspectives may not be fully adequate for explaining many extant ethnic patterns of childbearing.

Immigrants: Economic Performance

Five issues have dominated labor market research about immigrants: (a) the determinants of immigrants' economic gains, (b) whether native-born residents gain or lose, (c) the changing labor market wages and skills of immigrants, (d) life-cycle assimilation of immigrants, and (e) generational progress. Despite extensive research, they remain controversial. The vast bulk of existing empirical research describes the American experience, but according to Zimmerman (1995) the less plentiful research on European migration does suggest that the wage and employment effects of immigration on European natives are similar to the USA. Consequently, while the conceptual issues that I discuss transcend national boundaries, I will rely in this article on empirical research findings from the USA.

1. The Gains of Immigrants

Ex ante, immigrants gain from immigration, or else they would not have moved. Yet, some basic questions about the selectivity of immigrants, the magnitude and determinants of economic gains from immigration, and the transferability of skills across national borders remain unresolved. The number of migrants and the gains from immigration depend on economic and political conditions in sending and destination countries, the costs of migration, and legal limits placed on numbers and types of migrants.

Individuals move if the gain is positive and stay at home if it is negative. The benefits from immigration

are related to differences in skill prices and moving costs across countries and the set of legal and administrative rules governing immigration. If the costs of moving are low (say geographically adjacent countries or more similar cultures), migration flows will be larger and less skilled migrants will find the move profitable. Consequently, less proximate countries will send the fewest immigrants but immigrants with the highest skills. Similarly, a place such as the USA, a country with a high skill price, should attract immigrants from countries with low skill prices (such as Mexico and the Philippines). But those immigrants who do come to the USA from countries with high skill prices (such as Western Europe and Canada) must be relatively high skilled to justify the move. Finally, migration flows will be smaller when skills are less transferable across borders.

Legal immigrants to the USA are highly selective. In 1996, male legal immigrants in their last job in the country from which they came earned about $20,000, almost twice the average wage in the sending country. The economic gains from legal immigration to the USA are also large and highly variable (Jasso et al. 2000a). The average gain exceeded $10,000 in the first year and was much higher among employment visa immigrants than those who came for marriage or family reunification. Immigrants with high incomes in the USA relative to their skills were more likely to be from countries with high gross domestic product (GDP), low income inequality, and politically competitive systems (Borjas 1987). Finally, labor market skills are imperfectly transferable across borders, with skill transferability lowest for those with a different language and among those who migrate for family-related reasons.

2. *Gains to Domestic Residences*

Do native-born residents gain from immigration? Economic theory points to possible effects of immigration on employment and wages of native-born workers, trade in products with other countries, the growth rate of the economy, and prices people pay for goods and services. Under reasonably general assumptions, a receiving nation, overall, gains economically from immigration. By increasing the supply of labor in receiving countries, immigrants produce new goods and services, but are only paid the marginal value of the last good they produce. Marginal values are less than the total value of the new goods produced; the difference goes to receiving-country residents who must gain as a group. Immigration allows domestic labor to specialize in producing goods at which they are relatively more efficient, thereby breaking the rigid link between domestic consumption and domestic production. From this perspective, the effects of immigration are comparable to those of international trade.

Even when the economy as a whole gains, there are losers and winners among native residents. The gainers are the owners of productive factors complementary with immigrants and those who buy goods and services produced by immigrant labor. The losers are substitute native-born workers who compete with immigrants and whose wages will fall. Another group that suffers from new waves of immigrants are immigrants from earlier waves who are close substitutes in the labor market.

In the longer run, immigration can affect rates of economic growth only to the extent that immigrants arrive with a different skill mix than the native-born. To affect growth rates, this difference must persist over each new generation. If the children or grandchildren of immigrants come to look just like the native-born, all that immigration does is augment the population and the scale of the economy; it does not change per capita income at all. There is evidence that the skills of the descendants of immigrants converge over a few generations toward the national norm, suggesting that long-run impacts on economic growth are modest.

The literature summarized in Smith and Edmonston (1997) places the domestic gain to the US economy for all immigration since 1980 between one and ten billion dollars a year—a small but positive number relative to total GDP. The negative distributional impacts appear to be concentrated on domestic workers with less than a high school education. Perhaps a third of the 10 percentage point decline in the relative wage of those with less than high school education that was observed between 1980 and 1988 was due to immigration. This effect does not appear to be concentrated in the areas where immigrants live, but instead is dispersed across the USA. This dispersal comes about because competing native workers migrate out of or do not migrate to areas to which immigrants move.

3. *The Changing Labor Market Performance of Immigrants*

In the USA, the foreign-born on average have earned less than native-born workers, a wage gap that has been significantly widening in recent decades (Smith and Edmonston 1997). There also exists considerable economic heterogeneity among immigrants. Among men and women, 'recent immigrants' and those from Latin America have received the lowest wages. In 1970, the wage gap compared with native-born workers for immigrant men was 48 percent; by 1990 it had almost doubled to 83 percent. Similarly, the gap for Mexican immigrants rose from 65 percent in 1970 to 94 percent by 1990. This large and increasing immigrant wage gap can largely be attributed to expanding skill differences between immigrant and native-born workers. On average, immigrants come from countries where the average education, wages, and

skill are far below those in the USA. A shift in national origins of the foreign-born toward countries where education levels are lower, such as Mexico and Latin America, contributed to the expanding skill and wage differential. As this skill gap widened, the wage gap widened even more owing to the rising wage inequality in the USA. Rising wage inequality implies larger wage differences holding constant skill differences.

Since the mid-1980s, these trends have reversed as relative incomes and schooling of immigrants rose during the 1990s (Jasso et al. 2000b). This economic improvement is especially pronounced when comparisons are limited to legal immigrants. Many foreign-born respondents in surveys are not legal immigrants. For example, only 20 percent of Mexicans who reported that they immigrated since 1990 in the 1995 and 1996 Current Population Survey were legal immigrants (Passell 1999); the remainder were either nonimmigrants or illegal immigrants. Data on legal immigrants alone indicate that during most of the last 25 years their labor market quality has been as high as that of native-born workers and has been rising since the mid-1980s. Given the vast differences between legal and illegal immigrants, research must more clearly distinguish among types of foreign-born residents.

Much less research has been conducted on immigrant employment. Employment rates of immigrants are initially below those of native-born workers, and employment rates of recent immigrants have fallen relative to those of natives. However, immigrants catch up to natives relatively quickly, so that after some years in the USA their employment rates are similar to those of natives.

4. *Life-cycle Assimilation*

Economic assimilation over an immigrant's lifetime has been a source of considerable controversy, but some consensus is now being reached. Chiswick's (1978) original study using cross-sectional data from the 1970 Census indicated considerable catching up in the sense that immigrants who had been in the USA a longer time had lower wage gaps with native-born workers. The Borjas (1985) critique argued that this was an inappropriate comparison since more recent immigrants were members of different entry cohorts who may have been of lower labor-market quality. To address this question appropriately, it is necessary to follow immigrants over their lives in the receiving country. Since no large panel surveys of immigrants exist, researchers instead have tracked synthetic cohorts (defined by their year of immigration) across successive cross-sections such as the decennial US Censuses. Using this analytical technique, on average, male and female immigrants both appear to narrow their percentage wage gaps with native-born workers as their stay in the USA lengthens (Smith and Edmonston 1997). Over time, the percentage wage gap closes significantly for immigrants from Europe and Asia and modestly for others. But initial wage gaps at time of entry has been growing so the time it takes to reach wage parity with native-born workers will take longer. Mexican immigrants are the principal exception to this general rule as they essentially maintain their initial percentage wage gaps with native-born white workers. To date, there is no convincing answer to why Mexican immigrants do less well. One can be speculative about the role of language or the implications of the geographic closeness to country-of-origin, but there is little concrete evidence to document any explanation.

A difficulty common in all existing research is that the analytical technique of tracking across successive cross-sections is problematic if immigrant cohorts are not closed. An immigrant cohort can be depleted if immigrants subsequently emigrate. If emigrés are highly selective, wage trajectories obtained from cohort tracking will be biased. The problems caused by out-migration may not be trivial as about one-third of Mexican immigrants who said in 1970 that they arrived after 1965 had emigrated by 1980. Given the repeated back-and-forth movements between origin and destination countries, a second problem involves the ambiguity in the Census question on year of immigration. It is unclear whether respondents have in mind their first, last, or most salient entry when answering this question. Combined, these methodological problems imply that conclusions about economic assimilation of immigrants must be qualified. These problems will only be resolved by surveys that actually follow immigrants (including those who emigrate) over their full careers.

5. *Generational Assimilation*

The long-run economic achievements of immigrants have more to do with generational progress than life-cycle assimilation. There has been some concern expressed that generational assimilation has slowed, at least compared with earlier European immigrant experiences. However, recent research indicates that no decline exists in the degree of intergenerational assimilation in education or earnings since the 1950s, and that changes in rates of exogamy (marriage outside one's ethnic group) across generations appear stable over time (Card et al. 2000). Generational increases in exogamy are also related to the economic status of the immigrant father.

The conventional wisdom for Hispanics is more pessimistic. Cross-sectional comparisons between first-, second-, and third-generation Hispanics typically show a narrowing of schooling and income gaps between the first and second generations, but either retrogression or little progress between the second and

third generations. However, these patterns do not relate to generational issues because, in any cross-section, members of the second generation are not the children of current immigrants, nor are the third generation the direct descendants of the contemporary second generation. The demographically appropriate analysis aligns generations so that each generation was born 25–30 years later than the previous one. When this is done, Hispanic schooling and wage deficits with the native-born are uniformly smaller in the second generation than in the first and are lower still in the third generation (Smith 1999). Based on the historical record, second- and third-generation Hispanics have narrowed their economic and education disparities with native-born whites.

Immigration

Immigration is the permanent movement of people across states, seen from the perspective of the receiving (rather than sending) states. While a 'transfer of jurisdictions' (Zolberg 1981, p. 5) is thus constitutive of immigration, traditional theories of immigration have surprisingly ignored the state, focusing instead on the economic motivations and social ties that initiate and perpetuate migration flows. The traditional view can be found, for instance, in this encyclopedia's 1968 predecessor, which discussed 'migration' only under its 'social' and 'economic,' but not political aspects (Petersen 1968, Thomas 1968). Still a recent state-of-the-art review of the world's major 'migration systems' indirectly defended the traditionally non-political migration theories, in arguing that states were in principle incapable of controlling social-network based migration flows (Massey et al. 1998).

While the study of immigration continues to be a domain of economic sociologists and demographers, a major development in the past two decades has been a growing interest by political scientists and political sociologists in the central role of the state in soliciting, channeling, and absorbing immigration. This reflects not only a disciplinary evolution and renewed interest in the state across the social sciences, but some changing features of contemporary immigration itself, for which the state has become increasingly central. The classical notion of immigration was coined in the 'stateless' period before World War I, when some 48 million Europeans moved relatively unhindered by entry controls to the Americas and to Oceania. After a brief, restrictionist interlude in the inter-war period, the image of 'stateless' immigration was revived after World War II, when the classic settler nations abolished racially motivated restrictions on immigration, and when some northern European countries underwent large-scale labor migrations from the south. States already figured prominently for these flows, because a conscious change of policy (as in North America or Australia), bilateral agreements with the governments of sending countries (as in Germany or Switzerland), or a geopolitically motivated absention from controlling postcolonial flows (as in Britain or France) were necessary to initiate them. However, the involvement of states was invisible, because this immigration was wanted and considered unproblematic. A typical example of this period is France, where until the late 1960s immigration from the south proceeded largely spontaneous and outside the official channels of the *Office Nationale d'Immigration*, but was legitimized *ex post* by the generous distribution of residence and work permits (see Viet 1998, pp. 233–54).

The picture of 'stateless' immigration—though always a fiction—changed radically in the mid-1970s, when under the impact of a serious economic recession

European states shifted to zero-immigration policies, and when seemingly 'uncontrolled' illegal immigration across its southern land border galvanized a restrictionist turn in the USA. Now, 'states' began to matter, either as bulwarks against unwanted immigration (as in the rhetoric of political elites), or as sieves that chronically failed to live up to their restrictionist intentions (as in the account by some academics, like Cornelius et al. 1994). In this historical moment, when the central role of the state in international migration became problematic and—therefore—visible, political sociologists and political scientists discovered 'immigration,' suggesting models to explain states' immigration policies and how the latter derived from—or violated—their sovereignty (Sect. 1), and investigating the impact of immigration on the membership component of nation-states, which is the topic of a new literature on 'immigration and citizenship' (Sect. 2). Some demographers and economic sociologists, the traditional 'owners' of the immigration domain, still think that the relationship between state policies and international migration, while considered increasingly important, has remained 'under-theorized and little studied' (Massey et al. 1998, p. 286). As the remainder of this entry shall show, this view is mistaken.

1. *Explaining Immigration Policy*

A state's decision to admit immigrants, without which there is either no immigration or at best 'illegal' immigration, is formally a function of its sovereignty, as codified in international law, according to which states are free to reject or to expel non-citizens. This linkage between immigration policy and sovereignty is expressed in the standard notion, propagated by governments around the world, that immigration policy is 'national interest' policy (see US Commission on Immigration Reform 1997, p. 1). The problem is that, particularly in liberal states, the 'national interest' is no fixed thing, standing above group interests, and notoriously short of organizational manifestation. In a path-breaking essay, Gary Freeman (1995) explained in rational-choice terms why 'special' instead of 'national' interests shape the immigration policies of liberal states.

Because the costs of immigration are diffusely spread over the population, while its benefits are concentrated (for employers and co-ethnics), it follows from the logic of collective action that the beneficiaries of concentrated benefits win over the bearers of diffuse costs, in a constellation that Freeman calls (following Wilson 1980) 'client politics.' This simple model explains the paradox that liberal states, despite their restriction-minded elite rhetoric and public opinion, have remained largely open to (certain kinds of) immigrants. A number of authors have quickly picked up and revised or amended Freeman's model. In a cogent analysis, Jeannette Money (1999) has argued that because of the spatial concentration of immigration also the costs of immigration are concentrated, thus remedying the free-rider problem in these geographic areas, and giving rise to a constellation that J. Q. Wilson (1980) has called 'interest group politics.' The restrictionist impulse, first picked up by local politicians, can go nationwide if the respective district is crucial for maintaining or gaining a national electoral majority. Demonstrating this swing-vote dynamic in the cases of France, Great Britain, and Australia, Money's revision of Freeman's model helps explain why some states remain open to new immigration, while in others immigration control is put on the national political agenda. Joppke (1998b, 1999b) has argued that the logic of client politics is more firmly established in classic immigrant nations than in European states, where pro-immigrant lobbies are much weaker, and where nominal 'zero-immigration policies' fit more easily with the rhetoric of 'national interest' policy. In addition, he stressed (much like Hollifield 1992) that liberal norms, which invest immigrants with rights, are a second constraint on state policy, next to interest-group pressure. Reference to liberal norms helps explain why European states, despite the absence of an ethnic lobby there, have remained open to certain kinds of immigrants, most notably the family members of labor migrants.

The analysis of immigration policy is often linked to the larger question of the resilience or transformation of state sovereignty in an era of 'globalization' (see the contributions in Joppke 1998a, Part I). This debate has suffered from a loose definition of sovereignty. Stemming from International Relations theory, the notion of sovereignty refers to the formal last-instance authority of the state within 'its' territory. In this formal sense, even ineffective immigration controls say nothing about the presence or absence of state sovereignty over immigration. Instead, the crucial test is if actors other than the state have acquired formal last-instance authority over immigration matters.

With some important exceptions, such as the free movement regime within the European Union (which is unlikely to be emulated elsewhere), this test will almost always be negative. An altogether different question is whether the presence of unwanted migrants within their territories (such as illegal migrants or asylum-seekers) indicates a declining empirical capacity (as against formal authority) of states to control immigration. The gruesome effectiveness of western states to bring down the numbers of unwanted asylum-seekers in the 1990s through 'safe-third-country' rules, tightened legal procedures, and social deterrence measures, suggests that there is little evidence for this (see Guiraudon and Joppke 2001)

2. *Immigration and Citizenship*

A second line of new and innovative scholarship on immigration has opened up over the impact of

immigration on states as 'membership associations' (Brubaker 1992). A variety of authors have concluded from the upgrading of immigrant rights across liberal states that 'citizenship' as the unitary membership form and focus of collective identity in modern states has been devalued (Schuck 1984), if not set on a path of decline (Soysal 1994). At the same time, migrants' 'transnational' practices and 'diasporic' forms of association are said to increasingly bypass the nation-state, thus rendering irrelevant old models of one-directional integration and assimilation (Glick Schiller et al. 1992).

'Post-' or 'trans-national' approaches have underestimated the resilience and adaptability of the national citizenship construct (see Joppke 1999a). The judicially nonreviewable 'plenary power' of the American federal state over immigration matters has allowed the drastic 1990s curtailment of social welfare rights and benefits even for long-settled legal immigrants, thus showing the inherent vulnerability of non-citizens (see Schuck 1998). In Europe, immigration has triggered not a decline, but a transformation of citizenship. The continent that two centuries ago had been the pacesetter of the postfeudal, 'modern' principle of blood-based citizenship (*jus sanguinis*) is now undergoing a reverse trend toward territorial citizenship (*jus soli*), which had been precisely found wanting in the dawning era of nation-states. In the 1990s, all member states of the European Union (except Greece, Austria, and Luxembourg) have facilitated the access to citizenship, especially for second- and third-generation immigrants, granting them a right to citizenship either at birth or majority age (see Hansen 1998).

The de-ethnicization of citizenship in response to immigration goes along with an intransitive mode of immigrant integration in liberal states. According to this intransitive mode, immigrants are not the object of forced assimilation, as in the 'Americanization' campaign in the early twentieth century, but are to be allowed to be the subjects of freely willed integration. Curiously, immigration scholars (as well as policy makers) often stick to a naive and unquestioned notion of integration with regard to immigrants, while it is notoriously unclear what actually 'integrates' the vast non-immigrant 'rest' of modern societies. Nevertheless, against the backdrop of weakening nationalist semantics in western states, all that immigrants are expected of is adherence to the procedural values that constitute liberal-democratic states; they are not expected to become 'assimilated,' that is, to take on the substantive life forms of a particular nation-state. Nathan Glazer (1997) has expressed this new consensus, which sets a sharp counterpoint to the assimilation request in the early twentieth century, in the happy notion that 'we are all multiculturalists now.' This change of attitude on the part of liberal states is visible, for example, in Germany's new naturalization rules, issued in the early 1990s, according to which cultural assimilation was no longer an individually examined prerequisite for the discretionary granting of citizenship. Now, the applicant had a right to citizenship, after having legally resided in the territory for a certain period. The *de facto* multiculturalism of liberal states is also visible in the new 'Americanization' program suggested by the 1990s US Commission on Immigration Reform, according to which 'ethnic and religious diversity based on personal freedom is compatible with national unity' (1997, p. 25).

Ernest Gellner (1983) famously defined the principle of modern nationhood as the congruence of political and cultural boundaries. As carriers of legitimate cultural difference, immigrants are one (but only one) destroyer of nationhood thus defined, contributing to the general process of cultural pluralization in western states. However, this *de facto* multiculturalism is to be distinguished from the public recognition and the granting of special group rights to oppressed minorities, which is the content of stronger programs of *de jure* multiculturalism. Its perhaps most concise philosophical formulation (Kymlicka 1995) concedes that immigrants, by voluntarily leaving their society of origin, have 'waived' the right to have their homeland resurrected in the receiving society. Despite some exceptions (such as Australia or the Netherlands), liberal states have implicitly followed this normative reasoning, allowing immigrants as individuals to pursue their religious and cultural ways of life, but denying them special rights of representation or self-government as ethnic groups.

There is one interesting exception to the cultural laissez-faire of liberal states vis a vis immigrants: language. Most states continue to make competence in their official language(s) an individually tested condition of voluntary citizenship acquisition (naturalization). In fact, in some states—such as Germany—the removal of a cultural assimilation test has gone hand in hand with the introduction of tougher language requirements. It is not far-fetched to assume that old-style assimilationists have found in language an eagerly embraced substitute. However, the status of language as a prerequisite of citizenship is ambivalent. On the one hand, language may be related to the self-conception of a political community, and thus be elevated into a quasi-ethnic marker. This is clearly the case in the Canadian province of Quebec, which prefers francophone over all other immigrants, and forces the children of immigrants to attend French-language schools. On the other hand, language is also a functional necessity for states—the exercise of authority and the democratic process depend on agreeing on a common language. It is thus unlikely that a de-ethnicized immigrant integration will ever drop language as a key concern. Whether language plays more the role of ethnic marker or of functional necessity will depend on the context. But the cases of Quebec and Germany (concerned more than most

other states about the nation-building implications of immigration) suggest that in liberal states language obligations are the rather thin residuals of the obsolete project of cultural assimilation.

Immigration and Migration: Cultural Concerns

In recent years, there has been a renewed interest in the study of human migration. During the last decades of the twentieth century, most major nation-states have seen the topic of immigration emerge as a significant issue with important public opinion, policy, and research implications. Indeed, with well over 100 million international migrants worldwide, plus an estimated 30 million refugees, immigration has become a topic of global concern (Suárez-Orozco 1996).

Migration, in Latin, *migrare*, meaning to 'change residence,' has been a defining feature in the making of humanity from our very emergence as a species in the African savanna. Social scientists have traditionally defined migration as the more or less permanent movement of people across space (Petersen 1968). In the language of the social sciences people 'emigrate' out of one location and become 'immigrants' in a new setting.

1. Immigration and Time

The definition of migration as the more or less permanent movement of people across space suggests a number of important cultural concerns. First is the matter of the relative permanence of immigrants in a new setting. For many, perhaps most, immigration represents a permanent move, for others it is a temporary state before eventually returning 'home.' A central feature of the great transatlantic immigration that took place between Europe and North and South America from the 1890s until the 1910s was the high proportion of people who returned to Europe. By

some accounts, well over a third of all the Europeans who came to the Americas went back 'home' (Moya 1998).

'Sojourners' represent yet another pattern where temporality defines immigration. They are the large numbers of immigrants who move for well-defined periods of time, often following a seasonal cycle to eventually return home. Large numbers of Mexican agricultural workers in California have historically followed the sojourner pattern (Cornelius 1992).

A third type is the constant shuttling back-and-forth that seems to define the lives of many new immigrants. In recent years, some scholars of immigration have argued that new transnational and global forces structure the journeys of immigrants in more complex ways than was previously seen (Basch et al. 1995). This research suggests that many immigrants are players (economically, politically, and culturally) both in their newly adopted lands *and* in their communities of origin—moving 'back and forth' in ways seldom seen in previous eras of large-scale immigration (Suárez-Orozco 1998).

1.1 Immigration and Space

The idea of immigration as movement across space also requires some elaboration. Immigration, at a minimum, involves a change in residency and a change in community. Over the years, scholars have concentrated on two major types of large-scale migration: 'internal migration' (within the confines of a nation-state) and 'international migration' (across international borders). While many scholars would argue that the large-scale movement of people *within* a nation-state is a phenomenon of a different order than the large-scale movement of people *across* international borders, the differences between these two broad types of migration are often quite blurred.

Internal migrants might share many characteristics with international migrants: many move from rural villages to urban centers, many experience linguistic and cultural discontinuities, and many face the same bureaucratic and legal restrictions international migrants do.

While much attention has been focused on international migration, most immigrants today are internal migrants staying within the confines of their nation-states—China, Egypt, and Brazil are countries that have experienced high levels of internal migration. Indeed, *contra* the impression that most international migrants head to the developed world (i.e., Europe and North America), most immigration today is an intracontinental (i.e., within Asia, within Africa, etc.) phenomenon.

2. The Causes of Immigration

Why do people migrate? Scholars of immigration have generally theorized patterns of migration flows in terms of economic forces, social factors, and cultural practices. Social scientists who study the economic causes of immigration have long-ago examined 'push' factors including unemployment, underemployment, and wage differentials (Dussel 1998). Changing cultural models about social standards and economic expectations have also been implicated in why people migrate (Moya 1998). 'Pull' factors include demand for foreign workers in various sectors of a host country's economy. In many settings, transnational labor recruiting networks deliver low-skilled foreign workers into jobs that native workers have come to culturally construct as unappealing. In Japan, for example, immigrant workers are sometimes called '3k workers' for the Japanese words for 'dirty, demanding, and dangerous' jobs (Tsuda 1996).

In other cases, immigrants become a vital part of the well-remunerated knowledge intensive sector of the economy. Nearly 40 percent of all engineers in the Silicon Valley of Northern California are immigrants. Indeed, in recent years, countries of immigration have witnessed an unprecedented pattern of economic mobility among new arrivals (Suárez-Orozco and Suárez-Orozco 2001).

Immigrants today tend to be highly heterogeneous—in terms of sociocultural and religious background, race and ethnicity, and educational background and skill. They defy easy categorizations. In the United States, for example, immigrants are at once among the most educated and skilled *and* least educated and skilled workers. Immigrants tend to be over-represented in the category of people with doctorates or, indeed, winners of the Nobel Prize—just as they are over-represented in the category of people without a high school diploma. Worldwide immigrants now tend to be much more 'bimodal' in their socioeconomic profile than ever before.

2.1 Transnational Networks

Scholars of immigration have long maintained that cultural and social practices can generate—and sustain—substantial migratory flows. People migrate because others—relatives, friends, and friends of friends—migrated before them. Indeed, the best predictor of who will migrate is who migrated before. Transnational family reunification continues to be a critical vector in immigration today. In the year 1996, 915,900 immigrants were formally admitted in the US. Among them, 594,604 were family-sponsored immigrants (Suárez-Orozco 1999). Since the early 1970s family reunification is one of the few formal ways to migrate into Europe (Suárez-Orozco 1994). A number of studies have examined how transnational migratory social chains can generate a powerful momentum of their own. Roger Waldinger (1997) has explored the sociocultural dynamics of transnational immigrant labor recruiting networks.

Immigrants find their kin and kith jobs. Waldinger's research in immigrant-rich Southern California suggests that immigrant social networks provide employers with a nearly unlimited supply of workers with little or no outlay. Transnational social networks provide connections to people able to fill jobs, at times even before the jobs are vacant. The social networks function optimally when they efficiently and economically generate quality information—about jobs, about applicants, about bosses.

2.2 Immigration and War

We have a reasonable understanding of how 'love' (family reunification) and 'work' drive immigration. On the other hand, the role of war and its relations to large-scale migratory flows has been generally neglected. Yet throughout history war and migration have been closely linked. The threat of labor shortages during World War II led to the creation of temporary labor recruiting efforts to attract much needed immigrant workers to the United States (Calavita 1992). The resultant 'bracero' program became a powerful force in building—alas, via family reunification—a Mexican migration momentum that eventually turned into the largest and most powerful immigration flow into the United States this century (Suárez-Orozco 1998).

In the aftermath of World War II, many of the major Northwestern European democracies such as Germany and Belgium developed 'guest worker programs' to recruit foreign workers—initially in southern Europe, and subsequently in the Maghreb region of North Africa and in Turkey (Suárez-Orozco 1994). These programs came to an end in the early 1970s. Yet family reunification and chain migration continued to bring immigrants from North Africa into Europe for years.

The Cold War both deterred immigration—because of strict Iron Curtain controls—and generated large population displacements. The robust Cuban diaspora in the United States can be traced more or less directly to the Cold War (Molyneux 1999). The low-intensity warfare in Central America during the 1980s generated a new wave of large-scale immigration. As a result, there are now well over a million Central American immigrants in the United States (Suárez-Orozco 1989). In the 1990s, the ongoing conflicts in Zimbabwe and Angola have generated large-scale migratory flows especially into South Africa.

Natural disasters have also displaced populations and started new migratory flows. The 1999 hurricanes, which devastated much of Central America, initiated significant flows of emigrants into North America.

3. Immigration and the State

Whether social scientists examine the case of internal or international migrants, there is a consensus that the apparatus of the nation-state is decidedly implicated in migratory processes: by both what the state does and by what it cannot do. States are, *inter alia*, in the business of regulating the movement of people—both internally and internationally. The right to leave a country, that is the right to emigrate, is a relatively recent phenomenon (Moya 1998).

Nation-states regulate, and carefully police, the inflow of international immigrants across borders. Large-scale international immigration is in significant ways the product of nation building—Argentina, Australia, and Israel come to mind as archetypal examples. Likewise, the reconfigurations of national boundaries have historically and contemporaneously generated large-scale migratory flows. The partition of British India into Pakistan and India was accompanied by one of the 'largest migrations in human history' (Petersen 1968, p. 290). More recently, the disintegration of the former Yugoslavia led to massive, mostly involuntary migratory movements.

In the area of international migration, nation-states generate policies designed to establish who is a 'legal' or 'illegal' immigrant, who is an 'asylum seeker,' a 'refugee,' and a 'temporary guest worker.' States regulate how many immigrants are legally admitted every year. In the US, for example, since 1990, an average of about a million legal immigrants have been admitted annually. On the other hand, legal immigration into Northwestern Europe was greatly curbed following the oil crisis of the early 1970s (Cornelius et al. 1994).

3.1 Asylum Seekers

States also regulate the flows of asylum seekers—those escaping a country due to a well-founded fear of persecution. Agents of the states decide who is formally admitted as a refugee. In the post-Cold War era, there has been an explosive growth in the numbers of asylum seekers worldwide. For example, some 369,000 foreigners requested asylum in Europe during the year 1998. Only a small portion of those seeking asylum are eventually granted formal refugee status.

In recent years, many postindustrial democracies—including the United States and throughout Northwestern Europe—have developed new strategies to deal with increasing numbers of asylum seekers (Suárez-Orozco 1994). For example, the 13,000 Kosovars that arrived in Germany in mid-1999 were given a three-month renewable 'Temporary Protective Status' on the condition that they not apply for refugee status—in effect, forfeiting all the rights and entitlements that come with formal refugee status. Similar arrangements were made for asylum seekers from Bosnia.

In the face of growing numbers of asylum seekers, and a widespread public concern that many of them

are 'economic refugees' in search of a better life in wealthier countries, new formal and informal strategies have been put into place in varied countries. Many of these new strategies seem to be designed to prevent asylum seekers from accessing 'safe countries'—where, under Geneva Convention agreements, they would have the right to a 'fair hearing.'

The high-seas interdiction program put into effect in the United States in the early 1990s is an example. The strategy was conceived to prevent large numbers of Caribbean (especially Haitian) asylum seekers form arriving in US territory—or even within its territorial waters—where they could establish certain legal protections. Apprehending them in international waters, and returning them to Haiti, leave asylum seekers with little practical recourse under international law. In Europe, a similar strategy has been to deem certain areas in international airports not part of the national territory—for example, parts of Zaventem airport are not technically Belgian territory but are considered to be international territory. Asylum seekers entering such airports have been turned back because they are said to remain in international territory, and hence not come under the jurisprudence of the Geneva Convention (Suárez-Orozco 1994).

While advanced postindustrial democracies are likely to continue to face significant numbers of asylum seekers, the greatest numbers of asylum seekers are in the developing world. For example, at the close of the millenium there are over three million asylum seekers in the African continent.

3.2 Illegal Immigration

While the state wields substantial power—both in regard to internal and international migration—there are nevertheless areas where it faces strict limitations in the management of human migratory flows. Nowhere are the limitations of state power more obvious than in its inability to control illegal immigration. In many parts of the world, undocumented or illegal immigration has become a more or less permanent problem, which periodically emerges as an unsettling political issue.

In the United States, for example, it is estimated that there are some 5–10 million illegal immigrants constituting roughly 20 percent of the total foreign-born (immigrant) population (National Research Council 1997). In Europe, the ratio of illegal immigrants to legal immigrants is a more carefully guarded secret because of its dangerous political connotations. Most hard-core right wing political parties in Europe, including France's *Front National*, Belgium's *Vlams Bloc*, and Austria's *Freedom Party* revolve around anti- (illegal) immigration platforms. In the 1990s, these once-marginal parties have made substantial gains with electorates quite concerned with the problem of undocumented immigration.

The enduring problem of illegal immigration in many parts of the world suggests that immigration is now structured by powerful economic factors, social forces, and cultural practices that seem impervious to state actions such as controls of international borders (Cornelius et al. 1994). Transnational labor recruiting networks, enduring wages differentials between nation states, and family reunification generate a powerful migratory momentum that is not easily contained by unilateral, or even multilateral, state interventions to curb it.

4. Economics of Immigration

Few topics are more controversial than the economic consequences of large-scale immigration. Do immigrants help or hurt the economies of host countries? Do immigrants carry their own weight or do they represent a burden to citizens and other established residents? Do complex postindustrial economies need low-skilled immigrant workers or have they become redundant? Much of the recent scholarship on immigration and the economy has tended to focus on such concerns as the fiscal implications of immigration, the issue of immigrant competition with native workers, and the related issue of immigration and wages. Another important theme has been the economic integration and progress of immigrants over time.

The research findings on the economic consequences of immigration are somewhat contradictory—some economists claiming that immigrants are a burden to tax payers and an overall negative influence especially on postindustrial economies (Huddle 1993) and others suggesting that they continue to be an important asset.

A recent study on the economic, demographic, and fiscal effects of immigration by the US National Research Council (NRC) concludes that in the American setting 'immigration produces net economic gains for domestic residents' (NRC 1997, p. 3). Not only do immigrants 'increase the supply of labor and help produce new goods and services' but their presence also 'allows domestic workers to be used more productively, specializing in producing goods at which they are relatively more efficient. Specialization in consumption also yields a gain' (NRC 1997, pp. 3–4). The NRC estimates that the immigration-related 'domestic gain may run on the order of $1 billion to $10 billion a year' (NRC 1997, p. 5). Given the size of the US economy (about 7 trillion dollars), it is clear that immigrants will neither 'make it' nor 'break it.'

In fiscal terms the NRC data suggest, 'Immigrants receive more in services than they pay in taxes' (NRC 1997, p. 7). The panel estimates that 'if the net fiscal impact of all U.S. immigrant-headed households were averaged across all native households the burden

would be … on the order of $166 to $226 per native household.' The NRC study an other studies conclude that while immigration is a plus in overall economic terms, low-skilled new immigrants have contributed to a modest drop in the minimum wage of low skilled workers. They found that a 5 percent drop in wages since 1980 among high school dropouts could be attributed to the new immigrants. There is, however, no evidence to suggest that new immigration has 'hurt' the economic condition of native minority workers such as African-Americans (NRC 1997, p. 5).

4.1 Immigrant Workers in the Global Economy

Other recent research engages the theoretical debate over the role of immigrant workers in the global, postindustrial economy. In the context of the increasingly advanced knowledge-intensive economies of today, are low-skilled immigrant workers simply anachronistic? Are immigrant workers a left over from an earlier era of production? Wayne Cornelius' comparative research of the use of immigrant labor in two paradigmatic postindustrial economic settings, San Diego County, California, USA, and Hamamatzu, Japan, suggests a remarkable convergence in patterns of growing reliance on immigrant labor—in spite of rather marked differences in national context (Cornelius 1998). Cornelius' data reveal a pattern of enduring, indeed voracious, postindustrial demand for immigrant labor. Cornelius concludes 'As immigrants become a preferred labor force, employers do more to retain them, even in a recessionary economy' (Cornelius 1998, p. 128). Cornelius argues that immigrant workers are desirable to a wide variety of employers for three basic reasons. First, immigrants are willing to do low-pay work that is boring, dirty, or dangerous with little or no prospects for upward mobility and that even in firms involving highly advanced technologies such work is critical. Second, employers perceive them quite favorably—as reliable, flexible, punctual, and willing to work overtime. Indeed, employers often prefer them to native-born workers. Third, immigrant transnational labor recruiting networks are a powerful method for 'delivering eager new recruits to the employer's doorstep with little or no effort on his part' (Cornelius 1998).

Other studies examine the issue of the socioeconomic progress made by immigrant workers. The research of Dowell Myers tracks, over time and across generations, various dimensions of the economic adaptations of immigrant-origin men in the state of California. His work explores three sequential outcomes: educational attainment, occupational mobility, and earnings. In some fundamental ways, the recent Mexican immigrant experience in Southern California seems to replicate earlier patterns of immigrant adaptation. Yet in other ways, Myers findings suggest new—and disturbing—patterns.

Myers' research reveals that upon arrival Mexican immigrant men tend to be poorly educated, work in low-skilled occupations, and earn low incomes. Myers finds that over time immigrant men make modest improvements in their economic condition. However, he also suggests that important changes occur across younger cohorts within the first generation. These changes, according to Myers, are strongly related to the much higher educational attainment of immigrant children. In other words, Myers finds an old story with a new set of characters: poorly educated immigrant men make modest gains over time but their children are able to attain more education in the new country. Still, Myers data reveal a disturbing new pattern: among the children of immigrants higher education 'does not appear to fully convert into higher occupational status or earnings; and higher occupational status translates even less well into higher earnings. These under-returns are most pronounced for the more recent arrivals from Mexico and for young cohorts, including native-born, both of whom newly entered the labor market in the 1970s and 1980s.' Myers concludes 'The social implications of these falling returns to education and occupation are regrettable, because the declining reward system may discourage other immigrant children from investing in schooling as the route for status mobility' (Myers 1998, p. 188).

5. Immigration and Cultural Transformation

In all countries of immigration there have been major debates surrounding the cultural consequences of large-scale population movements. In the US a palpable concern, not always fully articulated, relates to how the new immigrants, the majority of whom are non-English speaking, non-European, people of color migrating in large numbers from the developing world, will culturally adapt and, indeed, transform their new country. In Western Europe, there are similar concerns about the cultural adaptations of large numbers of immigrants coming into the Judeo-Christian continent from the Islamic world (Suárez-Orozco 1991). Likewise in Japan, a country where racial and cultural homogeneity is deeply implicated in the construction of cultural identity, there are questions about the long-term consequences of increasing migration from Thailand, Korea, China, the Philippines, and South America (Tsuda 1996). Large-scale immigration is both the cause and consequence of important cultural transformations. Immigration inevitably leads to cultural changes and accommodations among both new arrivals and native citizens (Ainslie 1998). Immigration can be said to be the consequence of cultural change in that new cultural tastes and changing

cultural conceptions of what is an acceptable standard of living have been implicated in large-scale migratory flows (Sassen 1988). Culturally immigrants not only significantly reshape the ethos of their new communities (Ainslie 1998, Gutierrez 1998) but they are also responsible for significant cultural transformations 'back home' (Durand 1998). As immigration researcher Peggy Levitt has argued, in many settings, immigrant 'social remittances' profoundly affect the values, cultural models, and social practices of those left behind (Levitt 1998). Because of a new ease of mass transportation and because of new communication technologies, it seems that immigration is no longer structured around the 'sharp break' with the country of origin that once characterized the trans-oceanic experience (Ainslie 1998). Immigrants today are more likely to be at once 'here' and 'there'—bridging increasingly unbounded national spaces (Basch et al. 1994) and in the process transform both home and host countries.

Studies of an earlier era of large-scale immigration in the US argued that those who abandoned their cultural practices in favor of quickly 'assimilating' to the uniform norms of the mainstream tended to display successful outcomes in terms of health, schooling of children, and socioeconomic mobility. More recent research suggests a somewhat more complex picture—where the long-term benefits of unambivalent assimilation may not be so obvious.

Various contemporary researchers stress that we can no longer assume that upon arrival immigrants face a uniform mainstream society. Rather, immigrants are most likely to interact in complex ways with many *other* immigrant and native minority groups. In the United States, increasing residential, labor, and school segregation means that many immigrants, especially poorer immigrants of color, are much more likely to interact with other ethnic minorities rather than with the white mainstream population (Orfield 1998).

For large numbers of immigrant children today, the social point of reference is not 'white,' mainstream, culture but rather the culture and social structure of ethnic minorities. In the words of the eminent scholar of immigration, Alejandro Portes:

> This puzzle is whether today's children of immigrants will follow their European predecessors and move steadily into the middle-class mainstream or whether, on the contrary, their ascent will be blocked and they will join children of earlier black and Puerto Rican migrants as part of an expanded multiethnic underclass (Portes 1994, p. 634).

Increasingly immigration will need to be framed in the context of powerful—and as of yet little understood—transnational formations. New patterns of capital flows, new information technologies, new patterns of communication, changing cultural expectations, and the ease and affordability of mass transportation are generating dynamics that transverse the traditional boundaries of the nation state. Global capitalism is increasingly characterized by 'borderless' economies predicated on transnational capital flows, newly opened markets, and immigrant-dependent economic niches. All of these factors would suggest that immigration is certain to remain a vital social phenomenon in the new millenium.

Immigration: Consequences for Fiscal Developments in the Receiving Population

Immigration, particularly when it is from poorer to richer countries, often gives rise to concerns about economic impacts on the receiving country. One leading concern is that immigrants will impose a net fiscal burden on the nonimmigrant taxpayers by disproportionately drawing on public assistance, and, through their children, the educational system. At the same time, other people believe that immigration will alleviate population aging of industrial nations and bring them fiscal relief from the costs of providing health care and pensions to their growing populations of elderly. Most immigrants pay taxes as well as receive benefits, so it is the net effect that matters. In modern industrial states, immigrants are seen as imposing net costs through public education, poverty programs, and some health programs; and potential net benefits through programs for providing health and pensions for the elderly, with ambiguous effects on net health costs in general. Do immigrants, on net, impose a burden on taxpayers, or provide relief? The answer may influence policy decisions on the numbers and characteristics of immigrants to be admitted.

1. *Sources of Fiscal Impacts*

The history of these concerns extends at least into the nineteenth century in the US, and perhaps farther in other countries. However, the potential fiscal impact of immigration grew larger in industrial nations over the course of the twentieth century, as government spending grew in relation to the sizes of their economies, and as new welfare programs were initiated and grew to take a larger share of these expanding government budgets.

Some of the fiscal effects of immigrants would arise in a similar way from adding any new member to the population, for example a newborn native (see *Childbearing, Externalities of*). Thus an immigrant increases the size of the population and increases the number of tax payers. The increase in the size of the population will increase the demand for social infrastructure and public capital of many kinds, such as roads, water supplies, sewer systems, police stations, fire departments, airports, and court systems. Either these must be expanded, requiring both capital outlays and increased current expenditures, or the quality of services delivered to the pre-existing population must decline. Given the nature of the tax system, these increased costs will be born by everybody, constituting a negative fiscal impact. We call these congestible services. For other services provided by the government, the quality of the service received per person is not degraded nor costs increased when the population

grows. The goods generating such services are called public goods, and national defense (and related expenses such as services for veterans) the leading example. A larger tax base reduces the cost to each individual taxpayer of paying taxes to provide such public goods, so immigration has a positive fiscal impact through this route. An additional member of the population also dilutes common ownership rights in any collectively owned goods such as public lands and forests, fisheries, or oil reserves, but also dilutes fixed financial responsibilities such as national debt and its servicing. The net effect can be positive or negative.

Other fiscal impacts arise because immigrants have different characteristics than natives. For example, immigrants have different demographic behavior: relatively high probability of returning to the source country, different fertility (in industrial countries, typically higher), and different mortality (controlling for ethnicity, typically lower). They have different cultural backgrounds (and may be less likely to put their elders in nursing homes, for example), and speak different languages (which may impede their absorption in the labor force or require special educational treatment). Immigrants tend to be in their young adult ages on arrival. Their educational attainment may be higher or lower on average than that of natives. Their incomes after arrival may be quite different than those of natives. These characteristics affect the taxes they pay, and the cost of the benefits that they and their children receive. The task is to assess these various impacts, and arrive at a quantitative evaluation.

Surveys or censuses often provide information on tax payments and benefits used by individuals or households, that can be identified as immigrants or immigrant-headed households. This information can be supplemented from the national income and product accounts and other sources to estimate public debt, defense expenditures, educational expenditures per pupil, and so on. From these building blocks, an estimate of fiscal impact can be constructed.

Although this may appear to be a straightforward accounting exercise, results depend heavily on just how the question is framed. For example, what is the net fiscal impact of: an immigrant in the current population? A currently arriving immigrant? A household headed by immigrants? An immigrant, over the life cycle? An immigrant, over the life cycle, together with all descendants? The biggest differences in approach are cross-sectional analysis vs. longitudinal, and analysis of immigrants only vs. immigrant households.

2. *Cross-sectional Analysis*

Immigrants tend to be in the younger working years at the time of arrival; relatively fewer children and elderly immigrate. People of working age typically pay far more in taxes than they receive in benefits. Consequently, if the focus is on more recent immigrants still in the working ages, or if the pace of immigration has been increasing so that most immigrants are recent arrivals, then the finding will generally be that immigrants are a net fiscal benefit, simply as a result of their particular age distribution. For example, in the US in 1994, the average immigrant in the population had a beneficial net fiscal impact of $1,800 per year (Lee and Miller 1997, p. 316–17). Many problems arise because this is a cross-sectional calculation based on a single year. Some of these immigrants arrived early in the twentieth century and still survive, while others arrived within the most recent year studied. Such immigrants may have characteristics that are very different from those arriving today, yet all are lumped together in the calculation. Furthermore, the immigrants will impose different costs or benefits as they age, and the representation of ages among the current immigrant stock may be misleading, particularly if immigration has fluctuated in the past. After arrival, immigrants will themselves age in the future, at which time taxes and benefits may be quite different. In addition, children pose special problems. Foreign born children are counted as immigrants, but they are relatively few. Often the children of immigrants born in the country of destination are not themselves considered to be immigrants, in which case their costs and benefits do not enter into this calculation. However, the presence of these children is a consequence of their parents' arrival as immigrants, and therefore is a part of their fiscal impact. Omitting these children (by counting only immigrants) imparts a positive (beneficial) bias to the estimated impact.

In an effort to take these children into account, some analysts focus on the net fiscal impact of households headed by immigrants (Garvey and Espenshade (1998) is an excellent example, and Akbari (1991) an interesting variation). These will include foreign-born children as well as those who are born in the destination country. Changing the unit of observation from the individual immigrant to the immigrant household has a profound effect on the results. In the US case, the +$1,800 impact per immigrant now becomes a −$400 per immigrant per year (Lee and Miller 1997, pp. 316–17). This estimate is still cross-sectional and has all the associated problems. In addition, although now the children are counted, there are new problems, as follows: In many countries, including the US, the children born in the destination country are considered to be citizens, not immigrants. Such children enter the calculation only so long as they remain in their immigrant parents' households, which is mainly during ages when they are receiving costly public education. Once they become financially independent and move out of their parents' households, they no longer enter into the calculation. This approach therefore misses their working stage, in which they pay more in taxes than they pay in benefits.

Consequently, the immigrant-household method is biased toward finding an adverse impact because it counts these children only when they are young and costly and not when they are older and net contributors. If we were to include the costs and benefits of the whole second generation for the US, the average impact per immigrant would rise from −$400 when only children under 20 are counted, to +$900. Even within the cross-sectional approach, these variations in definitions lead to wide variation in the results. This is not satisfactory.

Until a few years ago, almost all analyses of the fiscal impact of immigration were based on one of these two methods: the individual immigrant or the immigrant household. Rothman and Espenshade (1992, p. 411) review 17 US studies; of these, nine take the individual immigrants approach, and the remaining eight take the immigrant household (or family) approach. Vernez and McCarthy (1996, pp. 7–8) update this survey with a look at nine studies since 1992, most of which use the immigrants-only approach. All these studies are biased one way or the other due to the method used.

3. *Longitudinal Analysis*

Consider the purpose of this analysis. It is intended to address the concern that additional immigrants admitted today will impose net costs on the pre-existing population. From this perspective, it is clearly new immigrants that matter, not immigrants that arrived decades ago and that may have very different characteristics. It is clear that the fiscal impacts of admitting an incremental immigrant will not all be exerted immediately, but rather will unfold over the immigrant's lifetime, conditional on survival and on remaining in the country. It is also clear that children born to the immigrant, and their taxes and benefits throughout their own, and their children's lives, are all part of the fiscal impact unfolding over time. In sum, the approach must be longitudinal. In principle, a household-based approach could be used, provided that all individuals were tracked after leaving one household and entering a new household, for many decades or even centuries. However, in practice this is not feasible, and an individual approach is therefore preferable.

The first thoroughgoing and detailed application of the longitudinal approach in this context was Lee and Miller (1997), followed by Auerbach and Oreopoulos (1999) and Storesletten (2000). The first two take a partial equilibrium approach, in which many potential feedbacks through the economy are ignored. Storesletten takes a general equilibrium approach, incorporating the effects of immigrants on wages and interest rates, in a dynamic perfect foresight setting; however, he includes less demographic detail and does not include public goods. Auerbach and Oreopoulos use a generational accounting framework. The approach of Lee and Miller will now be briefly described. Although the results from these three studies may appear to differ, once comparable assumptions are made they are all roughly consistent.

Lee and Miller (1997) estimate taxes paid and the cost of benefits received for immigrants by age, educational attainment, and time since arrival, as well as by age and educational attainment for the children of immigrants, and separately for all others in the population. These age profiles are then projected forward in time for a long time, based on assumptions about future rates of labor productivity growth, interest rates, trajectories of other government expenditures, and the assumption that taxes are adjusted so that the government debt to GDP ratio does not exceed 0.8. This requires tax increases when population aging accelerates. They also project the child-bearing, survival and re-emigration of all immigrants and their descendants. Estimated impacts take into account effects through public goods, congestible goods, and collective wealth or debt, in addition to transfers through the welfare state. What initially appeared to be a straightforward accounting problem based on hard numbers has thus become a highly speculative and uncertain exercise in very long-term projection.

Results can be summarized in various ways. For example, the net present value (NPV) of the long stream of taxes minus cost of benefits due to an incremental immigrant can be calculated, perhaps separately for each age and level of education at arrival by country of origin, sex, or other attributes. For the US, the NPV averaged across the actual age–sex–education composition of the immigrant stream around 1994, and using a real interest rate of 3 percent was +$80,000. This comes to $2,400 per year. Multiplying by 1.4 million gross immigrants per year, and dividing by the US population of 260 million in 1994, this implies an impact per destination resident of only +$13 for all the immigrants arriving in a given year, which is small. It is useful to examine the results more closely by level of government, by characteristics of the immigrants, and by time horizon.

In the US, the federal government has the main responsibility for providing pensions and health care for the elderly. The state and local governments have the main responsibility for providing public education and some other services for children. Consequently, immigrants are highly beneficial to the federal budget, with an NPV of +$105,000 per immigrant in 1994, while they impact state and local governments negatively with an NPV of −$25,000, combining to the net value of $80,000. In other countries, with a different division of responsibilities, the situation would, of course, be different. But in the US, certain states and local areas that receive large numbers of immigrants suffer a substantial negative fiscal impact. The federal gains from immigration are spread evenly

across the residents of all states, whether those states receive immigrants or not. This leads to political tensions between local, state, and federal governments. Some states have sued the federal government for compensation, particularly for the costs of undocumented immigrants.

Results also vary by characteristics of the immigrants. As suggested by Storesletten (2000), governments wishing to achieve a positive fiscal impact could use estimates like these to inform their policy decisions. The NPV for immigrants and their descendants is highest for immigrants arriving between ages 15 and 25, peaking earlier for those with little education at arrival, and later for those with more. At any age, more highly educated immigrants have higher NPVs. For example, for arrivals at age 20, those with less than a high school education have an NPV of +$33,000; of exactly high school education, +$146,000; and for more than high school, +$288,000. Much of this is due to the contributions of descendants for arrivals before age 30 or so. Arrivals later in life who do generate descendants have low or negative NPVs, and elderly immigrants are particularly costly. For example, an immigrant arriving at age 70 has an NPV of between −$149,000 and −$225,000, depending on education.

Finally, results vary strongly by horizon. The NPVs abstract from this dependence on time. Immigrants are initially quite costly while they assimilate into the job market and while their US born children are young. It takes about 20 years before the federal benefits per year begin to outweigh the costs at the state and local level. Thereafter, the net effect is positive.

Suppose there are an additional 100,000 immigrants per year in perpetuity, with the same distribution of characteristics as in the current flow. The fiscal consequences of this scenario can be projected for each year in the future, with no need to calculate present values. This avoids many of the uncertainties of the projections many generations into the future. For the US this incremental perpetual stream of immigrants would initially impose a cost per US resident of about $10 per year for the first 20 years, and thereafter there would be a growing net benefit, reaching about $80 per person per year by 2050.

4. Final Reflections

The topic of fiscal impacts of immigration has generated heated political controversy in many countries. It is true that depending on governmental structures and the degree of decentralization, immigration may cause serious fiscal pressures in certain years in certain localities. However, the net effect for the average immigrant in a typical industrial country might well be positive, since most industrial countries currently have tax-based public pension systems and face severe budgetary stresses from population aging. However, the net effect would also depend on the level of national debt and on the proportion of the national budget spent on defense. Perhaps the most important message from the studies reported above, though, is that the net effects of immigrants are surprisingly small at the national level. They hardly appear sufficient to be an important consideration in forming immigration policy.

Immigration: Public Policy

A common feature of twentieth century life was the immigration line. It is considered quite normal for states to regulate movement across international borders and sometimes within them. Anyone expecting to cross an international border is expected to have a passport with all the necessary documentation. In many countries, an internal passport (or some sort of national registration document) is mandatory for everyday business and official transactions.

From a historical perspective, the issuance of passports and the regulation of international migration by states are modern phenomena (Torpey 2000, p. 7). Prior to the nineteenth century, international borders were only approximately known and rarely policed. The strict regulation of international migration followed from the creation of 'nation–states'—the very peculiar form of state organization that has proliferated around the globe over the past two centuries. In the twenty-first century, there is very likely to be a gradual crumbling of the rigid laws and restrictions about who can cross international boundaries and settle in other countries. In the closing decades of the twentieth century, quite a few countries liberalized their immigration laws to allow more immigration and more diversity among the immigrants admitted. The European Common Market allows citizens from any country in the association to move to (and work in) another. Although it is unlikely that there will be a complete end to immigration restrictions, the radical limitations on international movements that characterized much of the world in the mid-twentieth century are likely to fade.

1. Long Distance Migration in Historical Perspective

Long-distance migration is as old as humankind (Davis 1974, McNeill 1984). Although some views of human history paint a portrait of immobile communities, wedded to the land and local villages over the millennia only to be disrupted by modern civilizations and global capitalism, this is a very partial view. Local communities did persist over long stretches of human history, but the peoples who inhabited them were connected to frontier regions and cities through periodic waves of out-migration in times of population surplus. Moreover, local villages and communities were periodically subjected to conquest that led to displacement, enslavement, or absorption into dominant populations. Patterns of uneven population growth, environmental changes, and technological differences between populations inevitably made migration, voluntary and involuntary, a recurrent feature throughout history. These patterns of population movement, however, were rarely regulated by state policies.

Prior to the rise of nationalism in the eighteenth and nineteenth centuries, the primary forms of state organization in the world were empires and kingdoms ruled by absolutist monarchs. Empires were defined by their centers—the city where the monarch ruled. The boundaries of empires were, however, ill defined and probably oscillated with the power of the center to extract taxes and conscript labor from the periphery. The cities of empires were invariably multiethnic and drew peoples from a variety of distant locations. The primary imperative for the openness of cities to migrations was survival. With the exception of Japan, concentrations of populations inevitably led to high levels of mortality far in excess of natural increase. Cities required a continuous influx of labor from rural areas just to maintain their population. Moreover, workers for various urban roles, including artisans, traders, slaves, and soldiers, were often imported or recruited from distant, culturally distinct peoples. These multiethnic cities were not necessarily harmonious or even tolerant, but social and cultural antagonisms were usually held in check because of common interests or by political force.

During the nineteenth and twentieth centuries, the political map of the world was transformed with the dissolution of empires, the rise and fall of imperialism, and the emergence of many new states. In many cases, state formation was based on a claim of nationalism, which usually implied an ethnic homeland or a sense of belonging to a common people. Nationalism has proven to be an extremely potent ideology of state building in the modern era. Indeed, the boundaries of Europe were redrawn after World War One to give many nations their own state, a policy legitimized by the ideology of national self-determination.

Among the many problems created by nationalism was the uncertain political status of domestic minorities in modern 'nation states.' McNeill (1984, p. 17) notes that the 'barbarian ideal of an ethnically homogeneous nation is incompatible with the normal population dynamics of civilization.' According to McNeill, the European nineteenth-century ideology of nation building (based on a single people in one country) was only realized by the coincidence of rapid population growth and the incorporation of regional peoples into a national myth of a common language and culture. If other ethnic groups could not be absorbed in the national population, the alternatives were expulsion or the removal of the rights of citizenship. The logic of nationalism was expressed by Hobsbawm (1992, p. 134) as 'The homogeneous territorial nation could now be seen as a programme that could only be realized by barbarians, or at least by barbarian means.' Although there is no simple one-to-one correlation between nationalism and the tightening up of international boundaries to migration, the logic was similar. A country that wanted to preserve a homogeneous ethnic homeland would not want to open its borders to other peoples.

Just as nationalism was taking hold in Europe in the nineteenth century and beginning to spread around the globe, there were other forces that were expanding the numbers of the potential migrants and the feasibility of large scale, long distance population movements. The most important factors were the acceleration of population growth in many parts of the globe after 1750, opportunities for settlement in frontier societies, and the demand for labor in the emerging industrial economies. Population pressures, with growing numbers of people living at the margins of subsistence, were exacerbated with the commercialization of the agricultural economy and displacement of peasants from the land. In different countries, famines, persecution, and pogroms added to the reasons for exodus in the nineteenth century. These pressures combined with the cheapening costs of long distance travel increased the attractions of sparsely settled frontier areas, especially in the New World. All of these conditions led to massive waves of migrants, numbering in the millions, crossing the Atlantic (and the Pacific) over the later half of the nineteenth century.

In most areas of the New World, the initial reaction to the increasing numbers of immigrants in the nineteenth century was positive. Immigrants were thought to contribute to economic growth and the general concern was of too few, not too many newcomers. But as the decades passed, the numbers increased, and alarm bells began to ring.

2. *The Closing of the Borders of the United States*

The most open borders of the nineteenth century where those in the New World and Australasia. With the depopulation of the indigenous peoples through conquest and the spread of Old World diseases, the New World became the demographic and economic frontier that attracted long distance migrants from around the world, especially from Europe. The migration to the New World was monumental, both in its demographic size and the diversity of its origins. For the 75-year period from the mid-nineteenth century to the end of the first quarter of the twentieth century, almost 50 million Europeans went to the United States alone (Massey 1988). In spite of some frictions, immigrants were generally welcomed in the New World. Labor was scarce and the endless frontier needed to be settled. Land grants, ksubsidized passage, and labor recruitment were among the strategies used to induce migrants at various times during the eighteenth and nineteenth centuries.

Not everyone came voluntarily. For decades, Great Britain would send English and Irish 'convicts' to its colonies in North America, and after the American Revolution, to Australia. It is estimated that more than 10 million Africans were transported as slaves to the Caribbean and to North and South America (Klein 1999, pp. 208–11).

By the middle of the nineteenth century, some of the occasional fears and antagonisms against immigrants were beginning to coalesce into social movements. In the decades prior to the American Civil War, there was a substantial movement against Catholic immigrants, particularly from Ireland, in several American states. These antipathies crystallized in the 'Know Nothing Party' which in 1855 elected six governors and sent a number of representatives to Congress (Jones 1992, p. 134). The term preferred by party members was the American party, and their philosophy was simply that of 'Americanism,' which seemed to represent a fear of internal minorities because of their foreign connections (Higham 1988, p. 4). The Know Nothing movement collapsed before the Civil War, and did not have any lasting impact, except as a harbinger of the nativist trend that emerged in subsequent decades.

The first American effort to close the door to immigration was directed against Chinese on the West Coast in the 1870s (Saxton 1971). By 1882, the anti-Chinese coalition had become so strong that Congress passed, and the President Chester A. Arthur signed, a bill that was popularly known as the 'Chinese Exclusion Act' (Hutchinson 1981, pp. 77–84). Although the facts of immigration restriction are clear, the motivations for it are still debated. There is no doubt that the anti-Chinese sentiments (and later anti-Japanese) were thoroughly infused with racial ideology. Popular prejudices against Asians were openly expressed in newspapers and by most political leaders (Saxton 1971, Daniels 1977). The question is whether racism was the primary reason or just a convenient ideology for those who had genuine fears of economic competition with the new immigrants. In her theory of the 'split labor market,' Bonacich (1972, 1984) argued that much of the antagonism and discrimination against Asian immigrants by working class whites, who led the movement for immigration bars, was based on fears that Asian immigrants' willingness to work for very low wages undercut the incomes of white workers.

The movement to exclude Chinese (and other Asian) immigration to the United States was not a singular event. In his book, *The Great White Walls are Built*, Price (1974) describes how similar restrictive immigration laws were passed in Australia and Canada. Moreover, the restrictions on Asian immigration foreshadowed the movement to exclude immigration from Southern and Eastern Europe to the United States, which culminated with the 'national origins' quotas in the 1920s.

The movement to restrict European migration to the United States was a complex phenomenon that extended for several decades with strange political, economic, and ethnic alliances on both sides. The standard economic account posits capital and labor as the main protagonists with business and employer

groups advocating free immigration and workers arguing the opposite. There were, however, many other sides to the debate. Immigrant communities, particularly in big cities, were a strong political force against immigration restriction, while Congressional representatives from rural areas were generally opposed to open immigration.

Perhaps the most important force moving the United States toward limits on immigration was the rising tide of nativism—the fear of foreigners, which gradually became intertwined with racial ideology in the first two decades of the twentieth century. American nativism had deep roots in anti-Catholicism and a fear of foreign radicals, but the belief in the inherent superiority of the Anglo-Saxon 'race' became the dominant element of the ideology in the late nineteenth century (Higham 1988, Chap. 1). These beliefs and the link to immigration restriction had widespread support among many well-educated elites. The Immigration Restriction League, founded by young Harvard-educated Boston Brahmins in 1894, advocated a literacy test to slow the tide of immigration (Bernard 1980, p. 492). It was thought that a literacy test would reduce immigration from Southern and Eastern Europe, which was sending an 'alarming number of illiterates, paupers, criminals, and madmen who endangered American character and citizenship' (Higham 1988, p. 103).

For three decades, the battle over immigration restriction was waged in the courts of public opinion and in Congress. In 1910, the Dillingham Commission (a congressionally appointed commission named after Senator William P. Dillingham of Vermont) issued a 42-volume report, which assumed the racial inferiority of the new immigrants from Eastern and Southern Europe relative to the old stock immigrants from Northwestern Europe (Bernard 1980, p. 492). Social Darwinism and scientific racism were in full flower with many leading scholars warning against allowing further immigration of 'beaten members of beaten breeds' (Jones 1992, pp. 228–30).

When the passage of a literacy test in 1917 did not have the intended impact of slowing immigration from Southern and Eastern Europe, Congress passed the Quota Act in 1921 to limit the number of annual immigrants from each country to three percent of the foreign-born of that nationality in the 1910 Census (Bernard 1980, pp. 492–3). These provisions were not strong enough for some restrictionists, who passed another immigration law in 1924 that pushed the quotas back to two percent of each nationality counted in the 1890 census, a date before the bulk of the new immigrants had arrived. The policy then led to the 'national origins quotas,' which were based on very dubious means of estimating the national origins of the American population (Higham 1988, pp. 316–24, Anderson 1988, pp. 140–9). There were no quotas allocated for Asian countries and no mention of any possible immigration from Africa.

Timmer and Williamson (1998) argue that the immigration restrictions that took hold in the United States and many other countries about the same time in the early decades of the twentieth century were primarily motivated by economicconsiderations and not by xenophobia or racism. There is some evidence that immigration from poorer areas might have slowed gains of domestic workers (Hatton and Williamson 1998; however, see Carter and Sutch 1998), and that the political alliances that did finally lead to immigration restriction were shaped, at least in part, by fears of competition with immigrant workers (Goldin 1994). Although restrictive policies were clearly formulated to address the fears of wage competition of American workers, the conclusion that this was the only causal variable seems to ignore the highly charged ideological climate of the era of immigration restriction.

Nationalism and racism were the reigning ideologies of the late nineteenth and early twentieth centuries. Although not every political outcome was determined by these ideologies, they did shape the immigration policy agenda in fundamental ways. In the United States, racial arguments were used by politicians, scholars, and the mass media to convince the American public and the government that the historically open door of immigration should be closed (Higham 1988). This was not an easy case to make in a country whose identity was that of a 'nation of immigrants.' It took several decades of overt anti-immigrant rhetoric and a broad political coalition before the US Congress was able to pass restrictive immigration legislation that closed the door to mass immigration.

Another factor that probably helped to turn the tide against an open system of international migration was the increasing rate of population growth. For most of the nineteenth century, migration had been a necessity because of the high mortality in cities and a general shortage of labor to settle the frontier and to work in the factories of the new industrial age. With declining levels of mortality in the early twentieth century, most countries were generally able to meet their labor needs from natural increase. In such circumstances, the nationalist and racial impulses were, perhaps, given a freer hand to regulate immigration policies over the middle decades of the twentieth century.

3. *The Immigration Door Begins to Open*

The imposition of the national origins quotas in the 1920s, followed by the Great Depression and World War Two, lowered immigration to its lowest levels since the early decades of the nineteenth century. The 'racial' character of the national origins quotas was exemplified by the very limited numbers of Jewish refugees fleeing Nazi Germany who were allowed to enter the United States while the quotas for Great Britain were not utilized. After World War Two, US immigration policies came into conflict with America's

new leadership role in the international system. If American political ideals were to influence other countries, the discriminatory character of the national origins quotas could be held up as an example of hypocrisy. In vetoing the McCarran–Walter Immigration Act of 1952 (which reaffirmed the national origins quota system), President Truman stated:

> The quota system—always based upon assumptions at variance with our American ideals—is long since out of date… The greatest vice of the present system, however, is it discriminates, deliberately and intentionally, against many of the peoples of the world… It is incredible to me that, in this year of 1952, we should be enacting into law such a slur on the patriotism, the capacity, and the decency of a large part of our citizenry (quoted in Keely 1979, pp. 17–18).

Congress overrode Truman's veto, and the national origins quota remained the law of the land for another 13 years. The domestic and international pressures for immigration reform continued to grow with each passing year. The dam finally broke with the landslide 1964 election, which brought a reform minded Congress into office. Among the major pieces of Great Society legislation passed was the 1965 Immigration Act, which was championed by a number of senior members of Congress who were the children of immigrants from Southern and Eastern Europe.

The 1965 Immigration Act replaced the national origins quota system with a new preference system based on the principles of family reunification and skills. In the decades following the 1965 Immigration Act, there have been a series of new laws that have modified the numerical limits and procedures of immigration and the admission of refugees (Smith and Edmonston 1997, pp. 22–30). In general, these reforms have liberalized immigration to expand the numbers and to create more possibilities for admission.

The sponsors of the 1965 Immigration Act were primarily interested in allowing a freer flow of immigration from Southern and Eastern Europe, the countries hit hardest by the national origins quotas. The primary response, however, has been a major immigration flow from Asia. The first wave of Asian immigrants in the late 1960s and early 1970s were able to utilize the provisions allowing for those in skilled occupations of high demand (nurses, engineers, doctors, etc.) to enter. These early arrivals were then able to use the family reunification criterion to sponsor their relatives. At about the same time, there was a major new wave of immigration from Latin America, especially from Mexico and Cuba.

The movement to a less restrictive policy of immigration to the United States has been paralleled by comparable reforms in other countries. In the early 1970s, Australia ended its 'White Australia' policy and allowed significant numbers of Asians to immigrate. In the early 1990s, the countries of the European Common Market loosened restrictions on interstate migration. Citizens of any country in the European Common Market can move to any other country and are free to seek employment or attend schooling on equal terms with natives of the country. The appearance of these common patterns in a number of countries and regions suggests that the nationalist impulse, which sought to limit and control international migration, was waning during the last few decades of the twentieth century.

Underlying the change in immigration policies were broad economic and demographic forces. Population growth in advanced industrial countries had slowed, and there was a shortage of native-born persons who were willing to work in lowly paid positions in the economy, including seasonal agricultural labor. For the second half of the twentieth century, there was virtually an unlimited supply of immigrant labor, sometimes skilled and always highly motivated, from developing countries. The prejudices against immigrants and nativist fears have not entirely disappeared, but their open expression has been sharply reduced in most modern postindustrial societies. These changes in economics, demography, labor demand, and ideology have contributed to a much freer flow of international labor migration in the late twentieth century (Castles and Miller 1998, Massey et al. 1998).

In terms of policies of international migration, two distinct patterns emerged in Europe and the United States. Many European countries adopted 'guest worker' programs, which were intended to be temporary stays by workers from the labor surplus countries of Southern Europe and North Africa. Guest workers were generally not eligible for citizenship and were expected to return home when their contracts were completed. The United States maintained a formal immigration framework, whereby legal immigrants could apply for citizenship after five years, but also tolerated a parallel system of 'illegal immigration.' Both policies were reluctant to acknowledge the realities of international migration. Most temporary workers did not return home, and they often brought their families and became permanent residents of the host society. The relative openness of the US society to illegal or 'undocumented immigration,' has led to the conclusion that efforts to regulate immigration are primarily symbolic. Understanding the 'failure' of immigration policies requires looking beyond mistaken assumptions and inadequate enforcement to see how deeply embedded international migration has become in the modern world economy.

4. *International Migration in the Twenty-first Century*

The contradictions between tightly regulated international borders and the modern world economy are becoming increasing clear. Most immigration policies, of whatever type, are residues of the first half of the twentieth century, when regulated borders were a

hallmark of modern statecraft. If the role of a state was to promote the welfare of the national population (a group defined by descent or membership), then a clear objective was to keep others (nonmembers of the nation) out, or to keep the numbers of immigrants to very modest levels. Policies of tightly regulated borders developed in nineteenth-century nation-building states, initially in Europe, and then spread around the globe in the twentieth century, including the traditional immigrant receiving societies in the New World and Oceania.

These policies 'worked' because domestic population growth in most countries was sufficient to meet labor demand. Indeed, population growth reached record levels everywhere in the twentieth century. Although rapid population growth created immense pressures in many labor surplus countries, there were few places that needed additional labor or allowed open migration. Passport controls were expensive and irksome to many, but they became accepted as normal features of modern states. Over the last few decades of the twentieth century, however, strains in the system of tight immigration policies were beginning to show.

The first sign was 'labor demand' in industrial countries that could not be met by domestic supply, at least not at the wages offered. Employers found it more desirable to import labor from abroad than to raise wages or to mechanize production. If this pattern were found in only one country or in only a few sectors, then it might be possible to consider a fairly narrow explanation in terms of political cultures or market rigidities. The demand for 'cheaper immigrant labor,' however, spans many sectors (agriculture, manufacturing, construction, repair services, restaurants, and childcare) in most industrial countries, including a growing number of rapidly growing developing countries. The increasingly global international economy seems to create recurrent needs for labor greater than that available from domestic population growth.

The demand for immigrant labor is not restricted to unskilled manual labor. The United States and other industrial countries have encountered a shortage of scientific and engineering workers, particularly in the high tech sector. This demand has been met, in part, by allowing many talented foreign students in American universities to convert their student visas to immigrant status. There has also been a gradual shift over the last few decades to more open immigration policies for a variety of reasons—refugees, agricultural workers, 'illegal' immigrants with long residences in the country, peoples in countries that have too few American citizen relatives to sponsor them, and workers in high demand by US employers.

These moves toward more liberal immigration policies in the United States are part of a broader international context with comparable patterns emerging in other countries. The policy of free movement of citizens in the European Common Market is the most striking example, but there are trends toward generous policies of admitting refugees and temporary workers in many parts of the world. There are even a few examples of more generous citizenship policies, but these are halting, often facing a domestic backlash from nationalist sentiments that have been weakened, but not disappeared.

More liberal immigration policies appear to be highly functional in modern industrial and post-industrial societies. Standard economic theory posits that domestic migration is a functional response to wage differentials between areas. Migration allows for workers to benefit from higher wages in growing areas and stimulates the economy to operate more efficiently by creating larger and more porous labor and consumer markets. Indeed the logic for lessening barriers to migration is similar to that of international free trade. Economic theory suggests that all countries benefit from the free flows of capital, goods, and technology across international borders. International migration is often excluded from discussions about expanding international trade (such as in the NAFTA debate), largely because of political considerations rather than economic theory.

Globalization is the most powerful trend in the world today. There are few places on Earth that are not exposed to the presence of the international forces of the mass media, multinational corporations, and Hollywood images. Every commodity from fresh food to electronic products moves around the globe in such profusion that most persons are unaware of the nationality of the producers of the goods (and services) they consume. Although international trade has always created competition between businesses and workers in different countries, the current era with instantaneous communication and cheap transportation has created a qualitatively new international community. In this setting, barriers to international labor mobility are an anachronism of the earlier era. Just as most countries, regardless of political ideology, have striven to make passport lines more efficient in recent times to encourage the very profitable tourist sector, it seems that most twenty-first century societies will ease immigration barriers in order to profit from the increasingly globalized world economy.

Imperialism, History of

1. Introduction: The Problem of a Definition

'Imperialism is not a word for scholars,' Sir Keith Hancock remarked a long time ago, and he was right (see Wesseling 1997, p. 74). Scholars have to make clear what they mean when they use certain concepts or terms, and therefore have to give definitions. This, however, is impossible with the word 'imperialism.' The problem is not that there are no definitions of imperialism, rather the contrary. There are about as many definitions of imperialism as there are authors who have written on the subject. They vary from those that refer to one specific form of imperialism, mostly Europe's nineteenth century colonial expansion, to others which give a very general meaning to the word, such as the one in Webster's Dictionary: 'any extension of power or authority or an advocacy of such extension.' Clearly, such a definition can cover almost any situation. Not surprisingly therefore, the word has often simply been used as an invective in order to criticize the policy of another country.

So defined, imperialism is useless as a scholarly concept. However, in serious studies, the word has always had a more limited meaning. The problem is exactly how limited its meaning should be. Sometimes the word is used in a universal historical way in order to characterize the politics of a dominant power. Thus, some historians have spoken of Roman or even Assyrian imperialism, but this is highly exceptional. In historical studies, imperialism generally refers to the policy of European countries, and primarily of the UK during the nineteenth and twentieth centuries, aiming at the expansion of their power and influence over other continents. It is in this context that the term imperialism originated and began to be used as a political and historical concept. Historically speaking, the word imperialism is therefore obviously closely associated with colonialism. While colonialism was only used to refer to one specific form of alien rule, namely the colonial one, imperialism acquired a wider meaning and included various other forms of influence over alien nations and states. For example, the financial influence of France and Germany in the Russian and Ottoman Empires, or such things as British 'gunboat policy' and American 'dollar diplomacy.'

After the end of the colonial empires the word 'colonialism' could only be used to refer to a phenomenon from the past and thus fell out of use. 'Imperialism' however continued to be used, and from then on also indicated those forms of domination that were formally different from, but factually comparable to, those formerly practiced by the colonial powers. For a while the word 'neocolonialism' was also used for this purpose, but somehow that term was less successful. By the end of the Second World War, America had become the new superpower. Accordingly, imperialism was now mainly applied to describe the foreign policy of the USA vis-à-vis other countries, in particular in Latin America, Asia, and Africa. There was also an attempt to make the concept applicable to the policy of the Soviet Union with regard to the Central and Eastern European countries that came under its influence after 1945 (Seton-Watson 1961), but this was not very successful. The reason for this is that historically speaking, imperialism has connotations with capitalism and not with communism, and with overseas possessions, and not with adjacent countries. Although there clearly was a Soviet Empire, it was not considered to be an example of imperialism but of traditional power politics. Only in its very general meaning as another word for all forms of power policies or simply as an invective, was it also used to describe communist countries such as the Soviet Union and China. After the end of the Cold War this use of the word imperialism lost much of its earlier attraction.

In this article imperialism is used in the sense of its initial meaning, that is to say as a term to indicate the extension of formal or informal, mostly European, rule over Asian and African countries in the late nineteenth and early twentieth centuries as well as, more generally, for some other forms of Western predominance during and after the colonial period.

2. *Imperialism: The History of a Concept*

Like 'colonialism,' which was probably first used in the title of a book of a French socialist critic of the phenomenon, Paul Louis' *Le Colonialisme* from 1905, 'imperialism' was originally a French word. It was from the 1830s onwards that the terms *impérialiste* and *impérialisme* came into use in France. They referred to the empire of Napoleon and to the imperial pretentions of his nephew Louis Napoleon, later known as Napoleon III. The colonial connotation only came after the word had begun to be used in the UK in the 1860s. Then, of course, the empire it referred to was no longer the continental one of France but the overseas empire of Great Britain (Koebner and Schmidt 1964).

Although the word imperialism was already used in the UK in the 1860s, the historical concept only appeared in 1902 with the publication of J. A. Hobson's *Imperialism. A Study* (Hobson 1938). Hobson, a radical but not a socialist, was deeply impressed by the South African War (1899–1902). In 1900 he published a book on this subject, *The War in South Africa. Its Causes and Effects*, in which he argued that power in South Africa had fallen into the hands of a small group of financiers 'chiefly German in origin and Jewish in race' (Hobson 1900, p. 189). In his famous book *Imperialism. A Study* he elaborated this vision into a general theory of imperialism, and used the term imperialism to indicate the 'expansion of Great Britain and of the chief continental Powers' (Hobson 1938, p. 27). The word expansion referred to the fact that over the previous thirty years a number of European nations, Great Britain first and foremost, had 'annexed or otherwise asserted political sway over vast portions of Africa and Asia, and over numerous islands in the Pacific and elsewhere' (Hobson 1938, p. 15). For Hobson the meaning of the word imperialism was very clear: it was the establishment of political control. He was also explicit about the forces behind it. Various people such as an 'ambitious statesman, a frontier soldier and an overzealous missionary' might play some role in it, 'but the final determination rests with the financial power' (Hobson 1938, p. 59). Thus Hobson offered us a definition (imperialism is the expansion of political power of European countries over the non-European world), a periodization (im perialism took place over the previous thirty years, thus between 1870 and 1900), and an explanation: it was the result of the workings of the financial powers. In order to explain their behavior, Hobson argued that, as a consequence of the capitalist system, the British economy suffered from underconsumption. As a result of this, surplus capital could no longer be invested profitably in England itself. Therefore, the capitalists were 'seeking foreign markets and foreign investments to take off the goods and capital they cannot sell or use at home' (Hobson 1938, p. 85).

As Hobson's theory implied a criticism of capitalism, it had a certain attraction for Marxist thinkers. As a result of this, a new Marxist theory of imperialism was born. While originally Marx and Engels had considered colonialism as an 'objective' progressive force (Avineri 1968), now Marxist theorists such as Karl Hilferding and Rosa Luxemburg scorned late nineteenth century imperialism as a form of exploitation and suppression. The Marxist theory of imperialism became very influential when it was appropriated by a man who was not only a theorist but also a practical politician, Lenin. In 1916 he published his famous brochure *Imperialism. The Highest Stage of Capitalism* (Lenin 1916).

Lenin's ideas were mostly based on the work of the previous-mentioned Marxist authors, who in turn had been inspired by Hobson's theory. It was therefore understandable that a direct link was seen between Hobson's and Lenin's theories, so much so that it became fashionable to speak of the 'Hobson–Lenin thesis.' There are, however, two important differences

between Hobson and Lenin. First, for Hobson the flight of capital from the metropolis to the overseas world was a consequence of the development of capitalism, but not a necessary consequence. The origin of the problem was underconsumption. Therefore, theoretically, it should also be possible to solve the problem by increasing the purchasing power of the working classes. Indeed, Hobson remarked: 'If the consuming public in this country [Great Britain] raised its standard of consumption to keep pace with every rise of productive powers, there could be no excess of goods or capital clamorous to use Imperialism in order to find markets' (Hobson 1938, p. 81).

Second, and more importantly, Hobson and Lenin tried to explain two different things. Hobson, who wrote his book during the South African War, wanted to explain the division of the world, and more specifically of Africa, in the late nineteenth century. Lenin, who wrote in 1916, tried to explain the redivision of the world of which the First World War was the most spectacular outcome. The word Africa hardly appears at all in Lenin's brochure. The period he referred to was also different from the one dealt with by Hobson: not 1870–1900 but thereafter. He wrote explicitly about this: 'I have tried to show in my pamphlet that it [imperialism] was born in 1898–1900, not earlier' (see Stokes 1969, p. 289). Thus Lenin parted ways with Kautsky and Luxemburg, for whom imperialism was little more than another word for colonialism (Stokes 1969, p. 297). For Lenin it was something else: not the highest stage of colonialism but of capitalism.

Although the capitalist theory of imperialism was not generally accepted, and alternative interpretations were launched and had some influence, some form of economic interpretation became the standard explanation of imperialism during the 1920s and 1930s. Imperialism was considered as having originated from economic problems in Europe that were characteristic of the late nineteenth century, in particular the need to guarantee the flow of raw materials to the industrialized countries, and the protection of overseas markets for the sale of their industrial products. This consensus broke down after the Second World War under the influence of decolonization and the rise of the American empire. The new world political situation also had an impact on the theory of imperialism. In a famous article, 'The Imperialism of Free Trade,' two Cambridge historians, Jack Gallagher and Ronald Robinson, developed the concept of 'informal empire' (Gallagher and Robinson 1953). They argued that the real zenith of the British Empire was not to be found in the late nineteenth century but rather in the mid-Victorian period of informal British economic hegemony. For Britain, the entire nineteenth century was one of expansion. It was an imperial century. Britain's imperial expansion manifested itself in various forms: emigration, trade, overseas investments, the establishment of naval bases, etc. The extension of political authority over foreign people was only one form of imperialism, and not even the most important one. The mid-Victorian empire was comparable to the informal American empire that came into being after 1945. It worked with informal means because that was the best way of doing things. The maxim of British policy makers was: informal empire if possible, formal only if necessary. Due to foreign competition and rivalry, however, the late Victorians were forced to formalize their Empire, and they did so, willy-nilly.

While Gallagher and Robinson discovered imperialism before empire, other theorists also discovered imperialism after empire. This resulted not so much from a reflection on the rise of the American empire, but from a reassessment of decolonization. While after the First World War the European powers had increased their territorial possessions—for example, by the division of parts of the Ottoman empire—and stabilized their colonial rule, the situation was very different after the Second World War. In Asia, the process of decolonization started immediately after the war and was followed later in Africa. Thus, in the 1960s, most of the former colonies had become independent politically. But political independence did not automatically bring an end to the social problems, nor to the economic dependency of the ex-colonies. Some of the new states became even more dependent on the Western-dominated world system than they had been before. For many observers it was clear that the end of empire was not at the same time also the end of imperialism. Some theorists worked this out in the theory of dependency. According to the *dependencianistas*, imperialism was not only the extension of political control, but it also included the dependency of less developed parts of the world on the industrial powers. Empire was only one form of imperialism, one stage in the history of Western dominance.

However, why one form of imperialism was replaced by another remained a question, an answer to which was also given by Gallagher and Robinson in their famous book on the partition of Africa: *Africa and the Victorians* (Gallagher and Robinson 1961). Here they argued that changes in the periphery, that is in the overseas world rather than in the mother countries, were responsible for the changes in the ways and means of imperialist control. Although *Africa and the Victorians* dealt primarily with British policy, the theories developed here had a wider meaning. While the theory of the imperialism of free trade was typically a theory about British imperialism, the peripheral theory was applicable to the imperialist activities of other nations as well. In many cases, changes in the non-Western world were decisive in determining imperialist action. Egypt's financial problems, for example, led to increasing foreign interference, and this, in turn, to a 'nationalistic,' or rather proto-nationalistic, reaction which plunged Egypt into an internal political crisis led again to foreign intervention and occupation. The discovery of minerals in South

Africa, to give another example, led to a complete change in the balance of power in that part of the continent.

Ronald Robinson later elaborated this interpretation into a more general theory based on the observation of the important role of the African and Asian partners of the imperialist rulers. In this so-called 'collaborationist theory,' imperialism is conceived of as a system of collaboration between European and non-European forces before, during, and after colonial rule. The changing forms of imperialism are considered as changing forms of collaboration that resulted from changes in the bargaining positions of the various parties (Robinson, in Owen and Sutcliffe 1972, pp. 117–42).

The Gallagher and Robinson theories were followed by a greater number of studies on the economic significance of the British Empire and the role of economic factors in British imperialism (Davis and Huttenback 1986, Cain and Hopkins 1993a, 1993b). The important place of Britain in the debate on imperialism is understandable, because Britain was the imperial power *par excellence*. But for that very reason Britain was not the most typical imperial power. Rather, it was atypical and therefore the discussions in other European countries on imperialism have followed different lines and focused on different questions. Chronologically speaking, however, the European revisionist theories were developed in the same years as the British: the debate started in the 1960s and continued well into the 1980s.

3. *National Articulations*

In France, Henri Brunschwig's *Mythes et Réalités de l'Impérialisme Colonial Français, 1871–1914*, which appeared in 1960, set the tone for the debate on French imperialism (Brunschwig 1960). According to Brunschwig, the causes of French imperialism were not to be found in economic demands but in the development of French nationalism after the defeat in the Franco-Prussian war of 1870. The protectionist factor was a myth, political factors were decisive. Given the specific intellectual climate that existed in France after the Second World War, and in which Marxism played such an important role, it was to be expected that Brunschwig's book would lead to great controversy, as it did. But the Marxists could hardly deny the fact that the French colonial empire had been of little economic importance in France. In order to rescue the Marxist theory of imperialism, they therefore argued that French imperialism was not to be found in the French colonies but elsewhere, in the Russian and Ottoman empires. They argued that French colonialism was not imperialist, and French imperialism not colonial (Bouvier and Girault 1976). In 1984, an important study by Jacques Marseille, based on an extensive data bank on French colonial trade, threw new light on the question of economic interest. His conclusion was that in the beginning the colonies were useful to French industry from an economic point of view, but subsequently they became a burden (Marseille 1984).

There was also a strong connection between imperialism and nationalism, but it is not altogether clear to what extent imperialism was a result of nationalism. This is because the decision to found a German colonial empire was very much the decision of one man, Chancellor Bismarck. Therefore, in Germany, the discussion on imperialism has always been concentrated on Bismarck and his motives. There were two main interpretations, a foreign political one (imperialism as a move in Germany's international relations) and one in terms of domestic policy, like electoral success, financial pressure groups, etc. The discussion was reopened when H.-U. Wehler (1969) added new elements to this debate. Although he stressed the economic background of imperialism, he agreed that, as in the case of France, the German colonial empire had not been very profitable. In his view, the link between economics and empire must be sought on a different level. He emphasized the social problems of the *Reich* (its lack of legitimation because of its creation *von oben*, by force) and considered Bismarck's bid for colonies as a shrewd political move intended both as part of a general, more-or-less anti-cyclical, economic policy, and of a social policy seeking to unite the Germans around issues of foreign policy, and thus to overcome internal tensions. Thus Wehler's emphasis was more on the domestic than on the diplomatic motives of German imperialism under Bismarck (Wehler 1969). Here, the debate on German imperialism touched upon a wider discussion, the one on the problem of continuity and discontinuity in German foreign policy, the so-called German *Sonderweg*, and the place of national socialism in German history.

Italian imperialism was also studied from a special perspective. It was not very successful during the classical period of imperialism but it continued during the interwar years, under the influence of fascism. The French historian Jean-Louis Miège has emphasized not only the demographic factor in Italian imperialism, but also its political and ideological dimensions—the nationalistic reaction to the loss of population as a consequence of emigration—comparing it in this respect to Spanish imperialism (Miège 1968). The interpretation of Portuguese imperialism was long dominated by Hammond's theory of an 'uneconomic,' that is to say a primarily nationalistic, form of imperialism. Gervase Clarence-Smith later challenged this view by making a strong case for an economic interpretation of Portuguese imperialism. He argued that economic motives went hand in hand with other ones such as missionary zeal, nationalism, and others (Clarence-Smith 1985).

The case of Belgium is very special, because in the nineteenth century, Belgium was an anticolonialist country, but in spite of this, it was eventually to acquire one of the biggest European colonies in Africa, the Belgian Congo (later called Zaire, now Congo again). That this happened was due to the extraordinary zeal, tenacity, ruse, and ruthlessness of one man, King Leopold II. Jean Stengers has analyzed the singular nature of the king's imperialism which was one of old-fashioned economic exploitation and in this respect inspired by the example of The Netherlands (Stengers, in Owen and Sutcliffe 1972, pp. 248–76).

In the Netherlands the historical discussion on imperialism began rather late. The most important contribution to the debate came from a book by Maarten Kuitenbrouwer (Kuitenbrouwer 1991). In this he argued that the Dutch case was roughly analogous to others, and that the Netherlands followed more or less the general pattern. It has also been noted, however, that Dutch imperialism was defensive rather than offensive, reluctant rather than enthusiastic. In this respect it was comparable to that of Britain. In both cases there was more continuity than discontinuity, and what discontinuity there was, derived from a change in circumstances, not in policy (Wesseling 1997).

The historical debate on imperialism was mainly about the traditional colonial powers of Western Europe but observations have also been made about other countries. Russian imperialism poses interesting questions and offers paradoxical aspects because, on the one hand, Russia was an object of Western European financial imperialism, but on the other it was itself also acting as an expansionist power by extending its empire to the East and eventually to the shores of the Pacific (Geyer 1977, Le Donne 1997). The case of Japan is particularly interesting, because it is the only Asian nation which became an imperial power. Like other Asian countries it was first confronted with Western influence but it reacted in a very different way to this challenge. After having been forced to 'open' the country in 1853, it accepted Western notions and techniques very rapidly, so much so that already by the 1890s it had started its expansion into China. Japanese imperialism was continued in the 1930s and of course during the Second World War. Some analysts have also considered Japan's economic expansion after 1945 as a form of informal imperialism (Mommsen and Osterhammel, 1986, pp. 53–82).

The concept of American imperialism is a very complicated one. Of course America has been considered as the main imperialist power since 1945, but how this was related to its earlier expansion is unclear. While some authors consider the Russian expansion to the East as a form of imperialism, the American conquest of the West has hardly ever been interpreted in this way. Traditionally, one has observed that American imperialism only came about at the turn of the twentieth century, with the Spanish–American war of 1898 and the American take-over of Cuba and the Philippines from Spain.

3.1 *Explanation: Motives and Means*

The rich literature on imperialism that has been published from the 1960s onwards has led to a revision of the traditional views on the origins and meaning of late nineteenth century imperialism. Transformations in Europe, but also in the overseas world, have received attention as factors that can explain the new imperialist attitude. The main distinction is between European interpretations on the one hand, which underline economic, political, strategic, and ideological motives, and peripheral interpretations which give special attention to activities and developments in the overseas world and in particular to the 'frontiers' of European influence. The new research has also given attention to such topics as the ecological aspects of imperialism (Crosby 1986), cultural imperialism (Said 1978, 1993), the impact of imperialism on the sciences (Petitjean et al. 1992), etc.

Much of the debate on imperialism concerned the motives of the imperialists. In order to understand the origins of imperialism, however, attention has also to be given to another aspect, not the motives but the means. The development of imperialism cannot be understood by looking only at transformations in Europe and the overseas world, and the incentives for imperialist actions that were created by these. What also was necessary for such action was the disposal of the necessary means (Headrick 1981, 1988). It had always been virtually impossible for Europeans to survive in the environmental conditions of tropical Africa. New developments in the medical sciences, such as the prophylactic use of quinine (as from the 1840s), made it possible for Europeans not only to live, but also to work and even to fight under such conditions. The development of new means of transportation (steamships, railways), the opening of new sea routes (like the one via the Suez Canal), the revolution in the means of communication (the telegraph, and later on the telephone and wireless communication) made the extension of imperial rule possible. Finally, but perhaps most importantly, the development of new weapons, and in particular of the machine gun, gave the Europeans an enormous advantage in their battles with non-European nations. Colonial wars became successful almost by definition and the European colonial armies became 'ever victorious' armies. Entire continents could be conquered at very small cost to the conquerors.

Thus the great technological superiority of the Europeans came into existence during the latter part of the nineteenth century due to the so-called Second Industrial Revolution which took place in Western

Europe and created rivals for British trade. These technological transformations not only offered the means for imperial expansion, but also led to new demands in the European societies which had their effects on foreign and colonial policy. Social and economic questions assumed increasing importance. State welfare provisions expanded. The import of tropical products at affordable prices was considered as a matter of public concern. This called for sustained economic exploitation which presupposed the existence of peace and order; in other words, effective authority.

The balance of power in Europe also changed dramatically in the 1870s. In the early nineteenth century, from Napoleon to Bismarck, Europe had found itself in an exceptional political situation. Germany and Italy did not yet exist. Britain had eliminated France as a maritime and colonial rival. Spain, Portugal, and the Netherlands, the old colonial powers, had had their day. Hence, Britain enjoyed *de facto* world supremacy, much as the USA was to do after the Second World War. All these factors were swept away in the 1870s. After its defeat in 1870, France sought compensation for its loss as a continental power by strengthening its overseas role. Germany and Italy, newcomers both, claimed a place under the sun.

Internal political factors also played a part. European governments were faced with a new phenomenon: they had to take the wishes of their electorate into account. Economic growth and social harmony became declared objectives of government policy. The Paris Commune of 1871 accentuated the danger of social revolution and hence the importance of social issues. The state was asked to do more things for more people. Conversely, technical progress, economic growth, and growing political involvement by the citizens of Europe created the conditions for a strong state. The military might of the European powers reached unprecedented heights. At the same time in the overseas world, transformations took place which often proceeded from previous contacts with Europe or European settlers, and which changed the existing internal balance of power. Thus in many respects a new situation came into being after 1870, in Europe as well as in the overseas world, and therefore, after all forms of revisionism, it is still justified to speak of the period of 1870–1914 as an age of imperialism, as Hobson did when he introduced the concept about a century ago.

Imperialism: Political Aspects

Imperialism is a form of international hierarchy in which one political unit, or polity, effectively governs or controls another polity. It is one of the oldest known political institutions, characterizing relations between peoples in ancient Mesopotamia, China, and Rome through modern Europe. It includes both rule within relatively contiguous areas—as in the Habsburg and Ottoman Empires—and the overseas colonies held by various European states after the age of discovery.

The term has a long and tortured history. It was apparently first used as an invective against the expansionist policies of Napoleon I, and has been employed most frequently to refer to the colonial practices of the European states in the late nineteenth and early twentieth centuries, attempts to revise the international territorial status quo, and the economic domination of one country by another (also referred to as 'neo-colonialism,' see below). Used as a tool of political rhetoric, the term is highly malleable and often devoid of any general meaning.

As an analytic concept, imperialism refers to the effective domination of one political community by another. According to Michael Doyle (1986, p. 19), '(e)mpires are relationships of political control imposed by some political societies over the effective sovereignty of other political societies … . Imperialism is the process of establishing and maintaining an empire.' By domination we mean the ability of the dominant polity, the metropole, to decide policy for the subordinate policy, the colony. This ability may entail substantial delegation of decision-making authority to elite members of the colony, but the metropole retains the power to decide what gets delegated and how, and when this authority is revoked.

Three corollaries are important. First, imperialism occurs only where distinct political communities exist. Subordinate communities may have a prior history of independence or a new political consciousness may emerge that creates a relationship of imperialism. Without the possession of a distinct political identity, however, class conflict or unequal political opportunities may exist but not imperialism. Second, the colony lacks an international political 'personality'; that is, while it possesses an identity as a distinct polity, it does not interact with other states as a sovereign equal. Finally, exploitation of the weak by the strong is not essential to imperialism, but it is an often natural outgrowth of effective domination. The affinity between domination and exploitation explains the typically pejorative status of the term.

Imperialism is an extreme form of international hierarchy in which the colony is, in principle, a subject of the dominant state. If imperialism forms one end of a continuum of international hierarchies, and 'anarchic' relations between sovereign equals forms the other, we can identity a range of increasingly hierarchical relationships. In spheres-of-influence, the subordinate members remain independent but are constrained by dominant powers from forming relationships such as alliances with other great powers. Latin America under the Monroe doctrine is a classic example. In protectorates, subordinate states yield control over their foreign and defense policies to dominant powers; although subordinates remain independent, they transfer control over specific areas of policy to other states. With continuing responsibility for their defense, the United States today retains protectorates over the Federated States of Micronesia and the Republic of the Marshall Islands. In informal empires, subordinates are subject to imperial states across wide ranges of policy but retain their international personalities and interact with third parties on the basis of sovereign equality. Eastern Europe under the Soviet Union is a particularly clear example. Protectorates and informal empires are often grouped with formal empires as forms of imperialism.

Neocolonialism is a hierarchy produced through the functioning of an impersonal international market. In this variant, the dominant state need not intend to control the subordinate but the latter is sufficiently dependent upon the former economically that it has little choice other than to comply with (and even anticipate) the metropole's desires. In this case, economic dependence produces political dominance—the core of imperialism—but the mechanism of control is indirect. For some, this is a virulent form of modern imperialism. For others, the absence of intent negates the political relationship. Neocolonialism remains a contested concept.

1. *Theories of Imperialism*

The major explanations for imperialism can be grouped into three general categories. Metrocentric theories focus on the dispositions or internal charac-

teristics of imperial states. Writing in 1902 (1965), for instance, John Hobson grounded the motivation for overseas expansion in the necessity for advanced capitalist states to export their surplus capital. This theme was later the foundation for V. I. Lenin's famous monograph, *Imperialism: The Highest Stage of Capitalism*, first published in 1917. Neo-Marxists later argued that the military–industrial complex and other features of capitalist states actually created a need for capital, leading states to create colonial and neocolonial relations with developing regions in order to extract wealth (see Magdoff 1969).

Pericentric theories emphasize conditions within the colonial polities. Where metrocentric theories focus on the push behind expansion, pericentric theories draw attention to the forces that pull imperialists into hierarchical relationships. John Gallagher and Ronald Robinson's *The Imperialism of Free Trade* (1953) set the direction for much research in this tradition. Positing a constant drive for domination and a preference for indirect rule wherever possible, Gallagher and Robinson explained variations in imperialist outcomes by conditions in the periphery. In particular, where peripheral polities possessed stable regimes and effective collaborators, they argued, imperialists could govern indirectly through informal empires. Only where the peripheral societies were unstable politically or lacked elites willing to protect their interests would metropoles be forced to create formal empires and govern directly. As it was effectively ruled by landed interests tied to the British market, in their view, Argentina escaped the need for recolonization but was nonetheless caught within Britain's free trade web. Later work on neocolonialism further developed these insights.

Systemic theories of imperialism, typically part of larger realist theories of international relations, highlight competition between the great powers (see Cohen 1973). The struggle for survival and influence between great powers creates an ever widening gyre of competition, in this perspective, that both leads metropoles to seize territories to augment their resources and allows them to compensate one another using peripheral territories to maintain an effective balance of power. The classic case of imperialism driven by systemic competition was the so-called race for Africa in the late nineteenth century.

The best explanations of imperialism have always combined ideas from more than one of these traditions. Even Hobson and Gallagher and Robinson, for instance, augmented their theories with a focus on systemic competition, which they both saw as accentuating the metropolitan or peripheral causes of imperialism. More recently, synthetic works integrating all three approaches have appeared that provide relatively complete explanations of imperialism (see Doyle 1986 Smith 1981). Although different authors emphasize different dimensions and different episodes, any single instance of imperialism carries traces of all three sets of factors. The 'state-of-the-art,' therefore, recognizes and builds upon metrocentric, pericentric, and systemic insights.

A fourth, nascent explanation is also being developed that draws upon neo-institutionalist theory, and especially theories of relational contracting as developed in economics. In this approach, imperialism is understood as simply another form of organizational hierarchy. Emphasis is placed on explaining why hierarchy, in general, and this form, in particular, is superior for obtaining the goals of the actors rather than alternative institutions, such as confederations, protectorates, and state-to-state relations. Three considerations are central. First, the larger the benefits from pooling resources and efforts between the units, in this case the metropole and colony, the more risks or costs the units are willing to accept in building a relationship. Second, the greater the expected costs of opportunistic behavior by the subordinate polity, the more important it is to the dominant state to control the actions of its partner. Especially significant here are assets that are specific to the two parties and which would be costly to the metropole if they were withdrawn. In the absence of some specific assets, we would expect an 'arms-length' relationship between independent units, as the benefits of cooperation could then be captured through market exchange. Only where there are substantial assets that are specific to the two parties is imperialism necessary. Finally, there are costs to governing any relationship, and these are likely to escalate with greater hierarchy. Imperialism is typically costly both for the colony, which gives up valued freedom, and for the metropole, which must either bind its own hands to limit its ability to exploit its partner or use coercion to impose its rule. Thus, states avoid empire if control is either unnecessary or can be achieved in some less hierarchical fashion. In this approach, empire is most likely when there are large benefits from pooling resources between the units, highly specific assets at risk, and the costs of governance do not rise sharply with greater hierarchy.

Employing this approach in the case of classic imperialism, Jeffry Frieden (1994) argues that formal empires arose in the age of plantation agriculture and raw materials extraction as a means of preventing local elites from appropriating site specific assets in production: once foreign investors opened a copper mine, for instance, this site specific asset was then subject to expropriation by the local government. Knowing this, foreigners would not invest in such assets without the control made possible by the formal empire. As multinational corporations have increasingly taken the place of agricultural or raw materials investors, Frieden continues, formal empires have become obsolete. Multinational corporations possess firm specific assets such as technology or brand names that cannot be easily appropriated by host governments; a government can seize an axle assembly plant, for example, but it is of little value without access to

the multinational's worldwide production and marketing network. Thus, formal empire is less necessary to protect corporate assets. David A. Lake (1996) has applied similar arguments to the case of hierarchies motivated by national security needs. In its emphasis on comparative institutions, this approach brings an additional dimension to the study of empires.

2. *The End of Empire?*

Decolonization was one of the most significant events in modern world history. At the dawn of the twentieth century, most of the globe was ruled from Europe. By 1963, the overseas empires had seemingly evaporated. The strong norm against imperialism as affirmed in numerous United Nations declarations strongly suggests that the age of empire is over. Its imprint endures, however. In the periphery, imperial rule destroyed local structures of governance. In some areas, such as India, the foundations of parliamentary rule were erected in their place. In other regions, especially Africa, only weak state structures existed when independence arrived, producing political instability and continuing impediments to economic progress (see Jackson 1990). In the imperial states themselves, political elites underwent a wrenching process of accommodation to their now diminished international political and economic status (see Kahler 1984).

Although scholarly interest waned with decolonization, imperialism nonetheless remains a vibrant issue in the contemporary world. Weakly institutionalized groups within multinational states, such as the Chechens in Russia or the Tibetans in China, are pressing demands for independence, declaring in words and actions that the states within which they are embedded are empires. Other groups are rediscovering nationalist identities, like the Scots in Great Britain, and asserting new political rights—transforming intrastate politics into imperial politics. Even as the overseas empires have ended, a new age of imperial struggle is emerging.

This new age will be politically more complex than the old. The principle of national self-determination, articulated by President Woodrow Wilson at the Versailles peace conference, could be easily employed in the fight against overseas empires. Today, this principle directly contradicts contemporary notions of sovereignty as an inviolable whole. As demonstrated in the recent NATO intervention in Kosovo, Western nations abhor the political domination of the local Albanians by their Serb rulers but they cannot condone and even less promote the breakup of a sovereign state. As both old and new imperial relationships within multinational states become contested, politicians and analysts alike will need to rethink issues of political identity, statehood, and empire—and perhaps experiment with new forms of political hierarchy.

Implementation: Political

Implementation studies are inevitably normative. In 1973, the field was created virtually overnight by Jeffery Pressman, and Aaron Wildavsky, in whose book 'Implementation' the guiding research questions were: 'how well was this authoritative mandate (law, regulation, program, official policy pronouncement) implemented?' and 'how might it have been better implemented?' Later researchers redefined the normative standard as achieving the values implicit in some mandate rather than in executing its prescriptive details. Then the guiding question became: 'how can a complex implementation process bring out the values implicit in, or improve upon the raw materials provided by, some authoritative mandate?' Such normative questions have provided an intellectual focus for a field unified by little else.

1. 'Implementation' Defined

For simplicity, I restrict discussion to legislative mandates. The raw materials are typically: (a) a legislative mandate; (b) some new budgetary resources and; (c) a designated responsible agency. In most circumstances these three assets are not enough. Other resources are needed. Mandates defining regulatory programs will often require compliance resources from businesses or ordinary citizens. Service-delivery programs will often need participation from citizens who perceive the availability of the program, are willing to make the effort to establish eligibility, and can manage to sustain continued participation. The responsible agency may also wish to involve relevant nonprofit agencies. Other program agencies with overlapping jurisdictions or responsibilities must sometimes be asked to cooperate. Overhead agencies must supply permission to recruit personnel, lease office space, enter into contracts, and so on. 'Implementation' is therefore a process of constructing an operational program out of both newly mandated and extant resources. 'Successful' implementation means that the result is at least minimally cost-effective and is produced without unacceptable delay.

2. Explaining Success and Failure

The early implementation literature, inspired by the troubles of Great Society programs, was focused on documenting and explaining implementation failure. The (partial) subtitle of 'Implementation' was '*How Great Expectations in Washington Are Dashed in Oakland; Or, Why It's Amazing that Federal Programs Work at All* …' The principal explanatory framework in the early literature highlighted the institutions and practices of American pluralist and federalist democracy that were unfriendly to implementation, e.g., the susceptibility of programs to continuing political conflict over their goals and resources, weak or nonexistent interagency and interjurisdictional coordinating systems, and cumbersome accountability procedures and heavy-handed overhead agencies. In this world of fragmented political power, the many resources required for program construction are controlled by different actors—from front-line regulatory enforcers and service professionals to personnel officials writing civil service job descriptions—with only partially overlapping interests and with highly variable abilities and motivations to induce cooperation among one another (Nakamura and Smallwood 1980). Furthermore, these actors normally—and often quite properly—have different priorities from those of the advocates for the new mandate. They have ongoing responsibilities, after all, some of which are poorly fulfilled as it is, given normal governmental resource constraints.

Consider these institutional problems in system terms. Constructing a complex operational system out of many, varied, and interdependent elements is vulnerable to failure from many quarters. Bureaucratic resistance, prolonged bargaining, political sabotage, weak technical capacity, and a host of other conditions could affect many of these elements (Bardach 1977). Failure seems overdetermined. Yet failure appears to be much less frequent than this model suggests. The model omits the possibility of adaptation, i.e., strategically sacrificing controversial or overly ambitious goals and creatively improvising with respect to means. It also omits momentum, the fact that success with respect to securing one system element helps to beget success with respect to others.

The capacity to plan and execute effective adaptation and momentum-building strategies often takes the form of committed political leaders, entrepreneurial program managers, clever legislative staff and their principals, and the like. This, at least, is the impression conveyed by many of the case-study reports of successful implementation. Although lacking a methodological and theoretical rationale, such case studies may nevertheless have illuminated an important phenomenon. The current theoretical challenge of greatest significance is to explicate the process of adaptation and to identify factors that increase the likelihood of success or failure. The corresponding empirical challenge is to identify the conditions under which skilled adaptive leadership is drawn into certain implementation processes but not into others.

3. Design Failures and Implementation Failures

The early literature usefully distinguished failures of implementation from three common design-stage mistakes that simply show up during the course of implementation and which might have been aggravated (or occasionally ameliorated) by the implementation process. First, design-stage expectations are usually too high. To survive the legislative process, a policy or program mandate will often have had its merits oversold and its limitations understated. Second, designers sometimes commit fundamental conceptual errors, e.g., supposing that price controls in competitive markets can be implemented without causing shortages. Third, they may choose an inappropriate policy instrument. Arguably, the programs studied by Pressman and Widavsky, concerning the subsidized creation of low-skill jobs in a poor city, represented failures of instrument selection. The chosen instrument was a subsidy to firms promising to hire from a general target population. With no easy way to enforce the promises, however, the implementing agency probed the prospective employer firm for months on end, trying to clarify what might count as a legitimate excuse for underperformance and trying to test the firm's good faith and resolve. A much better choice of instruments would have been an *ex-post-facto* wage subsidy for workers actually hired.

4. The Characteristics of Generic Governmental Instruments

In the literature 'implementation problems' also include those that beset most operational governmental programs. Although the early implementation literature focused on 'control' problems, the focus is now broader, encompassing the standard problems of public administration and public management, e.g., how to recruit good personnel and motivate quality performance, how to keep a focus on results rather than on personal or careerist objectives or simply on following procedures and staying out of trouble, how to protect the program from ideological opponents in the legislature or within the cadre of higher-level political appointees, how to build trust and communications channels within and across agencies, and how to create a culture of continuous improvement. The 'reinventing government' movement has been a modest source of ideas and inspiration about how to cope with general management problems.

But the distinctive contribution of implementation research regarding such problems has been to analyze the forms they take when expressed in generic governmental instruments (Salomon 1989). Two of the most important of these are regulation (e.g., sanitary code enforcement and electric utility rate-setting) and pure service-delivery (e.g., employment and training) either directly or through provider subsidies.

4.1 Regulation

Command-and-control (or 'social') regulation is typically a response to information failures—regarding unsafe bus maintenance, say, or filth in restaurant kitchens—which prevent consumers or employees from protecting themselves through either market action or the threat of lawsuits. Command-and-control programs typically have three main components: a set of standards, a cadre of inspectors and auditors to detect noncompliance, and a set of sanctions with which to threaten noncompliant firms or citizens. This sort of regulation is vulnerable to errors of under-regulation or over-regulation or to both simultaneously. Political pressures and scientific uncertainty can lead to overly stringent or overly lax standards. Standards can also be too prescriptive or too ambiguous. The enforcement process is vulnerable to budgetary strictures, over-concentration on symbolic targets, go-by-the-book rigidity, and in some cases corruption.

Economic regulation includes natural monopolies such as local telephone service and (former) oligopolies such as long-distance freight hauling. Most scholars observe that the regulators tend to get 'captured' by the more powerful firms within the regulated industry. Arguably, the regulators are as much captured by a sense of responsibility for the economic well-being of the industry they regulate, however, and allow 'well-being' to be interpreted through the self-interested lenses of the major firms.

Technological change and more realistic economic analysis have undermined the rationale for much traditional economic regulation, and many regulatory activities, along with a few agencies, have been abolished. A new addition, however, has been environmental regulation. Although it often uses command-and-control methods, it also counts as 'economic' regulation because implementers are concerned with how their decisions on standards and enforcement actions affect interfirm, interindustry, and inter-regional competitive balances.

4.2 Service Delivery

The chief implementation challenge in service delivery programs is preventing inequitable distribution to constituencies favored by politics or by the preferences of service professionals. Middle-class neighborhoods, for instance, tend to attract better teachers to their schools for both reasons. A second challenge is keeping service quality at a high level while being unable to rely on traditional market-based incentives such as the threat of consumer exit.

When government uses subsidies to enlist private providers, such as hospitals treating Medicaid patients or nonprofit organizations to provide vocational training, it typically relies on regulations and audits to attempt to ensure that the providers are targeting their services correctly, maintaining a minimal acceptable quality, and not engaging in fraud or abuse. Many of the problems of command-and-control regulation are thereby imported into service delivery programs.

Service programs aimed at 'deviant' populations such as drug abusers, criminal offenders, the mentally ill, and welfare recipients typically have a regulatory, paternalistic component as well as a pure service component. Implementing personnel usually have considerable discretion over how to balance the two components. Large-scale ideological trends, and more immediate political pressures, also affect the balance.

5. The Practitioner's View of Implementation

Because implementation studies are normative, their results can be helpful in guiding practice. The literature advises policy designers to: (a) 'map' the functional requirements of a projected operational system and how they are each to be obtained (Elmore 1979); (b) write 'scenarios' regarding possible implementation pitfalls en route to such a system; and (c) estimate the probability of 'compliance from target groups' whose cooperation is needed for critical tasks (Mazmanian and Sabatier 1983). Designers can also consider

institutional solutions, e.g., contracting with an organization in the private sector to take on the responsibility of starting and running a new AIDS clinic or building and operating a new jail.

Implementers can also view the experience of operational implementation, whether successful or otherwise, as a way to improve long-run policy design and to create a mandate of sorts for what they are doing. Consider some program domain such as welfare-to-work, and construe all the 'implementers,' from the Secretary of Health and Human Services, through the state and county senior managers, down to the lowest level case workers as a sort of network through which ideas and effort can flow and can become organized. These ideas concern both policy design and the choice of implementation instruments. From the mid-1980s through the mid-1990s, this network produced a good deal of lore, and a bit of experimental evidence, that a more work-oriented welfare policy might be effective and would not be unduly harmful to the poor. Counter-claims were also produced. But in the end, the experience of many implementers combined with conservative Republican political leadership and very widespread support in public opinion created the federal welfare reform legislation of 1996. The preferred implementation instruments were a high degree of devolution to the states with regard to means but rather sharp financial incentives to compel adherence to federal government objectives. Deficiencies in the legislation will no doubt be brought to light in the course of implementation and further change will occur.

In some sense, then, 'the policy system is learning,' or 'evolving,' and the implementation process is a part of that system (Goggin et al. 1990, Majone and Wildavsky 1979). To be sure, 'learning' and 'evolving' are implicitly favorable ways to characterize a policy change. Many observers would object to this characterization of welfare reform. But eschewing value-laden language altogether would denature a phenomenon like implementation, which is so intimately connected to democratic policy choice and to the challenges of creating public value for the citizenry.

Implicit Learning and Memory: Psychological and Neural Aspects

Learning is the acquisition of new information that leads to lasting changes in behavior, and memory reflects the storage and retrieval of learned information. Implicit learning and implicit memory refer to instances in which acquisition, storage, and retrieval of learned information proceed without the person's awareness that they are learning or remembering. For example, how many times must you turn an automobile's steering wheel to smoothly execute a right turn? This is a difficult question to answer explicitly, yet we skillfully make many such turns each day. At some level we have learned the information and we use it each time we drive. However, skills, such as driving, rely primarily on implicit forms of learning and memory. Few of us intentionally learn the requisite number of steering wheel turns—we simply acquire the skill through practice. Rarely do we consciously reflect upon the information that is controlling our steering movements—we perform them automatically without awareness. The present review focuses on laboratory studies of implicit learning and memory that have provided a foundation for understanding the nature of the underlying psychological and neural processes.

1. Implicit Memory

'Implicit memory is revealed when previous experiences facilitate performance on a task that does not require conscious or intentional recollection of those experiences,' Schacter (1987, p. 501). By contrast, explicit memory 'is revealed when performance on a task requires conscious recollection of previous experiences.' Implicit memory subsumes various different types of phenomena, and we do not attempt to comprehensively review all of them here (for review and discussion, see Roediger and McDermott 1993, Schacter and Buckner 1998). Instead, we focus on a type of implicit memory known as priming. Priming

refers to a change in the ability to identify or produce an item as a result of a particular prior encounter with the item. Priming is assessed with tests in which subjects attempt to identify briefly flashed stimuli, complete word stems or fragments, with the first word that comes to mind, or produce items from a category in response to a category cue. In stem-completion priming, for example, after recently reading a list of words that included 'COFFEE,' people are more likely to complete 'COF—' with 'COFFEE' than with an alternative (e.g., COFFIN). Priming can be implicit because it can occur without the ability to remember explicitly that 'COFFEE' was on the original list.

Scientific interest in priming was piqued by the discovery of fundamental differences between priming and explicit memory. Psychological research established that explicit memory typically depends upon learning and remembering semantic information (i.e., information about meaning). If you forget to bring your grocery list to the market, you would be likely to remember 'COFFEE' in terms of its semantic associations: a morning drink, helps you stay awake, and so forth. You would be much less likely to remember 'COFFEE' from superficial perceptual characteristics, such as the spelling or sound of the word, the appearance of the word on the written list, and the like. Unlike explicit memory, many instances of priming depend greatly upon memory for such perceptual characteristics (Curran and Schacter 1996). In addition to such psychological differences between priming and explicit memory, differences in the underlying brain systems were indicated from studies of people with brain injuries (Squire and Knowlton 2000). A variety of studies have shown that amnesic patients with damage to medial temporal and diencephalic brain regions, and severe deficits in explicit memory, nonetheless often show normal priming effects. Intact priming in amnesia has been shown for a variety of stimuli, including visual and auditory words, nonsense words (e.g., TARB), pictures, and novel objects (Schacter and Buckner 1998, Squire and Knowlton 2000).

Recognition that priming relied on perceptual information and brain systems distinct from those supporting explicit memory lead to the hypothesis that priming depends upon brain regions that normally support perceptual functions. Several neuroimaging studies, using positron emission tomography (PET) and functional magnetic resonance imaging (fMRI), have shown that perceptually based visual priming is accompanied by reduced activity in posterior cortical brain regions that have previously been implicated in visual word and object processing (Schacter and Buckner 1998). Complementary studies have shown that perceptual priming is absent in patients with damage to the visual cortex (Gabrieli 1998). Thus, the neuroimaging and neuropsychological data converge on the conclusion that visual cortical regions play an important role in perceptually based priming effects.

Even before recent neuroimaging and neuropsychological research began delineating the brain systems underlying perceptual priming, psychologists began to appreciate that not all forms of implicit memory are perceptually dependent (reviewed by Roediger and McDermott 1993). Whereas perceptual priming tests typically provide subjects with information that is perceptually related to the to-be-remembered item (e.g., word stems), 'conceptual priming' can be demonstrated when conceptually (i.e., semantically) related cues are provided (e.g., 'DRINK —?,' 'TEA—?,' or 'Grown in South America?' for 'COFFEE'). Delineating psychological differences between conceptual priming and explicit memory has been difficult because they share many features, but the underlying neural substrates have been dissociated. As with perceptual priming, amnesic patients with explicit memory deficits can show normal conceptual priming effects (Schacter and Buckner 1998, Squire and Knowlton 2000). Neuroimaging studies indicate that conceptually based priming effects are accompanied by reduced activity in the prefrontal cortex (Schacter and Buckner 1998). These priming-related brain regions are also implicated in a wider variety of semantic information processing functions (e.g., understand the meaning of words). Thus, the same brain areas that normally allow us to process semantic information appear to support conceptual implicit memory.

In addition to providing neuroanatomical localization, neuroimaging studies of priming can potentially elucidate the nature of the underlying processes. Most priming studies indicate that activity levels are higher when relevant brain regions process unprimed rather than primed stimuli. Such 'priming attenuation' may indicate that primed information is processed more efficiently than unprimed information (analogously, priming an engine makes it start more easily). Conversely, other studies have found higher levels of brain activity for primed than unprimed information. Such 'priming enhancement' may reflect the formation of new perceptual representations for primed information. Recent work has indicated that attenuation is observed for stimuli that are previously known to subjects (e.g., famous faces, familiar symbols, words), but enhancement is observed for previously unknown stimuli (e.g., unfamiliar faces, unfamiliar symbols, novel objects). Thus, the mechanisms underlying priming effects may fundamentally differ according to the nature of the to-be-remembered information. Efficient processing may prime familiar stimuli, whereas the establishment of new perceptual representations may prime unfamiliar stimuli (Henson et al. 2000).

2. *Implicit Learning*

Reber first coined the term 'implicit learning' to describe the ability to learn complex information in the absence of awareness (reviewed by Reber 1993). In

contrast to implicit memory, which primarily emphasizes limited awareness and/or intention during retrieval, implicit learning primarily emphasizes limited awareness/intention during encoding (Stadler and Frensch 1997). Reber developed an artificial grammar-learning task in which subjects are exposed to seemingly random consonant strings that, unbeknownst to them, were generated from a complex set of rules (an 'artificial grammar'). After viewing a list of grammatical stimuli (e.g., XRNRTV, FRNRTZ, etc.), subjects are able to discriminate between grammatical and nongrammatical strings despite their limited ability to articulate the information upon which their judgments are based.

Reber originally believed that subjects in an artificial grammar-learning experiment develop an abstract mental representation of the rules that comprise the grammar (e.g., the second and fourth letters are always the same). In contrast, episodic theories maintain that subjects learn by storing individual exemplars (e.g., XRNRTV, FRNRTZ, etc.). Episodic theories can account for subjects' abilities to correctly classify grammatical strings that they have never seen before by positing that judgments are based on the global similarity between the test item and stored exemplars. For example, one could categorize *F*RNRT*V* and *X*RNRT*Z* as grammatical because of their similarity to the previously stored exemplars (*X*RNRT*V*, *F*RNRT*Z*). Grammatical test items will tend to be more similar to encoded exemplars than nongrammatical items, so subjects will be more likely to classify grammatical items accordingly.

The debate over abstractionist and episodic theories will not be settled here (reviewed by Neal and Hesketh 1997), but one possible resolution is that implicit learning leads to abstract representation whereas explicit learning results in exemplar storage. This possibility has been addressed by studying implicit learning in amnesic patients. Amnesic patients can learn to make grammaticality judgments as accurately as control subjects, despite their impaired explicit memory for studied exemplars (Squire and Knowlton 2000). Exemplar-specific implicit learning was inferred from amnesic patients' normal sensitivity to the frequency of letter bi-grams (e.g., NR) and tri-grams (e.g., NRT) that were in the original training set (e.g., XRNRTV, FRNRTZ). Abstract implicit learning was inferred from amnesic patients' normal ability to transfer learning across physical changes in the letters entered into the grammar (though letter-set transfer is not universally agreed to demand an abstract representation, Neal and Hesketh 1997). For example, the grammar could be modified to shift each letter two positions back within the alphabet (e.g., compare VPLPRT and DPLPRX with the original examples). As a whole, these results suggest that implicit learning can result in both abstract and episodic representations.

Currently, there is no evidence to directly link artificial grammar learning to particular neural mechanisms beyond the data from amnesic patients indicating that medial temporal and diencephalic regions are not necessary for such learning to occur. Other evidence for priming-like effects has been documented with categorization tasks that are conceptually similar to artificial grammar learning. Artificial grammar learning can be considered to be a special case of category learning in that subjects are required to judge whether individual stimuli (e.g., consonant strings) are members of a larger class (e.g., a grammar). Patients with amnesia show normal category learning in tasks requiring subjects to decide if novel dot-patterns belong to the same category as a set of training patterns (Squire and Knowlton 2000). A recent fMRI experiment showed that processing of categorical dot-patterns elicits less visual cortex activation than does processing of noncategorical patterns (Reber et al. 1998). Thus, perceptual categorization may involve mechanisms similar to those that support perceptual priming.

Another form of implicit category learning has been demonstrated with probabilistic classification tasks (Squire and Knowlton 2000). These classification tasks require subjects to predict which of two outcomes (e.g., sunshine or rain) will follow particular cue combinations (e.g., combinations of one to four geometric symbols). The cues are probabilistically predictive of outcomes, so that subjects' predictive accuracy increases with training. As observed for the other forms of category learning, amnesic patients show normal probabilistic classification learning. Probabilistic classification learning is impaired in patients with Parkinson's disease (PD) and Huntington's disease (HD). PD and HD are neurological diseases that cause severe movement impairments because of damage to a subcortical brain region know as the basal ganglia. Thus, the basal ganglia may make a critical contribution to probabilistic classification. However, basal ganglia damage has not been shown to interfere with category learning of novel dot-patterns or artificial grammars (Reber and Squire 1999).

Implicit sequence learning is another task that, like probabilistic classification learning, requires subjects to learn associations between multiple cues and outcomes, and it has been more clearly linked to activity within the basal ganglia (reviewed by Clegg et al. 1998, Curran 1997). Implicit sequence learning has been primarily studied with a serial reaction time (SRT) task. Subjects typically view a stimulus moving across different visual locations and press location-corresponding response keys as quickly as possible. Normal subjects and patients with amnesia show improved performance (i.e., respond faster and more accurately) when stimulus locations follow a repeating pattern, compared with conditions in which stimulus locations are randomly determined. This form of learning does not depend on explicit knowledge. Implicit sequence learning is impaired in patients with PD or HD.

Impaired sequence learning in PD and HD patients suggests a basal ganglia contribution that has been confirmed by sequence-learning studies using PET and fMRI (Clegg et al. 1998, Curran 1997). These studies additionally have identified learning-related changes in primary motor cortex, supplementary motor areas, premotor cortex, and the thalamus. The distribution of learning-related brain activity suggests that SRT learning involves changes in motor areas that subserve visually guided movement. Cognitive psychologists have similarly concluded that implicit sequence learning involves response-based information processing by showing that learning depends more upon response consistency than stimulus consistency (Willingham et al. 2000). Neuroimaging studies have primarily found that sequence learning leads to increased activity in implicated areas—as would be expected from the view that implicit learning and memory for novel information should enhance relevant brain activity. However, learning-related changes in brain activity are not so simply described when one considers the multiplicity of implicated brain areas and the complete time-course of learning. Across the temporal course of sequence learning, thalamic activity initially decreases then later increases (Rauch et al. 1998). Rauch et al. hypothesize that these effects reflect input from distinct basal ganglia circuits that respectively suppress and enhance thalamic activity. Further understanding of the functional significance of learning-related increases and decreases in activity will depend on more detailed temporal information as well as a better understanding of the neurophysiology of implicated brain areas.

Why would basal ganglia function be related to probabilistic classification and sequence learning, but not categorization of artificial grammars or random dot-patterns? The categorization tasks typically include a passive learning phase in which subjects are exposed only to category members, followed by a distinct discrimination test designed to tap categorical knowledge. Learning and test phases are procedurally identical in probabilistic classification and sequence-learning experiments, and feedback is given to differentiate incorrect from correct responses. Task consistency or the provision of feedback may be relevant to understanding basal ganglia involvement. Behavioral studies have demonstrated the importance of response consistency for sequence learning (Willingham et al. 2000), but this issue has yet to be investigated with probabilistic classification learning. Others have emphasized the importance of feedback for types of learning that depend upon the basal ganglia (Reber and Squire 1999).

3. Conclusions

The discovery of implicit learning and memory has advanced the view that learning and memory are not the product of a unitary neurocognitive system that is dedicated to learning and memory. Dissociations between implicit and explicit forms of learning/memory exemplify the perspective that learning and memory depend upon multiple brain systems. Further investigations have indicated that implicit learning and memory are attributable to diverse processes. The over-riding principle appears to be that many, if not all, brain systems can support implicit learning and memory. Implicit learning and memory involve changes in information-processing systems that normally contribute to specific cognitive or behavioral functions, such as perception, movement, and the like. Visual perceptual processes support visual priming and visual category learning. Semantic processing regions support conceptual priming. Brain systems related to movement control underlie implicit sequence learning. Ongoing research is aimed toward understanding the relationships among these forms of implicit learning and memory, and specifying the characteristics of each.

Implicit Memory, Cognitive Psychology of

1. Phenomena, Methods of Investigation, and Explanations of Implicit Memory

Does experience influence our thoughts and actions without being aware of it? A growing body of scientific literature on implicit memory deals with this question. In the databases for psychological literature we can find e.g., 19 references to 'implicit memory' for the five year period between 1984 and 1988, and more than 200 titles between 1999 and September 2001. What makes this concept so attractive, what is its definition, and what phenomena does it explain?

'Implicit memory is revealed when previous experience facilitates performances on a task that do not require conscious or intentional recollection of those experiences' (Schacter 1987, p. 501). This can be illustrated by the use of a picture-naming task: subjects are more successful in terms of speed or correctness when naming pictures or words that have been shown previously compared to pictures or words that have not been presented before. The assumption that such facilitation effects (called priming) do 'not require conscious or intentional recollection' of previous experience, is taken for sure from the point of view of the experimenter, who in fact does not instruct the subjects to use any kind of recollection when naming the pictures. Thus, 'implicit memory' refers to memory effects that can be shown by implicit tasks or indirect tasks that, in contrast to explicit tasks, do not instruct the subjects to remember what happened in the past. Here, the terms 'implicit' and 'explicit' refer to different tasks, distinguished operationally by the instructions given to subjects at test. The terms 'indirect memory tasks' and 'direct memory tasks' are also frequently used in the literature to make this distinction in instruction.

The most commonly used explicit memory tasks are free recall, cued recall, and recognition. In free recall, subjects are instructed to report a prior episode without any additional help, while in cued recall, additional cues are presented that might prompt the answer (e.g., the first word of a studied word pair is given in test while the second has to be recalled). In recognition, a previously presented item or episode is presented again (together with new ones), and subjects are asked whether they have seen the item before or not.

The most frequently used implicit memory tasks are identification, fragment completion, word stem completion, and lexical decision. In identification, subjects are given brief exposure (some milliseconds) to a stimulus, which they have to identify. A variation of this task is the clarification procedure. In this version the subjects are presented repeatedly with degraded pictures or words that gradually become more complete in each presentation until the subjects can identify the items. In completion tests, subjects are either given a word stem (g a r _ _ _) or a word fragment (g _ r _ e _) together with the instruction to complete it with the first word that comes to mind (e.g., g a r d e n). In a lexical decision task, subjects are required to state whether or not a particular letter string (words and nonwords are presented) is a word. In all of these tasks, implicit memory is revealed if items of a prior study phase receive more frequent, more correct, or faster responses compared to control items not presented in the study phase.

The notion of implicit memory has become particularly attractive because of the assumption that measures of implicit memory tap an unaware or unconscious form of retention. In this sense, implicit memory refers to a special memory system or to memory processes that are different from the memory system or memory processes underlying explicit memory. In this rationale, implicit memory refers to the saving and use of experience that lies outside of conscious retrieval or recollection of the past. Thus, implicit memory stands in contrast with explicit memory, where retrieval is used with recollective experience of the past.

The main evidence for the distinction between implicit memory and explicit memory comes from the stochastic independence of memory performance on implicit and explicit memory tests and from functional dissociations between explicit and implicit measures of retention. Stochastic independence refers to the finding that memory for a single item in one test cannot be predicted by the memory performance for the same item on the other test. Functional dissociations denote the fact that certain variables affect explicit memory tests but not implicit memory test, or do so in the opposite way.

It was demonstrated that the manipulation of levels of processing (structural or shallow encoding vs. semantic or deep encoding), attention and reading vs.

generating a word during study had strong effects on explicit measures of memory, but no effect on priming. On the other hand, manipulations of surface features of the stimuli, such as typography or study-test changes in modality of presentation reduced or eliminated priming in implicit tasks, whereas performance in explicit measures was not significantly influenced (for a review, see e.g., Roediger and McDermott 1993).

Functional dissociations have also been found in quasi-experimental research. Amnesic patients with bilateral damage to the medial temporal lobes and to related limbic and diencephalic structures are severely impaired on explicit tests of memory while showing normal memory on implicit tests (Squire et al. 1987). The same pattern of functional dissociation between explicit and implicit measures is revealed in young children and mentally retarded subjects (Perrig-Chiello and Perrig 1993) and elderly people (La Voie and Light 1994).

Given this data, it seems perfectly reasonable to infer the existence of a cognitive system with separate mechanisms that refer to the apparent divide in terms of implicit and explicit memory. Many individual theories have evolved to explain this data, and why they differ. They can be classified in one of two general approaches: memory systems theories and processing theories. The memory systems theories assume that there are distinct memory systems in the brain, that these systems provide the neural underpinnings for performances on various memory tests, and that the systems can be selectively impaired. The most prominent distinctions refer to episodic memory, semantic memory, procedural memory, and perceptual representation systems (Tulving and Schacter 1990). In processing theories, the principle of Transfer-Appropriate-Processing (TAP) and the distinction between perceptual and conceptual processing are held responsible for explaining the empirical findings of implicit memory research. In this view, transfer between learning and test—and thus performance—is best if the task and processes involved share a maximum of features (Roediger 1990). Conscious recollection of past events, as assessed by explicit tests of memory, is attributed to the episodic memory in the system approach, and to dominant conceptual processes in the process view. Priming in the implicit tests of memory is related to semantic memory, procedural memory, and perceptual representation systems in the system theory, and to perceptual processes in the processing account.

2. *Refinement of Tasks and Theories*

In the last decade of the twentieth century, more than two dozen tasks have become standard to investigate implicit memory performance (Roediger and McDermott 1993). Different types of implicit memory tests have been established. Distinctions are made on different dimensions: the contrast of perceptual and conceptual tests, the degree of resemblance of a target item between learning and test, the reference to different modalities involved to process the stimuli (verbal, nonverbal, visual, acoustic), and the information contained in the stimuli (item-specific, relational or associative).

More subtle functional dissociations between memory tasks challenge simple views of both the system approach and the TAP approach. The TAP framework has great success accounting for experimental dissociations of implicit and explicit memory tests that are rather perceptual or conceptual in nature. It comes to its limit, however, when dissociations among conceptual implicit and conceptual explicit tests or perceptual implicit and perceptual explicit tests are obtained. Such is the case, when, e.g., large age-related differences are found in two explicit memory tasks, regardless of the perceptual–conceptual difference, while age-related differences in implicit memory are revealed in a conceptual category-production task, but not in a perceptual word-fragment completion task (Jelicic et al. 1996). The authors explain these different realizations of perceptual and conceptual information in free recall and priming with selective age-related impairments in different cortical regions (see *Implicit Learning and Memory: Psychological and Neural Aspects*).

Further demonstrations on how implicit memory research comes to continuously more precise task analysis, and how finer grained theories relate to effects of levels of processing (LOP) on priming. It could be shown that the effects of levels of processing on a category-exemplar production test were greater when study lists were organized by category than when they were presented randomly (Mulligan et al. 1999). The explanation of these results by the authors might indicate the direction of development of the processing view to explain dissociations within classes of implicit tests (either conceptual or perceptual). They refer to the distinction between item-specific and relational processing. Relational information is shared by to-be-retrieved items, whereas item-specific information is unique to an item. LOP is viewed as a manipulation of item-specific encoding, and list organization is considered to affect relational encoding. Their data show that LOP effects in a category-exemplar production task are greater when relational information is highly salient.

3. *Towards the Measurement of Individual Differences in Implicit Memory*

It would be a superb achievement of memory research if theoretical distinctions of experimental psychology could be used to diagnose a special aptitude or ability

of one specific subject on the basis of population norms. Implicit memory research seems to be aimed at a successful integration of experimental research and an individual difference approach. For example, quasi-experimental research will possibly succeed in discriminating amnesic patients with different etiologies by the use of different implicit memory tests (see Moscivitch et al. 1993 for a review). At this point, however, it is mandatory that memory tasks have to be evaluated not only on the basis of experimental criteria but also according to the psychometric standards of the individual-difference approach. The critical question concerns the reliability of an individual's characterization, or the reliability of the assignment to one group or another. In the light of these considerations, it is essential to assess the reliability of tests and validity of constructs. This issue is just beginning to come into the discussion, and the first empirical findings are somewhat disappointing (Meier and Perrig 2000, Buchner and Wippich 2000). In a series of experiments the test–retest reliability, split-half reliability, and parallel-test reliability of explicit measures (recall, cued recall, and recognition) varied between $r = 0.43$ and $r = 0.65$. With the implicit measures (perceptual clarification and word stem completion) the highest correlation was $r = 0.39$, and the others ranged between $r = 0.08$ and $r = 0.29$ (Meier and Perrig 2000). Such a lack of reliability, of course, is unacceptable for diagnostic purposes; at the same time it is problematic for experimental research. Lack of reliability could even be responsible for functional dissociations, when a variable has an effect on explicit memory performance but not on implicit tasks. Lower reliability leads to a higher proportion of error variance in the observed variance. If the influence of an independent variable on two different kinds of tests is investigated, then the test with low reliability must show a greater effect than the more reliable test to reach significance. Given the fact that the expected maximum correlation of a test with any other test is limited by its reliability, it is clear that low correlations of implicit memory measures with any other variable are at least partly due to the low reliabilities of these measures. Thus, there is clearly a problem that has to be put on the top of the research agenda of implicit memory research.

4. *Confounded Factors and the Phenomenological Status of Implicit Memory*

The special attractiveness of implicit memory lies in the assumption that measures of implicit memory tap a nonconscious, automatic form of retention, or incidental retrieval. However, the issue of awareness is a thorny one that will keep the field busy for some time to come. The distinction between implicit memory tests and explicit memory tests are well established at the operational level. On the other hand, despite neat dissociations between explicit and implicit memory tests and stochastic independence between them, we do not know for sure whether and to what degree subjects use intentional retrieval and conscious recollection in implicit memory tasks. Furthermore, we do not know to what degree automatic and nonconscious processes are involved in intentional retrieval. In order to speak of automatic or unconscious effects of memory, criteria have to be satisfied that exclude contamination with intentional retrieval (Perrig 2000). This challenge is not unique to implicit memory but to any approach that tries to separate conscious from unconscious processes as in implicit learning, implicit expertise, skill acquisition, automatic detection, or nonconscious perception.

There are different techniques to disentangle conscious recollection from automatic or unintentional retrieval. (a) A strict retrieval intentionality criterion asks for holding constant all overt conditions affecting subjects at study and test except for the instructions given at time of the test (Schacter et al. 1989). (b) The subjects can be queried about the strategies they used in completing the task to separate 'test aware' from 'test unaware' subjects. Test aware subjects are those who realize at one point during the implicit memory test that some items are from the study phase. (c) The process dissociation procedure developed by Jacoby (1991) estimates the amount of automatic and controlled processing within one and the same task. In recognition e.g., the measurement model assumes that either recollection or automatic retrieval facilitates a yes-response. The basic logic to separate controlled and automatic processing includes an experimental condition where the subjects have to say 'no' to old items if they remember that the items belong to a specified set of items from the study list. If the subjects nevertheless say 'yes' to some of those items, it is assumed that this is based on an automatic response because conscious recollection works in opposition to the automatic response and would produce a 'no' answer. (d) The sensitivity criterion of Merikle and Reingold (1991) states that one should be able to show greater effects of a variable on an implicit test than on an explicit test in order to speak of unconscious or automatic effects. This must be so, because the information would be used in the explicit measure if it were available for conscious retrieval. Empirical data fit this assumption when priming can be produced in absence of recognition or recall.

5. *Implicit Memory in the Broad Range of Implicit Mental Processes*

An important question is whether implicit memory represents processes that are unique or at least distinct from processes that are studied in implicit learning,

implicit expertise, skill acquisition, automatic detection, or unconscious perception. It could well be that the very same implicit processing principles underlie phenomena that are studied in other research areas using different experimental paradigms (Graf and Masson 1993, Kirsner et al. 1998, Reder 1996). A broader view that integrates procedures and data of different research domains could open the researcher's mind for valuable progress in explaining implicit processes and their differences to explicit information processing.

Is there a common psychological explanation for automatic and controlled processing, and for the behavior of a patient with brain stroke, who spontaneously switches between English and French in answering questions but cannot translate words and sentences when asked to do so? Are the same principles involved when people gradually improve in solving complex perceptual or conceptual problems despite the fact that they cannot identify the feature or principle on which their new expertise is based? Would those principles even explain the fact that information can be extracted from words during brief presentation under conditions where the words cannot be identified?

In fact, the terminology to describe what seems to control behavior outside of intentional control in other research areas comes very close to the definition of implicit memory. Cohen (1984, p. 96) speaks of 'procedural knowledge,' '… when experience serves to influence the organization of processes that guide performance without access to the knowledge that underlies the performance.' Reber et al. (1991, p. 888) speak of 'implicit learning,' '… when a complex, rule-governed knowledge base is acquired largely independently of awareness of both the process and the product of the acquisition.' The fluent switch between notions like 'implicit knowledge,' 'implicit learning,' and 'implicit memory' either confronts us with the fact that psychology has—despite precision at the operational level—weaknesses at the terminological level, or it asks for synthesis in the explanation of implicit phenomena or implicit cognition. This endeavor is not a question of semantics, but the need for definitions that point out problems rather than hide them. Future work will have to show whether different definitions are needed for skill and habit learning, simple classical conditioning, and priming, all phenomena that for the time being can be considered as instances where memory is expressed through performance rather than by recollection.

Impression Management, Psychology of

Impression management (also called self-presentation) refers to the processes by which individuals attempt to control how they are perceived by other people. By conveying particular impressions of their abilities, attitudes, motives, status, emotional reactions, and other personal characteristics, people can influence others to respond to them in desired ways. Impression management is a common means by which people influence one another and obtain various goals (Jones and Pittman 1982).

The concept of impression management was popularized by Erving Goffman (1959), a sociologist and ethnologist, who viewed impression management not only as a means of influencing how one is treated by other people but also as an essential aspect of social interaction. According to Goffman (1959), social encounters are mediated by the impressions that people form of one another. As a result, smooth and effective interpersonal interaction requires that each interactant projects a public identity to guide others' behaviors. The study of impression management was introduced into social psychology by Edward Jones (1964), whose early research on ingratiation focused on the ways in which people influence others by making themselves appear likeable and socially attractive. During the 1960s and 1970s, research on impression management developed along two distinct paths. One line of research focused on the situational and dispositional factors that affect the kinds of impressions people try to convey of themselves, and the other line applied self-presentational perspectives to the study of other psychological phenomena, such as attitude change, conformity, leadership, psychological disorder, and health risks.

1. *The Nature of Impression Management*

People use many different behaviors in the service of impression management. Any behavior that conveys information about an individual may be used as a self-presentational tactic (Leary 1995, Schlenker 1980). This is not to say that all behavior is necessarily self-presentational—only that virtually any behavior may be used for self-presentational purposes. Most empirical research has focused on people's descriptions of their attributes and attitudes to foster impressions in others' minds. However, people also impression-manage nonverbally. For example, people can regulate how others perceive them through their facial expressions, gestures, ways of standing and sitting, and choices of seating location (around a table or in a classroom, for example). They also use props—physical objects such as clothing, furnishings, automobiles, and other personal possessions—to promote certain images of themselves. Behaviors as mundane as eating, grooming, and driving also have a self-presentational component. Furthermore, many instances of helpfulness, as well as aggression, may reflect people's efforts to be viewed as helpful versus threatening, respectively.

Self-presentation has sometimes been viewed as a deceitful and manipulative means of influencing other people, and sometimes it is. However, impression management is not necessarily deceptive. People often engage in strategic impression management to assure that other people perceive them accurately. Because personal characteristics and inner states are not always obvious to other people, people must often take steps to insure that others perceive them accurately. Furthermore, although people sometimes present images of themselves that they know are untrue, more often they veridically present those aspects of themselves that they believe will help to achieve their interpersonal goals in a particular situation. Although self-presentation is tactical, it is not necessarily deceptive.

Most self-presentation involves efforts to convey a socially desirable impression in order to be regarded positively. Generally, people are more likely to achieve their goals if they are perceived as likeable, competent, ethical, or otherwise socially desirable than if others regard them negatively, so desirable self-presentations predominate. However, people sometimes wish to convey socially undesirable impressions of themselves. For example, people may want to be seen as hostile because doing so helps them to intimidate others to do as they wish, or as weak or helpless to elicit support from other people. For this reason, it is important to distinguish between desirable self-presentations (i.e., those that are likely to result in favorable evaluations) and desired self-presentations (i.e., those that the individual believes will accomplish his or her goals).

Although little research has examined self-presentational behaviors in children, evidence suggests that children begin to show a concern with other people's evaluations of them soon after the emergence of self-awareness, typically by age two. By age three, children show evidence of trying to influence other people's perceptions of them, for example, by denying that wrongdoing was their fault. Children become increasing skilled at controlling others' impressions of them

with age, although they do not appear to attain an adult level of self-presentational ability until late adolescence.

2. The Determinants of Impression Management

People have many reasons to monitor and regulate how they are perceived by others. Most important outcomes in social life—including friendships, group memberships, romantic relationships, desirable jobs, status, and influence—partly depend on other people perceiving the individual as being a particular kind of person or possessing certain kinds of attributes. Because most of people's goals depend on making particular desired impressions and not making undesired impressions, people are pervasively concerned with the impressions that other people form of them. People appear to monitor how they are coming across on an ongoing basis, but the degree to which they are motivated to impression-manage and the nature of the impressions they try to foster vary across situations and among individuals.

2.1 Impression Motivation

Three primary factors affect the degree to which people are motivated to impression-manage in a particular social encounter (Leary and Kowalski 1990). First, people are more highly motivated to control how they are perceived by others when they believe that their public images are relevant to the attainment of desired goals. Conversely, when the impressions that other people form have few implications for one's outcomes, the motivation to impression-manage will be low. This fact is one reason that people are more likely to impression-manage when interacting with powerful, high status people than with less powerful, low status individuals.

Second, people are more highly motivated to impression-manage the more valuable the goals for which their public impressions are relevant. When achieving important, highly desirable goals depends on the kinds of impressions others form of them, people are more motivated to monitor and control how they are perceived than when the goals are less valuable.

Third, people are more highly motivated to impression-manage when a discrepancy exists between how they want to be perceived and how they believe other people currently perceive them. Thus, public failures and embarrassing events that convey impressions that are discrepant from the images that people wish others to form cause them to engage in self-presentational efforts to repair their damaged image.

2.2 Impression Construction

When people are motivated to manage their impressions, features of the social context and their own personalities determine the specific nature of the impressions that they try to convey. Five sets of factors are particularly important determinants of impression construction (Leary and Kowalski 1990). First, the content of people's self-presentations is affected by the roles that they occupy and by the norms in the immediate social context. Typically people want to convey impressions that are consistent with their roles and the prevailing norms. Many roles—such as the roles of leader, military officer, and member of the clergy—carry self-presentational requirements regarding the kinds of impressions that people who occupy those roles should and should not convey. Furthermore, social norms may prescribe or proscribe how people in a particular social context should appear.

Second, people tailor their self-presentations to the values of the individuals whose perceptions are of concern. Sometimes people fabricate identities that they think others will value. More commonly, however, they selectively present truthful aspects of themselves that they believe coincide with the values of a particular target and withhold information about themselves that they think others will value negatively. In this way, people can present accurate impressions of themselves that are nonetheless tailored to the preferences and values of other people.

Third, people's choices of public images are influenced by how they think they are perceived currently. Often, self-presentational behaviors are aimed at dispelling undesired impressions that other people currently hold of the individual. When people believe that others have, or are likely to develop, an undesired impression of them, they often try to refute the undesired impression by showing themselves to be different from what others believe. When refutation of the negative impression is not possible, they may compensate by projecting particularly desired impressions on other, unrelated dimensions.

Fourth, the kinds of impressions people try to create are influenced not only by the social context but also by their own self-concepts. People often want other people to see them as they really are, but must deliberately manage their impressions in order to be viewed accurately. In addition, people's self-concepts constrain the images they try to convey. Not only do many people believe that it is unethical to present images of themselves that are inconsistent with how they really are, but they usually doubt that they will successfully sustain public images that are inconsistent with their actual characteristics. The risk of self-presentational failure, and the social sanctions that accompany it, deter people from presenting impressions that are vastly discrepant from how they see themselves.

Finally, the images that people try to project are also influenced by their desired and undesired selves—how they wish to be and not to be. People tend to manage their impressions in ways that coincide with their desired selves and that steer away from their undesired selves.

3. *Self-presentation and Behavior*

When people are in the presence of others, few of their behaviors are unaffected by their desire to maintain certain impressions in others' eyes. Even when people are not expressly trying to create a particular impression, prevailing concerns with their public images constrain their behavioral options. Whatever else people may be doing, they typically do it in ways that don't create undesired impressions. Concerns with others' impressions impact virtually all areas of social life.

3.1 *Interpersonal Behavior and Emotion*

In an early effort to offer a self-presentational explanation of interpersonal behavior, Tedeschi et al. (1971) argued that phenomena that had previously been attributed to the need to maintain cognitive consistency actually reflected people's efforts to maintain an impression of consistency in other people's eyes. Several studies subsequently supported their suggestion that phenomena that had been attributed previously to cognitive dissonance were affected by self-presentational processes (Schlenker 1980).

Self-presentational perspectives have been applied to the study of a variety of social psychological phenomena, including conformity, aggression, prosocial behavior, leadership, negotiation, social influence, gender, stigmatization, and close relationships (Baumeister 1982, Leary 1995, Schlenker 1980 Tedeschi 1981). In each instance, research has shown that these phenomena are affected, in part, by people's efforts to make particular impressions on others. In group settings, for example, people in positions of leadership have been shown to tailor their public images to the current demands of the group's situation. Research also shows that prosocial behavior is affected by self-presentational motives; people are more likely to be helpful when their helpfulness is publically known rather than anonymous, and they behave more prosocially when they desire to repair a damaged social image by appearing helpful. Likewise, many instances of aggression are self-presentational efforts to show that the individual is willing to hurt others to get his or her way. Many differences in the behavior of men and women can be traced to gender-biased norms regarding the kinds of impressions that are appropriate for men versus women. In brief, self-presentational concerns pervade social life.

Self-presentational processes also affect emotional experience. People become socially anxious when they are motivated to make a desired impression on others but doubt that they will do so successfully. Whenever the self-presentational stakes are high, doubts in one's self-presentational efficacy evoke anxiety. The nervousness that people experience on first dates, in job interviews, and while speaking in public can be traced to self-presentational concerns. Furthermore, when events occur that have undesirable implications for people's public images—showing them to be less competent, likeable, ethical, or otherwise socially desirable than they desire—people experience embarrassment. The face-saving behaviors that accompany episodes of embarrassment are efforts to undo whatever self-presentational damage has occurred (Leary 1995, Schlenker 1980).

3.2 *Mental and Physical Health*

Impression management processes have also been studied in the context of mental and physical health. The self-presentational use of psychological symptoms has received considerable attention. Braginsky et al. (1969) showed that hospitalized schizophrenics modify the severity of their disordered behavior depending on whether making a disturbed or nondisturbed impression will be most beneficial to them. Research on samples of university students likewise shows that people will exaggerate, if not fabricate, reports of psychological distress when doing so serves their social goals. Similarly, hypochondriasis appears to have self-presentational features: people convey impressions of illness, injury, and infirmity when doing so helps to achieve desired outcomes, such as excusing poor performance, eliciting support, or avoiding onerous responsibilities.

Self-presentation is also a risk factor for physical injury and illness. People engage in a number of dangerous behaviors for self-presentation reasons. Risky behaviors as diverse as suntanning, steroid use, excessive dieting, practicing unsafe sex, and fast driving can be traced to efforts to make certain impressions on other people. Furthermore, concerns with one's impressions may deter people from seeking medical attention when needed because of embarrassment about the presenting condition or about the medical examination itself. People may even refuse to undergo medical treatments if doing so compromises their public images (Leary et al. 1994).

Imprisonment: Sociological Aspects

Most people have an opinion about imprisonment: prison is a place for criminals, a room behind solid walls and bars, a nasty place for nasty people. But, as so often, complexities of meaning emerge with reflections and studies. To start with, an examination of the roots of the concept introduces new associations. In Old French, two meanings of the term exist. The first is associated with being apprehended, or held captive. The second meaning has to do with considering a person as being a capture, a prize, a person with a value for other persons.

The first sense, that of being captured, might also have several meanings. It might be understood as being captured in the small room behind walls and bars. But a single parent living on the tenth floor with three sick children at home might also experience a sense of being captive there. People in a caste or rigid class society might also have opinions on what it is to be captured in one's position in life, as might remote villagers watching life in London on the BBC. And so might the electronically tagged factory worker whose bracelet would trigger an alarm in the police or probation service if he did not go straight home after work. Imprisonment is not only in small rooms. Whole societies, or segments of them, can experience the meaning of being in prison. Attempts to grasp the phenomenon of imprisonment open up renewed perspectives on what freedom is. A prisoner on hunger strike, naked in a punishment cell, was reported as saying that he had never felt so free, because there was nothing more to lose.

Prisons can also contain prizes, valuable to those who keep them. Rich or important people are of value to those who capture them. They can be exchanged for money or political privileges. Whole segments of populations might be valuable to power holders. Slaves are often useful for labor-intensive tasks. They were also useful in the war industry both in the USSR and Germany. Ordinary prisoners can also be seen as precious. Large segments of societies make a living from keeping them captured.

1. The Penal Picture

Moving back to the phenomenon as most people in the Western world experience it, prison is a place for those waiting to receive a sentence, or having received such a sentence. A useful measure of prison populations in a country is the number of prisoners per 100,000 inhabitants. There are many alternative indicators, e.g., the flow through the system, but it is difficult to find reliable comparative data for this flow. The figures presented here include both people waiting for trial and prisoners who have received their sentence. Most figures are for year 2000. Sources are Walmsley (2000) and Christie (2000).

Table 1 gives the information for Western Europe. As a general tendency, the Scandinavian countries have low prison populations, none of them with more than 70 prisoners per 100,000 inhabitants. At the top in Western Europe is Portugal, with the UK in second place.

Table 2 demonstrates the dramatic differences between Western Europe and Central and Eastern Europe. The Russian Federation is at the very top in

Europe with no less than 640 prisoners per 100,000 inhabitants. Close to Russia are the former members of the USSR, also with extremely high prison figures compared to Western Europe. Particularly surprising is the high number of prisoners in the Baltic countries, Latvia, Lithuania, and Estonia. But some of the countries from the former Eastern block are by now abandoning the tradition of having a large prison population. This is particularly the case for Poland, Hungary, and Slovakia, and most of all for little Slovenia, with only 57 prisoners per 100,000, similar to the Scandinavian countries.

Table 3 gives the figures for the American continent. The USA is at the top, in the table as in the world. For the other countries, there is great variations in the use of prisons. Particularly in South America there are great similarities to the figures for Western Europe.

2. *Behind the Variance*

Confronted with the differences between countries in these tables, the need for an explanation becomes urgent. The conventional view is that the relative differences in the number of prisoners are related to differences in crime level. But this explanation has two major flaws. First, countries otherwise rather similar might differ when it comes to the relative number of prisoners, while other very different ones might have similar numbers of prisoners. The difference between Canada and the USA is a point in case. Two countries, so close, with a joint border, the same language for most people, the same type of media and economic system, and to a considerable extent even common views about money—but still this enormous difference in the number of prisoners. While Russia and the USA, with all their differences, have nearly exactly the same relative number of prisoners. A second element which weakens the 'crime' explanation is the historical development behind many of these figures. Russia decreased its prison population from 1,400 per 100,000 in 1950 to 353 in 1989 under Gorbachev. But since then they have again increased, and since Glastnost have more than doubled their relative number of prisoners. They now have one million prisoners. It was not crime that changed, but politics. This was also the case with Poland and Hungary after the collapse of the USSR. Finland had a similar development in the 1960s. The US figures departed in 1980 from a level much closer to the European, but later exploded, an explosion not reflected in indicators of their crime situation. This growth shows no indication of flattening out. In 1999, the increase was 110,000 new prisoners. In 2000 the USA passed the two million mark.

3. *Prison Life*

On a global scale, Russia and the USA stand out as the big incarcerators. They are similar in their large numbers of prisoners, but extremely different in living conditions within the prisons. In both cases, prisons are dangerous places to live in, but more so in Russia. Of the one million prisoners there, 92,000 have tuberculosis—30,000 having a multiresistant type. Those waiting for trial live under particularly harsh conditions. Overcrowding is extreme. In some prisons there is not sufficient space for all prisoners to lie down at the same time. After trial, prisoners are sent to the so-called 'colonies,' the former Gulags. Here, material conditions are better, but social life is often filled with strains. The internal life in these colonies is often

characterized by extreme internal differentiation, with a caste system developing in many camps. Some prisoners gain a large amount of power; they become the internal commanding force with privileges and comfort. At the bottom, there is a pariah caste living under the most miserable of conditions, eating leftovers and serving the power holders in all ways, including sexually.

While overcrowding and disease are major problems in the Russian situation, extreme forms of isolation are a problem in a number of the prisons in the USA. This is particularly the case in the so-called maxi-maxi prisons, where inmates are often isolated in windowless cells, built from solid blocks of concrete and stainless steel. Metal doors of each cell open to the inside corridor and do not allow prisoners to communicate between cells. Smaller doors within each door allow officers to pass in food and to shackle prisoners before opening the cell door. In some of these prisons, each cell has its own toilet, sink, and shower. They also have doors leading outside to very small enclosed balconies where inmates can take their daily one hour of exercise. The doors to the balconies can be controlled electronically from a central control room. There is very limited possibility for the prisoner to meet any other human beings.

These descriptions do not do justice to all prisons or colonies, either in Russia or in the USA. In both countries well-ordered prisons and colonies can also be found, with considerable contact both between inmates and between inmates and staff, and where self-government among prisoners seems to function without abuse.

4. *The Goal of the Operation*

With the enormous increase in the prison population in major industrial countries, attempts to understand this whole area gain a new focus. Penal law and sociology has an old, learned tradition in studies of the reasons for punishment. Theories of deterrence, treatment, or incapacitation were compared and evaluated. A great number of studies tried to compare the effects of various measures. But a shift in research interests seems to be under way. Theories on reasons for punishment and the treatment effects of various measures are not quite as interesting when it becomes clear that the political system puts people into prison for reasons far outside any of the main reasons for punishment in the old theories. Studies such as the one on 'administrative criminology' by Feeley and Simon (1994) become more relevant.

From the 1950s to the 1980s, much energy was also spent on studies of the inside life of relatively well-ordered prisons. Sykes (1958) studied the society of captives, the roles that appeared within prison, and the power structure between prisoners and their guards. Cohen and Taylor (1972) described the survival mechanism of long-term prisoners, and conveyed not only their misery and despair, but also the great resources and the will to survive found among those contained for a life without future. Goffman (1961) helped us to see the general character of various types of total institutions. But sophisticated studies of life within well-ordered prisons are not in themselves able to explain the recent situation where prison figures in leading world powers are exploding, and the suffering involved is so overwhelming. Instead, new types of studies appear, such as Stern (1998) on the global situation and Walmsley (1998) on the World Prison Population. Highly relevant links between the old penal situation and the new can be found in Foucault (1977), Cohen (1985), and Mathiesen (1990). Imprisonment is a reflection of the social structure. Prisons are there to capture segments of the population, particularly those seen as superfluous, those not able to participate in the consumer society (Bauman 1998). In their captured position, they are also a prize—they are here given a use function as raw material for the control industry (Christie 2000). Studies of the crime control industry provide an indicator of the importance of the protection of civil society.

In Vitro Neurophysiology

1. *Background*

Neurophysiology is the study of the functional properties of neurons, glia, and networks. Historically it has been dominated by electrophysiology—the electrical recording of neuronal events ranging from the molar (the electroencephalogram, EEG) to the cellular (intracellular recording of the properties of single neurons). However, as the neuron is an electrochemical machine, it is impossible to separate electrical events from the biochemical and molecular processes that bring them about. Thus neurophysiologists today use techniques from chemistry (calcium imaging), physics (functional magnetic resonance imaging, fMRI), and molecular biology (site directed mutations) to study brain function. As we shall see, the use of *in vitro* techniques has facilitated all aspects of modern neurophysiology and can be fairly stated to have permitted many of them.

In vitro literally means 'in glass' and here refers to keeping isolated small pieces of brain alive in a special chamber (usually made of plastic, not glass) that provides life support and permits electrophysiological access (stimulation and recording). *In vitro* neurophysiology has its origins in the biochemical studies on energy metabolism by Henry McIlwain and others in the 1950s (McIlwain 1984). They cut brain and other tissue into thin (< 0.5 mm) slices, which were kept alive in vials of artificial cerebrospinal fluid (ACSF) from which was extracted substances of interest. It was a small step to immobilize the slices on a net and place recording and stimulating electrodes into them to determine if they exhibited 'normal' activity. To the great surprise of some, the neurophysiological responses they exhibited were remarkably normal in spite of the trauma of extracting and slicing the delicate tissue.

In vitro approaches are not appropriate for all neurophysiological studies. As the slice is removed from the network of which it is normally a part, it follows that studies of network properties are generally inappropriate for *in vitro* approaches. Most slice preparations preserve monosynaptic junctions well and allow for the controlled neurophysiological study of pre- and/or postsynaptic properties of the preserved synapse. As a consequence slices are best suited for cellular neurophysiology, as opposed to systems neurophysiology.

2. *The* In Vitro *Technique*

Two aspects of preparing brain slices (Alger et al. 1984) are of utmost importance: being gentle in handling the tissue (to minimize trauma) and doing so rapidly (to avoid ischaemic damage). Brain slices are prepared from living animals either under general anesthesia or following rapid cervical dislocation. The whole brain is removed and the area of interest blocked and transferred to a cutting device. Brain slices are typically cut 400 μm thick with a manual slicer or a Vibratome. Thicker slices will experience difficulty with O_2 diffusion into the center of the slice, whereas thinner slices will behave abnormally due to damage to inhibitory local circuit neurons. Once cut, slices are either directly transferred to a slice chamber, or are placed in a holding chamber for use later. In both cases the slice is exposed to warmed (usually) and oxygenated ACSF. Investigators have used a wide variety of conditions to maintain brain slices, differing principally in temperature, ACSF composition, and slice chamber design.

A basic brain slice chamber (Fig. 1) consists of a well holding one or more slices, a means of maintaining a constant temperature, a source of oxygen and ACSF, along with a binocular dissecting microscope to view the transilluminated slices, and recording/stimulating electrodes, their manipulators, and associated electronics. Chambers maintain slices either on a net at the interface of warmed, oxygenated ACSF and humidified 95 percent O_2/5 percent CO_2, or totally submerged in warmed and oxygenated ACSF and held in position between two nets. Which slice chamber is superior is a

Figure 1
Brain slice chambers place thin (400 μm) brain slices either at the interface of bathing ACSF and oxygenated atmosphere or submerge the slices completely in oxygenated ACSF. Both varieties have their adherents and supply an appropriate physical and chemical environment to allow the tissue to remain relatively normal for periods ranging up to 10 hours

Figure 2
The hippocampus has been often employed for *in vitro* studies of cellular and synaptic physiology and plasticity due to its unique anatomy. The *in vitro* hippocampus in the photograph is a slice cut transverse to the long axis of the hippocampus and preserves a three synapse network (dentate gyrus > CA3 > CA1)

subject of debate and controversy. Studies exposing slices to drugs often prefer the submerged design as it offers fast drug access to both surfaces of the slice. However ACSF flow rates are generally higher in submerged designs (interface slices obtain O_2 from the atmosphere), resulting in greater washout and, it is claimed, less healthy slices. The temperature at which slices are maintained varies from room temperature ($\sim$ 22°C) to physiological body temperature (37°C), with most studies being done at 30 to 35°C. Given that most mammalian systems are optimized to body temperature, surprisingly little difference is noted across the temperatures used. In general, slices are viable longer at lower temperatures. ACSF composition also varies across laboratories, principally in the concentration of K^+ and Ca^{2+} and whether or not drugs are added to attenuate inhibitory influences. The effect of these ACSF differences is reasonably well understood.

Between the time the blood supply is interrupted and the slice is exposed to oxygenated ACSF it experiences anoxia. To prevent ischaemic damage during this period (particularly important for neocortical tissue) investigators have employed several tactics. The use of general anesthetic agents offers considerable protection from ischaemia. To further reduce metabolism during the slice preparation some investigators use whole-body cooling prior to extracting the brain, often in conjunction with performing the dissection and transfer to the slice chamber over ice.

Slices have been made from a wide variety of brain structures. The first and by far the most common tissue studied *in vitro* is the hippocampus (Fig. 2, Teyler 1980). The hippocampus is particularly well suited because of its unique anatomy. It is a primitive, three-layered cortical tissue wherein the principle cell types are found in dense sheets and whose dendritic and axonal processed are highly ordered. The experimenter can visually guide electrodes into specific cell body or synaptic areas with a high degree of confidence and with an understanding of the origins and properties of the fibers being stimulated and cells from which recordings are made. In less ordered tissue, like neocortex and subcortical nuclei, visual cues are largely absent and their heterogeneous anatomy makes the precise identification of what is being stimulated less certain. The hippocampus is also unique in that its slices preserve a three-synapse circuit, due to the laminar anatomy of this structure. Most other brain areas do not lend themselves to preserving a polysynaptic circuit within the two-dimensional brain slice. While this can sometimes be addressed by preparing slices with curved cutting blades or by manipulating the tissue on the cutter, as a rule most other regions are limited to the study of single synapses. While this is a limitation to the study of networks, it is an advantage in the detailed cellular study of specific synaptic nodes in a network.

3. *Advantages*

Neurophysiological studies of neurons and circuits *in vivo* must deal with the inaccessibility of the tissue (protected by the cranium) and its complexity (which renders interpretation difficult). Neuroscientists have approached these two issues by adopting model systems—animals or preparations displaying less complexity and greater access. One approach is to use organisms with simpler nervous systems, such as *Aplysia* and *Hermissenda*, or surgically reduced preparations, such as isolated spinal cord, sub-pial cortical islands, and isolated cells maintained in culture. Both approaches have been extremely useful in the study of cellular neurophysiology because they have reduced the complexity of the tissue to a more manageable level while greatly improving experimental access. The former, however are nonmammalian organisms whose evolution may favor different cellular processes making extension to mammalian systems problematic, while the latter are cells that have either undergone development in a unique environment or, in the case of primary cultures, have undergone the trauma of isolation and plating into a culture system where they generally do not form patterns of connectivity as *in vivo* and may be exposed to a foreign chemical environment which results in an altered phenotype.

The *in vitro*, or brain slice, technique is also an example of a surgically simplified preparation, but an acute one made from forebrain tissues in most cases. Such a preparation can be made to preserve some of

the normal connections of the neurons under study and renders them exquisitely accessible for experimentation. The removal of a synapse from the network in which it is found greatly reduces the confounding influence of the network and facilitates the detailed study of synaptic/membrane function. In addition to simplifying the tissue, it is made two-dimensional, thus obviating the need for stereotaxic devices and their inherent inaccuracies (requiring histological verification of electrode placements) to place recording and stimulating electrodes accurately. In slice preparations the tissue is typically directly observed via microscope and electrodes are directed to structures or areas of interest under visual control. *In vivo* cellular neurophysiological studies seek to record from single neurons (extracellularly or intracellularly) or small groups of nearby neurons (field recordings) and are plagued by problems of movement derived from normal cardiac and respiratory activity. While ingenious solutions have been devised to permit such studies *in vivo*, these problems are totally absent *in vitro*, which represents a major advantage. While these practical matters are experimentally advantageous, the slice approach potentially offers more significant advantages in terms of the degree of experimental control the investigator possesses. As the investigator determines the composition of the bathing ACSF, its composition can be manipulated at will. *In vivo* studies do not have the experimental luxury of, for example, changing the extracellular composition of K^+ or Ca^{2+}, as can be done readily *in vitro*. Similarly, the introduction of drugs or compounds *in vivo* involves first breaching the blood–brain barrier and then dealing with uncertainties of drug distribution, concentration, liver degradation, and actual locus of drug action. In slice preparations drugs can be applied in known concentration with guaranteed access by superfusion (adding the drug to ACSF) or by pressure ejection or iontophoresis through a pipette. Drugs toxic to whole animal preparations (e.g., enzyme inhibitors, metabolic blockers) can be safely delivered to isolated brain slices. Similar experimental advantages are seen with respect to temperature and pH.

Often neurophysiological studies are combined with subsequent histological studies, for instance, to identify cells expressing particular markers. In slice preparations such experiments can be done online by exposing the slice to appropriate illumination revealing the cells possessing that feature and allowing physiological manipulations to be done only to those cells. Similarly, intracellular (whole cell or sharp electrode) recordings can be directed to individual cells possessing particular morphologies by utilizing infrared microscopy (Jaffe and Brown 1997). The combination of electrophysiological and optical technologies is particularly well suited to slice preparations. The spatial and temporal dynamics of $[Ca^{2+}]_i$ are important for understanding many aspects of synaptic transmission, synaptic plasticity, and cell death; and their study in hippocampal and neocortical pyramidal cell dendrites has relied heavily on *in vitro* approaches (Perkel et al. 1993).

4. *Limitations*

Like all simplified preparations, brain slices possess limitations. A fundamental limitation is that slices have a limited lifespan—generally on the order of 8 to 10 hours, although longer survival times are possible. The limited viability of brain slices is advantageous in that they do not have the time to alter their structure and function in response to their changed environment, as gene expression, protein synthesis, and transport generally require longer times (but see Kirov et al. 1999). Slices do not suddenly die; rather their behavior gradually deteriorates, suggesting the extreme view that slice neurophysiologists are studying slowly dying tissue. A window of relative normalcy has been documented, but its limited duration means that studies that require extended observation (gene expression, protein synthesis, growth, repair) cannot generally be done *in vitro*. To address this temporal limitation the *ex vivo* slice preparation has been developed. In this approach a manipulation is performed *in vivo* and brain slices made after an appropriate period of time (days to weeks). This allows the process under study to go to completion before the slice is prepared (or slices can be obtained at intervals to track the process). A further variant places standard brain slices in a tissue culture environment where the slice undergoes simplification while retaining connectivity, thus allowing the *in vitro* study of long timecourse events (Gahwiler et al. 1997). These long-term organotypic slice cultures are subject to the same kinds of alterations in gene expression (and thus structure and function) experienced by any cells maintained in culture and deprived of their normal *in vivo* environment. Brain slices are maintained in a chamber (described in Sect. 2) that is usually continually bathed with fresh ACSF. The flowing ACSF, however, can wash out extracellular modulatory agents (like neurotrophins) normally present and released by the tissue.

Several of the advantages of brain slices are also limitations. While surgical simplification reduces complexity it also removes the tissue from normal synaptic and extracellular influences. Thus the tissue may not behave as *in vivo*. As the investigator controls the ACSF environment, an incomplete understanding of the roles of compounds normally present *in vivo* and thus generally absent in *in vitro*, coupled with the washout of compounds released from slices, has unknown effects on cellular function.

A caution in the use of brain slices is that certain phenomena are readily observed *in vitro* but difficult to duplicate *in vivo*, and vice versa. Examples include the establishment of a seizure focus (facilitated *in vivo*), the

expression of long term-potentiation (facilitated *in vitro*), the expression of long-term depression (facilitated *in vitro*), and the presence of spontaneous activity (facilitated *in vivo*). While many of these differences are understood, they serve to caution that the *in vitro* preparation is not the same as an *in vivo* preparation. A recent example is the observation that pyramidal cells from hippocampal slices possess almost twice as many dendritic spines as their *in vivo* counterparts—a difference attributed to decreased spontaneous synaptic activity *in vitro* (Kirov et al. 1999).

5. *Future Uses of* In Vitro *Preparations*

In vitro preparations have been employed for a wide variety of investigations and will continue to be in the twenty-first century as new brain areas are studied using this technology. Three areas of emerging research using *in vitro* techniques seem destined to become more widespread. First, as greater understanding emerges regarding specific neural networks from functional imaging studies of intact organisms, *in vitro* methods will be ideally suited to characterize and analyze the cellular and synaptic properties of individual elements of the network. Second, brain slices will be increasingly employed for approaches that utilize optical techniques in which a thin, relatively normal, two-dimensional slice are ideal. As optical methods become more precise (e.g., more sensitive detection methods, smaller pixel sizes to improve resolution) and as new dyes are developed to visualize new molecules of interest, *in vitro* approaches will be adopted more and more for purely morphological experiments. A third area for *in vitro* approaches lies in molecular neurobiology. As molecular approaches allow for the elimination or over-expression of a wide variety of specific proteins, brain slices will be employed to ferret out the neurophysiological functions of these molecules.

Incest, Inbreeding, and their Consequences

The terms inbreeding and consanguinity are used to describe unions between couples known to share at least one common ancestor. While now rare in Western societies, marriages between close biological kin are preferential in many parts of the world, including North and sub-Saharan Africa, the Middle East, the Turkic- and Farsi-speaking countries of Central and South Asia, and much of the Indian subcontinent. Although the rates and types of inbred union may vary according to religious and societal norms, marriage between first cousins is especially common and in a country such as Pakistan accounts for over 50 percent of all marital unions. An incestuous relationship is a union between biological relatives that is closer than permissible under prevailing legislation. Most commonly, incest is defined as mating between first-degree relatives, i.e., father–daughter, mother–son, or brother–sister, who have 50 percent of their genes in common. However, in some countries the definition may be widened to include half-sib and uncle–niece unions.

1. *Human Inbreeding*

Many examples of successful consanguineous unions are cited in the biblical texts, including the marriage of Abraham with Sarah his half-sister (Genesis 20:12), and Amram and Jochebed, the parents of Aaron and

Moses who were nephew and aunt (Exodus 6:20). At a later date the permitted degrees of marital relationships were extensively defined, with marriages up to and including uncle–niece permitted (Leviticus 18:7–18). These guidelines were generally adopted by the Protestant churches after the Reformation, although in most denominations the closest form of approved union has been between first cousins. For Roman Catholics, diocesan dispensation has been and remains a prerequisite for marriage between first cousins, and the Christian Orthodox church adopts a similarly proscriptive stance even with more remote relationships. Among the other major world religions, attitudes to close kin marriage are generally favorable or neutral in Buddhism, Confucianism, Islam, and Judaism. However, for the Aryan Hindus of North India, pedigrees are examined over the preceding seven generations for males and five generations for females to ensure avoidance of a consanguineous union.

1.1 Attitudinal Changes in the Response to Consanguineous Marriages

Prior to the mid-nineteenth century, first-cousin marriages were commonly contracted in many Western societies, including countries such as Spain and Italy where a large majority of the population was Roman Catholic. From the 1850s onward an often acrimonious debate commenced within the scientific and medical communities of North America and Western Europe into the biological effects of close kin marriage, with Charles Darwin, who had married his first cousin Emma Wedgwood, a leading protagonist (Bittles 1994). In Europe, and in most countries that had been colonies of the major European powers, this debate resulted in few if any legislative changes. However, within the USA the eventual outcome was the passage of laws at state level to control, and in many cases to ban, first-cousin unions, even though the information on which these laws were based frequently appeared to be more emotive than factual in nature. Michigan, New Jersey, and Ohio subsequently rescinded their prohibition on first-cousin marriages, but they remain illegal in twenty-two states and are a criminal offense in eight others (Bratt 1984, Ottenheimer 1990). Interestingly, the legislation passed by some individual states recognized the traditions of specific constituent communities and so, for example, uncle–niece marriages (but not aunt–nephew) are permissible within the Jewish community of Rhode Island, while Native Americans in Colorado are free to marry their stepchildren.

1.2 Contemporary Societies in which Consanguineous Marriage is Preferential

As indicated in Sect. 1.1, the current legal situation in the USA differs markedly from that in many other parts of the world where consanguineous unions, a term derived from the Latin *consanguinitas* and indicating 'shared blood,' are strongly preferential. The reasons for this preference are mainly social and economic in origin, and include the strengthening of family relationships and the maintenance of family property and land-holdings. Prenuptial arrangements also are greatly simplified, and the security of marrying a partner whose entire family background is known is perceived as a major benefit in ensuring both the initial success and the lasting stability of the union. Variation in the specific types of marriage contracted, e.g., with father's brother's daughter first-cousin unions preferred in Arab Muslim communities as opposed to mother's brother's daughter in the Dravidian Hindu states of South India and among the Han Chinese, does however indicate additional customary influences.

1.3 The Genetic Effects of Inbreeding

In consanguineous unions the partners share genes inherited from one or more common ancestor and, for example, in first-cousin marriages the spouses are predicted to have 12.5 percent of their genes in common. This means that on average their progeny will be homozygous at 6.25 percent of gene loci, i.e., they will have received identical gene copies from each parent at these sites in their genome. If the same mutant gene is inherited from both parents the individual will express the disorder, either at birth or later in life depending on the nature and site of the mutation, thus contributing to the phenomenon of inbreeding depression.

The coefficient of inbreeding (F) is a numerical estimate of the degree of inbreeding of an individual, and so for first-cousin offspring $F = 0.0625$. Similarly, for the progeny of uncle–niece unions $F = 0.125$, while for second-cousin offspring $F = 0.0156$. In many communities there is a long and continuous history of consanguineous unions, and so the cumulative level of inbreeding may be significantly higher than the value calculated for a single generation. Under these circumstances, a correction can be applied to account for the effects of ancestral inbreeding using the formula:

$$F = \Sigma(1/2)^n\,(1 + F_A)$$

where F_A is the ancestor's inbreeding coefficient, n is the number of individuals in the path connecting the parents of the individual, and the summation (Σ) is taken over each path in the pedigree that goes through a common ancestor.

2. Incest

With a few notable exceptions, incest avoidance is, and appears to have been, a practice common to virtually all societies. Various explanations have been

offered for incest avoidance including Freudian guilt, and theories ascribed to Lévi-Strauss and others that it serves both to maintain the existence of the family and to encourage the establishment of affinal relations with other kin groups. According to the Westermarck hypothesis, incest avoidance arises principally because of negative imprinting against close associates of early childhood (van den Berghe 1983). Studies conducted on individuals raised under mixed-sex child-rearing regimes in Israeli *kibbutzim* have been cited in support of the negative imprinting theory, since they rarely marry or enter into sexual relationships (Talmon 1965, Spiro 1965). Perhaps more convincingly, a detailed investigation into the practice of *sim-pua* marriage in Taiwan, whereby a girl is adopted with the expectation that she will marry a son of the adoptive family, demonstrated aversion on the part of some intended spouses. Where a marriage did occur, *sim-pua* unions often were characterized by lower mean fertility and lesser marital stability (Wolf and Huang 1980).

2.1 Historical Examples of Dynastic and Non-dynastic Incest

There have been a number of societies in which dynastic incest was practised over multiple generations, including the Eighteenth and Nineteenth Dynasties and the Ptolemaic and Roman periods in Egypt, Zoroastrian Iran, the Incas, and the royal families of Hawaii (Middleton 1962, Shaw 1992). In Pharaonic Egypt, brother–sister or half-sister unions were regarded as a potent means of maintaining and strengthening the royal house and bloodline, although the Pharaoh also had ready access to other females who were non-relatives. Information has emerged on incestuous marriages outside these ruling classes. During the period of Roman Egypt, from the first to the third centuries AD: the records indicate that full brother–sister unions accounted for 19.6 percent of marriages in the city of Arsinoe, with a further 3.9 percent between half-siblings (Scheidel 1997). However, it has been argued that these unions may have been atypical, having been contracted in response to the restricted numbers of potential marriage partners in the minority Greek settler community. Among the Zoroastrians in Persia, the underlying rationale for incestuous unions appears to have been based on specific religious beliefs, and to have emerged just prior to the Arab invasion in 636 AD. All three types of incestuous union, father–daughter, brother–sister, and mother–son were advocated. In each case they were described as being of especial religious merit, with their practice a means of expiating mortal sin.

2.2 Incest in Contemporary Societies

There is the conundrum that, despite the claimed near-universality of an incest taboo, an extensive and growing literature exists on the occurrence of incest in contemporary Western societies. Most commonly these reports have emanated from case studies conducted either on persons examined because of intellectual handicap or in psychiatric clinics, thus leading to the general conclusion that incestuous relationships are highly detrimental to those classified as victims. In some cases, however, it has been suggested that the outcome need not necessarily be psychologically destructive, with women in stable marriages acknowledging earlier father–daughter sexual relationships which had commenced prior to puberty in the female. As will be discussed in Sect. 3.2, given the fact that incest is both illegal and widely regarded as morally reprehensible, it would be difficult to determine how common this latter response might be without exposing respondents to the risk of self-incrimination.

3. Biological Outcomes of Consanguinity and Incest

The first major study into the biological effects of inbreeding was conducted by Dr Samuel Bemiss of Louisville, Kentucky in 1858, using reports forwarded by medical colleagues on the outcomes of unions ranging from incest to third-cousin marriages. Since that time hundreds of additional studies have been undertaken based on a variety of sampling techniques, including pedigree analysis, household surveys, questionnaires administered to hospital in- and out-patients, Roman Catholic dispensation records, and surname analysis. In populations such as Dravidian South India, where uncle–niece ($F = 0.125$) and first-cousin unions ($F = 0.0625$) are preferential and jointly account for some 30 percent of marriages, unions beyond second cousins ($F < 0.0156$) are of limited biological significance (Bittles et al. 1991). Conversely, in a country such as Finland where consanguineous unions are rare, or in endogamous communities in which close-cousin marriage has been proscribed on religious grounds, biologically remote relationships including third-cousin unions ($F = 0.0039$) may result in moderate levels of cumulative inbreeding through time and so prove to be of clinical relevance.

3.1 Measuring the Biological Outcomes of Inbred Marriages

In an attempt to rationalize the results of inbreeding surveys into a biologically meaningful and reproducible format, a method was devised to calculate the numbers of lethal gene equivalents in a community or population, by comparing death rates in the progeny of consanguineous and unrelated couples. Lethal gene equivalents are the numbers of detrimental recessive genes carried by an individual in the heterozygous state, which, if homozygous, would result in

Table 1
The outcomes of first-degree incestuous unions

Country of origin	No. studied	Follow-up (year)	Death and severe defect	Other defect/ mild intellectual handicap	Normal	Source
USA	18	0.5	6	5	7	Adams and Neel (1967)
UK	13	4–6	4	4	5	Carter (1967)
Czechoslovakia	161	1–37	65	18	78	Seemanová (1967)
Canada	21	0.5–19	9	4	8	Baird and McGillivray (1982)
Totals	213		84 (39.4%)	31 (14.6%)	98 (46.0%)	

death and so add to the genetic load of the population. The number of lethal gene equivalents in a population can be calculated according to the formula:

$$-\log_e S = A + BF$$

where S is the proportion of survivors in the study population, A measures deaths that occur under random mating, B represents deaths caused by the expression of recessive genes via inbreeding, and F is the coefficient of inbreeding (Morton et al. 1956). By plotting a weighted regression of the log proportion of survivors (S) at different levels of inbreeding (F), A can be determined from the intercept on the Y-axis at zero inbreeding ($F = 0$), and B (the number of lethal gene equivalents) is given by the slope of the regression.

Despite a number of limitations, this regression technique offers a simple and convenient method of assessing and comparing data on the effects of inbreeding in different populations. Through time, estimates of the mean number of lethal gene equivalents in the genome have been revised downwards, in part resulting from improved sampling techniques and the recognition that earlier surveys may have produced spuriously high values because of inadequate control for non-genetic variables. Most recently, an excess mortality rate of 4.4 percent was calculated for deaths among first-cousin offspring from approximately 6 months gestation to 10 years of age, equivalent to 1.4 lethal genes per person (Bittles and Neel 1994). The measurement of postnatal morbidity is less precise since it is reliant on the diagnostic criteria employed. As a result the estimates obtained can vary quite widely, e.g., from 1.4 percent to 4.1 percent for total morbidity prior to the age of reproduction (Schull and Neel 1965).

3.2 The Biological Outcomes of Incest

As first degree relatives have 50 percent of their genes in common, the progeny of an incestuous union will be homozygous at 25 percent of loci and so $F = 0.25$. Given the strongly antagonistic legal and social attitudes to incest, direct assessment of associated biological outcomes may be subject to significant ascertainment bias, since a detailed examination including determination of paternity may only be initiated if a child shows symptoms of physical and/or intellectual handicap. The net result is a paucity of data, which may or may not reflect the incidence of incestuous pregnancies that successfully proceed to term. Problems can also arise in attempting to control for the potentially adverse effects of non-genetic variables, which include maternal and paternal age, parental disease, and unsuccessful attempted interruption of the pregnancy.

3.3 Direct Examination of the Progeny of Incest

Table 1 comprises data from the four most comprehensive published studies of incest. The first and obvious observation is that very few cases have been systematically investigated, surprisingly so since the topic of incest features prominently in the social and behavioral literature. Three of the studies were prospective, and in one investigation strenuous efforts were made to recruit matched non-incestuous controls (Adams and Neel 1967). There were no control subjects in two of the other studies (Carter 1967, Baird and McGillivray 1982), and the brief report by Carter (1967) was further restricted by a lack of information on the physical and mental status of the parents or their socioeconomic background. In several studies the period of follow-up was brief, and so disorders with a later age of onset may not have been detected.

By far the largest survey was that of Seemanová (1971), conducted retrospectively in the former Czechoslovakia on incestuous births reported between 1933 and 1970. An ingenious approach to the problem of controls was employed, with the outcomes of incestuous matings compared to those of pregnancies undertaken by a subset of the same women with unrelated partners. Unfortunately, the methodology could not overcome the fact that the physical and mental status of these women, 33 percent of the

original total, was significantly superior to the remainder of the study group. In addition, many of the incestuous pregnancies had taken place when the women had just completed menarche, with mean and modal ages of 18.9 and 16 years in the father–daughter matings and 19.9 and 14 years in the brother–sister matings, versus 24.9 and 21 years in the married pregnancy group. As very young maternal age is associated with an adverse pregnancy outcome, these discrepancies while unavoidable nevertheless cause significant problems in comparing the test group and their half-sibs.

How then should these four sets of data be assessed? Clearly, the mean rate of physical and mental abnormality of 39.4 percent is very high. But, as discussed in Sects. 2.2 and 3.2, the collection of data on this subject is extremely difficult and, as acknowledged by several authors, control for non-genetic variables in the incestuous unions may have been incomplete. In the two studies for which unrelated reference groups were available, 9 of the 113 control children died or had a serious defect (8.0 percent). Thus the mean excess level of death and severe defect in the offspring of incestuous unions was 31.4 percent, not all of which was necessarily genetic in origin.

3.4 Comparison of Incest with Other Categories of Inbred Union

The second major method of estimating the probable levels of defect in the progeny of incestuous matings is based on information gained from legal consanguineous unions. For example, it is assumed that as the progeny of an incestuous mating have a coefficient of inbreeding of $F = 0.25$, their levels of disease and disability will be four times higher than in first-cousin offspring ($F = 0.0625$). The main advantage of this approach is that information on first-cousin unions is more plentiful, and it is less likely to be subject to bias during data collection. A potential disadvantage is that the relationship between the level of inbreeding and rates of disease and disability may be nonlinear, with disproportionately larger increases in the prevalence of deaths and defects at closer degrees of inbreeding. This situation could arise if incest was associated with increased rates of conditional lethals, genes that are only expressed under especially stressful circumstances, as might be encountered in an incestuous pregnancy. To date there has been no evidence that conditional lethals are expressed in the progeny of close kin unions. Therefore the excess mortality rate of 4.4 percent derived for deaths among first-cousin offspring (Bittles and Neel 1994) can be applied to estimate the prevalence of lethal defects in an incestuous pregnancy, i.e., 16 percent to 20 percent excess deaths. Likewise, from Schull and Neel (1965) excess morbidity among incestuous offspring would predictably range from 6 percent to 16 percent, suggesting a total rate for excess death and major disability in children born to first-degree relatives of between 22 percent and 36 percent.

4. Conclusions

The data currently available on the outcomes of both legal consanguineous marriages and incestuous relationships merit further examination and updating. Since the major study undertaken by Schull and Neel (1965) in Japan no comparably detailed investigation has been attempted, despite the remarkable epidemiological transition which has occurred during the last two generations. Across Asia, genetic disorders are becoming increasingly obvious as deaths due to infectious diseases decline, and early childhood mortality is replaced by extended morbidity. This change is especially important among couples in consanguineous unions, where higher rates of genetic disorders are to be expected, involving both autosomal recessives and polygenic disorders. In fact, because of better access to diagnostic and health care facilities, the burden of genetic disease will probably be most obvious and of greatest immediate significance among migrants from Africa and Asia now resident in North America, Western Europe, and Australasia, who have chosen to continue their tradition of close kin marriage. With respect to incest, it seems remarkable that the voluminous social and behavioral literature is still so inadequately matched in biological terms. Studies to identify the precise nature, extent, and timing of any genetic defects that may be expressed are needed, especially since in a significant proportion of cases the children of incestuous unions are offered for adoption. The advent of DNA-based analytical methods will greatly facilitate this process, and provide information of previously unparalleled insight and sophistication. In the interim, appropriate caution should be exercised in judging the biological outcomes of all categories of close kin union.

Incest Prohibition, Origin and Evolution of

Most anthropologists now agree that there is at least one universal institution—the incest taboo, which is usually defined as socially sanctioned disapproval of sexual relations between certain classes of kin. There is also general agreement that while the scope of the taboo and the sanctions invoked by its breach vary widely, it applies universally to sexual relations between mother and son, and almost universally to father/daughter and brother/sister relations. The exceptions are the Greek-speaking population of Roman Egypt and the ruling families of several old, long since defunct tributary states (see Hopkins 1980).

The incest taboo, like Berlin before German reunification, is located on the border between two great empires and, like Berlin in the 1950s, has symbolic as well as strategic significance. The taboo is a rule that is commonly codified as law and thus, in one respect at least, clearly belongs to the domain of inquiry ruled by the social sciences. But the taboo is about sex, and specifically about sex between people, most of whom are related genetically and thus, in another respect, clearly belongs to the domain of inquiry ruled by the biological sciences. Put another way, the taboo may be said to stand at the long-disputed boundary between nature and culture.

The great French anthropologist, Claude Levi-Strauss, recognized this, and tried to use the taboo to define that boundary and defend social science's claim to an exclusive right to everything on the cultural side. The taboo was, in his memorable phrase, 'a passage from nature to culture, from animal to human life' (Levi-Strauss 1960, p. 278). By accepting Sigmund Freud's claim that 'the first choice of object in mankind is regularly an incestuous one' (1923, p. 343), he located the taboo on the cultural side of the frontier and turned it into a frontier fortress. The taboo was social not only in form. Its origins were social and could only be divined by social scientists. Far from expressing an innate inclination, the primary purpose of the taboo was to repress an innate inclination.

The passage effected by the invention of the incest taboo was, in Levi-Strauss's account, a heroic journey. At some early stage in its history, mankind was forced to recognize that 'in order to free itself from a wild struggle for existence,' it had to forswear its preferred sexual objects. Instead of marrying the women born into their natal group, men had to exchange them for women born into other groups. The choice was between

> biological families living in juxtaposition and endeavoring to remain closed, self-perpetuating units, over-ridden by their fears, hatreds, and ignorances, and the systematic establishment, through the incest prohibition, of links of intermarriage between them, thus succeeding to build, out of the artificial bonds of affinity, a true human society, despite, and even in contradiction with, the isolating influence of consanguinity (Levi-Strauss 1960, p. 278).

Levi-Strauss's account of the incest taboo is best read as a sociological version of the story told by Freud in *Totem and Taboo* (Freud 1950). Another version is Bronislaw Malinowski's (1930) account of the taboo as the means by which the family is saved from the sexual competition that would inevitably erupt if men were allowed sexual access to their mothers and sisters, and women to their fathers and brothers. A third version, that still attracts attention, argues that the incest taboo exists to protect human beings from the biologically deleterious effects of

inbreeding. The common element in all of these stories is that the incest taboo exists to protect human beings from human nature. In its absence, society would dissolve into small, isolated groups; or the family would be torn asunder by sexual competition among its members; or the population would degenerate as a result of close inbreeding.

On the topic of the incest taboo, anthropologists act like a segmentary lineage. No matter how bitterly they oppose one another on other issues, Marxists such as Claude Meillassoux and Maurice Godelier, cultural materialists such as Leslie White and Marvin Harris, structuralists such as Claude Levi-Strauss and Rodney Needham, and radical social constructionists such as Marshall Sahlins and David Schneider unite to oppose vigorously anyone who suggests that instead of restraining human nature, the incest taboo may be rooted in human nature. Faced with an argument that says the incest taboo is not entirely conventional, they return to Sir James Frazer's assurance that 'we may always safely assume that crimes forbidden by law are crimes which many men have a natural propensity to commit.' On this assumption it is easy to argue that 'if the law represses [incest], as it represses other natural instincts, it does so because civilised men have come to the conclusion that the satisfaction of these natural instincts is detrimental to the general interests of society' (Frazer 1910, p. 97).

Larry Arnhart (1998) has called the tradition these arguments represent 'ethical transcendentalism.' It is a tradition that began in Greece with the sophists and found expression in the writings of Thomas Hobbes, Bernard Mandeville, and Immanuel Kant as well as in work of such modern social scientists as Emile Durkheim and Max Weber. Its counterpart is the 'ethical naturalism' that originated among the Socratic philosophers and was developed by Thomas Acquinas, Francis Hutcheson, Adam Smith, David Hume, and Charles Darwin. Its most important representative in the modern debate over the origins of the incest taboo was the Finnish anthropologist/sociologist/philosopher, Edward Westermarck. Frazer's purpose in insisting that 'the law only forbids men to do what their instincts incline them to do' (1910, p. 97) was to counter Westermarck's suggestion that 'there is a remarkable absence of erotic feelings between persons living closely together from childhood' and that this sexual indifference, 'combined with a positive aversion when the act is thought of,' is the cause of the incest taboo (1922, pp. 192–3). The suggestion was an anathema to a transcendentalist like Frazer because it located the source of the moral disapproval that forms the core of the taboo on the natural side of the great nature/culture divide.

When Westermarck published his proposal in 1891 it was greeted by the leading scientists of the time, including Anthony Wallace and E. B. Tylor, as 'the solution' to the problem of the incest taboo (see Wolf 1995, pp. 7–9). But by the time the fifth edition appeared in 1922, criticisms initiated by Frazer and developed by Freud had reversed this judgment. In his review, Bronislaw Malinowski, then Westermarck's colleague at the London School of Economics, admitted that 'Prof. Westermarck's theory of exogamy … seems to find favour with no one.' The list of Westermarck's critics reads like an honor role of twentieth-century social scientists—Robertson Smith, Andrew Lang, Sir James Frazer, Havelock Ellis, Sigmund Freud, William MacDougall, Emile Durkheim, Brenda Seligman, Bronislaw Malinowski, George Peter Murdock, and Claude Levi-Strauss. When a distinguished consortium of social and biological scientists gathered in 1960 to evaluate research on the incest taboo they did not even discuss what by then was known as 'the Westermarck hypothesis.' It is mentioned in their report 'only for the sake of completeness' (Aberle et al. 1963, p. 258).

Westermarck sank beneath a rising tide of transcendentalism initiated by the institutionalization of the social sciences in the early years of the twentieth century. To establish sociology and anthropology as specialized fields of study with buildings and budgets, their founding fathers had to identify independent subject matters. They had to make society and culture autonomous phenomena. The Westermarck hypothesis threatened this effort by breaching the barriers set up to defend these newly created domains from the claims of psychologists and biologists. Westermarck was mentionable only for the sake of completeness, because his hypothesis surrendered to the competition the only institution that everyone accepted as universal.

The evidence social scientists cited in rejecting the Westermarck hypothesis consisted exclusively of Freud's claim that 'psychoanalytic investigations have shown beyond the possibility of doubt that *an incestuous love-choice* is in fact the first and regular one' (Freud 1923, pp. 220–1). That this was not their real reason for rejecting the hypothesis is clearly evident in the fact that they did not cite Freud's views on any other important subject. The real reason social scientists cited Freud on incest was to capture the taboo for their newly founded disciplines. Freud served their purpose admirably. He was the most famous psychologist of the century, yet concluded that the causes of the incest taboo 'are not to be sought in the psychology of the individual' (1923, p. 221).

The Westermarck hypothesis was hailed initially as the solution to the problem of the incest taboo, because it appeared before the social sciences had erected transcendalist barriers to define their domains. It was resurrected 50 years after its announced demise by a generation of social scientists trained in the 1950s and early 1960s when, for a brief period, these barriers were left ungarrisoned. The Vietnam War did not mark the beginning of a revolutionary period in the social sciences. It marked the end of a revolutionary period. In the 1950s the rapid growth of higher

education created such an ample supply of money and jobs that, for a few years, competition between the disciplines gave way to an intellectual euphoria in which interdisciplinary training was encouraged. The result was a small cohort of social scientists who were relatively undisciplined.

The members of this cohort who did the most to effect a Westermarck revival were Robin Fox and Arthur Wolf. Although Fox (1952) was reluctant to reject Freud's account of the incest taboo, he initiated the Westermarck revival by treating his hypothesis as a respectable alternative. He also encouraged Joseph Shepher to undertake what turned out to be an influential study of the effects of the early association experienced by children raised together in Israeli kibbutzim. The problem with testing the Westermarck hypothesis had always been that the only children who are commonly reared together are brothers and sisters. Evidence that they are not attracted to one another could not be used to support Westermarck, because this is exactly the effect predicted by social scientists such as Levi-Strauss, who argued that the incest taboo 'remodels the biological conditions of mating and procreation' (1960, p. 278). The kibbutzim practice of communal rearing offered a rare opportunity to disentangle the effects of the confounded variables. Though the children of some kibbutzim were reared together from birth as intimately as any brothers and sisters, they were not brothers and sisters, and were not subject to the strictures of the incest taboo. Yet Shepher's survey of 2,769 marriages turned up only 13 cases in which the couple had been reared together, and in 12 of these cases the couple had not been brought together until after age three. The one exception was a couple brought together at birth but separated between ages two and six (Shepher 1971, pp. 296–7).

Westermarck's papers at the Åbo Academy in Turku include a letter from a former student inviting him to teach in China. He accepted the invitation, but was unable to make the trip, unfortunately, for if he had he might have discovered the natural experiment that would have proved his hypothesis. For reasons pointed out by John Hartung (1985), the data from Israel were not conclusive. A better test was available in China, where women commonly gave away their daughters and reared in their place wives for their sons. Arthur Wolf (Wolf and Huang 1985) calls the marriages that result 'minor marriages,' and contrasts them with what he terms 'major marriages.' Where couples married in the minor fashion were reared together from an early age, couples married in the major fashion did not meet until the day of their wedding.

Although the Taiwanese legal scholar Tai Yen-hui had noted as early as 1943 (Tai 1943) the relevance of minor marriages to the Westermarck hypothesis, the opportunity offered was not fully appreciated until 1958, when Wolf undertook a study of children's play in a small village in the Taipei Basin. He found that more than half of his subject's parents had been reared together and were not happily married. Village gossip indicated that they were far more likely to engage in extramarital relations than their neighbors who were married in the major fashion (Wolf 1968). This unanticipated discovery led Wolf into what became a 40-year effort to vindicate Westermarck. With evidence drawn from household registers compiled by the Japanese colonial government, he reconstructed the marital histories of 14,200 women, demonstrating that minor marriages produced 40 percent fewer children than major marriages and three times as many divorces. What made these results particularly compelling was the further discovery that they only held among women who had joined their future husband's family before age three (Wolf 1995). The critical variable was, as Westermarck had always maintained, *early* association.

It is puzzling that, despite spending much of his adult life in Morocco, Westermarck did not attempt to gather systematic information about the effects of *bint'amm* marriage, which was the preferred form of marriage in many Arab communities, and united cousins raised in the same household. Fortunately, Westermarck's failure in this regard was made good by Justin McCabe and Alex Walter. McCabe's 1974–5 study of 93 marriages in Lebanon, and Walter's 1991 study of 275 marriages in Morocco demonstrated that, among Arabs, as among Israelis and Taiwanese, 'there is a remarkable absence of erotic feelings between persons living closely together from childhood.' The only question these studies raised is why Westermarck did not pit *bint'amm* marriages against Freud's hysterics.

In most discussion of the orgins of the incest taboo, 'the Westermarck hypothesis' refers to Westermarck's claim that early childhood association inhibits sexual attraction. In fact, this is only one of three linked propositions that together constitute his explanation of the incest taboo. The first, highly controversial when proposed in 1891, is now accepted as dogma by biologists. It is simply the claim that inbreeding depresses reproductive fitness. Westermarck took this to be the reason childhood association inhibits sexual attraction. He argued that 'in this case, as in other cases, natural selection has operated, and by eliminating destructive tendencies and preserving useful variations, has moulded the sexual instinct so as to meet the requirements of the species' (1934, p. 159).

In his introductory lectures in 1917, Freud suggested that his audience 'would hardly recall without smiling' the view that 'sexual attraction is diverted from members of the opposite sex in one family owing to their living together from childhood' (1923, pp. 343–4). As we enter the twenty-first century, it is Freud's view that elicits smiles. The testimony of kibbutz marriage, minor marriage, and *bint'amm* marriage all agree that this, Westermarck's second proposition,

was right all along. Attention is now turning to the third of Westermarck's three propositions. It addresses what Bernard Williams (1983) has termed usefully 'the representation problem,' the problem of how a behavioral tendency comes to be represented in language and conceptual thought as a rule. Westermarck's (1906 and 1908) solution was to argue that incest is one of a class of acts that causes us to feel hostile toward another person even though that person's behavior does us no harm. This is because what the person does arouses painful emotions by forcing us to contemplate an emotionally unacceptable possibility. Thus the taboo is simply the reaction of the community to acts that arouse painful emotions in the majority of its members.

At the time of writing, the most widely accepted alternative to Westermarck's solution to the representation problem is an argument advanced by Richard Burton (1973) and William H. Durham (1991). They claim that human beings have long recognized the deleterious effects of inbreeding, and that the taboo was instituted to avoid these effects. Thus the debate is turning from the question of whether or not early association inhibits sexual attraction to the question of whether or not early humans would have noticed that the children of incest are less fit than other children. It is still far too early to say whether or not Westermarck will win a third round, but no one can now doubt that he will be credited with the solution to the problem of the incest taboo. In an obituary that reads like an indictment, Levi-Strauss characterized Westermarck as 'less a continuator than a survivor' (Levi-Strauss 1982, p. 181). His judgment now says more about him than it does about Westermarck.

Incidental versus Intentional Memory

The distinction between incidental and intentional memory deals with differences in people's expectations and strategies while encoding episodic information. In a standard memory experiment, intentional memory refers to study conditions in which participants are

forewarned that they will be tested on material to which they are exposed. By contrast, learning is said to be incidental when participants are not expecting a memory test. Although learning in everyday life is both incidental and intentional, the former type of activity is more prevalent in most everyday situations in that people observe events and activities without having explicit instructions about a forthcoming memory test.

Other things being equal, intentional learning instructions typically produce better recall and recognition performance than incidental learning instructions. A central issue in this context is, however, whether differences in performance following incidental vs. intentional leaning instructions are due to the nature of intent *per se* (e.g., through increased motivation, arousal, and activation). An alternative possibility is that these effects can be attributed to processing differences following incidental vs. intentional learning instructions (e.g., due to differences in study time, elaboration, organization and subsequent rehearsal).

Concerning the latter notion, although intentional learning instructions produce better memory performance than incidental learning instructions in a variety of task conditions, these differences can be understood without making specific assumptions about the nature of intent *per se*. Instead, past research indicates that intent to learn is not of crucial importance, and that the effect of intentional learning can be attributed to the nature of processing activity during encoding and subsequent retention interval. In other words, memory performance following incidental learning instructions is comparable to that of intentional learning instructions given that similar encoding processes are used in both conditions.

As a support for this notion, Hyde and Jenkins (1973) reported an experiment in which they attempted to equate participants' encoding activities, while manipulating learning instructions (i.e., incidental vs. intentional learning). Participants studied lists of words under five different conditions. These *orienting tasks* differed in terms of *level of processing* with some tasks reflecting relatively shallow processing level, whereas the other orienting tasks involved deeper, more semantic processing. Hyde and Jenkins (1973) found that recall performance increased as a function of processing level and, more important in the present context, that the same pattern of results was observed for the incidental and intentional learning conditions. In other words, participants' orientation toward a stimulus, rather than explicit intention to remember, was the important determinant of retrieval success. These findings indicate that intentional learning instructions have indirect, rather than direct, effects on subsequent memory performance in that intention to learn induces more effective encoding strategies, including rehearsal and recoding.

Similar findings have been observed when participants' motivation has been manipulated by using different forms of incentives. For example, Nilsson (1987) reported a study in which three groups of students were instructed to memorize lists of words for subsequent free recall and recognition tests. To manipulate motivation, one group of participants was informed of a monetary incentive prior to study. A second group was informed of these incentives after study but prior to the test, whereas no mention of incentives was made to the third group of participants. The results of the study indicated a dissociation between subjective reports and objective memory performance. Subjective reports indicated that the incentives had affected the amount of effort put into the memory task, but these subjective reports did not reflect differences in actual memory performance. Instead, the three groups showed comparable levels of recall and recognition performance.

As noted by Roediger and McDermott (1993), the distinction between incidental and intentional learning during study parallels the distinction between implicit and explicit memory instructions at test. In the latter case, *explicit memory* tests direct participants to recall past experience (i.e., intentional retrieval), whereas in *implicit memory* tests the influence of past experience is revealed under task conditions that reflect incidental retrieval (see also Schacter et al. 1989). Consistent with Hyde and Jenkins' (1973) findings with explicit memory tests, intention to learn has no effect on implicit memory performance. For example, Roediger et al. (1992) used a standard levels-of-processing manipulation with a graphemic and semantic orienting task. Participants were either informed or not about the forthcoming (explicit and implicit) memory test, in which word stems and word fragments were presented as cues. Roediger el al. (1992) found no effect of intention either on implicit or explicit memory performance (see also Bowers and Schacter 1990, Greene 1986).

Although intention to learn has minimal effects on explicit and implicit memory, research on delayed intentions, or prospective memory (see Brandimonte et al. 1996 for an overview) indicates that representation of intentions may have specific dynamic properties. One basis for this hypothesis was Lewin's (1961) notion that unfulfilled intentions produce a persistent 'goal tension.' According to Lewin, the after-effect of intention is a force that produces a 'quasi-need' to carry out planned action. Lewin stated that the clearest subjective experience of this force occurs in the resumption of interrupted tasks, when a general pressure—that 'that there is something I should do'—appears (Lewin 1961, p. 1251).

Zeigarnik, Lewin's student in his Berlin laboratory, examined the memorial consequences of interrupting actions. Zeigarnik (1927) (see also Ovsiankina 1928) presented participants with a series of concrete tasks, such as threading beads or drawing a vase. Participants were allowed to complete one half of the tasks, whereas

the experimenter interrupted the remaining tasks, interspersed throughout the series, before participants could complete them. Immediately after the completion of the series, participants were given a free recall test in which they were asked to recall the names of the tasks. Zeigarnik demonstrated superior recall of activities that were interrupted prior to completion as compared to completed actions. Although these findings were consistent with the assumption that incomplete intentions produce a persisting task tension, task interruption research has been criticized for conceptual and methodological shortcomings (see Butterfield 1964, van Bergen 1968, Ryan 1970 for reviews).

Goschke and Kuhl (1993, 1996) provided more recent support for the notion that representation of intentions may have specific dynamic properties. Consistent with Lewin's notion of goal tension, Goschke and Kuhl reasoned that intended actions are represented at a heightened level of activation as compared with material which is not intended for future action. Goschke and Kuhl (1996) proposed that the retrieval of an (nonroutine) intention depends upon both the quality of available retrieval cues and the level of activation at which the intention is represented at any given moment.

To examine whether intentions are represented at a higher or more sustained level of activation, Goschke and Kuhl (1993) developed a paradigm in which participants first memorized verbal descriptions of two different activities (e.g., setting the dinner table and clearing a messy desk). After the study phase, participants were informed that they should later either execute one of the scripts or observe the experimenter executing the action and register possible mistakes. The second script in each condition was neither executed nor observed, but the participants were informed that their memory for both scripts of a pair would be tested. Immediately after the execution or observation instructions, the participants received a recognition test for words for both scripts. Goschke and Kuhl reasoned that if intention-related concepts are characterized by a higher level of activation than nonintention-related concepts, the recognition latencies for words from the to-be-executed script should be faster than words from the to-be-remembered script. The results of Goschke and Kuhl's (1993) study supported this prediction by showing an 'intention-superiority' effect even when the use of strategies was limited. However, in a control condition in which the participants had to observe someone else executing a script, latencies for words from the to-be-observed script did not differ from neutral words.

Although these findings indicate that intention-related concepts are characterized by a heightened and more sustained level of activation than other memory contents, they do not necessarily justify the conclusion that the intention-superiority effect underlies successful (prospective) memory performance. In other words, although the intention-related concepts were recognized faster than nonintention-related concepts in Goschke and Kuhl's study (see also Koriat et al. 1990, Mäntylä 1996, Marsh et al. 1998 for similar findings), the question remains open as to whether an increased activation of intention representation also facilitates subsequent memory performance.

Income Distribution

The subject of income distribution is concerned with explaining and evaluating the way in which the total national income is divided. The concern of classical economists with the shares of factors of production (capital, labor, and land) in national income has evolved into an analysis of the distribution among persons. Distribution by factors is still relevant, but largely as a means to understanding the personal distribution. Statistics are regularly published in most countries showing the shares of, for example, the top 20 percent in total personal income, or summary measures of inequality such as the Gini coefficient. But several issues arise when interpreting them in the light of positive and normative economic theory.

1. *Income Distribution and Economics*

For David Ricardo, writing in 1817, 'to determine the laws which regulate [the distribution of income] is the principal problem in Political Economy', and for many non-economists today, the issue of how national income is divided must appear one of the central questions of economics. Why are airline pilots paid more than railroad drivers are? Why are CEOs paid in a week what others take a year to earn? Do large fortunes arise mainly from inheritance?

Classical economists, such as Ricardo, were concerned with the determinants of payments to factors of production, and much of what can be found in today's textbooks under the heading of the 'Theory of Distribution' is concerned with the factor distribution of income. But it is the personal distribution of income—how much is received by individuals—which is more obviously of interest in public debate. The subject of the personal distribution has not however always been regarded as important by the economics profession. In the first part of the twentieth century, there were important contributions, but the topic was never central to the concerns of economists. In the second half of the century, there were indeed times when interest in the distribution of income was at a low ebb, economists appearing to believe that differences in distributive outcomes were of second order importance compared with changes in overall economic performance. People justified a lack of distribution concern by the argument that those at the bottom would gain more from employment policies and the promotion of economic growth than from redistribution.

At the start of the twenty-first century, the position is different. Europe has seen prolonged unemployment. There has been widening wage dispersion in a number of OECD countries, notably in the USA. Rising affluence in rich countries coexists, in a number of such countries, with the persistence of poverty. Economists have responded quickly to the renewed policy interest in distribution, and there is an extensive recent literature, both theoretical and empirical (see Atkinson and Bourguignon 2000). What can we say about the determinants of the distribution of income, its evolution over time, and the way it is affected by policy? There are many competing theoretical answers to these questions. Theoretical inquiry has an empirical counterpart. Statistical institutes publish evidence on the distribution of income on the basis of various statistical concepts and indices: dispersion of earnings, inequality of household's net income after taxes and transfers, inequality of wealth, etc. We have to ask whether we have developed the concepts necessary to interpret this evidence, and whether the data are of adequate quality.

Studying income distribution is important not only in its own right but also because it assists our understanding of various fields of economics. Even if there were no ethical reason for studying distribution, it would still be required as a conditioning parameter in other economic phenomena. A good example is the relationship between growth and distribution. Growth may affect distribution, and conversely changes in distribution may lead to faster growth. Aggregation is the methodological bridge between distribution issues and mainstream economic analysis. For example, aggregate consumer demand is the sum of the demands of individual households. The treatment of differences between households has long been standard in consumer theory, but other examples are emerging, such as the introduction of heterogeneous agents in macroeconomics. Distribution has always been prominent in development economics. It was clearly central to Marxian economics.

2. *Seeking to Explain the Distribution*

No unified theory of income distribution exists; instead the literature offers a series of building blocks

which provide part of an explanation. This section reviews these various blocks and the links between them.

2.1 Factor Incomes

A natural starting point is the theory of competitive general equilibrium, which in its standard Walrasian formulation takes as given the distribution of all productive factors in the economy and focuses on the rate at which they are paid. It is a simple model, but it underlies much of applied and theoretical literature on income distribution.

In a static framework, each individual is endowed with productive factors, where these may include different types of capital or labor skills. Firms produce various goods using these factors of production. Individuals receive income from the sale of their productive factors and from their ownership of firms. The competitive equilibrium model is closed by determining the prices and factor rewards that equilibrate demand and supply of the various goods and factors. The distribution of income thus results from the combination of the multi-dimensional distribution of endowments, the per unit returns to these endowments, and of the distribution of the ownership of firms within the population. In such a framework, a theory of income distribution is essentially a theory of factor rewards, and this explains the location of the subject in many economic textbooks as part of the theory of pricing.

This general equilibrium formulation has been applied both in empirical detail, as in Computable General Equilibrium models of income distribution, and in relatively simple theoretical versions. An example of the latter is where there are two factors of production: labor supplied by workers who make up a fixed fraction of the population, and capital owned by capitalists, who do not work and make up the rest of the population. The relative distribution of incomes in the population depends only on the income and population shares. This two-class economy, reminiscent of Ricardo, is the simplest justification for reducing the issue of income distribution to that of factor shares. At the beginning of the twenty-first century, however, this is scarcely adequate for several reasons. We need to explain the distribution of factor incomes within classes, such as the size distribution of wages. Capital takes the form not only of material assets, but also of human capital: the investment which people make in themselves in the form of education and training. People cannot be identified with a single source of income: one individual may be in receipt of wages, interest income, and rent (for example through owning a house). We cannot therefore draw any direct implications for the personal distribution from observations of changes in factor prices.

2.2 Wage Differentials

There has been a long-standing historical interest in the evolution of the differential between the wages of skilled and unskilled workers, with evidence going back to 1300 in England, when building craftsmen were paid 3d a day, compared with 2d a day for laborers. At the end of the twentieth century in the USA, there has been considerable debate about the causes of the observed increase in wage dispersion, this being interpreted in terms of the supply and demand for skill.

One set of theories of the distribution of wages has emphasized the role of random shocks, whereby individual earnings are governed by a stochastic process. If the logarithm of earnings follows a random walk, then, after some time, earnings are distributed lognormally among individuals with an increasing variance over time. This is the well-known Gibrat's law. With a Galtonian mean reversion process, the distribution of wages tends toward some limit that depends only on the characteristics of the distribution of the stochastic shocks and the reversion parameter. It is via the latter that 'economics' may enter, determining the degree of magnification of the inequality due to the stochastic term, and the convergence or otherwise of the process.

Stochastic models have been repeatedly criticized on the grounds that they do not incorporate individual optimizing behavior and market clearing. In contrast, in a supply and demand framework, changes in wage differentials, say between skilled and unskilled workers, depend on shifts in demand or in supply. A model of this kind was the basis for the 'race' between technological development and education described by Tinbergen (1975) and is very much behind today's debate on increasing wage inequality. Tinbergen referred to people being educated to graduate or high-school level. (The analysis refers to an advanced country, in that it assumes that everyone receives at least a high school education.) Total output is produced using graduate labor, high school labor, and capital, and from the production function we can obtain the profit-maximizing choice of labor by competitive firms. If the relative supplies are fixed in the short-run, then we can solve for the market clearing wage differential. It has been argued that this differential increased because demand has shifted away from unskilled labor: for example on account of technological factors biased in favor of skilled labor, or, in a multisectored model, biased in favor of sectors intensive in the use of skilled labor. An alternative explanation is that the expansion of world trade has led to a drop in the relative price of goods that are relatively intensive in unskilled labor.

Over time, the supply of factors will respond to shifts in demand possibly canceling the initial increase in the wage differential. For Tinbergen, the outcome depended on a race between the growth in the relative

numbers with graduate education and the demand shifts increasing the importance of graduate labor in production. Behind the supply adjustment lies a theory of investment in human capital, of the kind developed by Mincer (1958) and Becker (1967). Investment in human capital by an individual is governed by the equalization of marginal return and marginal cost. If the return on investment in education, or its marginal cost is individual-specific, then accumulation differs across persons. In such a model, the long-run cause of income differences, apart from stochastic terms, becomes the difference in abilities; we have therefore simply pushed the problem back one stage to the explanation of these ability differences.

Applied to the skilled/unskilled wage differential, the human capital theory has two important implications. First, to the extent that there are no differences in ability, and no stochastic terms, then no lifetime inequality is introduced: the wage premium for skill is simply a compensating differential. Second, the compensating wage differential depends on the rate of interest. A rise in real interest rates could explain observed widening in the wage distribution.

Present-day theories of wage differentials are essentially framed in terms of supply and demand. They contrast markedly with earlier writing, where there has been a creative tension between market force and alternative explanations of wage differentials. The competitive model has to be modified to allow for trade union/employer negotiations and for the impact of government, both on collective bargaining and directly on wage determination. If it is the case that unions lead to lower earnings dispersion, then one possible cause of observed increases in dispersion is the decline in union power and coverage. The direct impact of government has included minimum wage protection, income policies, and 'fair wages' requirements for government contractors. Trade union bargaining and statutory wage determination may be incorporated into the supply and demand framework, as is actually done in modern theories of wage setting; and the same applies to monopsonistic behavior by employers. More of a challenge is the view that supply and demand only place limits on the possible wage differentials, with other factors such as notions of fairness or equity determining where between these limits wages actually lies. Such a 'range theory' of wage differentials has long been implicit in much institutional writing on labor economics.

Institutional models have also emphasized labor market segmentation. Wages are fixed in some firms or sectors at a level above the competitive rate for a given type of labor. Workers outside this privileged segment of the labor market would like to enter, but the number of openings is limited and rationing occurs according to some scheme that is arbitrary or partly dependent on the characteristics of the workers. Several mechanisms have been invoked to explain this segmentation of the labor market and the wage dispersion that it creates: efficiency wages, the existence or the uneven strength of labor unions, and more generally the distinction between insiders and outsiders in the internal labor market. An extreme case of segmentation is labor market discrimination by which some individuals in the labor force are simply prevented from being hired in some jobs or at some wage levels on the basis of their ethnic origin or their gender.

2.3 *Wealth Accumulation*

Income from financial capital and real assets forms a smaller part of total income for persons than labor income, but it is typically more unequally distributed in market economies. The distribution of capital income depends on that of personal endowments and assets. To understand this, the theory must tackle the issue of the accumulation of productive factors.

The standard assumption is that accumulation decisions are based on maximizing behavior, and hence depend on the sequence of current and expected future factor rewards. The most elementary version of the accumulation equation refers to a single asset, possibly including human capital, being accumulated by individuals who are identical apart from their level of asset-holding and who operate in markets with constant prices. The dynastic model offers a benchmark where the altruism of a person extends to his/her descendants, their descendants, and so on for an infinite future. This is equivalent to assuming that the person lives forever and optimizes over an infinite horizon. Under certain further assumptions, including that stochastic shocks on wealth are persistent, the optimal consumption at each point of time is simply the income flow from wealth. Wealth, income, and consumption then all follow a random walk, and their variance in the population increases linearly with time. There is some evidence that the dispersion of consumption expenditures tends to increase continuously with age in a given cohort, so that the preceding model could be satisfactory for an intragenerational theory of income and wealth distribution. However, it does not seem to fit the most obvious stylized facts of the intergeneration transmission of inequality, and in particular the apparently nonincreasing variance of wealth.

The model of accumulation just described relies on a rather extreme form of altruism. If agents were selfish and indifferent to the fate of their descendants, wealth should decrease at the end of one's lifetime and bequests should essentially be involuntary, explained by the natural uncertainty of life duration, coupled with the absence of a good annuity market. But a host of intermediate cases may be envisaged where bequests enter personal utility and transfers to children are made at death or during one's lifetime under the form of human capital. Fertility behavior must be taken

into consideration. Large families mean that, with equal division, wealth is divided more rapidly; where families die out, on the other hand, wealth passes into other hands. There is a rich literature on the simultaneous determination of fertility and intergeneration transfers of wealth and/or human capita, and on how estates are divided among heirs.

In the models just described, differences across individuals arise on account of random shocks on income and their magnification over time, and of their initial endowments. Individuals are also likely to differ in their preferences for saving, for number of children, and in the degree to which they wish to pass on wealth. But the heterogeneity in their initial endowments of wealth is likely to play a key role and to leave a long shadow on the distribution. Imperfections in the capital market may mean that some people become increasingly trapped in low wealth. Because of information asymmetries between lenders and borrowers leading to moral hazard and risk selection problems, people with a low level of wealth cannot borrow against future incomes or can do so at a rate of interest which depends negatively on their current wealth used as a collateral. In the field of human capital, and financing entrepreneurship, these imperfections can exacerbate initial inequalities. Two families with similar initial wealth may end up with different long-term wealth.

All the preceding dynamic theories of the distribution of productive assets assume that the price system, as summarized by the rate of return on wealth, is independent of the distribution. In a dynamic general equilibrium framework, the personal distribution of assets, the distribution of fixed factor among firms and the price system all depend on each other. This relationship has been analyzed within the framework of Solow's aggregate neoclassical growth model by Stiglitz (1969). With an identical linear savings relationship, the behavior of aggregate capital converges to a steady state level of capital, and this implies in turn that ultimately the individual wealth-holdings also converge. But very different results may be obtained by modifying the assumptions about the model of growth and factor shares, and in particular by introducing the capital market imperfections described earlier.

2.4 Public Policy and Redistribution

The state can affect the distribution of income in many ways apart from the taxes, transfers, and spending (on education, health, etc.) of which people naturally think. Minimum wage legislation is an obvious example, as are other forms of government intervention in the labor market, including trade union legislation, income policies, legislation governing hiring and firing, immigration controls, occupational licensing, and public employment. In the capital market, there may be distribution consequences of government monetary and debt policies, but in addition the government regulates financial institutions, legislates for consumer credit protection, and may operate savings and other banks. Industry is affected by competition policy, company law, and rules governing public procurement. In recent years, there has been privatization of nationalized enterprises or the sale of other state assets. The impact on the distribution of income of all these policy areas needs to be studied in any assessment of the overall impact of the government.

Turning to the impact of the government budget, we see that the gross incomes generated by production are typically reduced by taxation, used to finance public spending, including transfers which constitute a source of personal incomes which has no counterpart on the production side. The state may in part finance spending through borrowing, and the national debt adds to the range of assets held by the personal sector.

The impact of taxes and transfers on the distribution of income depends crucially on their incidence, in that the existence of the taxes and transfers may change market incomes. If, for example, top pay rates are set in net of tax terms (to attract executives on an international market), a tax increase will lead to higher gross pay and not to lower disposable income. The redistributive effect of taxation cannot be measured by comparing market and disposable incomes; the comparison needs to be with a counterfactual market income in the absence of taxes. In order to determine the latter, we have to make assumptions about the working of the economy, and this is one of the standard issues in public finance.

The importance of taxes and transfers in the distribution of personal income means that the behavior of the government has to be part of our explanation. The government's actions cannot be treated as purely exogenous, and we need to look to the theory of public choice, or 'political economy.' There has indeed been a resurgence of interest amongst economists in the politics of income redistribution. Most models share a common approach to the determination of political equilibrium, which is some version of the median-voter model. It is however important to ask how far the findings depend on whether the outcome is governed by the preferences of the median voter, or by the ideology or preferences of political parties, or by political pressure from different interest groups, or by bureaucratic control of civil servants or agencies. There has been relatively little research by economists, which has set side by side different possible explanations of income redistribution, and examined the sensitivity of the conclusions drawn to the choice of model.

3. Measuring Inequality

The preceding section reviewed existing economic theories seeking to explain the distribution of income.

The empirical counterpart of these theories consists of studies, which compare income distribution data across various societies, or at different points of time for the same society and which try to relate observed differences to a set of exogenous characteristics of the societies being analyzed. Considerable work has been developed along these lines since the comparisons undertaken by Pareto (1897), who fitted a particular mathematical distribution to the upper part of the income distribution and used the resulting parameters as the basis for an explanation of differences. As has been evident even from the days of such pioneering studies, the measurement of inequality raises both conceptual problems and questions concerning the quality of the underlying evidence.

3.1 Conceptual Issues: Measuring Inequality

Traditionally, individual observations were arranged into a vector indicating the proportion of people falling in selected income bands. Comparing two distributions of income then consisted of comparing these frequency histograms. At the beginning of the twenty-first century, modern computing possibilities allow one to work directly with the individual observations rather than grouping them and to obtain more flexible estimates of the income frequency function through Kernel techniques (Silverman 1986). Other representations of the distribution of income include the 'distribution curve' and the Lorenz curve. The former simply cumulates people below a given income level. The Lorenz curve cumulates the population in increasing order of income, and shows on the vertical axis their cumulative share in total income. The Lorenz curve is equivalent, up to the division by mean income, to other representations of the data, but it allows a ready comparison of two or more distributions. A situation of particular interest is where one Lorenz curve lies everywhere above, or at least not below, another, which means that the bottom X percent of the population always have a larger share of total income, for all values of X. This situation is referred to as 'Lorenz dominance.' Where distributions differ in their mean incomes, as where comparing different countries, we may use the generalized Lorenz curve. This replaces the relative percentage of total income on the vertical axis by the absolute total income per head, so that it is now denominated in currency.

Comparisons of Lorenz curves may however be unclear or ambiguous because curves are close to each other or cross several times. This is one reason why so many authors prefer to rely on scalar inequality measures that summarize the departure of the distribution from equality and satisfy various basic properties. The Gini coefficient has for long been the most popular such measure. The reasons for its popularity are not entirely clear, but may be due to its graphical interpretation as the area between the Lorenz curve and the diagonal, relative to the whole triangle. Other inequality measures used include the relative absolute or logarithmic mean deviation, the coefficient of variation and entropy measures. Using different scalar inequality measures to compare distributions may lead to contradictory conclusions, one distribution appearing more unequal than another with respect to one measure, but the opposite being true with another measure. A condition for such a contradiction not to occur, for a wide class of inequality measures, with distributions with the same mean and total population, is Lorenz dominance.

3.2 Conceptual Issues: Definition of Income

A second conceptual issue is the definition of the variable under consideration: inequality of *what*? Income is typically studied on the basis that it is a reasonable indicator of individual welfare, but this may be criticized on at least two grounds. The first is that we need to enrich the informational basis for welfare judgments, including for instance life expectancy or quality of life; this has been emphasized by Sen (see Sen 1992), who has contributed to the development of a nonwelfarist approach.

The second argument is that income provides an unsatisfactory measure of individual welfare. Income may for example be subject to transitory fluctuations that can be smoothed out by the individual; this may provide a rationale for using observed consumption expenditures rather than income to estimate inequality. According to the permanent income hypothesis, differences in consumption expenditures over time and between agents should reflect differences in permanent disposable household income rather than transitory shocks to income. As a matter of fact, it is typically true that the distribution of consumption expenditures is less unequal than that of current income. This being said, the use of consumption rather than income data raises problems of definition and observation, notably the treatment of durables and the necessity of imputing a value for their services.

If income is chosen as the variable to be considered, then a comprehensive definition embraces all receipts that increase a person's command over resources in a specified period. As such, it includes all income in kind, such as production for home consumption or fringe benefits; it includes all capital gains or losses on all assets (not just those that are realized); it includes imputed rent from home ownership and other physical assets. The definition is in principle far-reaching and in practice hard to achieve.

3.3 Conceptual Issues: Unit of Analysis

A third conceptual issue concerns the definition of the recipient unit: inequality among whom? Empirical

analysts generally have to choose between a range of alternatives, depending on the data at hand and the issue to be addressed:

(a) individuals, whether they have an income or not,

(b) individual income recipients,

(c) families of related adults and dependent children,

(d) spending units, that is individuals pooling their income together and sharing the same consumption budget,

(e) households, that is, people living at the same address.

These definitions may lead to different evaluations of the degree of inequality of a distribution, and possibly to different representations of its evolution over time. The main difference between distribution data defined with reference to these various recipient units has to do with the 'matching' of individual earners into households and the size of these households. The choice of recipient unit depends on the issue that is addressed. Individual earnings data are better adapted to positive studies focusing on the labor market, whereas household income may be more appropriate in normative studies addressing the issue of inequality in living standards, although this is influenced by the degree to which resources are shared within the household.

Whatever unit of analysis is chosen, an adjustment has to be made for the differing needs of units of different size and composition. The most meaningful concept from that point of view is the distribution of 'equivalized incomes' where total income is expressed per adult equivalent. One such adjustment is to take per capita income, but this makes no allowance for economies of scale, and a commonly used alternative adjustment is to divide total household income by the square root of the household size. There is a voluminous literature on equivalence scales: see, for example, Deaton and Muellbauer (1980). A further choice to be made is the weighting to be given to each unit: between treating each household as one and treating each person as one, so that we impute to every member in the household the per adult equivalent income.

3.4 Income Distribution Data

There has been considerable improvement in the availability of data about the distribution of income. Advances have been made at the national level, where in many countries a significant investment has been made in carrying out new household surveys, in linking administrative data, and in refining methods of analysis. Administrative data, of which the most important are income tax records, have historically provided long runs of continuous data; today they may be linked with other sources such as social security and labor market agency records. One major step in the case of surveys has been the establishment of panel studies such as the Michigan Panel Study of Income Dynamics (see Brown et al. 1996) and the German Socio-Economic Panel (see Burkhauser and Wagner 1994), which provide data on the same individuals or households over a span of years. Of particular significance has been the assembly of data sets that can be compared across countries. Here the way has been pioneered by the Luxembourg Income Study (LIS), which brings together microdata on households; this provided the basis, for example, for the comparative study of income inequality in OECD countries published by the OECD in 1995 (Atkinson et al. 1995).

Different sources of data have different strengths and weaknesses. Household surveys are perhaps the most common source. They suffer from non-response that is differential across groups of the population, for which only approximate corrections can be made. Among respondents, there is the problem of people failing to disclose income sources or understating income. Comparisons of total household income reported in surveys with National Accounts data suggest an average rate of underestimation between 10 and 20 percent of total disposable income, reflecting both differential nonresponse and under-reporting by respondents. Administrative data may be more complete, although declarations to fiscal authorities may not be more reliable than those of household surveys. Administrative data may also be less tailored to the purpose of studying income distribution, for example containing less contextual data and employing income definitions that reflect tax law rather than the comprehensive ideal described above.

Income data generally refer to a well-defined observation period: the week, the month, or the year. The shorter the observation period, the less subject the earnings information may be to inaccuracy but the more contaminated are the data by transitory income components—premium payments, sickness leave, delay in transfer payments, etc. In the case of investment incomes, payments may only be made annually. On the other hand, where the data refer to an extended period, such as a year, they may be less accurate if based on recall questions. Also account has to be taken of what to do with people who are present in the sample for only part of the period.

In some income distribution estimates, information is combined from several sources to yield 'synthetic' estimates. For instance, income tax data on higher incomes may be merged with household survey data for the rest of the distribution, drawing on their relative strengths. The estimates may be adjusted using national accounts or administrative data. Taxes and transfers may be calculated using a simulation model and added to a survey data set. Such a procedure may be required where the original survey does not contain the information, or where the tax information in the survey relates to a different time period from the income information.

All data sources are imperfect, and any empirical study should include information that can be used to assess the reliability of the conclusions.

Income Distribution: Demographic Aspects

Demographic variables are often cited as important determinants of the distribution of income. The following sections discuss the effects on the distribution of income of three demographic variables: (a) age structure; (b) marriage and household composition; and (c) differential fertility by income class. These are topics that have received considerable attention and demonstrate important issues in analyzing demographic aspects of inequality. For a more complete review of these issues and other important demographic aspects of income distribution that are not treated here, see the surveys by Pestieau (1989) and Lam (1997).

1. Age Structure and Income Inequality

One of the most important demographic variables differentiating populations is their age composition. To the extent that changes in age structure affect economic variables such as saving rates and the age profile of wages, there are likely to be effects of age structure on the observed distribution of income. Even if the direct economic effects of age structure are small, age structure may affect standard measures of income inequality for purely compositional reasons. We may want to consider, for example, whether a population dominated by young workers tends to have higher income inequality than a population dominated by older workers, simply because of compositional effects of age structure.

The concave relationship between age and earnings observed in virtually all populations will tend to create a relationship between the age structure of the population and overall income inequality. There is no obvious prediction about whether a younger or older population will have higher inequality, however, based on this component alone. An additional factor is that age-specific income inequality tends to vary with age. One theoretical argument about this relationship was advanced by Mincer (1974) based on a model of life-cycle investments in human capital. Mincer argued that at young ages some individuals trade off current earnings for schooling and training, creating relatively high intracohort inequality. As better-trained individuals reach the 'overtaking' age at which their steeper age-income profiles cross the profiles of individuals with less training, there is relatively low inequality. Beyond the overtaking age the income profiles for better-trained individuals rise above the profiles for lesser-trained individuals, causing inequality to rise at older ages. Taking a different theoretical approach, Deaton and Paxson (1997) note that the life cycle theory of savings implies that within-cohort inequality in income and consumption will increase steadily over the life cycle as a result of the accumulation of transitory shocks experienced over individual lifetimes. They provide empirical evidence of just this sort of 'fanning out' of within-cohort incomes over the life cycle using data from Taiwan, the US, Great Britain, and Thailand.

The fact that both the mean and variance of intracohort earnings vary as a function of age makes it difficult to predict the overall effect of population age structure on income inequality. As noted by Lam (1984) and Deaton and Paxson (1997), the effects of age structure can be productively modeled as a decomposition into between- and within-cohort components of overall inequality, exploiting the features

of stable population models. Changes in age structure affect both within- and between-cohort components, with changes potentially in opposite directions. Deaton and Paxson find important interactions between population growth and economic growth in analyzing the effects of age structure on inequality. With low economic growth, an older age structure tends to increase within-cohort inequality, but it tends to decrease between-cohort inequality by an offsetting amount. With more rapid economic growth, however, an older age structure implies increases in both within-cohort and between-cohort inequality, leading to potentially sizeable increases in overall inequality associated with population aging.

2. *The Role of Marriage and Household Composition*

A standard issue in analysis of income inequality is whether the unit of analysis should be individuals, families, or households. There are many good arguments for using families or households for analyzing income inequality, but moving beyond individual incomes introduces a host of demographic issues relating to marriage, fertility, and household structure.

One frequently analyzed link between demographic behavior and the distribution of income works through marriage markets and the correlation in spouses' incomes. A large literature has developed analyzing the effect of increasing women's labor force participation rates on the distribution of family income. The issue is directly related to the nature of assortative mating on wages and the relationship between one spouse's wage and the other spouse's labor supply. An early important contribution to this literature by Mincer (1962) noted the empirical regularity of a negative relationship between a husband's income and his wife's labor supply. Mincer argued that this negative relationship will tend to have an equalizing effect on family income because the labor market earnings of married women will have a bigger effect on families with poor husbands than those with rich husbands. As with many other issues discussed here, the relationship between women's labor supply and income inequality turns out to be less predictable than Mincer's conjecture suggested, although Mincer's analysis and the decomposition approach he introduced had a major impact on subsequent research.

A large literature has continued to analyze this issue in recent decades, a period characterized by rapid increases in female labor force participation and substantial changes in the distribution of both individual and family incomes in many countries. Decompositions of family income inequality into components attributable to different family members have been a staple of this literature. These decompositions produce conflicting results, sometimes implying an equalizing effect of wives' earnings and sometimes suggesting a disequalizing effect. Cancian and Reed (1999) provide a recent update on the US experience. Their decompositions show rising correlations in husbands' and wives' earnings, a disequalizing trend that is offset by large declines in women's earnings inequality. They estimate that the net contribution of wives' earnings in explaining recent increases in US family income inequality is relatively unimportant, although other authors estimate larger effects using different time periods and different methodologies.

A related issue is the role that household size and composition play in analyzing income inequality. Kuznets (1976) explores the relationship between household income and household size and resulting implications for the distribution of household income. A consistent cross-national empirical regularity demonstrated by Kuznets is a tendency for household size to vary directly with total household income but inversely with per capita household income. This empirical pattern does not imply a general prediction about whether total household income or per capita household income will be more equal, however, and numerous empirical investigations indicate no consistent pattern across countries. A useful approach is provided by Schultz (1982), who decomposes per capita household income into components related to total household income, the number of adults, and the number of children. Schultz finds that total household income is more equal than per capita household income in Colombia, while the opposite is the case in rural India, a result he attributes in part to a stronger negative relationship between income and fertility in Colombia.

3. *Differential Fertility, Intergenerational Mobility, and Inequality*

An argument that is often made connecting demographic change and income inequality is that differential fertility rates across income groups will lead to increasing income inequality across generations. The dynamics of differential fertility and the distribution of income turn out to be quite complex, even in relatively simple models. A considerable literature has developed in economics, demography, and sociology analyzing these dynamics, with several important points emerging.

Consider the question of whether higher fertility rates for the poor will lead to increases in the proportion of poor across generations, and the impact such changes would have on the distribution of income. Analyses of the effects of differential fertility on the distribution of income are more realistic if they recognize that children will not necessarily inherit the income class of their parents. Preston (1974) provides an important demonstration of the role of inter-

generational mobility in analyzing the relationship between differential fertility and the distribution of occupations. This analysis builds on basic principles of Markov processes, noting that intergenerational mobility introduces stability into intergenerational dynamics, even in the presence of differential fertility. Lam (1986) applies similar models to the distribution of income, analyzing the dynamics of a system in which differential fertility across income classes is combined with intergenerational mobility. In such a system it is not the case that higher fertility rates by the poor cause the population to eventually become 100 percent poor. As long as there is sufficient intergenerational mobility there will be a steady state, with differential fertility affecting the nature, but not the existence, of that steady state.

Lam (1986) shows that these models can in general produce surprising results, with no general predictions about the effect that higher fertility for the poor will have on either the proportion poor or the level of inequality in the steady state. Some additional reasonable restrictions on the models can lead to plausible predictions, however. Chu and Koo (1990), for example, show that if fertility falls with income, and if children of poor parents have lower probabilities of being rich than the children of rich parents, then a decrease in the fertility of the poorest income class will cause a reduction in steady-state income inequality.

A further important refinement on these models is to relax the Markovian assumptions, making fertility, investments in education, and wages endogenous with respect to the skill distribution in each period. Kremer and Chen (1999) present a model in which multiple equilibria are generated. One equilibrium is characterized by high inequality and high income differentials in fertility, while the second equilibrium is characterized by low inequality and low income differentials in fertility. The model implies that exogenous investments in education of poor children could induce a movement from the high-inequality to the low-inequality regime.

4. Conclusion

The topics discussed above demonstrate some common themes in research on the demographic aspects of inequality. Working with measures of dispersion tends inherently to complicate analysis of the links between demographic change and inequality. In each of the literatures discussed above it is easy to find examples of plausible-sounding conjectures that turned out to ignore important complications in the demography or the economics. Significant advances have been made in each of these areas in recent years by creatively combining modeling of the population dynamics with careful attention to economic–demographic interactions, and by incorporating these models with the wealth of household survey data that is now available.

Income Taxes

In the eyes of the taxpayer, income tax is the most visible form of taxation and therefore also politically the most controversial. Controversies surround the issues of how income tax affects individual behavior in areas such as labor supply, saving, home production, and tax evasion, as well as how it affects the overall distribution of income and the standard of living.

Even more controversial, obviously, is the use of income tax to redistribute income, which raises the more normative question of how progressive income tax ought to be.

1. The Nature of Income Taxation

Income tax is the prime example of a *direct* tax; it is levied directly on the incomes of the individual consumers in the economy, and it can be designed to take account of the individual circumstances of the taxpayer. In contrast, indirect taxes are levied on anonymous market transactions and are paid at the same rate irrespective of the taxpayer's income, number of children, age, health—to mention just a few of the taxpayer characteristics that have over time been taken into account in the design of the personal income tax. It is this tailoring of the tax to the individual's *ability to pay* which makes it such a potentially important instrument for the redistribution of income.

The definition of taxable income varies in the legal systems of different countries and over time. Labor income—wages and salaries—forms the central element of the tax base. To this is added income from capital in the form of interest, dividends, etc. However, income from capital is a more elusive concept than income from labor. Thus, countries differ in the extent to which capital gains are subject to taxation, and they differ in the extent to which non-cash income, such as the imputed income from owner-occupied housing, is subject to tax. Perhaps even more important, rules differ regarding the deductibility of negative capital income, such as interest payment on mortgage loans. Tax laws also differ in the extent to which they allow the deduction of particular expenses, such as the cost of travel to work, the cost of child care, trade union fees, etc.

These differences in the tax base may reflect different perceptions among policymakers of what is a just and fair tax system; they may also reflect differences in the balance of political power among various special interests. What is clear is that different legal definitions of the tax base create different economic incentives for the taxpayers as well as different consequences for the after-tax distribution of income.

Income tax may be progressive, proportional or regressive. A proportional tax is one where the *average tax rate* is constant; the proportion of income paid in tax is the same for all levels of income. Note that this implies that the *marginal tax rate*—the percentage tax paid out of a small increase in income—is also constant. In a progressive tax system the average tax rate increases with income, and this implies that the marginal rate is higher than the average rate. Finally, in a regressive tax system the average tax rate is decreasing, with the marginal tax rate being lower than the average rate.

Countries differ considerably both in their legal definitions of the tax base and in the degree of progressivity of their income tax schedules. There is also significant variation between countries as regards the importance of income tax as a source of revenue. To illustrate, in 1993, on average for the EU as a whole, the personal income tax (inclusive of social security taxes) accounted for 36.4 percent of total tax revenue, whereas in France it was 27.5 percent and in Denmark 54.7 percent (Sørensen 1998).

2. The Income Tax and Economic Behavior: Labor Supply

How do variations in income tax rate affect the labor supply of individuals and households? The economic theory of labor supply takes its point of departure from a model of a single individual who faces certain market opportunities. In the simplest version of this model, the wage rate per hour worked is constant, so that earnings are proportional to hours worked. In deciding how many hours to work, the individual takes account both of the fact that higher earnings make it possible to consume more, but that it also costs something in the form of less leisure. At the optimal number of hours worked, it must be the case that the subjective marginal value of leisure equals the real aftertax wage rate. For longer hours of work the subjective value of leisure is higher than the wage rate; at shorter hours it is lower.

Now consider what happens if the marginal tax rate increases. Two effects can be identified. First, since the reward to labor at the margin falls, there is an incentive to work less; this is called the substitution effect. Second, since the tax increase means that the taxpayer is less well off than before, his or her marginal valuation of leisure falls; this is what is known as the income effect, which in itself tends to increase work effort. Clearly, the two effects pull in opposite directions, so that it is not possible to formulate any clear hypothesis about the connection between taxes and labor supply.

A common objection to this theory is that there are in fact few individuals who are able to choose their hours of work freely, and that the theory therefore tends to focus attention on a problem of little importance. In the short run this is certainly true for a large number of employees. However, the theory can be interpreted in a number of different ways to make it applicable to many more aspects of labor supply. Consider, for example, a young worker who is entering the labor force and considering different job opportunities. Some jobs are offering long hours and high earnings, while others promise more leisure time at the cost of lower earnings. The occupational choice between job alternatives can in fact be modeled in a way that is formally similar to the hours of work model, and the substitution and income effects of

taxation emerge in this setting as well. The same is true of models of the choice of retirement age; a tax increase decreases the reward to a further extension of one's working life and creates an incentive to earlier retirement (the substitution effect), but it also makes it necessary to work longer than before to achieve a given standard of living during retirement (the income effect).

A number of attempts have been made to estimate models of labor supply and taxation using econometric methods. Since the nature of the data sets employed in these studies differ considerably, one might expect that the results would be highly specific with respect to the country, the time, and the nature of the industry to which the data pertain. This is true to some extent, but there are also some general results that characterize a large number of studies. One is that the labor supply of women tends to be more elastic with respect to tax changes than that of men. When women's marginal tax rates go up, they tend to work significantly less, whereas for men one typically finds very small effects. Attempts have also been made to follow the theoretical model and estimate the substitution and income effects separately. One then frequently finds that the reason that the total effect for men is small is not that both effects are insignificant, but rather that although each is of substantial magnitude, they tend to cancel each other.

How is one to interpret the result that the labor supply of women is more elastic than that of men? The most natural explanation is that in most data sets, women tend to be the secondary breadwinners in the family; they tend to work shorter hours and have lower earnings than their male partners. Variations in family labor supply in response to tax changes will therefore most naturally take the form of adjustments in the degree of labor force participation by women.

In the theoretical framework sketched above, 'leisure' was implicitly defined as 'the amount of time not spent working in the labor market.' But in fact people spend a lot of time on household work; studies of time use tend to show that household work takes up about as much time on the average as work in the labor market. The substitution effect of higher taxes in favor of leisure is accordingly also in favor of household work; in other words, income tax 'subsidizes' labor used in household production.

The tax rates that are relevant for the theoretical and empirical study of labor supply are most naturally considered to be simply the statutory rates of the tax law. However, in some contexts it is necessary to take a broader view. Suppose that an individual or household receives a transfer, in cash or in kind, which is income contingent; in order to qualify for it, one's income must not exceed a certain limit. Imagine now that the income of a particular household increases from somewhere below this limit to somewhere above. This increase is subject to the statutory rate of tax, which, in the case of a low-income household, can be supposed to be relatively low. However, in addition, the household loses its transfer, and this loss is in economic terms exactly like a tax increase. The combined effect of the statutory rate and the loss of the transfer payment results in an *effective tax rate* which could be much higher and might even exceed 100 percent, thus creating a powerful disincentive to work among low-income families, often referred to as a 'poverty trap.' This is not just a theoretical possibility but has been identified as an empirical fact in the tax and transfer systems in a number of countries. Clearly, it is very important to consider the interaction between tax and transfer systems in order to avoid unintended and unfortunate consequences of their combined effects.

3. *Income Tax and Economic Behavior: Saving and Portfolio Choice*

The base on which income tax is levied includes income from capital as well as from labor. A simple extension of the theoretical framework so far is to imagine that the individual lives in two periods, and that he or she saves some of his or her labor income in the first period. This will then become available, with interest added, in the second period. Interest income is subject to tax. What happens to saving when the tax rate increases?

As in the labor supply case, we can identify a substitution and an income effect. As the reward for saving (the aftertax interest rate) falls, there is an incentive to save less. On the other hand, the lower the net-of-tax interest is, the more it is necessary to save to achieve a given level of future consumption. The substitution and income effects clearly work in opposite directions. However, we also need to take account of the fact that some people are not net savers in the first part of their life. Instead, they borrow, with the loan to be repaid with interest in the later part of their life cycle. If the interest on the loan is tax deductible, a higher rate of tax provides an incentive to borrow more, i.e., to save less. This, again, is the substitution effect. But now the lower interest rate makes it possible to borrow more than before without having to reduce future consumption; thus the income effect on saving for a borrower is negative, not positive. Since some people are borrowers and some lenders, the income effect for all consumers together might not be very significant and the substitution effect would tend to dominate. Empirical studies also tend to show that there is in fact a negative tax effect on saving, although the magnitude is not always very strong.

This picture of tax effects on saving seems to assume that all saving takes the effect of lending or borrowing in some kind of homogeneous asset. In reality, of course, people hold a portfolio of assets (housing, bank deposits, mortgage debt, shares, etc.) and income tax can therefore be expected to influence not only the

aggregate amount of saving but also the composition of the savings portfolio. This is particularly so since income tax law in many countries does not provide for the taxation of different asset returns at a uniform rate. While interest on bank deposits is often taxed at the statutory rate, interest on some types of bonds may be tax exempt, capital gains may be tax free provided one has held the stock for a sufficiently long time, and the returns from collector's assets such as art, antique furniture, and stamps are usually not taxed at all. Empirical studies also seem to indicate that portfolio composition is indeed very sensitive to tax effects.

In the academic literature there is one type of tax effect which has received special attention by economic theorists. Some assets are relatively safe in the sense that their return can be predicted with a high degree of certainty; others are more risky. Could income tax be expected to change the balance between safe and risky assets in savers' portfolios? Suppose that there is full loss offset, so that any negative returns on risky assets can be deducted against the remaining income. Then one can deduce, basically from the assumption that the individual saver is averse to risk, that an increase in the rate of income tax will induce the saver to invest *more* in the risky asset than before. Although the government takes a share of the expected return, it also shares in the risk, thereby protecting the saver from the full consequences of low or negative returns. This theoretical insight has had a considerable influence on the way that economists view the bias of investment incentives related to income tax, but the hypothesis is not an easy one to test on empirical data. The major reason for this is, as argued above, that there are so many other tax incentive effects on portfolio composition that the risk substitution effect becomes very hard to trace.

4. *Corporate Income Tax*

All income ultimately accrues to private individuals, so that the tax on corporate income or profits is in the last instance also a tax on individual consumers. In fact, some economists have suggested that it might be a good idea to abolish the tax on corporations and instead collect all income from corporations at the hands of the individual stockholders. However, abolishing the tax on corporations might not be a politically popular issue, and in addition there are some real economic arguments why it should be preserved. One is that collecting the tax at the corporate level helps to reduce incentives for tax avoidance and evasion; another is that it is an efficient way to collect some tax revenue from foreign owners of domestic companies who are not subject to the domestic tax on personal income.

In the theoretical literature there is a further argument in favor of the corporate income tax. Assume that corporations maximize profits and that markets are efficient. Then it would be desirable to have taxes that do not lead to any distortions of production and investment decisions in corporations. However, if corporations are subject to a (say) 40 percent tax on profits, the decisions that would maximize profits in the absence of tax are obviously the same as would maximize 40 percent of profits. Hence the corporate income tax is *neutral*; it collects revenue for the government without leading to any distortions of decisions at the firm level and leaves the efficient market outcome unaffected.

However, this picture is very much simplified. The main reason for this is that the tax definition of corporate income is in several respects different from the concept of profits. One important source of deviation between the two is the treatment of real capital depreciation. The real depreciation of a piece of machinery or a building or another type of capital equipment during a year is part of the costs of the corporation, and in order for the corporate income tax to be neutral, real capital depreciation should count as part of the costs in arriving at a definition of taxable income that corresponds to true profits. However, a corporation may employ thousands of different types of real capital, and it is not possible for the tax authorities to allow for the deductibility of true depreciation for all of these. Instead, they typically allow standard depreciation rates for large groups of capital assets such as machines, buildings, transportation equipment, and so on. But this means that for some types of capital the corporation is allowed to deduct less than the true depreciation, for others more. In its interaction with the tax depreciation rules the corporate income tax in fact works as a selective tax on some types of capital equipment and as a subsidy on others. Similar issues may arise regarding interest deductibility, stock valuation, and capital gains on both real and financial assets. It is therefore not surprising that empirical studies tend to show that there are substantial tax effects on production and investment decisions in corporations (Jorgenson and Yun 1991).

5. *Tax Evasion*

Tax evasion is an illegal activity which aims to hide taxable income from the view of the tax authorities. It should be distinguished from tax *avoidance*, which consists in trying to reduce one's taxable income by exploiting the tax law while staying inside its boundaries. While the distinction between the two may sometimes be unclear, there are at least a large number of cases that definitely belong in the evasion category; these are sometimes referred to as the hidden or black economy.

Tax evasion is a risky activity. By holding back information from the tax authorities, there is always a risk of being discovered, in which case one typically

faces a penalty rate on the unreported income. The gain on a dollar of unreported income, i.e., the regular rate of income tax, must be balanced against the probable loss, which is the probability of detection times the penalty rate of tax. When the regular income tax rate goes up, the gain increases, and it thus tends to encourage evasion, e.g., in the form of working in the hidden economy. Theory seems to support the common concern that a high tax level encourages cheating and dishonesty. However, this should not lead us to expect that high-tax countries necessarily have more tax evasion than countries with lower tax levels. The extent of evasion depends not only on the level of income taxation, but also on a number of other social and economic factors, and these are likely to vary considerably among countries.

Theoretical hypotheses in this area are particularly hard to confront with empirical data; in the nature of things, there are no official statistics for the hidden economy, and survey research faces some special difficulties in making individuals answer questions truthfully. A number of the empirical studies that have been made use very indirect methods, such as deducing the size of the hidden economy from the public's holding of cash, and the reliability of this kind of approach is highly disputed (Cowell 1990). More standard approaches tend to yield estimates which indicate that the hidden economy has a volume of 2–10 percent of the GNP of the official economy. Many studies also indicate that evasion is higher for self-employed than for salaried employees. This is in good accordance with the theory, for wages and salaries are usually reported directly by employers, so the probability of evasion being detected is much higher for employees than for the self-employed, implying that evasion is a less risky gamble for the latter.

It should be added that the emphasis on rational risk-taking behavior as an explanation of tax evasion does not imply that in the economist's view of the world all taxpayers are completely amoral, reporting their income only when a cost–benefit calculation has shown them that evasion does not pay. There are strong indications that many taxpayers report their true income even when under-reporting could easily go undetected. The chief aim of the theory is to explain the behavior of those who do evade taxes, and although they too may take moral considerations into account, they are also likely to consider the risk-taking aspects of their activities in a rational manner.

6. *Income Tax and the Redistribution of Income*

It is widely accepted in most countries that income tax should take account of the taxpayer's ability to pay, and the most common interpretation of this principle is that the tax should be progressive. This raises the question of whether income tax in fact has led to a situation where post-tax or disposable income is more evenly distributed than pretax or factor income. In most empirical studies the answer to this question is an affirmative one, although the estimated magnitude of the redistributive effect varies substantially. A general feature of empirical studies is that the redistributive effect is smaller than the formal progressivity of income tax schedule would lead one to expect, and the main reason for this is the role played by exemptions or tax credits. As an example, suppose that mortgage interest payments are fully deductible and that their share of gross income tends to increase with income. Then, as gross income increases, taxable income increases less than disposable income in percentage terms, and this mitigates the increase in the effective average tax rate. The importance of this effect has been well documented in a number of studies (Wagstaff et al. 1999).

From a theoretical point of view, one would expect that the progressivity of the tax system would have an effect on pretax incomes. The markets at least for some occupations would react to high marginal tax rates by increasing gross incomes; this is the problem of *tax incidence*. Since the gross incomes that would have existed had there been no income tax or a purely proportional tax are unobservable, this observation makes it much more difficult to study the redistributive impact of income tax. In this connection it is interesting to observe that countries with a high degree of pretax inequality also tend to be the ones with high post-tax inequality, and moreover that the redistributive impact of income tax is high in some countries which have a low degree of inequality in pretax incomes (Wagstaff et al. 1999). However, it is not clear whether this means that the incidence problem is in fact of little importance or whether there is some other explanation. If a country is dominated by egalitarian social and political values, these may influence not only the progressivity of the tax system, but also the structure of pretax earnings.

7. *Income Tax, Economic Efficiency, and the Equality–Efficiency Tradeoff*

Income tax has always been under attack from critics for leading to distortions of economic incentives and consequently to inefficient social outcomes. The criticism has been especially focused on the distortion of work incentives, which leads to incentives to work less than would be desirable from a social point of view. As pointed out in Sect. 2, there is clear evidence for such an effect in the case of women, whereas for men the net effect tends to be very small. However, in considering the efficiency loss from income taxation, it is the substitution effects, and not the total effects, that should concern us. The reason is that the income effects would always be present whatever the form of the tax system (and given the amount of revenue to be

collected). The substitution effects are the direct consequences of the distortion of wages as efficient market prices, and if our sole concern is with efficiency, we should attempt to design the tax system in such a way as to make the substitution effects as small as possible. Similar concerns are relevant in judging the effects of income taxation on saving and investment behavior. The taxation of interest income might lead consumers to save less and to invest in the assets or industries with the most favorable tax rules rather than in those with the highest rates of return.

However, efficiency is not the only standard by which to judge income tax. As demonstrated in the progressive structure of income tax in most countries, one of the goals of income taxation is to redistribute income from the rich to the poor, and the gains on the side of redistribution must be set against the cost of a less efficient allocation of resources. This is a recurrent problem in the design of economic policy; there is a need to choose a tradeoff between equality and efficiency (Okun 1975). However, if more equality is a real goal of economic policy, it should presumably be worth some cost in terms of less economic efficiency in order to achieve it. These ideas have been formalized in the theory of optimal income taxation, which attempts to show how the optimal marginal rate of income tax depends both on the efficiency cost, as measured by the elasticity of labor supply, and on the social attitude to inequality. Clearly, what economic theory can contribute to this issue is not to produce exact numbers, but to help establish a logically consistent way of thinking about a complex issue that involves both economics and ethics (Sandmo 1999).

8. *Proposals for Tax Reform*

A number of proposals have been advanced for basic reform of the income tax system, frequently motivated by the desire to improve the terms of the equality–efficiency tradeoff. For example, is it possible to achieve the same degree of redistribution at a lower efficiency cost? Tax reforms in a number of Western countries since the 1980s have tried to move in this direction by decreasing the formal degree of progressivity in the tax system, while at the same time eliminating many of the deductions and exemptions that had contributed to a lower degree of effective progressivity. Studies of the American (Auerbach and Slemrod 1997) and Swedish (Agell et al. 1996) reforms of 1986 and 1991 do in fact conclude that their overall effects have been to leave the redistributive effects of the tax system virtually unaffected, while removing many of the tax distortions both in labor and capital markets.

A more radical proposal for reform is the adoption of a so-called flat tax. There are several versions of this, but one that was proposed by Hall and Rabushka (1995) and has been much discussed in the USA involves imposing a constant marginal tax rate on all income above a certain exemption level. Although the name of the tax indicates that the major point in its favor is the simplification of the tax structure, probably its more important features are the elimination of a large number of deductions and a more uniform taxation of income from capital. In this it is in line with the general trends in the reforms of the 1980s and 1990s.

Another reform, the intellectual history of which goes back a long time and which was much discussed during the late 1970s and early 1980s, was the possible adoption of an expenditure tax (Meade Committee 1978, Kay and King 1990). Although the expenditure tax is often seen as an alternative to income tax, it may also be regarded as simply a particular form of income taxation. Briefly, an expenditure tax is an income tax with full deduction for all saving, but with negative saving being added to income. What is taxed is accordingly expenditure or consumption, not income. There are two main claims for the expenditure tax. First, since differences in the standard of living between persons are primarily related to their consumption, not income, consumption is the more logical base on which to level a progressive tax. Second, the treatment of saving and dissaving leads to a more uniform and therefore more efficient taxation of capital income.

Although neither the flat tax nor the expenditure tax have so far achieved any direct political success, the political and economic debates over these proposals may indirectly have had a considerable influence on the reforms which were actually adopted in the following years.

India, Religions of

Indian civilization contains a great number of religious traditions, such as Hinduism, Buddhism, Jainism, Islam, Christianity, and Sikhism. All these traditions have influenced each other and have become part and parcel of Indian civilization in one way or another. A large number of Indian traditions refer, positively or negatively, to a set of religious books, called the Vedas. These scriptures were, originally, the intellectual property of a priestly caste of Brahmans and the basis of their rituals and philosophies. Brahmans as a caste form the apex of a hierarchy of status categories which can be seen as an early form of the later much more elaborate Indian caste system. Buddhism and Jainism emerged around 500 BC in protest against the Brahmanical monopoly of Vedic ritual. They are essentially ascetic religions which have much in common with other speculative philosophies which continued to accept the authority of the Vedas. Buddhism spread from India to the rest of Asia, but became marginal in India, while Jainism did not expand outside of India, but continued in India as the religion of, primarily, businessmen. Christianity came to Kerala in the first centuries of the Common Era and in other varieties with the Portuguese to Goa in the sixteenth century and with other Europeans in the centuries thereafter. Islam came to India at the end of the first millennium, along the coast with traders and in the northern plains as an element of the military and religious expansion of a variety of groups from West and Central Asia.

1. *Hinduism*

The majority of the Indian population today calls itself Hindu. Hinduism is a term that only in the eighteenth century came to be used for a variety of religious traditions which dominate the Indian religious landscape. When they are Brahmanical, these traditions refer to the Vedas, but when they are not they can refer to a number of religious texts, oral or scriptural. Gods like Vishnu and his reincarnations Rama and Krishna are very popular. Likewise, a god like Shiva, often represented in an aniconic, phallic form, is worshipped all over India. In many localities one finds local manifestations of gods like Vishnu or Shiva. A special and important category of gods are Mother Goddesses which often protect against evil and diseases. The typical form of worship of images of gods is the offering of gifts like flowers or sometimes goats or buffaloes. These temples are serviced by Brahman or ascetic priests. Temples are everywhere, but especially in sacred places, which are somehow connected to the story of the god. Hindus make pilgrimages to these places, especially at auspicious times in the lunar calendar. There is also an elaborate complex of rituals which are performed in the domestic context, often related to moments in the life cycle. Finally, there are groups of priests, specialized in warding off evil and witchcraft and performing mortuary rites.

In terms of the social organization of religion there are five elements in Hindu traditions. First, there is caste. Brahman groups have continued from the earliest times to dominate a large part of religious beliefs and practices. Ritual purity and sacred knowledge are the foundations of their supremacy. Other castes have also created cults of their own, but often they are seen of lower status than the Brahmanical cults. Second, there are rituals of kingship. There is the conception of a generic relationship between royal deity and human king which is reflected in ritual practice. In a large number of regions in India one finds a network of temples and palaces which are mutually interdependent. Third, there is the level of the village. The local community is often ritually represented in a number of festivals. Fourth, there is the notion of world renunciation. Ascetics have for a long time up to the twenty-first century built monastic orders and drawn lay support for their religious and worldly activities. They are innovators of religious traditions, but also as free agents in a village society important long-distance traders, money brokers, and military entrepreneurs until the coming of the colonial state. Fifth, there is the concept of bhakti (devotion). One cult after another sprang up in India during the second millennium, channeling waves of devotional enthusiasm. Often ascetic leaders were involved in this and in a number of cases they revolted against the Brahmans and the caste system. By that token they were sometimes able to find a distinct religious tradition, such as the religion founded by Guru Nanak, which evolved gradually into Sikhism and defined itself as different from Hinduism.

Hinduism is a term which has developed from 'Hindu,' a term used by Muslims who came to the river Indus or Sindh (from Sanskrit Sindhu) in the second half of the first millennium. 'Hindu' designates the

inhabitants of this area of Al-Hind or Hindustan and their customs and beliefs. The term Hindu was made into an 'ism' by the British in the eighteenth century. The conceptualization of Hinduism as one particular religion among other religions and theoretically comparable to them can be understood in relation to a number of philosophical arguments about the universality of the category of 'religion' in the European Enlightenment. The conceptualization of their religious traditions by Hindus themselves had evolved along lines of philosophical argumentation about dharma (the sacred order of things) by religious scholars who are easiest divided in followers of the God Shiva and followers of the God Vishnu. Their philosophical arguments were often accompanied by ritual injunctions, especially for temple worship. Below this level of high philosophical argumentation there were a number of devotional movements which can broadly be divided into those which focus on the worship of images and those which have an aniconic image of God. The British introduced the essentialized and unified concept of Hinduism as a religion in an already existing arena of lively polemics about religious difference.

2. *Modern Period*

In the modern period the expansion of the colonial state is crucial for defining the location of religion in India. In the eighteenth century the British East-India Company followed a traditional policy of religious patronage benefiting the religious establishments in the areas which came under their growing influence. This policy was further supported by a strong interest in Hindu scripture from a viewpoint of comparative linguistics and comparative religion. This so-called 'orientalism' of the late-eighteenth century was vehemently attacked at home and in the colony by utilitarian administrators and evangelical missionaries who were united in their rejection of anything Hindu. In education and religious worship the colonial administration was forced to withdraw from giving its patronage to religious establishments and a policy of 'religious neutrality' was established gradually in the nineteenth century.

The response of Indian religious thinkers, institutions and movements to colonial interference under the aegis of religious neutrality has been central to the formation of modern religions in India during the nineteenth century. Especially attacks by evangelical missionaries on religious practices and social customs led to both reformist and conservative responses. In Bengal, Rammohan Roy (1772–1833) studied Christianity and felt great affinity with the rational critique of religious orthodoxy, launched in Britain by Unitarians. In 1827 he founded the British Indian Unitarian Association, but his study of the Vedas and Upanishads quickly led him to explore the limits of Unitarian universalism. In 1828 he decided that a universal, rational religion had to be based upon the Vedas and Upanishads and created the Brahmo Samaj, a small, but influential elite movement, propagating a deist and universalist kind of religion, based upon Hindu sources. The movement is particularly opposed to 'superstitious customs' of 'ignorant people,' 'deceived' by their Brahman leaders.

Rammohan was in the forefront of public action. In January 1830 he, together with 300 residents of Calcutta, presented a petition to Governor-General William Bentinck in support of government prohibition of widow immolation, a practice found in some parts of India when after the demise of a husband the widow throws herself on the pyre of her husband to be burned with him. Rammohan rejected this practice on the basis of his reading of Hindu scripture. He distinguished authoritative sources, such as the Vedas, from other sources. It is significant that he did not refer to authoritative interpretations by learned Brahmans, but relied entirely on his own judgement. This is an important step towards the laicization of Hinduism, that is to say, the formation of religious movements, carried by lay believers and relatively independent of traditional, sacred interpreters of the Hindu canon. The Brahmo Samaj was the cradle of an intellectual Hinduism which was at the end of the century personified by Swami Vivekananda (1863–1902), the founder of the Ramakrishna movement.

Movements like the Brahmo Samaj are sometimes called Neo-Hindu because they have been clearly influenced by European thought and Christianity. On the other hand, however, they are also in direct interaction with more traditional thinkers and movements. A good example is the illiterate saint Ramakrishna (1836–88), a priest of a Kali temple near Calcutta whose devotional practices, ecstasies, and unconventional behavior was very attractive to the intellectual Brahmo Samaj adherents, because he seemed to signify a certain untainted Hindu authenticity. The great reformer Vivekananda took Ramakrishna as his spiritual guide.

Vivekananda became famous after his visit to the World Parliament of Religions which was organized in Chicago in 1893. He offered a packaged Hinduism, in which spirituality and yoga (mental and physical discipline) were keywords, first to a world audience and later to an audience at home. Central to Vivekananda's religious message is the notion of 'practical Vedanta,' in which he combined the Vedanta (= philosophical commentaries on the Vedas) with participation in social activism rather than with ascetic withdrawal from the world, as had been common in Hindu traditions. It is this message which could be tied up with nationalism and political activism as was done by political leaders such as Mohandas ('Mahatma') Gandhi (1869–1948).

Also outside of Bengal we see a number of movements which interact both with Hindu tradition and

with modernity, as brought by colonial rule. The Arya Samaj is the most important among them. Founded by Dayananda Saraswati (1824–83), an ascetic who had been initiated in one of the most austere monastic orders in Hinduism, it is an iconoclastic movement which identifies image worship with the decline of an earlier pure Vedic religion. It attacked also the caste system and its system of marriage and the traditional Brahmanical priesthood. The Arya Samaj became and remains one of the central religious pillars of Hindu nationalism.

3. *Public Sphere*

It is not only Hinduism which is developing modern movements in the new public sphere created under colonial rule. The general pattern is an attack on traditional priestly leadership, on 'backward,' popular religion and an emphasis on free, lay access to scripture and to religious debate. In this way the foundation of religious authority changes and becomes mediated by education and new forms of communication, such as print, and later radio and television. Muslim movements such as the Deobandis, the Ahmadiyyas, and the modernist Aligarh movement share with the Hindu movements of the period the defense of their religion against the onslaught of missionary criticism and the attempt to formulate an answer to modern intellectual challenges. Clearly, they are all deeply political since they mobilize people against certain aspects of colonial rule as well as against aspects of their religious traditions and traditional leadership. They are the basis for the formation of the Muslim political party, the Muslim League, and for Muslim participation in the Congress Party. Also the Sikhs have to respond to colonial modernity. The British gave the Sikhs preferential treatment in their recruitment for the army, which made the rather fluid Sikh identity both more valuable and more fixed. The Singh Sabha movement is especially important, since it challenges the control over the centers of Sikhism, the temples or gurdwaras. These centers were owned by hereditary priests, but following the general pattern of laicization the Singh Sabha movement demanded that they came under the control of the lay community of Sikhs. Control over the committee which governs these temples is still one of the biggest prizes in Sikh politics. It is also the basis of the power of the Sikh political party, the Akali Dal.

The twentieth century witnessed a further politicization of religious identity. The greatest competition was between Hindus and Muslims. The colonial state reinforced this competition by creating separate job opportunities, separate civil laws, and separate electorates. The advent of mass politics brought with it the mass mobilization of people on the basis of reified identities. Mohandas Gandhi, the great leader of the Congress party, was brilliant in his strategies to dismantle British power, but these strategies were based explicitly upon Hindu practices. Both he and, to a lesser extent, Jawaharlal Nehru were perceived by Muslims as Hindu despite their open secular politics. Radical movements emerged which challenge the idea of India as a plural civilization. 'To be an Indian is to be a Hindu' was a slogan of V. D. Savarkar (1883–1966), one of the founding ideologies of Hindu nationalism. Movements such as the Rashtriya Swayamsevak Sangh (RSS) and the Hindu Mahasabha wanted to establish Hindu hegemony in independent India. The assassins of Gandhi in 1947 emerged from such organizations. On the Muslim side, the Muslim League became gradually more and more radical until it demanded Pakistan, a homeland for Muslims, in 1942 and ultimately forced the Partition of India. The tragedy of the violently enforced migration of Hindus to India and Muslims to Pakistan, the division of East and West Pakistan which led in 1971 to the foundation of Bangladesh, the territorial dispute about Kashmir, and the threat of warfare between these two nuclear powers, were all results of the political mobilization of religious difference on the Indian subcontinent.

4. *Nationalism*

Hindu nationalism needs to construct a Hindu majority among the Indian population to realize its claims to political hegemony. It not only runs against the resistance of non-Hindu religious communities, such as Muslims or Sikhs, but also against that of so-called 'untouchables' and 'tribals' who form a large minority in that section of the population which has to be constructed as a Hindu majority, but who are within Hindu practices severely discriminated. There are a number of anti-Brahman, and sometimes anti-Hindu, movements among these underprivileged groups which demand special protection and positive discrimination from the state. Most of these demands concern education and employment, but participation in Hindu rituals and access to temples are also important in the mobility of these groups. One of the most important movements among 'untouchables' was led by Bhim Rao Ambedkar (1891–1956), a Mahar untouchable from West India who has a doctorate in law from Columbia University. It was Ambedkar, one of the principal authors of the Indian constitution, who late in his life concluded that the untouchables would not be equal citizens in India as long as they continued to be second-rate Hindus. He led a mass conversion to Buddhism, primarily by his own community of Mahars, but also followed by other untouchable groups in India. The conversion to Buddhism, however, has not solved the discrimination of these groups in India and more recently a unifying tactic has been to claim a more secular, militant identity in terms of race rather than religion.

In Indian Islam, one of the major developments in the twentieth century was the founding of the Tablighi

Jama'at in 1927 by Maulana Muhammad Ilyas (1886–1944). In 1934 Ilyas started a great revivalist campaign among Muslims of Mewat, an area near Delhi. Going from person to person, he called upon them to follow their Muslim duties, such as praying in the mosque. Gradually he formed groups of laymen who went for fixed periods on tours to invite their fellow Muslims to perform their duties. This created a snowball effect whereby more and more people became involved in this activity. The groups went around first in the area of Mewat, then in other places in India and Pakistan, and, finally, in the 1950s abroad to countries such as Nigeria, Morocco, Britain, Canada, and France. The movement thus spread from South Asians to other Muslims and is now one of the most successful Islamic movements in the world. The Tablighi Jama'at is professedly apolitical and in that way very different from the major Islamist movement of the subcontinent, the Jama'at-i-Islami. This movement was founded in 1941 by a former journalist, Maulana Maududi (1903–79), one of the most influential Islamist thinkers of the twentieth century. It is a much smaller movement than the Tablighi Jama'at, but highly political and organized as a tightly and hierarchically run revolutionary force which aims to capture the state in order to transform society according to Islamic principles. In Pakistan it has a considerable influence in politics and also in the rest of the Muslim world revolutionary movements of the Islamist persuasion have taken it as an inspiring example.

The 1980s saw the development of some ultra-nationalist religious movements in India. The Vishwa Hindu Parishad, founded in Bombay in 1964 by some religious leaders with the help of the Rashtriya Swayamsevak Sangh, organized a country-wide protest against the conversion to Islam of a group of 'untouchables' in the South Indian village of Meenakshipuram in 1981. The success of this protest led to the staging of another All-India campaign in 1984 to demand the demolition of a sixteenth century mosque in Ayodhya, in North India, which had allegedly been built on the site of a temple commemorating the birthplace of the God Rama. This campaign became one of the most important issues in Indian politics in the decade following its start. In 1992, the mosque was demolished with the tacit acceptance of the Indian state.

The 1980s saw also the development of a radical Sikh separatism in the Punjab, led by Sant Jarnail Singh Bhindranwale (1947–84), a young religious leader. His militant career started with intersectarian strife among the Sikhs, but developed into straightforward confrontation with the Indian state. In 1984 the most important Sikh shrine, the Akal Takht in Amritsar, was captured by the militants who demanded Khalistan, a separate Sikh state, imitating the earlier demand for Pakistan by the Muslims of South Asia. In the same year the Indian army decided to attack the Golden temple and chase the militants. The action caused great disaffection with the state among Sikhs worldwide and led to the assassination of Mrs Indira Gandhi (1917–84), the then prime minister of India.

During the twentieth century there was a growing nationalization of Indian religions, which makes it difficult to separate them from processes of state formation. The migration of South Asians outside India has led to these forms of religious nationalism being spread to the rest of the world.

Indicator: Methodology

Concepts in the social sciences are often abstract. Current knowledge or data allows only imperfect empirical representations of them. But abstract ideas such as intelligence, the values of goods, individual attitudes, or social class are so important to the social sciences that we attempt to empirically track them even if our ways of doing so are limited. 'Indicator' is a common term to refer to the variables that we use to detect these concepts empirically. Other terms are *proxy variables*, *items*, *measures*, *scores*, *scales*, *indices*, or *observed variables*. Occasionally some of the terms have a 'part-whole' relation where, for instance, a

scale or an index might refer to the sum of items or the sum of indicators. But there is not complete consistency in these uses so that it is common for researchers to refer to a Likert scale even though it is a single item or indicator. Furthermore, the frequency of the use of these terms varies by discipline. Economists, for example, regularly refer to proxy variables while educational testing psychologists frequently refer to items or scales. Regardless of the name, they all refer to *a variable that is directly associated with a latent variable such that differences in the values of the latent variable mirror differences in the values of the indicator*.

Latent variables are variables that represent concepts. There should be a separate latent variable for each dimension of a concept and a minimum of one indicator per latent variable. The indicator's importance derives from what it reveals about the latent variable. The indicator informs us about the magnitude of the latent variable across cases or over time for the same cases. The key idea is that the indicator provides information on the latent variable. We might, for example, be interested in socioeconomic status (SES) of individuals where we define SES as the overall standing of an individual in the social and economic stratification systems of a community and use a single latent variable to represent this overall standing. Income and education are two indicators of SES, but they do not fully capture SES. Or we could have a test designed to tap the anxiety levels of individuals, but the item or overall test score would not perfectly measure anxiety. So the use of the term indicator and other related terms gives recognition to the fact that the variables we have to work with are not identical to their respective latent variables.

1. Measurement Strategies

When faced with latent variables for which there is no ideal measure, researchers typically follow one of three strategies: (a) ignore the latent variable, (b) include indicators, but ignore their measurement errors, or (c) include indicators, but take account of their measurement error. An example of strategy (a) is a study that is interested in the educational attainment of individuals. Suppose that the researcher recognizes that an individual's motivation or drive plays a role in educational attainment, but given the difficulty of measuring motivation she or he ignores it. The danger of this all too common decision is that the omitted latent variable is likely to bias the estimates of the impact of the other included explanatory variables. So in the educational attainment empirical analysis, part of the effect attributed to say, parental educational attainment might actually be due to the unmeasured motivation variable.

In strategy (b) we could include an indicator of motivation, but ignore its measurement error. Here we have a partial control for and an estimate of the impact of motivation, but bias is likely in both the estimate for motivation and those estimates for the other variables associated with motivation. Contrary to conventional wisdom disregarding measurement error is not a conservative approach. In general, random measurement errors in two or more explanatory variables will not always lead to underestimates of effects of motivation or the effects of the other variables in the analysis (Bollen 1989). A natural question is whether we are better off to include the indicator and ignoring the measurement error as in strategy (b) or ignoring the variable altogether as in strategy (a). Those researchers who have explored this question generally find that it is better to include an imperfect indicator than to ignore the latent variable altogether (Aigner 1974, McCallum 1972, Wickens 1972).

Strategy (c), including indicators and taking account of their measurement errors, is generally the best choice. Here we could include indicators of motivation and control for the influence of the measurement error in these variables. This approach would halt the spread of bias due to omitting the latent motivation variable or treating the motivation indicators as if they were perfect measures. A requirement for taking account of the measurement error is the formulation of a measurement model.

2. Measurement Models

Measurement models refer to the implicit or explicit models that relate the latent variable to its indicators. Several basic questions require consideration prior to building a measurement model: (a) Are there *causal* or *effect indicators*? (b) Are there *multiple* or *single indicators*of the latent variable? (c) Is the latent variable continuous or noncontinuous? (d) Are the indicators continuous or noncontinuous? (e) Does more than one latent variable influence the indicator?

The first question concerns whether the indicators influence the latent variable (causal indicators) or whether the latent variable drives the indicators (effect indicators). The overwhelming majority of social science work on measurement has focused on effect indicators where the indicators depend on the latent variable. Sometimes these are called 'reflective indicators.' Differences in verbal ability, for instance, determine the differences in values for a test of verbal ability. Or an antitax attitude should determine the responses that an individual gives to a question on attitudes toward taxes. Effect indicators are implicitly assumed in factor analysis and in much of measurement theory in the social sciences.

Blalock (1964) called attention to causal indicators, in which the indicator influences the latent variable rather than the reverse. Some refer to these as 'formative indicators.' Education and income of an

individual, for instance, can influence SES making these variables likely to be causal indicators. The amount that a child watches violent television shows, plays violent video games, or views violent movies are causal indicators of the latent variable of exposure to media violence. Often researchers do not consider that an indicator may be causal and treat all variables as effect indicators. This is not an inconsequential decision since causal and effect indicators have different properties and their incorrect classification can bias estimates from a model (Bollen and Lennox 1991). So a researcher needs to decide whether indicators are causal or effect indicators or some mixture of types.

The primary method for making this determination is performing mental experiments where the researcher imagines whether shifts in an indicator are likely to result in shifts in a latent variable as would occur with causal indicators or vice versa as would be the case for effect indicators. For instances, increases in time spent watching violent television shows increases the overall exposure to media violence. Increased overall exposure to media violence does not necessarily indicate increased watching of violent television. In some cases empirical tests can be brought to bear to test for causal versus effect indicators (Bollen 1989, Bollen and Ting 2000). A complication in dealing with causal and effect indicators is that the same set of indicators could be causal indicators with respect to one latent variable and effect indicators with respect to a different latent variable. As an illustration, the watching of violent television shows would be a causal indicator with respect to the latent variable of overall exposure to media violence, but the same television-viewing variable would be an effect indicator if the latent variable were propensity to seek violent entertainment.

The second characteristic of measurement models is whether there are multiple indicators of a latent variable or just one. Multiple indicators are generally preferable to single measures. In the case of effect indicators, multiple indicators are often essential in 'identifying' (permitting unique estimates of parameters in) the measurement model, are helpful in testing the number of latent variables underlying the measures, and enable assessments of the quality of the indicators. Multiple causal indicators can lead to a fuller description of the latent variable's main components. For instance, using education, occupational prestige, and income as causal indicators of SES provides a more comprehensive picture of SES than would income alone. In addition, leaving out causal indicators usually will bias the estimates of the effects of the remaining causal indicators on SES. So for both types of indicators it is better to have more rather than less.

The third and fourth distinctions from above are whether the latent variables and indicators are continuous or not. Continuous refers to whether the latent or indicator variable is best thought of as approximating a variable that has infinite gradations of magnitude or not. Indicators at best can approximate continuous variables since the limitation of measuring instruments will not permit infinite gradations. However, indicators approximate continuity in measurement to varying degrees. Population size, number of crimes, or counts of correct answers on a test are strictly speaking noncontinuous since the measures have interval units. However, in many situations, little harm is done in treating such indicators as if they were continuous. Alternatively, if we use a three-point scale to measure an attitude, it is difficult to consider the indicator continuous even if the corresponding latent variable is continuous.

One source of confusion when considering whether a latent variable is continuous or not is that researchers sometimes confound the indicators' properties with those of the latent variable. Consider the situation of a survey question on abortion that asks whether the respondent supports or opposes a woman's right to an abortion. Though the response categories for the question might permit only two answers, this does not mean that the abortion attitude *latent variable* is a dichotomy. It seems far more likely that the latent attitude is continuous such that not everyone who agrees to the right to abortion has the same degree of support. Some might be just above a threshold on the continuous abortion attitude and this leads them to choose the support category whereas others might be way above the threshold when they give their support response. In this and related situations, the latent variable is continuous even though the design of the measure forces the responses into categories. The researcher needs to consider whether it makes sense to consider the latent variable as continuous or categorical without confounding the nature of the indicator with that of the latent variable.

Theoretically, it is possible to have any combination such as a continuous latent variable and noncontinuous indicators or a noncontinuous latent variable and noncontinuous indicators. In practice some combinations are far more frequent than others. Consider effect indicators first. Treating both the latent variable and its effect indicators as continuous is particularly common. A typical equation for a measurement model for this case is

$$y_i = \alpha_i + \lambda_{i1}\eta_1 + \varepsilon_i \tag{1}$$

where y_i is the ith effect indicator that is approximately continuous and the right hand side of the equation includes an intercept (α_i), a factor loading coefficient (λ_{i1}) that gives the expected difference in the indicator for a one unit difference in the continuous latent variable (η_{1i}), and the continuous disturbance (ε_i). The disturbance has a mean of zero and is uncorrelated with the latent variable. This model captures many factor analysis (Mulaik 1972) and structural equation model formulations (Bollen 1998), though factor

analyses often deviate the observed variables from their mean so as to eliminate the intercept term.

An increasingly popular but less common formulation is to have a continuous latent variable with one or more noncontinuous indicators. With two exceptions, the same equation captures this situation. One is that a y_i^* replaces y_i where the y_i^* is a *latent*continuous indicator of the latent variable. The second difference is that there is an auxiliary measurement model that links the continuous y_i^* latent indicator to the noncontinuous observed indicator, y_i. For instance, if y_i is a dichotomous 0,1 variable the auxiliary equation might represent it as

$$y_i = \begin{Bmatrix} 1 \ if \ y_i^* \geqslant 0 \\ 0 \ if \ y_i^* < 0 \end{Bmatrix}$$

An exact nonlinear function would link the continuous latent indicator to the observed noncontinuous effect indicator. This is easily generalized to ordinal and censored effect indicators. This formulation is common in structural equation models (e.g., Muthen 1984). Item Response Theory (IRT) provides a related approach to having continuous latent variables and noncontinuous indicators (Lord 1980, Hambleton and Swaminathan 1985).

Less frequent are instances where both the latent variable and its effect indicators are categorical. For instance, we might have several informants who report whether the head of the household is receiving welfare or not. The latent variable is welfare status with only two categories: receiving or not. The informant indicators have the same two categories though each informant might make a classification error. Latent structure or latent class analysis (Lazarsfeld and Henry 1968) provides a means to handle this situation. Other combinations such as a categorical latent variable in combination with continuous effect indicators or a mixture of continuous and noncontinuous effect indicators are also possible, though they are rare in practice.

Causal indicators are far less studied than effect indicators. However, incorporation of continuous and noncontinuous causal indicators in a model with a continuous latent variable is possible provided the latent variable has sufficient outcomes to permit model identification (e.g., Joreskog and Goldberger 1975). Identification is too complicated to cover here, however, suffice it to say that continuous or categorical causal indicators do not create special difficulties. Perhaps the least studied case is that of having causal indicators (continuous or not) combined with a categorical latent variable.

A final consideration is whether more than one latent variable influences an effect indicator. It could be that two indicators derived from a questionnaire are from similarly worded questions such that the wording is a method latent variable that influences both items in addition to the substantive variable that they tap. Or indicators deriving from the same judge might share a common bias beyond their common dependence on the same latent substantive variable. It also is possible that two or more substantive latent variables help to determine the values of an indicator. For instance, a measure of the democracy of a political system might measure both democracy and the stability of the system. An indicator of depression might reflect both negative affect and sleep disorders. In these situations, the measurement model should allow two or more latent variables to affect the indicator. Generally researchers try to design indicators so that they primarily represent a single latent variable, but this is not always feasible.

3. *Properties of Indicators*

Properties of the indicators are useful to both current and future researchers who plan to use them. Among the two most important properties are the validity and the reliability of the indicators. Validity and reliability are properties that have received their greatest attention in the case of measurement models with continuous latent variables and approximately continuous effect indicators. Indicator *validity* concerns whether the indicator really measures the latent variable it is supposed to measure. Construct validity, criterion validity, and content validity are types of validity that researchers sometimes examine. Construct validity, for instance, assesses whether the indicator is associated with other constructs that it is supposed to relate to and not associated with those that it should not. Criterion validity compares the indicator to some standard variable that it should be associated with if it is valid. Content validity examines whether the indicators are capturing the concept for which the latent variable stands. See Nunnally and Bernstein (1994) for further discussion.

Reliability focuses on the consistency or 'stability' of an indicator in its ability to capture the latent variable. It is distinct from validity in that you can have a reliable indicator that does not really measure the latent variable. A general definition of the reliability of an indicator is the variance of the 'true' (latent variable) variance divided by the total indicator variance. A variety of statistics to estimate reliability exist. One of the most popular to measure the reliability of several combined effect indicators is Cronbach's (1951) alpha. It also makes a number of assumptions that might be difficult to satisfy in practice. Alternative measures of reliability built from less restrictive assumptions also are available (Bollen 1989).

IRT assumes a continuous latent trait and a categorical effect indicator, usually dichotomous or ordinal. IRT focuses on other properties of categorical items or indicators such as item discrimination and

item difficulty (Hambleton and Swaminathan 1985). IRT is similar to the traditional treatments of reliability and validity in that it too focuses on effect indicators. Latent class or latent structure analysis (Lazarsfeld and Henry 1968) also deals with effect indicators. It applies when we have latent categorical variables with categorical indicators. The degree of classification error of the observed categorical variables provides information on the accuracy of the indicator. The combination of a latent categorical variable with continuous effect indicators are less extensively developed than are the cases of continuous latent variables with continuous or categorical effect indicators.

The measurement properties of causal indicators are less discussed. An important point is that use of the causal indicator assumes that it is the causal indicator that directly influences the latent variable. If the causal indicator itself contains measurement error, then this needs to be part of the measurement model.

4. Indicator Development and Selection

A salient component of indicator methodology is the development or the selection of indicators. The most critical and most neglected aspect of this task is providing a clear *theoretical definition* of the concept that a researcher seeks to measure. The theoretical definition assigns the meaning to the concept. It should explain in as simple of terms as possible what it is that is to be tracked by the indicators. A clear theoretical definition should identify the number of distinct aspects or *dimensions* of the concept. Each dimension requires a separate latent variable. Furthermore the theoretical definition should clarify whether the latent variable is continuous or not. Each latent variable is ideally measured with several indicators.

Once a clear theoretical definition is in hand, the researcher collecting original data can design indicators that correspond to this definition. If only secondary data are available, the theoretical definition provides guidance in the selection of indicators. With the indicators selected to represent each latent variable, the next step is to decide whether each indicator is a causal or effect indicator. That is, an investigator needs to decide whether the indicator influences or is influenced by the latent variable to which it corresponds.

Next, the researcher should construct a model summarizing the relation between the indicators and the latent variable(s). The model should take account of the continuous or noncontinuous nature of both the latent variable(s) and the indicators. Once the measurement model is constructed, a researcher can then explore ways of estimating it. If, for instance, both the latent variables and effect indicators are essentially continuous, then confirmatory factor analysis applies. After estimation the researcher can assess the overall fit of the model and the properties of the indicators. This check might reveal that modifications to the model are required. It might be the case that some indicators prove faulty or the overall fit of the model might be poor, raising questions about the original specification. The analyst might then implement minor or major changes ranging from the introduction of additional parameters to the model to the formulation of quite a different model. The researcher would then estimate the new model and again assess its adequacy.

5. Summary

Indicators and related terms give recognition to the gap that exists between social science concepts and measures. During the last half of the twentieth century a variety of techniques and statistical models have been developed to enable researchers to study and to take account of the measurement error in our indicators. We also have the means to estimate relations between different latent variables while controlling for measurement error. Though the measurement models cover many situations, we still require further development of techniques to handle some combinations of categorical and continuous latent variables and indicators. However, a far more serious problem is the prevalent practice by social scientists of ignoring measurement error in their indicators or ignoring altogether latent variables that are difficult to measure.

Indigenous Conceptions of Aging

The phenomenon of aging is encountered by every individual in every society. Infancy, childhood and youth are periods of development of an individual, with one reaching one's maximum capacity during middle age. As the last stage of human life, old age acquires special significance.

1. *What is Aging?*

It is important to understand aging from different perspectives, e.g., biological, psychological, and social aspects. According to Birren and Renner (1997, p. 4), behavioral scientists define aging as the regular changes that occur in mature, genetically representative organisms living under representative environmental conditions as they advance in chronological age. Further they explain three aspects of human age and aging. The biological age of an individual can be defined as an estimate of the individual's present position with respect to his potential life span. Psychological age refers to the adaptive capacities of individuals, that is, how well they can adapt to changing environmental demands in comparison with average demands. Social age refers to the rules and social habits of an individual with respect to other members of a society.

2. *Markers of Old Age*

There is no single criterion for defining old age. Though chronological age is not a good criterion to identify a person as 'old' or 'aged,' it is the one most commonly used. In Western countries, 65 years is considered as the cutting point between middle age and old age, in developing countries it is between 55 to 60 years. The basis for this is the average life span of an individual, which is linked with the retirement age. Apart from chronological age, there are other indicators/markers of old age. Biologically, menopause is considered the beginning of old age in the case of women. In Indian society, like many other traditional societies, marriage of one's own children and becoming a grandparent herald the beginning of gradual withdrawal from active occupational and family life and turning towards spiritual growth.

3. *Societal Views on Aging*

The concept of aging varies from society to society and has undergone modifications over the passage of time. In many societies, aging is determined by existing cultural norms with regard to progressive stages of family life of an individual. The ancient Chinese scholars delineated seven phases in a man's life, while Pythagoras in the sixth century BC compared human life to seasons. The Hindu concept of Ashramdharm divided life into four stages, namely, Brahmacharyashram (apprenticeship), Gruhasthashram (householder), Vanprasthashram (withdrawal), and Sanyasthashram (renunciation).

Kakar (1982) compares Hindu concept with Erikson's theory of eight stages of man's life. In his view, the individual is not viewed in isolation, but in interaction with the sequence of generations and in shared mutuality. Referring to the last two stages, which are of importance to the present theme, he points out that care and wisdom are virtues in both these concepts. The difference between these two theories is their origin. The Hindu view is a religious or ideal one, while Erikson's approach is clinical and developmental.

In African society as in many other traditional societies, old age is regarded as sacred or pious since the older person is nearer to the state of ancestors than the younger generations. Old age is considered to be dignified, honorable, and respectful. To neglect one's parents is an unpardonable act of ingratitude. There is a saying that means, 'when someone looked after you to grow your teeth, you should look after that person when they lose teeth.'

Old age is depicted negatively in terms of physical decline and decrepitude. Older persons are often characterized or stereotyped as ill, tired, mentally slow, self-pitying, unhappy, and unproductive. They are often depressed by feelings of loneliness and alienation. The negative concept of old age derives from the relationship of individual and society—the absence of a role, the isolation from the significant social life, the marginality in family relationships, and the lack of commitment, partly induced, partly forced on old people.

3.1 Myths about Aging

The attitudes towards older persons are often based on myths rather than reality. Among these myths, we find: the basic needs of individuals change as they age, and most old people are pretty much alike. The older people are not viewed as separate entities with their own needs, past experiences, circumstances, and health status. In a study of women from a matriarchal society in Khasis, it was found by Chhagte (1992) that widowhood was perceived as a means for developing one's self to earn dignity and respect from the society. The aging women played important roles in decision making and provided emotional support.

4. Images of Aging

Many studies have indicated that chronological age and physical appearance are not important indicators of aging according to older persons. Positive images of aging across culture depict older persons as knowledgeable, wise, experienced guides, and caring, whereas negative images depict older persons as insecure, forgetful, interfering, and dependent. How the society or individual views aging depends on many factors.

5. Factors Affecting Conceptions of Aging

5.1 Demography of Aging

The aging of a population is an inevitable consequence of demographic transition and can create an imbalance in the age structure over a period of time. The world's population continues to age with increasing rapidity. According to the United Nations Populations Projections (UN 1991), the world had an aged population (60 and above) of around 488.8 million in 1990, which will increase to 1,205.3 million by 2025.

On a global level, the increase in the proportion of the elderly started only after 1956 from a level of around or below 8.1 percent and is expected to reach around 14 percent by 2025. Until recently, the problem of aging was viewed as a problem of developed countries. However, due to remarkable reductions in fertility levels and increasing life expectancy in developing countries, it is believed that the future demographic transition will proceed more rapidly in the developing regions than it did in the developed ones and will involve large absolute numbers. In the year 2025, there is a projection of 1.2 billion old people in the world, 71 percent of whom are likely to be living in developing regions. More than half of the world's old people by 2025 will be just in Asia (UN 1991).

5.2 Industrialization and Family Structure

Several studies have suggested that the effect of urbanization, industrialization, and educational background may influence the attitude towards the elderly. According to many sociologists, the higher position enjoyed by the elderly was due to the multi-generation family system and the common land holdings by the family. The older persons owned the land and managed the family affairs by virtue of their age and by holding the economic power. However, the breakdown of the joint family system due to urbanization and migration and the partition of common land holdings and property, has depleted the economic power in the hands of the elderly. It is also contended that the status of the aged declined with technological and economic development. Status in industrial societies is based on individuals' acquired formal skills and education. As the industrial society is oriented towards the individual rather than the group, the aged are bound to be rendered useless, generating a feeling of meaninglessness in them. (Mahajan 1992).

5.3 Residential Patterns

The shift from joint to extended and then to nuclear family is a product of industrialization and urbanization. This has altered the residential patterns of older people. Due to the migration of younger generations, older persons tend to live as a couple or as a single person, even in developing societies. Some villages in Asia have predominantly older people living on their own. This has a direct bearing on the familial roles and responsibilities.

5.4 Availability of Roles

By and large, society determines the status and roles assigned to an older person, which makes a person either a contributing member or a dependent member. What alternative roles are available to the older men and women, if the traditional roles become redundant?

5.5 Financial Dependence/Available Resources

In many societies, investments in children's education, career building, and marriage are heavily valued. The parents assume that children, especially sons, will provide for them during their old age. Hence, there are no savings. Due to materialistic attitudes, children may not feel obliged to reciprocate. The result is inadequate financial resources for maintaining one's lifestyle.

5.6 Changing Values

A shift is observed from collectivism to individualism as a by-product of materialism. The economic power has shifted from older generation to middle generation. The need for privacy has increased on part of the younger generations. Certain basic human values such as honesty and freedom are not defined and interpreted by young and old in the same way.

6. Research Priorities

Considering aging as an ongoing process, which has implications for various disciplines, there is a need for longitudinal interdisciplinary research which focuses on old age as one of the important stages of human life. Since aging has become a global issue, many research projects have been undertaken in this field. It would be worth consolidating cross-cultural research to enhance the understanding of this field. To enhance the quality of life of older persons, it is important to review the plans and implementations of global, regional and national policies.

Indigenous Knowledge and Technology

Social science discussions revolving around the term indigenous technical knowledge have a relatively recent pedigree. This is not to say that research, especially in geography, anthropology, and archaeology, was not interested in documenting peasant resource management technologies—indeed there is a long tradition of such work, above all in Third World settings (Wilken 1987; e.g., see *Ecology, Cultural*; *Agricultural Change Theory*). However, the popularization of 'indigenous technical knowledge' as a term, and as a point of reference in debates about technology, is a feature of the last three decades of the twentieth century, and owes much to discussions in international agricultural and rural development. Indeed it derives from a concern to influence development programs in order that they become more cognizant of the many values of indigenous technologies.

Even though some colonial officials and writers recognized the qualities and intricacies of small-holder farming systems, much colonial policy ultimately aimed to promote commercial cash crop farming, using technologies and practices modeled on principles of European farming and promoting quite profound changes in local agriculture. This belief in the importance of 'transforming traditional agriculture' (Schultz 1964) was subsequently enshrined in the period following the Second World War and particularly following the independence of former colonies. This was—and indeed remains—the era of development in which international (and national) organizations have aimed to foster the modernization of Third World societies and economies through a range of external interventions. Until recently one of the most important of these interventions was rural development—and an important component of rural development strategy was the modernization of agriculture through the introduction of packages of new 'improved' technologies intended to increase agricultural yields. The packages incorporated innovations such as high yielding and other improved crop varieties, agrochemical fertilizer, pesticide and herbicide inputs, irrigation (in some cases), etc. (e.g., see *Green Revolution*).

A range of institutions were created to foster such agricultural development, but internationally the most important have been the International Agricultural Research Centers. These centers, each with a particular focus (maize and wheat; potato; rice; livestock, etc.) are located in different parts of the world, but have regional and generally global mandates to support the improvement of production systems for their particular specialty commodities. These centers are supported financially by government, multilateral, and foundation funds. They in turn collaborate with national agricultural research and technology transfer programs. These programs—though often quite weak in practical terms—are in theory the axial national institution for the modernization and enhancement of agriculture. They similarly work in generating and adapting new crop technologies (many received from the international centers) which are then released to farmers through a range of mechanisms.

While in the early years this commitment to the modernization of agricultural technology brought some notable increases in yields and output, some observers began to argue that such approaches tended

to benefit wealthier rather than poorer farmers, often had deleterious environmental impacts, and were inappropriate for the ecological and socioeconomic conditions under which poorer farmers produced. These critical observations inspired a series of studies which concluded that this was the wrong way for external interventions to attempt to improve peasant agriculture. Instead, it was argued, rural people already possessed a wealth of indigenous technical knowledge—i.e., a knowledge of the qualities of and relationships among crops, soils, climate, pest control, water management, etc. According to such critiques, development ought to begin by respecting and understanding this knowledge, and then find ways of improving it 'from within.' This was a call for a bottom-up form of agricultural (and rural) development that would build upon the resources that farmers already had. Indeed, for this reason much of this work has been characterized, both by its authors as well as by critics, as 'populist' in intent, laying more faith in the capacities of the popular sectors than in those of modern science and bureaucracy.

This critique of the so-called 'top-down' development model has since inspired a large body of research into different aspects of indigenous technologies in many locations. In many regards this work has argued that people's natural resource management practices are generally adapted to local circumstances. In this sense, work on indigenous technology is part of a far longer tradition of work in cultural ecology and human ecology interested in the ways in which local societies adapt to their environments as part of a process of transforming them (e.g., see *Ecology, Cultural*). It is also related to work on agricultural intensification and decision making that aims to understand the conditions under which resource users change their practices in order to intensify (or in some cases disintensify) production (e.g., see *Agricultural Change Theory*). These different traditions share an interest in the ways in which technology mediates the relationship between society, population, economy, and the environment. This work has assembled an important body of knowledge on indigenous agricultural practice and change, some more encyclopedic, some more analytical (of the many examples, see for instance, Wilken 1987, Denevan and Padoch 1987).

A principle difference between these different approaches though is the extent to which research directs itself to issues of policy. While cultural and human ecological research has tended to keep its distance from development programs, indigenous technology research has been explicitly concerned with influencing policy debates and rural development programs. It has aimed to change the ways in which crop research is conducted, to press for far greater participation of people in technology development and agricultural policy formulation more generally, and to craft a different vision for the future of agriculture in Third (and increasingly First) World settings.

This concern for the policies and approaches of development reflects the origins of these discussions and also the people who have participated in them. Indeed the debate on indigenous technology owes at least as much to applied social (and biological) scientists working outside academia in the international agricultural research centers and other development institutions as it does to the work of academics (though several important studies on indigenous resource management by academic social scientists with applied concerns in the 1950s and 1960s also helped pave the way for this work). Though often hired by the international centers to address why it was that crop breeding and other forms of technology development were not having the positive effects that had been hoped for them following early successes, these social scientists often became critical commentators on the larger model of agricultural modernization being fostered through the work of the international centers.

Of the many examples of work done by social scientists in the international centers, Robert Rhoades' book, *Breaking New Ground* (1984), written from the author's vantage point as an anthropologist at the International Potato Center in Peru, constituted an important early statement. It addressed the limitations of the modernization model, and argued for the importance of better understanding indigenous technical knowledge in order to build on it, and to foster more constructive engagements between indigenous expertise and scientists' expertise through processes of participatory research and technology development. The book suggested that this had implications both for crop research as well as for the conduct of anthropology, and academic anthropologist Paul Sillitoe (1998) has recently reiterated much of this argument for a change in the way much anthropology is conducted.

Early, more academic collections (Brokensha et al. 1980, IDS 1979) were also important in arguing the case for indigenous technical knowledge, but it was the publication of Paul Richards' book *Indigenous Agricultural Revolution* in 1985 that marked a real turning point in the debate. Although it was an academic study involving careful, detailed cultural ecological research, this book spoke deliberately to the agricultural development community. On the basis of ethnographic, agronomic, and archival research, Richards demonstrated the ways in which farmers exploit a range of ecological opportunities, develop production systems, and actively manage varietal diversity in crops. In some sense, the book argued that the processes of active crop selection, creation of new niches for production, etc., emphasized so much by the literature on the origins of agriculture and crop domestication, applied equally to contemporary peasant agriculture, and that these everyday, grassroots processes could and should once again constitute the basis for another agricultural revolution on the basis of so-called

'peoples' science.' The breadth and academic rigor of the argument gave it particular weight.

While Richards' argued this case as a social scientist, a group of biological scientists have been similarly important in promoting the case for indigenous technology on the basis of its agro-ecological merits. These authors—working in a range of ecological contexts—have assembled more scientifically validated bodies of evidence to demonstrate that many indigenous technologies are effective in controlling pests, managing (and creating) soil fertility, managing water efficiency, etc. An important early synthetic statement of this position was Miguel Altieri's *Agroecology: The Science of Alternative Agriculture* (1983). Altieri's work, as a biological scientist, also shows what can be achieved when the researcher becomes more actively involved in initiatives to link indigenous technology to wider agricultural concerns. In particular he and colleagues have pointed to ways in which indigenous modes of managing biodiversity might become the basis for far larger programs of biodiversity maintenance—programs that differ substantially from the formal centralized germplasm bank approach.

Of the many other initiatives of note, the approach of the recently deceased Mike Warren merits comment. A researcher activist like Altieri (and perhaps like many committed to this topic), Warren dedicated a large part of his professional career to advocating for indigenous technical knowledge (see Brokensha et al. 1980 and Warren et al. 1995). He created programs, networks, and research initiatives documenting technical practices as a means of conserving them, validating them, and indeed arguing forcefully for the role that they might play in rural development.

The effect of this work has indeed been to change some—if by no means all—thinking underlying crop breeding and the development of new technologies in the agricultural research community. It has, however, also been subject to a series of critical appraisals that have themselves opened up other avenues of inquiry around the topic of indigenous technology. While the theoretical basis of indigenous technology research is generally implicit and often somewhat unclear, it is actor (rather than structure) focused. Others however have argued that there are serious structural constraints on agriculture deriving from the political economy and that to detach actor from structure is conceptually inadmissible and also leads to inappropriate policy recommendations (Watts 1983 is an important early statement of this position). Thus, critics suggest, to explain agricultural practice, productivity, and income in terms of choice, innovation, and knowledge without referring to this political economy is to give a deficient explanation. Any resulting policy recommendations will therefore fail because they are based on bad explanation: both actor and structure need to be part of any explanations of indigenous agricultural dynamics. Critics have also argued that the focus on 'farmer' knowledge is too generic: it does not elucidate sufficiently who knows what within local populations, nor the ways in which agricultural knowledge is revealed and hidden depending on the social relationship at stake (see some of the essays in Scoones and Thompson 1994). According to the analytical frameworks used in these critiques, knowledge cannot be understood nor talked about except in relation to the social position of the knower. Explanations which allow this separation will lead to policies that favor some types of knowledge (and therefore some knowers) and not others. These critiques begin to link discussions of indigenous technical knowledge to wider debates on the sociology of knowledge.

A third set of criticisms revolve around the very term indigenous technical knowledge. It is often unclear what makes this knowledge 'indigenous.' Many of the farmers ostensibly having indigenous knowledge are not in fact indigenous to a location: many have moved in from elsewhere, and been part of wider processes of cultural contact and hybridization. Thus, it is suggested, to use the term 'indigenous' is to make exaggerated claims to the authenticity and legitimacy of this knowledge, and that what is being discussed is instead 'local' knowledge—a more modest and more accurate label, although also oversimplified because much knowledge and practice is syncretistic, a product of cultural diffusions, interactions, and integrations. Such an interpretation may not lead to conclusions that such technical knowledge is any the less adapted to local conditions, but it does shift how such knowledge should be understood. Conceptually, such an interpretation re-opens the case for external introduction of technology, if it is in fact the case that local technology is already a product of the local and nonlocally.

Similarly, it is not clear why this is 'technical' knowledge. Technology and agricultural practices convey various meanings, which may be interpreted in different ways according to the age, gender, ethnicity, origin, and other characteristics of the interpreter. Thus, to discuss such knowledge only in technical terms is to give a partial interpretation. To understand the possibilities of recovering and building on this knowledge, it is essential—so such a reflection goes—to appreciate the fuller significance of this knowledge in a local context. A related reflection on the 'technical' dimension is that which—though sympathetic to the concerns and motivations of those who have worked on indigenous technology—suggests that a focus on technology is insufficient. Indeed many researchers who began with an interest in indigenous technologies have broadened their concerns to understand the relationships between technology, identity, local organization, and political economy as part of an effort to understand the conditions under which a locally grounded form of development might be possible (Bebbington 1993). Though consistent with

the initial motivation of those concerned with indigenous technical knowledge—i.e., to rethink rural development strategies and legitimate the ordinary practices of resource constrained farmers—this project works with a broader canvas. It has the aim of understanding what an alternative form of local development might look like, how it might occur, and, *inter alia*, what its technological basis might be.

Finally, it ought be noted that while work on indigenous technical knowledge has done much to improve understanding of farmer resource management and to change approaches to rural and agricultural development, small farm agriculture is still threatened in many ways. Contemporary threats, however, appear to come less from the modernizing ideologies of development programs that students of indigenous technical knowledge criticized; rather they derive from the evolving nature of a global food system in which control of seed stocks and supply chains is increasingly vested in a relatively few, powerful transnational corporations.

Indigenous Knowledge: Science and Technology Studies

1. Convergence in Definitions

Science and technology studies (STS) and the study of indigenous knowledge are both interdisciplinary areas of investigation rather than singular disciplines. Their social and institutional origins were distinct, and early development in these areas occurred largely in isolation from each other. STS has disciplinary origins in history, sociology, policy, and philosophy, while the study of indigenous knowledge originated in anthropology and grew to overlap with agrarian studies and environmental history. Recent scholarship in both areas, however, suggests a convergence of their definitions of knowledge and their methodological assumptions.

'Indigenous knowledge' has long been associated with the terms 'local knowledge' or 'ethnoscience,' indicating knowledge systems that are specific to cultures or groups in particular historical or social contexts (see Richards et al. 1989). Adding the prefix 'indigenous' or 'ethno' to the terms 'knowledge' and 'science' seemed to mark the embeddedness and context dependence of indigenous truths, in implicit contrast to the context-free, singular truth of science. The distinct meanings and uses of the terms 'indigenous knowledge' and 'science' both depended, thus, on a dichotomy that lay at the heart of modern definitions of knowledge, separating universal, value-free, static truth from situated, value-laden, changing cultural beliefs. This dichotomy has been radically challenged by STS, which suggests that all knowledge, including scientific knowledge, is specific to its particular cultural context. All knowledge, then, might be considered 'indigenous.' The methods of study of the two fields should converge, according to this argument, since all knowledge should be studied with attention to its cultural and historical contexts. As a result, the distinct and separate foci of the two fields (science being conventionally studied in First World locations, and indigenous knowledge in the Third World) would lose the logic of their original delineation.

The status of the separation between 'indigenous' and 'universal' knowledge, the conditions of its construction, and the consequences of its erasure are issues of critical debate in STS. In a polemical and influential essay, *We Have Never Been Modern* (1993), Bruno

Latour argued that if 'modernity' signifies the policing of boundaries between nature and culture, belief and reason, humans and nonhumans, then anthropological study reveals that we have never in fact been modern, for our practices have always involved hybrids of these categories. Latour and others, revisiting Western knowledge from a distanced perspective, adopted and popularized ethnomethodological research. STS practitioners pictured the communities they studied as 'tribes' with characteristic beliefs and rituals. Western knowledge is, in this method of analysis, 'estranged' from its context, or 'othered' (Douglas and Wildavsky 1982). Conversely, non-Western knowledges are presumed no less 'rational' or no more 'context-dependent' than their Western counterparts (Watson-Verran and Turnbull 1995, Turnbull 2000).

Studying the cultural and political role of scientific knowledge in different societies, scholars note that nature and culture are produced by networks of contingent histories; we encounter them not in their 'pure' states, but as hybrids—'socionatures' (Jasanoff et al. 1995, p. 58) or 'natures-cultures' (Latour 1993, p. 104). Anthropological observers of indigenous knowledge have always been interested in the ways in which boundaries were (or failed to be) drawn between nature and culture, and in the political weight of certain constructions of nature (see, for example, Lévi-Strauss 1969). Recent work in disciplines such as peasant studies, cultural geography and anthropology, and development also reveals how ideas of nature have historically shaped and been shaped by social, political, and economic relationships (Peet and Watts 1996, Bryant and Bailey 1997). These disciplines have supported interlinked analyses of the changing representations of nature, the production of ideologies of progress and modernity, and the functional relationship between the domination of indigenous groups and the production of scientific knowledge about them.

The study of indigenous knowledge has increasingly shifted away from the province of ethnocentric ethnographers who tended to value it in opposition to science, assuming it to embody primitive expressions of folklore that defy rationality and mythologize social relations. Since the 1980s, anthropologists and interdisciplinary social scientists have viewed indigenous knowledge rather as coherent systems of belief and explanation that are homologous with scientific thought and that can often offer better accounts of local phenomena than those theorized by universalist science. This sort of investigation has prompted the reassessment of operative assumptions in medicine, pharmacology, resource management, and science education, as well as in nonscientific fields such as international law, policy, and development studies.

Although definitions of 'science' and 'indigenous knowledge,' and the modes of their investigation, exhibited a convergence over the last three decades of the twentieth century, studies of these fields remain separated, institutionally and, at times, ideologically. Anthropologists, in the wake of postcolonial critiques of the imperial construction of ethnographic power, have become increasingly self-reflexive and critical of their own representations of indigenous knowledge. Anthropological studies exposing ideological constructions of indigenous knowledge have become inseparable from efforts (in theoretical, pedagogical, and political realms) to alter power differentials in favor of marginalized groups. STS, on the other hand, has privileged studies of canonical European sciences such as physics, placing relatively less importance on the study of non-Western sciences and the ideological practices of science in the context of global political differentials.

In the political sphere, the study of indigenous knowledge has generated a host of policy implications, ranging from support for collective cultural rights and intellectual property rights for indigenous communities to the re-examination of political assumptions about identity, modernity, and global citizenship. The politics of the nineteenth and twentieth centuries, especially in the contexts of colonialism, nationalism, postcolonialism, and globalization, have influenced, and in turn been influenced by, scholarship and activism on the subject of indigenous knowledge. The study of indigenous knowledge has facilitated, and in turn been enhanced by, the granting of an influential international voice to indigenous rights groups and environmental nongovernmental organizations. These dynamics continue to play themselves out in such local and global issues as the politics of multiculturalism, the ownership of knowledge in the information economy, and the role of nationalism and group identity in a globalized world. These are large, interdisciplinary topics in themselves, but even as they grow wider in scope and diffuse in their disciplinary underpinnings, the issues raised by the study of indigenous knowledge continue to intersect with questions about the authority of science and its representations of nature, about the politics of science and technology as interpreted by international institutions and policymakers, and about the role of technology and development in the forging of a more equitable world. Creative work in these overlapping regions of STS and indigenous knowledge studies has yielded both theoretical insights and practical results.

2. *Theoretical Results: Indigenous Knowledge and Epistemology*

Epistemological concerns are necessarily central to the study of indigenous knowledge. Scholars of indigenous knowledge argue that if we take non-Western knowledges seriously, we are quickly led to abandon a naive realism with respect to scientific truth. That is, if we investigate indigenous knowledges for their inter-

nal coherence, social role, and explanatory power, rather than as instances of nonrational narratives, then we accumulate strong support for the argument that explanation, evidence, and truth are socially constructed and context-dependent. This suggests, one argument continues, that what we see in the world, within and among cultures, are competing rationalities, rather than a singular mode of rationality and reason (commonly held to be the province of the west, and its sciences) vs. nonrational or mystical modes of thinking that are antithetical to science (commonly held to be found outside the west). Such an argument requires a complex and situated definition of rationality rather than a simple one assessing syllogistic consistency or the efficient choice of technical means for particular instrumentalist ends (see Wilson 1970, Sen 2000).

Disagreement persists about how best to characterize indigenous rationalities with respect to Western science, as illustrated in a well-known debate between anthropologists Marshall Sahlins (1995) and Gananath Obeyesekere (1992). Sahlins, holding that different cultures possess different rationalities, suggested that anthropologists ought to cultivate a 'regard for cultural difference.' He called on anthropologists to respect the worldwide resurgence of particular cultures as 'distinct forms of life,' and to value their opposition to a dominant, utilitarian, Western modernity. In his own work, Sahlins suggested that Hawai'ian thought, for example, does not distinguish the practical from the mythical, nor the observable from the fictional, although these oppositions characterize European epistemologies. Gananath Obeyesekere challenged this view, maintaining that all cultures possess a 'practical rationality'—that is, a flexibility and creativity expressed through manipulating and interpreting the world.

Obeyesekere's interpretation of Hawai'ian history via the attribution of a 'practical rationality' to the Hawai'ians was, in Sahlin's view, an example of 'symbolic violence' to the culture, and amounted to a neo-colonialist model that reduced all cultural practices to Western logic and rationality. Obeyesekere contended that the cross-cultural interpretation of practical rationality, although complex and difficult, is 'necessary if one is to talk of the other culture in human terms.'

The categories of this theoretical debate recur in the realm of activism. For example, many activists in developing countries have found it useful to employ a relativist argument that rejects the subordination of indigenous knowledge to science, while retaining the postulate of incommensurable difference. That is, they value indigenous knowledge over scientific reason, arguing that narratives of re-enchantment are needed to restore the integrity of indigenous cultures, lost or rendered inauthentic through violent encounters with European Enlightenment science. This position sees an incommensurability between tradition (seen as authentically indigenous) and modernity (seen as ethnocentrically European). Although phrased in the vocabulary of anticolonial struggle, it is reminiscent of eighteenth- and nineteenth-century Euro-American romanticist and primitivist discourses in its desire to value a nature-centered spirituality over a technicist instrumentality. In both industrialized and developing countries, however, romantic and biocentric attempts to preserve the authenticity of indigenous knowledge have been critiqued from perspectives suspicious of epistemological relativism and biocentric romanticism. For example, Meera Nanda, supporting practical, rational 'people's science' movements in India, argued that the nostalgia for authentic indigeneity has oppressive overtones of nativism and cultural nationalism (Nanda 1997).

3. *Practical Results: Indigenous Knowledge and Politics*

The notion of indigenous knowledge holds practical allure for biotechnologists who believe that local knowledge of nature might hold the key to decades of future research into medicine and pharmaceuticals. It represents an ethical dilemma for the architects of globalization, heavily criticized for seeming to obliterate diversity in the interest of a homogeneous and efficient global marketplace. This section surveys the practical results of research into indigenous knowledge, and the political gains made by the movement to preserve indigenous knowledge.

The term 'indigenous people' has a somewhat diffuse reference, and can range from small peasants, linked to domestic and global markets, to tribes, isolated from other groups. In the last two decades of the twentieth century, there was a surge in support, from many different interest groups, for indigenous peoples' rights to their knowledge, resources, and cultural practices. Advocates for indigenous knowledge often use the term synonymously with 'eco-friendly' or environmentally correct knowledge.

Historical changes have often altered indigenous communities' relationship with their environment, or altered the environment itself, so that methods once sustainable might not be so in a changed context. Nor are all indigenous communities necessarily committed to preserving natural environments. For example, the Kissia of the Republic of Guinea, who use forest resources, tend to conserve forest growth, while other tribes in the same region, who are not dependent on trees for their survival, try to reduce forest growth wherever possible (Fairhead and Leach 1997).

Practical struggles facing indigenous communities have often involved rights of access to water, fuel, and other elements of their natural surroundings that are crucial to their survival. Activists have defended the rights of indigenous people to manage their natural surroundings independently from 'top-down' projects

that seek to impose universalist models of productivity and resource management. In these arguments, indigenous knowledge is seen as having both cultural and pragmatic significance. The state and the global economy, representing hegemonic modes of resource extraction and cultural homogenization, are often seen as antagonistic to the interests of indigenous communities.

Antagonism between the state and indigenous communities dates back to the colonial era, when the expansion of European territories was in large part an effort to control not only more markets and labor power, but also natural resources. Colonial environmental management often met with strong resistance from indigenous communities whose control over their environment was weakened or destroyed by colonial policies (Ranger 1989, Peet and Watts 1996). Soon after the mid-twentieth century's wave of decolonization, in the 'development decades' of the 1960s, postcolonial nations struggled to catch up with the productivity of the industrialized west. Postindependence development involved, in many countries, shifts in economic policy to maximize resource extraction for exports, large conversions from food crop to cash crop cultivation, and increasing industrialization. The implementation of these policies (advocated by large international development agencies such as the World Bank) often caused growing pollution problems, and the depletion of soil, water, and other natural resources. This most dramatically affected small farmers and indigenous groups, displacing them from their livelihood and threatening their modes of survival. Indigenous environmental movements, such as the antidam movement in India's Narmada valley, have often characterized the World Bank and the postcolonial nation-state as perpetuating colonial exploitation by subordinating local knowledge and experience to the rationalizing forces of science and economics (Rich 1995, Scott 1998).

The rapid growth, through the 1970s, of environmental ethics and economics did not always bring support for indigenous communities (see Harvey 1996). Neo-Malthusian and neo-Hobbesian ecological scholarship identified overpopulation, poverty, and weakly governed communities as responsible for much environmental degradation, and led to policies promoting the privatization of common property, or advocating a global Leviathan. Influential theorists such as Garrett Hardin and William Ophuls predicted that the combination of resource scarcity with social complexities would lead to an ecological crisis (Hardin 1968, Ophuls 1977). Many saw these looming crises as legitimating more authoritarian state-led solutions, giving primacy to private property and modern resource management techniques. Since most indigenous communities are not affluent, and are dependent on jointly governed common resources, these theories often pitted them against the prevailing expert wisdom.

Hardin's 'tragedy of the commons' thesis spurred detailed studies of indigenous environmental knowledge, increasingly critical of Hardin's assumptions. New scholarship on the commons, combining historical and political economic analyses of ecology, discovered empirical evidence that commons use did not inevitably lead to tragedy (Ostrom 1990, Carney 1996). Indigenous use of commons land was found to be more complex than simply opening access to all users, including irresponsible 'free riders.' Research in diverse communities found that successful commons use was invariably tied to complex, differentiated sets of communities with separate but overlapping rights and responsibilities, facilitating individual as well as group uses of lands and resources. In order to recognize and maintain these delicate social relations of resource use, both indigenous participants and outside administrators needed to be aware of the complexities of social stratification, and historical changes in social relationships among indigenous communities, and between them and the state. In many developing countries, however, colonial and postcolonial administrations altered the meanings of landholding and resource use traditions through successions of new legal definitions and administrative hierarchies, over time squeezing indigenous systems into models that privileged private over communitarian interests. Histories of disparate indigenous groups reveal a continual flux of local, regional, and global knowledges and practices, rendering unviable a nostalgia for a pure localism, or notions of pristine authenticity (McCay and Acheson 1987). Third World political ecology argues that support for rights of indigenous peoples should be inseparable from the development of more nuanced historical analyses of environmental and social relations.

Since the 1980s, the importance of indigenous knowledge has been widely acknowledged by influential international institutions. In 1982, recognizing that disparate indigenous movements all over the developing world were articulating concerns similar to each other, the United Nations established the Working Group on Indigenous Populations, annually bringing together participants from indigenous communities around the world.

Indigenous groups, working in solidarity with each other and developing an international alliance facilitated by the annual working group meetings in Geneva, prepared a joint statement for the 1992 Earth Summit at Rio, asserting indigenous rights as a fundamental requisite to the future of sustainable development. Recognising the growing importance of biotechnology and its links with traditional knowledge of medicinal plants, it stated: '[W]e demand guaranteed rights to our intellectual property, and control over the development and manipulation of this knowledge' (Article 44, Charter of the Indigenous–Tribal Peoples of the Tropical Forests, reprinted in International Alliance of Indigenous–Tribal Peoples of the

Tropical Forest and the International Working Group for Indigenous Affairs 1996, p. 9).

The 1993 UN Declaration on the Rights of Indigenous Peoples recognizes indigenous peoples' rights to the preservation of all forms of their knowledge, including cultural, spiritual, medical, scientific, and technological. It also recognizes the right of indigenous peoples to protect their intellectual property, and to the restitution of any such property that was taken from them in violation of their laws or customs. In 1998, the World Intellectual Property Organization established the Global Intellectual Property Issues Division, recognizing indigenous peoples as the 'most important' beneficiaries of intellectual property (Roulet 1999, p. 129).

The successes of indigenous peoples' movements in the late twentieth century were accompanied by a popularization, at both expert and lay levels, of the terms and categories of 'indigeneity.' These successes were linked, paradoxically, to a tendency critiqued by political ecologists. Critics pointed out that increased funding for the protection of indigenous groups often went along with romanticized descriptions of such groups. In a study of South Asian environments and ethnicities, Sumit Guha suggested that the 'poetic vagueness' in the definitions of indigenous groups feeds into a tendency to regard such groups as static remnants of original racial groups, supporting policies that seek to preserve them as museumized 'endangered species' (Guha 1999, pp. 4–5). Although the discourse of authentic indigeneity preserves historically inaccurate, nativist assumptions, many movements have used it strategically for political gains.

International recognition and support for indigenous knowledge grew dramatically through the 1990s. Nevertheless, as conflicts between indigenous rights and international trade grew rather than diminished, it remained to be seen how far courts would go to enforce 'soft law' elements such as international conventions to impose regulations on transnational corporations and states protecting indigenous communities. The future of indigenous knowledge in this age of globalization may well be worked out in policy debates and legal battles rather than in philosophical texts. Interpretations of the various assumptions in environmental law, however, will depend on the application of scholarship to issues such as the construction of scientific certainty, the historical contingency of systems of knowledge, and the social construction of nature and culture. In this way, the theory and practice of STS and indigenous knowledge may become more closely interlinked, and have significant consequences for the shape of the globalized world.

Indigenous View on Human Development: West African Perspective

Development has four different meanings: (a) the act of developing or state of being developed, (b) a product or result of developing, (c) a significant event, and (d) a group of buildings, such as dwellings. This article focuses on the meanings in (a) and (b) to explore West African views on the human life course in the light of scientific psychology. The term 'indigenous' refers to that which is native or natural in an area or environment.

An indigenous viewpoint deals with what is salient and fosters understanding of a particular setting. Although most people cannot articulate an understanding of the world, their knowledge is organized generally into a worldview or outlook on the universe, and the place of human beings in it. It is social representation with which a given culture makes sense of human life. A set of social, cultural, and existential realities marks out an indigenous West African worldview, which differs remarkably from that informing scientific psychology.

1. *A Fragmented, Exclusive Science Inspired the Emergence of Indigenous Psychology*

Centuries before the rise of modern science and academic psychology, human cultures shared a folk psychology—a set of beliefs and practices about psychological issues in a particular culture. Folk developmental psychology is part of indigenous psychology derived from ethnotheories of development. It emerged from dissatisfaction with psychology's insensitivity to, and failure to connect with, the local context of rural and low class people and minority cultures around the world. For instance, a great deal of African knowledge exists in proverbs, folklore, and practices that are neither easily translatable into psychological jargon nor accessible to current research tools. In fact, many questions on human development in Africa are unanswered or, worse still, unasked, because the grids of scientific psychology were fashioned to suit and reveal primarily Western children or, more accurately, the (post)modern child. As a result, the field is contested terrain, not only because its tools have been derived from a tiny segment of European-driven cultures, but also because of the considerable diversity in how its mission manifests itself in theory, method, and practice. Diversity is not a problem, but the nature of the human condition *is*, and psychologists must come to terms with what the wide variety of childhood circumstances portend for the global image of human development.

Developmental psychology is a science of exclusion in that it purports universality but fails to attend to '95 percent of the world's children' (Zukow 1989). In fact, the extant developmental literature is mainly on the development of a segment of Western children. Other patterns of development exist, and deserve to be incorporated into the discipline's database. The need is to open up to the developmental paths of all people. Compelling logic for this necessity derives from the fact that between a universal humanity and specific individuality lies a huge cultural zone in every person created by a particular worldview, which inspires a specific course of life.

2. *West African Ontogeny: An Indigenous View on Human Development*

Indigenous psychology assumes that every culture conceives of human nature in its own terms, and organizes development according to that image. A West African social ontogeny draws on African life-journeys and conception of personhood in terms of its 'becoming.' It recognizes three phases of the life course: spiritual selfhood, social selfhood, and ancestral selfhood. While newborns are entering the world of the living, the dying are at the threshold of a spiritual world. This viewpoint extends the human life course to an afterlife. Developmental psychology has focused almost exclusively on social selfhood, the experiential self, itself divided into seven stages, the first and the last, respectively, linking spiritual and ancestral selfhoods. As in Erikson's psychosocial

theory, each stage of social ontogeny is marked by a distinct developmental task, conceptualized in terms of important transitions between patterns of social participation that define the culture's perceptions of the family, children, and their welfare. The stages include spiritual selfhood, period of the newborn, social priming, social apprenticeship, social entrée, social internment, adulthood, and old age, in juxtaposition with the conventional stages of prenatal development, neonatal period, infancy, childhood, puberty, adolescence, adulthood, and old age (see Nsamenang 1992). Children are socialized gradually and systematically to play more mature roles in valued social and economic activities at each successive stage. African (and other) cultures also grapple with the nonexistential phases of human selfhood in their own terms.

This perspective differs in theoretical concern from the more individualistic accounts by Freud, Erikson, and Piaget, but goes beyond them to specify that environments and cultures write specific texts on to human development, an essentially biological process. This introduces differences in the rate and purpose of development, thereby providing an innovative framework for examining developmental change as a biocultural phenomenon at the gene–environment interface.

3. *West African Conception of the Child*

The West African metaphor for child is *seed*, cultivated in a sociological garden in which child care is shared among adults and older siblings. In the garden, children learn systematically a cultural curriculum, from which they abstract the social, affective, cognitive, and other rule systems of the culture through observation, social participation, and anticipatory socialization. In so doing, children start to develop a shared identity from the moment they begin to distinguish 'that which is me' from 'that which is not me.' The practice of talking to children and projecting the personality that should emerge promotes the separation of 'self' from 'nonself.' This is a cognitive process that allows children progressively to develop an appropriate gender identity and personality.

3.1 *Socialization of Responsibility*

West African children perform a much wider range of economically productive and maintenance activities than is the case in contemporary, urbanized Western societies. The goal of training is to socialize responsible intelligence. The expectation that older siblings will care for infants and perform some chores is a priming process for such socialization. Priming is an ontogenetic strategy to prepare children progressively for their future adulthood. Through it, children make progress toward adulthood as they 'graduate' from one role to another. The Nso of Cameroon, for example, assign pivotal roles to children at different 'stations' of the life cycle, depending on the perceived level of the child's maturity and competence. Sending children on errands is another form of responsibility training that permits children to develop listening skills, ability to follow instructions, widen perspective, and follow goals. Yoruba children who went on errands demonstrated superior cognitive performance on an adapted Bayley Mental Scale (Yoruba Mental Subscale) compared to peers who did not (Ogunnaike 1997). Role assignment underscores parental awareness of children's cognitive maturity and readiness for specific tasks.

3.2 *Social Rather than Cognitive Competence as a Desirable Endstate of Development*

The West African social field is a dense network in which relatedness and sense of community are virtues. A central idea for developmental psychology, then, is the fact of human embeddedness and interdependence. As a 'situated' phenomenon, individual behavior and mentality are better understood within a network of behaving cognitive agents interacting with each other and the setting. It is perhaps in this light that West Africans value cognition not as an endstate of development, but as a means to social competence. Thus, whereas the Western child is socialized primarily through instructed learning by adults, with considerable cognitive stimulation, the West African child is trained primarily through participatory learning in ongoing cultural activities which highlight sharing and responsibility, particularly within the peer culture.

4. *Toward Internationalizing the Discipline: Theoretical and Methodological Challenges*

Although Lev Vygotsky ventured a sociocultural theory of psychological development, his framework viewed development cognitively, in terms of language and conceptual thought, rather than socially. Because theorizing has tended to dichotomize the social, cognitive, affective, and other components of development, an ideal situation is to weave them, and the interactions among them, into a comprehensive theory. Social ontogeny is a model that holds the potential to thread these facets together. The conceptual requirement is to open up to human diversity; the methodological challenge is to access and assess all facets of psychological functioning. This requires a multicultural mindset that accepts and grapples with all sources of developmental knowledge.

The conceptualization demands a new understanding of theory in close proximity to actual psychological phenomena, thereby necessitating a paradigm shift. It requires the researcher and researched to enter a

critical discourse within the hermeneutic circle of academic and indigenous psychologies in order to ground theory and method in sociocultural reality. It acknowledges that data *by* the people differ from data *about* the people. This approach is likely to advance a universalistic psychology of understanding, say, the development of thought and emotion in culture.

Evidence that the criteria psychologists and parents employ to judge children's competence do not always overlap reinforces the approach. The heart of the paradigm is collaborative interdisciplinary networking that permits several disciplines to cross-fertilize and enrich the research process. This approach calls for a learning posture that permits innovation to attend to phenomena in context rather than to focus stubbornly on predetermined samples of behavior. Because many aspects of developmental phenomena are inaccessible to current research techniques, it is absurd to adopt an either/or mentality to quantitative and qualitative methods. An ethnographic approach that utilizes both methods, especially with social learning, may reveal certain dimensions of psychological being, which are excluded by an either/or ideology, thus offering insights for theoretic innovation and creativity in methodology. The way forward is to borrow wisely and gain usefully and creatively from the perspectives of several disciplines rather than to hold obsessively to a single tradition. Furthermore, because physical, cultural, demographic, and other imperatives sometimes differ across cultures and contexts, indigenous psychology, being more sensitive to phenomena that might be ignored elsewhere, can enrich international psychology. It can inform the field of the extent to which some elements of human development portrayed by a Eurocentric discipline are inappropriate for non-Western peoples, thus highlighting what are, and are not, universal aspects of psychological functioning. Two contributions in this direction are the image of self and cognitive competence within the family among the majority of humanity (see Kagitcibasi 1996), and the introduction of social ontogeny as an alternative developmental theory (see Nsamenang 1992).

Indigenous psychology is not a project of cultural essentialism; neither is it a feature of a specific culture. Rather, it is an account of the dialectic between psychological attributes and the environmental conditions that shape them. In this sense, indigenous psychology in West Africa becomes an account of how the West African ecology primes human development. Because it resonates with African conceptions of family and childhood, it can inform psychologists and development agents about how West African communities will relate to interventions for children, a link that has been missing from development work in Africa.

If psychology was fashioned, say, within the African or Indian worldview, what difference might that make to its theory, method, and practice?

Individual Identities in Organizations

1. Trends in the Study of Individuals

Traditionally in Western (particularly American) studies, social scientists have treated the individual as a primary entity to be investigated. This pursuit entailed an essentialist view of the individual—assuming that the individual had '… an "authentic self" with knowable characteristics' (Gergen 1991, p. 7). Recently, these essentialist assumptions about individuals have been challenged as scholars have come to attach increased importance to the contexts in which people exist.

Although common sense, everyday experience, and a long history of psychological research in the Western world seem to suggest that organization studies should treat the individual person's self as a fundamental unit of analysis. These assumptions have been challenged at least both implicitly and explicitly. The implicit challenge was captured by Nord and Fox (1996) and Gergen (1991) advanced perhaps the most explicit challenge.

1.1 Implicit Challenge

Nord and Fox's (1996) implicit challenge was a serendipitous outcome of their attempt to summarize knowledge about the individual in organization studies using traditional headings such as personality, motivation, and learning. The difficulty they had in doing so led them to a surprise realization—the individual as previously assumed by organizational psychologists may have gradually vanished. However, to that point this disappearance (if it was one) was primarily a latent trend in American organizational behavior—a discipline that had traditionally rested on an assumption of the essentialist individual. Historically this discipline had grown out of psychology and had sought to uncover the essential properties of individuals, assess variations among individuals, and capitalize on this understanding to help to make organizations function more efficiently and more effectively.

However, the change was subtle. On the one hand, Nord and Fox reported considerable counter evidence that the essentialistic perspective was far from entirely dead. For example, the strong interest in the so called 'big five' personality characteristics and the increase in research on personality traits during the period 1987–1992 in comparison to the period 1974–1986 noted by Pfeffer (1997) revealed that many investigators continued to employ the essentialist view. On the other hand, both in applied, and basic psychology, many other researchers were finding it increasingly difficult to sustain it, for example, many psychologists and organizational behaviorists who were publishing in mainstream journals even though not confronting the essentialist view *per se*, were increasingly emphasizing the role of context. This development was evident over time as a number of psychological inquiries conducted in traditional terms that when viewed over time reflected a pattern of a partially conscious skepticism about the essentialist perspective.

Nord and Fox (1996) pointed to the existence of this implicit overall pattern cautiously ending the title *The Individual in Organization Studies: The Great Disappearing Act?* with a question mark. Despite the caution they noted that in contrast to the traditional essentialistic approach of a few decades earlier '… emphasis has shifted from viewing individuals independently of context to consideration of the interplay between individuals and their context' (p. 148). Defining context as '… attributes of the physical and social systems in which individuals exist' (p. 149), Nord and Fox found that the progression of chapters in the acclaimed *Annual Review of Psychology* as well as in the highly regarded *Handbook of Industrial and Organizational Psychology* revealed that from the late 1970s on, research on the individual in organizations had become increasingly contextualized. In addition, they pointed to the growing role of contextualized understandings in leading mainstream psychological journals such as work by Sampson (1985, 1988, 1989) in *American Psychologist*, Baumeister (1987) in the *Journal of Personality and Social Psychology*, and Markus and Kitayama (1991) in the *Psychological Review*. A key theme of Nord and Fox was that this disappearance of the individual in the organization studies and related literature was an emerging and implicit development over the last several decades.

For present purposes, Nord and Fox's suggestion that the individual may be disappearing in organization studies is best viewed as an inductive product from a review of work by researchers who were operating under the traditional positivist traditions of general and organizational psychology. For the most part these scholars were not even aware of an altered mindset about the position of the individual. In short, the trend from the traditional essentialist view of the individual to a much more contextualized stance was implicit, appearing to be a latent outcome of the mainstream literature where the contributors were probably operating within the relatively essentialistic traditional paradigm.

1.2 Explicit Trend

By contrast Gergen (1991) offered a much more explicit and less cautious recognition of a similar but longer term trend. In *The Saturated Self*, Gergen argued persuasively that an altered view of the individual had occurred. In contrast to Nord and Fox's inductive use of research from organizational studies and traditional social science, Gergen applied an avowedly postmodern perspective to a broad array of historical and academic knowledge. Despite this difference, the congruence between his notion of the saturated self and Nord and Fox's disappearence thesis is strong.

Gergen argued that '… traditional assumptions about the nature of identity are now in jeopardy … The very idea of individual selves—in possession of mental qualities—is now threatened with eradication' (p. x). The complexity of Gergen's book makes it difficult to summarize in a short space, so only a few highlights can be considered here.

According to Gergen the dominant intellectual trends of the twentieth century featured two vocabu-

laries, a first inherited largely from the nineteenth century he termed as the romanticist view of self (a view that attributed to each person characteristics of personal depth such as passion, soul, creativity, and moral fiber). Beginning in the twentieth century, a second vocabulary—the modernist one (the view in which the chief characteristics for the self did not reside in a domain of depth, but rather in the ability to reason, including beliefs, opinions, and countless intentions)—challenged the romantic vocabulary. Despite their differences both vocabularies shared essentialist views of the self.

However, Gergen asserted that both vocabularies were becoming outdated as a result of a set of forces that produce social saturation. As he put it: '… both the romantic and modern beliefs about the self are falling into disuse and the social range in which they support are eroding' (p. 6). Social saturation entails a multiplicity of incoherent and unrelated languages of the self. Everything that people know to be true about themselves is challenged by other voices within them, producing fragmentation due to the large number of incoherent and disconnected relationships a person has. Gergen wrote that these relationships: '… pull us in myriad directions, inviting us to play with such a variety of roles that the very concept of authentic self with knowable characteristics recedes from view. The fully saturated self becomes no self at all' (p. 7). As the saturated self develops under postmodern conditions, it throws the very concept of personal essences into doubt. Drawing on the work of anthropologist Clifford Geertz, Gergen suggested that some cultures contrast sharply with the American culture by not sharing the American emphasis on the individual; in these other cultures a person is often considered as a representative of some general category of social significance in the culture (e.g., 'first born' or 'grandfather of …'). Moreover, members of these other cultures do not hold the notion of biological givens as strongly as Americans tend to and in some of these cultures investigators have found it difficult to locate any terms referring to 'inner states.' Gergen observed that in America the essentialist view of the individual led people to view the human being more or less as a machine and further that holding the image of the individual as a machine but that recently, this essentialist self has given way to a new form of self-consciousness in the postmodern period, because the technologies of social saturation contribute to '… erasure of the individual self' (p. 49). Gergen suggested that what we take to be the individual self is increasingly indistinguishable from the pattern of social relationships with which the physical individual interacts. As people come to feel and express themselves more fully in a growing number of relationships they become populated with the character of others. They contain multitudes, even though they '… appear to one another as single identities, unified, of whole cloth. However, with social saturation, each of us comes to harbor a vast population of hidden potentials …' (p. 71).

Keeping in mind Nord and Fox's (1996) and Gergen's (1991) suggestions of the disappearance of or at least radical transformation of the individual as an analytical category and the growing emphasis on context, some other recent developments in sociology and psychology add support to the disappearance hypothesis. Here, two of these developments one from sociology and the other from social psychology are considered.

Recently, the famed sociologist Sennett (1998) coined the phrase 'corrosion of character' to describe the impact of recent changes in the nature of work upon people. Sennett began with a conversation he had with the son of one of his working-class respondents from Sennett and Cobb's (1972) famed study decades ago published as a book *Hidden Injuries of Class*. The changes were enormous. Nearly a half century ago the stable relationships people experienced at work contributed to them developing a rather stable sense of self. However, now the stable work relationships have vanished as recent changes in technology and life in economic organizations as exemplified by the motto now guiding many organizations 'no long term' have disappeared. As a result, people now encounter rapidly changing and temporary attachments to their work and organizations. As a result, individuals have experienced a 'corrosion of character.' As Sennett put it, the experience of disjointed time threatens '… the ability of people to form their characters into sustained narratives' (1998, p. 31).

Yet another challenge to the essentialist self can be found in recent social-psychological literature. Consider, for example, the October 1994 special issue of *Personality and Social Psychology Bulletin* focusing on the self and the collective. In their introductory essay, the issue's editors Miller and Prentice (1994) observed that traditionally social psychologists viewed the group as something external to people and focused on understanding how individuals behaved in a group. But then, roughly in the late 1960s and early 1970s, Tajfel (1969) and his co-workers pioneered a very different view—one that located groups inside the heads of individuals, instead of asking how individuals behaved in groups and demonstrated '… that the social categories with which a person identifies have a profound impact on his or her psychological functioning' (p. 451). Further, Miller and Prentice observed that this shift resembled a trend in anthropology that has led to conceiving culture in cognitive terms, that is, a conceptual structure in people's heads' (p. 451). They asserted that all the writers in the special issue assumed '… that the study of the collective is a necessary companion to a study of the self' (p. 451). In other words, they rejected an individuated view of the self in favor of a more socially embedded one that '… anchors the self-concept in the broader world'

(p. 451) and views the content of one's self-concept as derivative of the social groups a person identifies with. Thus, the collective is part of the self not merely a context for making judgments about oneself. This development helped to breakdown some barriers between psychology and other disciplines especially with contemporary cultural psychology in which the self is closely tied to the collective. As Miller and Prentice (1994) put it: '… cultural psychologists argue that collectives are important because a person's construal of the relation of the self to relevant social categories determines much of the *structure* of the self' (p. 452). Again, contemporary conceptions of the self tend to emphasize a social more than an individualistic nature.

Further, in the first paper in the special issue itself, Turner et al. (1994) advanced 'self-categorization theory.' Their view tends to de-personalize self-perception: '… individuals tend to define and see themselves less as differing individual persons and more as interchangeable representatives of some shared social category membership' (p. 455). Thus, the self varies as a function of social situations and the concept of the self as a separate mental structure is not necessary. Rather all a person's cognitive resources, including long term knowledge, implicit theories, cultural beliefs, and so on, are available and are deployed when necessary to create the needed self-category. In short, people deploy their cognitive resources reflexively to categorize themselves when appropriate. Turner et al. (1994) added 'we can therefore reject the notion of self-concepts as … stored, invariant structures and the associated model of category use as a process of *activating an already existing representation* …' (p. 459). Clearly, another example of the abandonment of the essentialist view of the person.

Having considered how the essentialist individual has in many respects been transformed into social identity or as Gergen (1991) put it the saturated self, we turn to a second recent trend—this one at a more macrolevel. The development of the concept of organization identity and an associated change in thinking about organizations.

2. *Conceptual Developments Concerning Organization Identity*

2.1 *Identity and the 'Disappearing' Organization*

In the 1980s, the concept of organization identity began to become popular. Interestingly in light of what we have seen about the fate of the individual, some students of organizational identity seem to have suggested that in a way the traditional organization may be disappearing too. But when we view the two trends together, we see more of a transformation of each into the other. For example, whereas the individual appeared to be moving into the collective, the collectivities we call organizations seem to be disappearing into the individual. For example, recently, leading students of organization identity (Albert et al. 2000) reasoned that environmental turbulence has driven organizations to become increasingly organic, therefore traditional bureaucratic structures are less prevalent. They wrote: '… increasingly, an organization must reside in the heads and hearts of its members.' Of course, we must be careful here. Their statement does not say the organization has disappeared but merely suggests, in developing an intellectual view, that its focus is changing. This shift reveals the potential organizations have to serve as forms of the collective relationships that Turner et al. (1994) and Miller and Prentice (1994) suggested define individual identity.

Knowledge from the growing literature on organization identity can be summarized under three headings: (a) conceptual work on the identity concept, (b) the concept's practical relevance for managing today's organic structures, and (c) identifying, that is, the process through which individuals become identified with organizations. Recent developments on these matters are reviewed below.

2.1.1 Conceptual work on organization identity. Two things can safely be said about efforts to conceptualize organization identity: (a) interest in the topic is relatively new and (b) knowledge about it is somewhat chaotic. First, while the topic is not totally new to organization studies it would seem that topics from the past such as organizational culture and Etzioni's (1961) classic typology of types of organization involvement share related concerns. However, recently 'identity' *per se* has attracted widespread interest. Albert and Whetten's paper (1985) paper in *Research in Organizational Behavior* sparked this interest. Albert and Whetten began by acknowledging that historically identity had been treated as a loosely coupled set of ideas; but it would be better if the term 'organizational identity' was made more scientifically tractable (i.e., a conceptualized term in a way to make multiple empirical questions and hypotheses become visible).

To this end, they suggested three criteria for an adequate statement of organizational identity: (a) central character, (b) distinctiveness, and (c) temporal continuity. The first criterion, a statement of central character, distinguishes the organization on a basis of something that is important and essential. In defining the second criterion, distinctiveness, they relied on parallels here between the organizational identity and the psychologist Erickson's (1980) discussion of individual identity. Following Erickson, they advanced identity as a classification that locates the individual as recognizably different from some others, but simultaneously similar to those who are members of one's

own class. Their third criterion, identity over time, treated the temporal aspect of identity. Again drawing on Erickson's work on individual identity they pointed to the negative consequences of the lack of fundamental continuity over time and formulated an intriguing model of paths of identity change an organization often follows over its life cycle. Further, they noted that oftentimes organizations have dual rather than just single identities, for example, universities have many features that are similar to those of churches and features that are similar to those of businesses.

Most writers who have drawn on Albert and Whetten's (1985) concept of organization identity emphasize some variants of these criteria and define identity as what members of an organization believe is central, enduring, and distinctive about their organization. However, although there is considerable agreement on these features of a definition, there also is substantial controversy about what the term means.

The controversy is great enough to justify saying that conceptualization of organization identity is somewhat chaotic. Information from two recent publications—Whetten's (1998) book *Identity in Organizations* and a special topic forum in the January 2000 issue of the *Academy of Management Review*—illustrates the chaos.

Scott and Lane (2000), commenting on the controversy about definition, observed that in contrast to Albert and Whetten's definition, some scholars have defined organizational identity at the individual level '… as a cognitive image held by a member of an organization' (p. 43). This definition is associated with efforts to link organization identity to an organization's image which following Gioia et al. (2000) '… includes notions involving the ways organization members believe others see the organization' (p. 63).

The definition controversy stimulated Gioia et al. (2000) to reconceptualize organization identity as '… a potentially precocious and unstable notion, frequently up for redefinition and revision by organization members' (p. 64). However, elsewhere Gioia (1998) had provided deeper insight into the sources of the problem. Writing on the conceptualization problem Gioia (1998) examined three perspectives: (a) functionalist, (b) interpretive, and (c) postmodern.

Social scientists who use the functionalist perspective, according to Gioia, believe it is appropriate to view phenomena through natural science like models, make realist and objectivist ontological assumptions, and to treat identity as something that exists and is available for study. Summarizing this view Gioia (1998) observed: 'The study of identity is often treated as the study of something someone or some organization has: it is thus rendered as understandable to an interested observer and usually is conceptualized in fairly dispassionate, theoretical terms' (p. 26).

In contrast, when one uses the interpretive lens things are more subjective and the distinction between the researcher and the researched is blurred. The project of the researcher under interpretivism is to render the constructions of the informants faithfully and to accurately represent their interpretations. Using the third (i.e., postmodern) lens introduces additional contrasts. The postmodern perspective encourages challenging or at least suspending judgment on most current ontological, epistemological, and methodological assumptions. It questions the basis for all beliefs and study, including its own. When organizational identity is studied under this lens, frequently it is construed as at best a fiction perpetuated by dominant parties.

Clearly, if all three of these perspectives are currently in use, and they seem to be, it is not surprising that there is a lack of agreement about what organization identity is. Gioia concluded '… organizational identity is still an embryonic area although of some significant potential for understanding how and why organization members think and act as they do' (p. 29).

Among others commenting on the conceptual problems in defining identity (whimsically one might say about the identity of identity) have been Bouchikhi et al. (1998) who concluded their published conversation about identity by observing: '… one's understanding of the concept of organizational identity depends upon the perspective one takes in approaching it' (p. 76).

The confusion about what 'identity' is was perhaps best summarized by Ashforth (1998) when writing the epilogue to the book *Identity in Organizations: Building Theory through Conversations*, reflecting back on the conversations that had produced the book, concluded: 'The identity question (Who Am I?) may be a question with which both individuals and organizations must struggle in order to create a sense of meaning, and a sense of direction, for their activities. This book attempts to convey a sense that identity is a concept (or construct) in its infancy. I invite you, the reader, to join us in the marvelous discovery process centered around organizational identity …' (p. 293).

Ashforth's statement is instructive in two ways. First, it captures the ambiguity surrounding the concept. Second, its upbeat tone captures the excitement that students (albeit at this point a relatively small number) of the subject have for the concept.

2.1.2 Sources of excitement. What exciting potential do these people see? For one thing they see the concept's potential for bridging across topics and levels of analysis. Albert (1998), for example, observed that a major advantage of the concept of identity is that it is a bridging concept—it facilitates asking cross-level questions that link micro- and macrostructures and processes.

In that same volume, Gioia (1998) suggested other reasons for excitement, its fit with how people see

things, its flexibility, and practical value to managers, and its openness. Reflecting on Albert and Whetten's original paper, he suggested that their view of identity '… captures the essential (in the phenomenological sense) features of an organization' (p. 21) and that the dimensions they outlined parallel those noted for individuals, although differing mainly in their collectively-shared character. Another reason for excitement is that the concept of organizational identity is highly flexible. This flexibility is especially valuable to modern organizations because their environments are changing so rapidly and to adapt, organizations need to be able to change their identities rapidly and they need to display identities of both stability and instability simultaneously. They need to manage the appearance of stability and order so that change can be managed, while still retaining central features of core identity. Thus, not only is identity useful as a conceptual bridge, it also is a potential aid to managers seeking to cope with opposing demands to maintain some sense of coherence while simultaneously adopting to the demands of rapidly changing environments. Further reason for excitement Gioia concluded is that the area of study is a '… wide open domain' (p. 29).

The role of openness in generating intellectual excitement becomes clear when we examine the identity concept in light of recent accounts of the scientific process such as the work of the physicist/philosopher Giere (1988). Giere observed that science proceeds through a process of individual scientists bringing their cognitive resources (special competencies) to bear on intellectual topics. Thus, one might expect a wide-open domain to attract the attention of a variety of scholars. Currently, the study of identity invites people of all stripes from many areas of study to apply their cognitive resources. Recall, for example, Albert and Whetten (1985) sought to shape a diverse network of ideas into a scientifically tractable concept. Then too note that the topic of identity is related to other popular organization concepts including culture and legitimacy, and also by its nature invites input from a host of diverse literatures and disciplines. In short, 'identity' offers great opportunities for people having diverse cognitive resources to become involved. The variety of contributors to the recent *AMR* special forum is a case in point; it brought writers with a host of diverse sets of cognitive resources, including stakeholder analysis, psychodynamics, postmodernism, and demographic diversity, to the table. All of this follows a paper seeking to make the concept scientifically tractable.

We have already seen that the concept of organizational identity offers practical as well as intellectual benefits. This fact deserves special attention.

2.2 Value of Identity to Contemporary Managers

If identity is a response to the particular question Albert and Whetten (1985) observed 'What kind of organization is this?' (p. 292). Answers to it refer to features that are '… core, distinctive, and enduring' (p. 292). Among other things this orientation leads to the practical value of the concept of contemporary managers.

Throughout the discussion so far, there have been hints that 'organization identity' is useful for managers of today's organizations because they need some way to achieve some modicum of internal stability while simultaneously responding flexibly to turbulent environments. Albert et al. (2000) showed that the concept of identity can serve in exactly this way. They wrote: '… it becomes more important to have an internalized cognitive structure of what the organization stands for and where it intends to go—in short, a clear sense of the organization's identity. A sense of identity serves as a rudder for navigating difficult waters' (p. 13). Similarly, Pratt and Foreman (2000) argued that a firm's identity can be a source of sustainable competitive advantage and that since organizations often have multiple identities, the concept may be helpful in conceptualizing ways to manage the pluralism. Scott and Lane (2000) extended the managerial value of the concept by relating it to stakeholder theory. They observed: '… Managers choose organizational images for presentation to stakeholders for strategic reasons. Corporate reputation building is principally concerned with promoting attractive organizational images … for purposes of goal attainment, and it is the primary job of leadership to mange organizational identity toward that end … Managers, as organizational leaders, are expected to assume the role of speaking for the organization. Making public commitments on the part of an organization influences people to chance their self-perceptions and act consistently with the presented self-image … Although all organizational participants have perceptions of organizational identity and can promote these publicly, they are not charged with doing so—this is not an expectation of their organizational role' (p. 47). In short, the concept of identity may help managers deal with external as well as internal constituents.

This leaves us with one final topic for completing our overview of current work on conceptualizing organization identity—the process by which people come to identify with the organization. In a word—identifying or the identification process.

2.3 Identifying

We have seen that students of identity believe that a major value of the concept of organization identity has been its ability to help bridge between the micro and macro levels of analysis. One path onto this bridge is study of the process by which individuals come to identify with collectivities such as organizations. To do this, it is useful to de-emphasize the noun 'identity' in favor of more process oriented terms such as

identifying and the 'identification process.' This shift draws attention to areas of study that shed light on related processes but were not originally concerned with identity. Here, two are considered: first some writings of Karl Weick and, second, the long-standing interest in organizational socialization.

Weick's (1995) work on sensemaking, especially his discussion of the individual as 'sensemaker,' using reactions of others to come to an understanding of self, is helpful. Weick's clever question 'How can I know who I am until I see what they do?' (p. 23) summarizes to this perspective neatly, revealing that individuals develop identities by observing how their actions and beliefs about themselves affect the reactions of others. These reactions are the substance for a sensemaking process that produces an individual's view of him/herself. This view helps us to see how (i.e., the process through which) what we have said about the individual becoming an expression of the social context may occur. However, Weick provided even greater insight into the process in this, the sense of self is highly influenced by a dynamic interaction with the organizational context in which people are seen engaging in a process of sensemaking through interaction in his study of the Mann Gulch disaster.

Weick's (1993) study of the Mann Gulch disaster (a forest fire that killed 13 firefighters) informs our understanding of identification process mainly by a negative instance—the loss of identity. Weick maintained that a major contributor to the breakdown in social structure that led to the disaster was a foreman's command to the trapped crew to drop their tools. How could such a command make for disaster? To many readers not facing an onrushing fire, the command to people facing one to drop the heavy equipment they were carrying seems sensible since the reduced weight should have made it easier for the men to run away (especially since some of the running was up a steep incline) from the fire. However, Weick argued it turned out to be a source of disaster because the tools defined the men's identity of themselves as firefighters. Dropping their tools removed their identity—the individuals could no longer answer the question 'Who am I?' Further, since an authority figure told them to discard this source of identity, the legitimacy of their whole social order came into question. Thus, Weick's analysis, although not intentionally directed to studying identity, revealed how everyday elements such as one's tools impact individuals' identification processes (another example of the socially created individual discussed earlier) and how people's identities are part of the collective order.

Insight into the identifying process can be gained from research on another topic—organizational socialization. Ashforth and Mael (1989) using social identity theory (SIT) argued that research on socialization reveals that in organizations, social identification occurs as situational definitions and self-definitions emerge through symbolic interactions and people develop self-definitions through interpreting responses of others. In addition to these insights into identifying from sources not grounded in the identity concepts, the identity literature itself provides helpful insights.

In the identity literature, Ashforth (1998) suggested four metaphors for thinking about the process: imprinting, love, play, and theater. Perhaps the most valuable study concerning identifying contained in the identity literature itself is Dutton and Dukerich's (1991) path-breaking case study of the Port Authority of New York and New Jersey. This study is especially useful in revealing the dynamic relationship between individual and organizational identities. By revealing the interplay between an organization's identity and the identity of its members Dutton and Dukerich called attention to the role of an organization's image (i.e., the way that members believe that outsiders view the members' organization). Because an organization's image is an indicator of each member's identity, image is directly related to the self-esteem one can derive from belonging to the organization. Dutton and Dukerich considered six attributes that their informants believed distinguished the Port Authority as an organization and discovered how these interpretations and the organization's responses to a troubling environment change coevolved. They concluded that the organization's identity acted as an important reference point that members used to assess importance of presenting issues and to guide how they responded. In sum, Dutton and Dukerich showed how individual and organization identity interact to influence how individuals come to identify with the organization.

3. *Conclusion*

In drawing together what we have seen so far, several key themes are prominent.

(a) Recently, strong challenges to the essentialist view of the individual have appeared. In a sense, as an analytical tool, the traditional, essentialist individual seems to be disappearing. As this is happening, social entities are increasingly recognized as a major source of data for people trying to answer an identity question such as 'Who am I?'

(b) In a similar sense, the entities called organizations, as we knew them in the twentieth century, seem to be disappearing and, as Albert et al. (2000) put it: 'Increasingly, an organization must reside in the heads and hearts of its members' (p. 13).

(c) In organization studies, the micro and macro sides of the field have not been fully integrated.

(d) In recent years, identity has been advanced as a concept with potential to provide a bridge between the micro (i.e., individual) abutment of the field and the macro (i.e., organizational) abutment.

We have seen evidence to support the validity of all four points. However, when the four are taken

together they reveal a somewhat bizarre result. Certainly, the idea of identity is a potential bridge between the micro and the macro. However, as we have seen, the abutments at both ends that are to be bridged seem to be in a sense disappearing with the two disappearing ends becoming enmeshed in each other as shown by points (a) and (b). If so, at the extreme we might be left with a bridge, that is, 'identity' from nowhere to nowhere.

If we extend this metaphor, we could envision being left with the bridge called organization identity. As the study of identity seems to be moving as summarized by combining points (a) and (b) above, for some purposes individual and organization identity could merge into one concept.

Although such an extreme outcome seems bizarre, the stimulus to even imagine it, derived as it was here from exploration of trends in the study of individual and organization identity, does suggest identity is a high potential concept for organization studies in the future. The fact that the idea already has practical as well as theoretical value further attests to its potential in the postmodern world where the hard substance of traditional entities seems to be softening.

W. R. Nord

Individual/Society: History of the Concept

The concepts 'individual' and 'society' are intimately related. Societies, whatever else they may have been thought to be, are collections or groups of individuals. Many philosophers and psychologists have thought

that individuals only took on the characters they did by virtue of the influence of the society in which they grew up. But which had priority? Which was the cause and which the effect? The problem of how the concepts of individual and society are related has been part of a more extensive philosophical debate on the nature of classes and their relations with their own individual members. Some have argued that we can dispense with class concepts in favor of ones referring only to individuals, others that any such attempt will necessarily fail.

1. Philosophical Aspects of the Individual/Society Contrast

1.1 Kinds of Groups

The problem of how to interpret the concepts of individual person and social collective is embedded in a more ample philosophical issue, the general question of how to understand the contrast between individuals and groups and the inter-relations between them. There are two main kinds of collectives or groups that are of relevance to social science. There are taxonomic groups in which the members share some set of qualifying properties but may have no real relations with one another. Two people may be members of an ethnic minority solely on the basis of their mother tongue, or their religious affiliation. This concept of a collective is particularly appropriate to the study of groupings like social classes. Then there are structured groups like families or institutions, the members of which may be biologically or socially related to one another. In structured groups members are usually different from one another with respect to group membership. Mum and Dad are members of the nuclear family just insofar as one is female and the other male. In recent sociology and social psychology such groups have been analyzed by the use of the concept of role. It seems particularly appropriate to the study of institutions and teams.

1.2 The Related Problem of Universals

Philosophical problems associated with taxonomic groups have a history that reaches back through Medieval attempts to deal with the problem of universals into antiquity and the Platonic forms. How could one account for the fact that many individual entities were the same color? Or the same shape? According to the Ancient Greek philosophers this fact had to be explained by some version of the form and matter distinction. Clearly similar things shared a common form. How did that form exist? Plato built his account on the principle that the property displayed by each individual entity was a realization in the material world of a form that transcended it. The Platonic account has often been rejected. In the later Middle Ages, William of Ockham argued that the only common element in a group of things of the same color, for example, is the use of the same *word* to describe each of them.

1.3 Emergent Properties

The idea that collectives are somehow more than the sum of their members has persisted, albeit in rather different ways, down to the present day. The notion of an 'emergent property' has been coined to describe cases in which a collective of parts, say a brain composed of neurons, has a property, a capacity for thought, that is not possessed by any neuron taken singly. Emergent properties contrast with aggregative properties such as weight. Both brains and their component cells have weight. An important debate in social science centers on the issue of whether among the emergent properties of social structures are causal powers. Some have argued that agency is an attribute only of the human beings who create these structures.

1.4 Internal and External Relations

The third main issue concerning the relation between individuals and collectives is tied in with the distinction between internal and external relations. Two beings are internally related if their natures are partly or wholly determined by their standing in those relations. Marriage is an internal relation in that a person becomes a husband or a wife by virtue of being related by marriage to someone else. Spatial relations are commonly cited as examples of external relations between people, though they may not be for material things in general. The general question is whether people are the products of the societies in which they have a place or are the societies' products of the activities of people? Contemporary structuration theory takes a middle way, seeing people as shaped by their social relations and in turn, in their subsequent ways of living, recreating those social relations, albeit imperfectly.

2. Hobbes and Locke: the Genesis of the Sovereign

2.1 Leviathan: Individuals Covenant to Maintain a Sovereign

In Protestant Europe the individualism of the renaissance soon evolved into the idea of the state as a corporation of citizens. What sort of collective could

such a corporation be? Where is the sovereign to be found in such a picture of the state? From what source does the state derive authority, when the Divine Right of monarchs is no longer accepted? The overt philosophical problem, which is to ask in what way a corporation exists other than as an aggregate of its members, was displaced by the more pressing question of how a group could come to have an identity to which a citizen owed a duty of obedience. The social contract, an agreement to give up some of one's individual freedoms for the benefits of civil society, in particular personal security, was invoked by Hobbes, Locke, and later Rousseau as a necessary precondition for a social order to arise out of individual aspirations and intentions.

This was the moment at which the collective emerged from the aggregate of individuals. It was also the ground of the state's authority. Both aspects of the social contract appear very clearly in Hobbes's *Leviathan* of 1651.

> [the agreement that creates civil government] is more than Consent or Concord; it is a real Unity of them all, in one and the same Person [the Sovereign], made by Covenant of every man with every man … [This creates a Commonwealth, the essence of which is] One Person, of whose Acts a great Multitude, by mutual Covenants one with another, have made themselves everyone the Author, to the end he may use the strength and means of them all, as he shall think expedient, for their Peace and Common Defence (Hobbes 1651, Part 2, Chap. 17).

Yet it is not the collective that is sovereign, since the purpose of the creation of the unity is the delegation of powers to an individual. Each person is the 'author' of the acts of whosoever is the sovereign.

2.2 *The General Will*

Rousseau, writing a century later, dispensed with the sovereign as such. Here we have the submergence of the individual in the collective.

> Each one of us puts into the community his person and all his powers under the supreme direction of the general will; and as a body we incorporate every member as an indivisible part of the whole (Rousseau 1764 [1968], Book I, Chap. 6).

Nevertheless he insisted that the legislative role of the social group was necessarily distinct from the power to execute the general will.

The metaphysical question of the kind of reality that the collective or group might have, by way of contrast with that of the members taken individually, is not directly addressed by these authors. For instance no one in the high era of the social contract paused to ask for the criteria of identity and individuality of a society, nation, or institution. Nor is the issue of the status of emergent properties raised so far as I know. It is certainly implicit in Rousseau's version of the social contract in that the 'general will' of the collective is explicitly distinguished from the aggregate of personal wishes and intentions, the 'will of all.'

3. *Vico and the Role of Unintended Consequences*

The question of how a group of individuals can come to have a collective identity troubled Giambattista Vico (1668–1774). Unlike his distinguished predecessor, Machiavelli, he did not see the collective as the product of the power and will of the sovereign. He remarks that

> It is true that men have themselves made this world of nations … But this world, without doubt, has issued from a mind often diverse, at times quite contrary, and always superior to the particular ends that men had proposed to themselves; which narrow ends, made means to serve wider ends, it has always employed to preserve the human race upon this earth (Vico 1725, p. 1108).

How is this possible? How can one account for the transition from anarchy to the institutions of the state? It cannot be by the accidental coordination of individual motivated acts. The superior 'mind' Providence employs individual intentions to bring about social order.

Providence is not God, but should be interpreted, I believe, as a metaphor for the flux of unintended consequences of individual acts. There is no need for a social contract to bring the conditions of order into being in Vico's view. Social order comes to be because the conditions for its emergence are already in existence.

> Yet chance did not divert them nor fate force them out of this natural order. For at the point when the commonwealths were to spring forth, the matter was all prepared and ready to receive the form, and there came forth the commonwealths composed of body and mind. The prepared materials were these men's own religions, their own languages, their own lands, their own nuptuals, their own names, their own arms … and because these things were their own they were completely free and therefore constitutive of true commonwealths. … The fathers at this juncture, by uniting themselves in an order, came to produce the sovereign civil power, just as in the state of nature they had held the family powers … (Vico 1725, p. 630).

By bringing about the birth of families, each with its own language and rules of life, Providence had at the same time brought into being the natural law to be used in the management of commonwealths.

The identity of a nation was identical with the identity of a family, only writ large. Vico's collectives were structural not taxonomic.

3.1 The Problematic Status of Collectives

Vico's account of the genesis of the state neatly avoids the issue of how individuals can jointly constitute a collective entity the properties of which are not just aggregates of the properties of individuals. He denies individual intentions an explicit role and at the same time traces the means of maintaining institutions back to simpler institutions in which individual intentions directly create social order. In essence Vico assumes the native character of institutions. They are just there.

4. Utilitarians and Collectivists

4.1 Individuals and Freedom

The Utilitarians, Jeremy Bentham (1789), and the Mills, father and son, had no difficulty with the concept of collectives of human beings, for rather the opposite reason from Vico. For them the properties of groups were just aggregates of the attributes of the individual members. The happiness of all was the arithmetical sum of the happinesses of each. The Utilitarian account of the relation between individual and collective is sometimes used to illustrate the fallacy of composition. To infer from the fact that each of the 20 soldiers in a platoon is six feet in height that the platoon is 120 feet high is an obvious fallacy. Is it not equally fallacious to give a measure of the happiness of a society as the sum of the happinesses of individual members?

John Stuart Mill's (1859) *On Liberty* presupposes a sharp distinction between individual and society, at least when 'society' takes the form of government, public opinion and so on. He argued for the fundamental moral propriety of resisting those who claim to be the voice of the mass. Freedom and individuality are more or less the same thing for Mill. There is a contrast for him between the self-subsisting power of the individual to resist and the power of the state to coerce.

We would now tackle the problem of picking out which properties could be aggregated and which could not by invoking the idea of an emergent property, and using examples of the difference between the properties of constituent cells and the organs of which they are components to illustrate the point. What could one make of the idea of a group happiness as an emergent property of the individual activities of the members of a society?

4.2 Collectives and Mass Societies

Running more or less parallel to Mill's individualistic utilitarianism, Hegelian idealism presented a very different picture. History is a collective progress since the world spirit, *Geist*, is embodied in the human race as material beings, more or less as individual minds are embodied in individual bodies. All relations between all beings whatsoever are internal and constitutive. As the realization of the one World Spirit human beings have a unity as a kind of supra-individual.

4.3 Marx and Durkheim

Marx's sociology, the structure of which is drawn more or less directly from Hegel's metaphysics, pitted class against class in a dialectic of contradictory interests (Marx 1867 [1965]). The this-ness of individuals gave way to the individual class member as relevant to sociology only as the vehicle for the necessary attributes of class membership. Borrowing from Hegelian Idealism, Marxian 'Man' was the nexus of internal relations, the relations of the social necessities of certain means of the production of the material necessities of life. However, Marx's two main social classes were taxonomic, in the sense I have defined above. To be a member of the working class or of the bourgeoisie was to exemplify a certain set of attributes, though those attributes were possessed by virtue of standing in certain internal relations to other people.

Durkheim's plea for sociology as the science of 'social facts' comes close to Marx's unpsychological sociology insofar as Durkheim's social facts are attributes of groups. In his *Elementary Forms of the Religious Life* (Durkheim 1895 [1982]), the ceremonies of the Native Australians are to be interpreted as presentations of collective facts about the local social order through participation in which loyalty and commitment to that order are renewed. Again the collective is thought of in aggregational rather than structural terms.

5. What Sort of Science is Sociology?

5.1 Windelband and the Nomothetic/Idiographic Distinction

The individual/collective issue appears not only in metaphysics and social theory, but in methodology as well. That there are two kinds of human sciences was the claim of Windelband (1894 [1998]). There are studies of individuals as such, an idiographic science. There are studies of people in groups or collectives, a nomothetic science. The analogue of a law of nature had no place in idiographic science while, perhaps with the help of statistical analysis, it could have a place in nomothetic science. This distinction is related to but not identical to that between two kinds of empirical enquiry. There is the intensive design, the study of a group by the study of a typical member and there is the extensive design, the aggregation of information about the members of a population into a statement about the population as a whole. The results of studies based on the extensive design will tend to ignore emergent properties, since they are not aggregates of the properties of individuals.

5.2 The Reduction of Collectives to Individuals

In the twentieth century the issue has surfaced again, this time in the guise of the problem of explanation. Are the collective aspects of human societies to be accounted for as just patterns of the unintended consequences of individual actions according to individual intentions? Or are they mass social effects of mass social causes? If we take the former view, explanations of mass phenomena must be sought not in other mass phenomena, but in the intentions of individual actors as they ramify through a population and interact with the intentions of other actors. This proposal has been called 'methodological individualism.' It has been revived by Popper (1961) and others. The idea is an old one. Adam Smith (1776) thought that individual choices in the marketplace 'added up' to the illusion of the 'hidden hand.' It had an important place in Menger's (1883 [1981]) advocacy of microeconomics, the study of the grounds of individual acts of choice as opposed to statistical analyses of vast masses of data. It cannot be a wholly individualistic story since some reference to structure seems to be essential to understand how individual actions could aggregate into something that could be perceived as orderly.

Adam Smith (1776) and Carl Menger (1883 [1981]) did not feel the need to offer arguments for methodological individualism, since each thought he had shown its methodological advantages. In the 1950s a more recognizably philosophical debate began, forcing the positions to be more clearly differentiated and the arguments pro and con more carefully formulated. Three lines of argument in favor of collectivism can be discerned. A metaphysical argument emerged to the effect that individuals are simply products of social processes (Lukes 1973). Then there was an epistemological argument that the tactic of studying only individuals will not allow the recovery of properties of groups. Finally there was a conceptual argument that collectivist concepts such as 'nation' or 'army' cannot be replaced by individualistic ones like 'citizen' and 'soldier' with preservation of meaning.

I think it is fair to say that the issue has not been resolved to anyone's entire satisfaction. The degree to which one sees the ideal form for a society along the polar contrast between collectivist and individualist is not just a question of one's political or religious affiliations. It is also a matter of how far one sees oneself as a product of ready-made social orders, and how far one thinks of oneself as a crusader against the tyranny of the majority.

Individualism versus Collectivism: Philosophical Aspects

The issue between individualism and collectivism, as it is taken in this article, is the ontological issue as to whether the regularities of social life, in particular the regularities that have come to light in social science, cast doubt on the status of human beings as more or less autonomous intentional subjects. This issue should be distinguished from the methodological issue as to whether the explanation of social phenomena ideally should be in terms of the properties of individuals, as it should be distinguished from the moral issue as to whether social institutions should always be assessed from the point of view of their impact on individuals. Emile Durkheim, the great French sociologist, was the most influential defender of ontological collectivism, according to which individuals, as seen from the perspective of social science,

lack the autonomy which they ascribe to themselves in common sense. Just as astronomy taught us that the sun does not literally cross the sky, and physics that solid objects are not solid in any literal sense, so the collectivist idea is that the social sciences teach us that individuals are not what they seem; they are not the self-determining centers of decision-making that they take themselves to be. But hard collectivism in this sense looks implausible, as we shall see; only some soft versions of the doctrine—versions that sideline or downgrade intentional psychology without undermining it—look to have any serious support (Pettit 1993).

1. *The Emergence of Collectivism*

The sociological way of thinking that brought Durkheim to this conclusion had its origins in the rise of social statistics in the early part of the nineteenth century. Responsive to electoral and utilitarian pressures, the governments of the newly industrializing countries, sponsored the statistical mapping of a great variety of phenomena. 'It was necessary to count men and women and to measure not so much their happiness as their unhappiness: their morality; their criminality; their prostitution; their divorces; their hygiene; their rate of conviction in the courts. With the advent of laws of statistics one would find the laws of love or, if not that, at least the regularities about deviancy' (Hacking 1981, 1990).

This statistical mapping of large-scale society, this avalanche of numbers, had an important intellectual impact, because it revealed that social aggregates display surprising constancies, constancies that are often invariant over changes in the individuals, and in the mentalities of the individuals, involved. The statisticians constructed indices of divorce, suicide, crime, sickness, prostitution, and a variety of other phenomena. It soon became clear from their work that there were constancies over time in many such indices, and there were constancies in the correlation of different indices with one another. At the beginning of the nineteenth century it would have been common to regard such statistical patterns as epiphenomena of intentional action which we should expect to be as variable as we seem to find one another. But from the earliest days of statistical mapping, it was obvious that the patterns were not as variable as that; it began to seem that they had a life of their own.

This revelation of unexpected pattern encouraged a sort of statistical determinism, one associated in the beginning with French writers like A. M. Guerry and Adolphe Quetelet. Already by 1832, Guerry could write: 'We are forced to recognise that the facts of the moral order are subject, like those of the physical order, to invariable laws' (Hacking 1991). Such determinism came to be described as an astronomical conception of society, a conception in which people were driven by forces akin to a cosmic force like gravity; the fact that Quetelet was an astronomer lent credence to this characterization of the view (Hacking 1991). The astronomical conception soon spread abroad, receiving a powerful impetus in the English-speaking world, and indeed more broadly, with the publication in 1857 of T. H. Buckle's *History of Civilisation in England.*

The astronomical conception of society received perhaps its most dramatic expression in Tolstoy's *War and Peace*, which was written between 1863 and 1869. One passage will serve to give the tenor of the view 'Ever since the first person said and proved that the number of births or crimes is subject to mathematical laws, that certain geographical and politico-economical laws determine this or that form of government, that certain relations of the population to the soil lead to migrations of peoples—from that moment the foundations on which history was built were destroyed in their essence. By disproving those new laws, the old view of history might have been retained. But without disproving them, it would seem impossible to continue studying historical events, merely as the arbitrary product of the freewill of individual men. For if a certain type of government is established, or a certain movement of peoples takes place in consequence of certain geographical, ethnographical, or economic conditions, the freewill of those persons who are described to us as setting up that type of government or leading that movement cannot be regarded as the cause' (Tolstoy 1972).

The avalanche of numbers and the statistical determinism associated with it led to the development of the new science of sociology. True, the person who invented the term 'sociology', Auguste Comte, was averse to seeing the discipline as a merely statistical enterprise. But the rise of statistical mapping had a crucial impact on Emile Durkheim, who was responsible for establishing sociology as a respectable science. The first empirically based study that he undertook was an investigation of suicide—published in 1897—and this reveals both how deeply he was impressed by the statistical constancies of suicide and how naturally he moved towards the conclusion that those constancies had a life of their own, a life independent of the whirl and flow of individual choice.'Each society is predisposed', he remarked, 'to contribute a definite quota of voluntary deaths' (Durkheim 1951).

Durkheim accepted that aggregate constancies have a life of their own, remaining surprisingly invariant over relevant changes at the individual, intentional level. He postulated aggregate, social regularities to explain those constancies. An aggregate regularity may explain a constancy by subsuming it, as when a constancy in the correlation between two indices—say, the divorce rate and the suicide rate—is taken to reveal a regularity. Or an aggregate regularity may explain a distinct constancy, revealing a relationship between it and some independent factor: say, a relationship

between an aggregate index or correlation of indices on the one side and a background factor like increased population density, an established current of opinion, growing urbanization, or even the fact that the factor in question—say, the correlation—is socially functional in some way. Durkheim gives expression to the sort of regularities that he saw at the origin of statistical constancies, when he writes in the study on suicide: 'the relations of suicide to certain states of social environment are as direct and constant as its relations to facts of a biological and physical character were seen to be uncertain and ambiguous. Here at last we are face to face with real laws' (Durkheim 1951).

In order to understand the sorts of regularities that Durkheim envisaged, here are some examples. They are not chosen on the grounds that Durkheim actually endorsed them or even considered them—he did not—but because they rPepresent a fair spread of the sort of sociological doctrine with which he was associated.

(a) Increased unemployment leads to a rise in crime.

(b) Urbanization leads to a decline in religious practice.

(c) Policies for increasing employment cause inflation.

(d) Economic stratification comes about in order to secure personnel for crucial positions.

(e) Capitalism is stable when it is optimal for developing productive power.

(f) States act internationally in their best economic interest.

(g) States decline in political influence as they fall behind in economic capacity.

(h) Companies maximize expected returns.

(i) The protestant ethic facilitates the rise of capitalism.

(j) Capitalism generates a breakdown in community values.

Regularities of these kinds are social-structural in character. They are social regularities, because they each demand that a number of individuals display certain intentional responses: they require that individuals commit crime in a certain proportion, give up attending church, and so on. And they are structural, because they are discontinuous with intentional regularities. It is not supposed that unemployment leads to crime, or urbanization to religious decline, because it causally impacts in some intentionally intelligible way on the antecedents of intentional regularities; it is not supposed, for example, that it is because people become aware of unemployment or urbanization that they produce the behavior required for the consequent.

Durkheim and most of those who followed him took the sorts of regularities illustrated to give the lie to intentional psychology. He saw them as pointing us towards constraints which undermine or limit human autonomy. He saw them as vindicating, in essence, something like the so-called astronomical conception of society. The constraining factors to which social-structural regularities pointed, in Durkheim's view, range from the morphological features of a society, like the density of its population, to the norms or rules institutionalized there, to the currents of opinion and the enthusiasms which take over from time to time (Durkheim 1938, Lukes 1973). He described all of these as social facts and argued that social facts constrain intentional agents from without. 'Currents of opinion, with an intensity varying according to time and place, impel certain groups either to more marriages, for example, or to more suicides, or to a higher or lower birth rate, etc … A social fact is to be recognised by the power of external coercion which it exercises or is capable of exercising over individuals' (Durkheim 1938).

In giving social facts this constraining role, Durkheim was explicitly challenging the individualist view—a view he naturally presents as an extreme position—that individuals enjoy intentional autonomy. Thus, he wrote of social facts that: 'when we define them with this word 'constraint,' we risk shocking the zealous partisans of absolute individualism. For those who profess the complete autonomy of the individual, man's dignity is diminished whenever he is made to feel that he is not completely self-determinant' (Durkheim 1938).

2. *The Implausibility of Hard Collectivism*

There are two different ways in which social-structural regularities might prove to compromise the intentional autonomy of individuals in the sort of measure that Durkheim apparently had in mind: in the measure, as we may take it, that would give the lie to individualism and support a position truly deserving of the title of 'collectivism.' Individuals will be autonomous in the relevant sense so far as they form their beliefs and desires—their intentional attitudes—and act on those beliefs and desires in a manner that satisfies the general expectations that we hold in relation to a rational or approximately rational agent. One way in which social regularities would compromise individual autonomy is by overriding those intentional regularities, the other by outflanking them (Pettit 1993).

The social regularities would override the intentional if they sometimes conflicted with them, predicting different outcomes for the same situation, and if they proved in those cases to be the more reliable laws. The social regularities would outflank the intentional if it transpired that things are organised at the intentional level—intentional agents and attitudes are selected—so that the social regularities are assured of being satisfied. In the overriding case, the social regularities would predetermine what happened; in the outflanking case, they would predestine it.

The social sciences have not produced results robust enough to support collectivism in the literal or hard sense associated with the overriding or outflanking

thesis. Hume argued that the testimonial evidence that a natural miracle occurred—that a law of nature was suspended—is almost always going to be outweighed by the day-to-day evidence of the reliability of the laws of nature. We might argue in parallel that the social scientific evidence in favor of an intentional miracle—in favor of the overriding of intentional regularities in otherwise normal agents—is almost always going to be outweighed by the day-to-day evidence of the reliability of intentional laws.

As it is with the overriding thesis, so it is with the outflanking one. This thesis would hold that in cases where human beings act so as to ensure that a social regularity obtains, that is, no accident: were they going to have attitudes that would lead them not to support that regularity, then they would not have been there; they would not have been selected. The case envisaged parallels that of natural selection. Assume that mammals have been selected so as to favor the regularity whereby they can digest certain foods. That means that were certain creatures going to have a system that did not support that regularity, then they and their ancestors would not have been there; they would not have been selected. But while there is evidence of certain forms of social selection, there is no evidence for the powerful sort of selection—parallel to natural selection—that would be needed to support the outflanking alleged.

It ought not to cause any embarrassment for social scientists, however, that the overriding and outflanking theses—and the hard collectivism they would entail—are not borne out empirically. For if we recur to the examples given earlier, we can see that social laws of the sort that impressed Durkheim can be intereting and significant, quite consistently with not entailing hard collectivism. That those laws obtain is fixed in part by the fact that human beings are intentional systems who obey standard intentional laws, and in part by contingent facts about the attitudes of those individuals. But that does not mean that just knowing about individuals and their intentional psychology will give us knowledge of those laws. Not at all. It may take considerable data-collection and considerable data-analysis before it begins to become plausible, say, that increased unemployment leads to a rise in crime or increased urbanization to a decline in religious practice. Such a regularity will be plausible in good part, because we can see how it fits with our knowledge of intentional psychology: we can see, for example, how unemployment might lead to crime by increasing both the opportunity and the incentive for criminal acts. But that does not mean that we can derive the law from armchair reflection on our psychology.

Not only will social laws be interesting in this sense, even if they do not entail hard collectivism. They can also be of explanatory importance. Explanatory or methodological individualists hold that explanations which go to the level of individual psychology are to be preferred in social science to higher-level, structural or aggregate explanations. Elster assumes that just the fact of getting nearer the detail of production makes such an explanation intrinsically superior: 'a more detailed explanation is also an end in itself' (Elster 1985). Taylor (1988) agrees: 'A good explanation should be, amongst other things, as fine-grained as possible.' But the rejection of hard collectivism does not necessarily entail the adoption of such explanatory individualism.

Assume that explanation usually involves giving information on causal process. The reason that social laws are explanatorily important is that reference to such a law may give information on the causal process at its origin that is not available just from the story about the detailed psychological profiles of the individuals involved. Thus, we might be told of the individual psychological aetiologies that produced the level of crime in a given year, and be told that that level is higher than previously, without being given the information provided by reference to the law, as we may assume it to be, relating increased unemployment to increased crime. Indeed, we might not even have noticed that most of the new or more frequent offenders were unemployed. The reference to that law provides the information that the increased crime would materialize, not only in the presence of the precise psychological profiles of actual offenders, but under any condition where there is an increase of unemployment. It serves an explanatory purpose that is neglected in the more detailed, individual-level stories (Jackson and Pettit 1992, Pettit 1993).

3. *The Plausibility of Soft Collectivism*

But there is also another line of thought that ought to reconcile many social scientists to the failure of hard collectivism. This is that the argument just given is consistent with the truth of some claims that have a collectivistic ring but that do not involve either the overriding or the outflanking of intentional law. Any one of these claims might be thought to support a soft collectivism: that is, a position that is collectivistic so far as it makes intentional psychology somewhat less important than it may have seemed but that is consistent, nevertheless, with the soundness of intentional psychology. I shall mention five such claims, three or four of which are quite plausible theses. The claims each address a somewhat different question from that to which hard collectivism provides an answer.

The first question which it is important to distinguish from the hard collectivism issue is the question that divides those who are well described as atomists and holists: the question as to whether the individual agent noncausally depends on relations with other people for the appearance of distinctive human capacities (Pettit 1993). Holists maintain that individual

people are dependent on one another for the possession of distinctive human capacities: say, for the capacity to think. But this belief need not lead them to hold that people cannot therefore have the autonomy of subjects who act more or less rationally in the light of more or less rationally held beliefs and desires. Intentional psychology is silent on the question of whether a capacity like that of thought requires communal resources. The holist assertion that thought does require those resources cannot, therefore, undermine that psychology.

The second question, that must be distinguished from the hard collectivism issue, has come to the fore in recent thought. Let us agree that people intentionally or nonintentionally produce—and reproduce—a variety of social entities by the patterns manifested in their attitudes and actions. They constitute social groups and instrumentalities and they constitute the social properties that attach to certain individuals: the status enjoyed by this person, the power enjoyed by that. But here now is a question raised by such entities. Do the entities exercise a reciprocal influence on individual agents? Do they serve to determine, and indeed rationally determine, the opportunities, the motives and the perceptions of those agents, and thereby to shape their further intentional responses? There are some who think, or who think certain individualists have to think, that the answer to this question is, no (Ruben 1985). Those who defend an affirmative answer, therefore, will appear in the guise of collectivists. And this means, in effect, that most contemporary social theorists will be given a collectivist cast (Giddens 1976, Coleman 1990).

The affirmative answer to this question is surely the correct one; social entities exercise a reciprocal influence on agents, at least so far as agents come to form beliefs and desires that involve those entities in their contents. But admitting the reciprocal influence of social entities in this manner does not in any way threaten the standing of our intentional psychology and does not involve a commitment to hard collectivism. I may be influenced by the objects in my social world, as I am influenced by the objects in my physical milieu, coming to form beliefs and desires in respect of them, but this does nothing to compromise my capacity as an intentional subject.

A third proposition that is collectivistic in spirit but not damaging to intentional psychology is a thesis of revisability. It is that thesis that the regularities identified in social science often challenge intentional psychology in the sense of pointing us towards unsuspected disturbing factors. Like the holistic and reciprocity doctrines, this revisability thesis is perfectly plausible. Consider the sort of regularity which much of Goffman's work is given to supporting: that people, in his language, are extremely loath to break frame; that they readily establish a set of shared assumptions about what is say-able and do-able in any interaction and that they generally conform to those assumptions, even at the cost of considerable frustration of their other desires or ideals (Goffman 1975). Anyone who has read the work of Goffman is likely to conclude, quite reasonably, that here we have been alerted to a factor that is often going to disturb people's intentional performance. The work of such social scientists bears out the truth of the revisability thesis ascribed to collectivists, that the identification of social regularities is likely to point us to conditions that disturb the operation or revelation of people's intentional processes and in that sense that it is likely to affect our intentional psychology.

But though the revisability thesis is plausible, it does not serve to displace intentional psychology in a collectivist manner. The frame law used in illustration leaves intentional psychology fundamentally intact. Intentional psychology is an open-ended practice; it remains possible at any stage for its practitioners—who are of course also its subjects—to revise their conception of favorable conditions. If social science can interact with intentional psychology to force such revisions, in particular revisions that can be internalised by participants in their practice, then that does not involve any displacement of intentional psychology; on the contrary, it serves as a way of enriching the practice. Consider the effect of the discovery in optics that a rotating disc with a certain black-white pattern looks to be colored in different ways at different speeds. This does not undermine the intentional-psychological story of color perception but simply points us to a perturbing factor—rotation—that generally goes unnoticed but that is of a kind with factors—say, to do with lighting conditions—that are commonly recognized. A similar gloss will apply to the deliverances of social science, under the revisability thesis.

So much for the holism, the reciprocity, and the revisability claims which should be distinguished from hard collectivism. The fourth claim that should equally be distinguished from it is a thesis about the dispensability of individual contributions to social life, the fifth a claim about the inevitability of those contributions.

The dispensability thesis would say that while any socially significant event is going to come about because of the actions of this or that individual or set of individuals, still no individual makes an indispensable contribution. Had that individual not existed or not acted appropriately, still the phenomenon in question would have occurred. It is either the case (a) that the individual's contribution was not a necessary part of the total cause of the phenomenon or (b) that in the absence of that individual some other agent would have taken their place.

Durkheim was motivated by the existence of certain social constancies—the suicide rate, the divorce rate, and the like—to defend a thesis of type (a). The fact that these constancies survive variation in the individuals and the mentalities of the individuals involved

shows that no one individual contribution is a necessary part of the relevant total cause. But in defending this sort of dispensability claim, Durkheim was doing nothing to displace intentional psychology, so that the claim could be defended equally well by an individualist. The social constancies in which he was interested are characterized at such a high level that the absence of one individual contribution would not make a difference to the obtaining of the constancy. An artefact of aggregation and abstraction accounts for the dispensability of individual contributions, not any radical questioning of intentional psychology.

What of the other sort of dispensability thesis: the type (b) thesis that even with social phenomena which do actually depend on particular individuals—say, something like a political revolution—that phenomenon would still have occurred even in the absence of a relevant contributing party; it would still have occurred, because there would have been someone else available to take the vacated place? This type of claim is not associated with Durkheim particularly but is to be found in other, more historically oriented traditions of social science. The main source is the Marxist tradition and here Engels is quoted as making a telling remark about Napoleon Bonaparte 'That such a man, and precisely this man, arises at a determined period and in a given country is naturally pure chance. But, lacking Napoleon, another man would have filled his place' (Sartre 1963). Is this sort of dispensability thesis inimical to our intentional psychology? Again, I think not, though I doubt that it is generally true (James 1984). All that is required for it to be the case that an individual's contribution is dispensable in this sense is that a number of individuals have the capacity and motivation required to make the sort of contribution involved but that at most one individual can have the opportunity. To think that this was true of all individually necessary contributions to socially significant phenomena might be dogmatic, but it would not involve rejecting intentional psychology.

The fifth and last sort of thesis that should be distinguished from hard collectivism fits better with less empirical parts of Durkheim's work than his study of suicide: for example, with his analysis of the division of labor characteristic of our sort of society. I describe it as an inevitability thesis, as distinct from a dispensability thesis. What it says is that various features of social life limit the opportunities available to individual agents—they are structural constraints on feasible options—in such a way that it is inevitable that agents will act so as to sustain certain social constancies: 'In an extreme version this would mean that the constraints jointly have the effect of cutting down the feasible set to a single point; in a weaker and more plausible version that the constraints define a set which is so small that the formal freedom of choice within the set does not amount to much' (Elster 1979). This could be what collectivists have in mind, at least some of the time, when they denigrate the place of the intentional subject. Certainly it is a thesis that many social scientists defend.

The inevitablility thesis, even in the weaker version, is generally unsound. But that is beside the point in our present discussion. More important, it does no more than the dispensability thesis to undermine intentional psychology. It just might be the case, as the inevitability thesis has it, that our opportunities are tailored to the production of certain social constancies: that we are so limited in our range of options that it is inevitable we will act so as to sustain such constancies. But even if it were true, that would cast no serious doubt on the soundness of intentional psychology or on our status as autonomous subjects. It would not mean that we individual subjects were compromised by social laws in a manner that undermined our view of ourselves as intentional subjects. Our intentional psychology represents us as more or less rational subjects but it says nothing on the range of opportunities that are actually available to us as agents.

It may come as a surprise that hard collectivism is not entailed by the inevitability thesis or the dispensability thesis. Many self-described individualists would certainly want to deny the general truth of such propositions. But even if that is so, the matters in question do not go to the heart of the issue between individualism and collectivism: they do not have an intimate bearing on the status of our intentional psychology. They support a soft sort of collectivism but not the hard kind that would provide a really significant challenge to our self-image.

Industrial and Organizational Psychology: Cross-cultural

Cross-cultural industrial and organizational psychology is the systematic study of behavior and experience in work and organizational situations that occur in different cultures, that are influenced by culture, or result in changes in cultures.

1. Domain

Specifically, cross-cultural industrial and organizational psychology examines work-related phenomena occurring in different kinds of organizations in more than one culture. It attempts to measure aspects of culture and relate them to each work-related, managerial, or organizational phenomenon. It examines cultural influence on work and health, job satisfaction, productivity, decision making, turnover, motivation, labor–management relations, multicultural teams, participation and industrial democracy, preparation of individuals for work in another culture, cultural diversity, and the fit of organizational and national cultures.

2. History

2.1 Early History of Industrial and Organizational Psychology

This field emerged in 1920. In that year two significant events took place. First, Garth (1920) published a paper that measured cultural differences in work behavior. It was based on the number of items of addition that were completed by samples of European, African, and Native Americans (of course, at that time they were called whites, Negroes, and Indians!). The point was to determine the 'work curves' of these samples. Fatigue reduced the number of additions completed at later points in time. The Native Americans were least susceptible to fatigue, while the African Americans were the most susceptible to fatigue, with the European Americans in between. The cultural differences were minor, and no controls for obvious rival hypotheses were presented. However, the author did mention that perhaps the way the samples were selected did not make them equivalent. Second, the Swiss psychologist Claparede established the International Association of Applied Psychology which focused on international industrial and organizational topics, and now holds an international congress every four years. At these congresses applied psychology data collected in different parts of the world are presented and discussed.

In addition, Frost (1920) published a paper which suggested that psychology can be valuable in studying the adjustment of immigrants to the American industrial environment. 'If the Swede, the Pole, the Italian, the Greek, are to be taught the advantages of industrial democracy, the lesson must be built upon a background of proper racial psychology' (p. 21). Soon after, Garth et al. (1933) presented a study of work behaviors that included Japanese and American data, and reported no cultural differences.

Wilpert (2000) traced the past, present, and future of applied psychology, and identified four periods. The first (1922–30) focused on health and satisfaction from work and on epistemological perspectives (e.g., should we use only experiments or also systematic observations of real life events?). The second (1931–7) reflected concern for international solidarity in view of imminent political threats. The third (1949–55) widened the concern for social and political problems and focused on the problem of living together as individuals, families, communities, and nations. The last (1964–) reflected global concerns, spiritual outlooks, and included some methodological backtracking. He noted that societal changes are reflected in the way applied psychology is evolving. Thus, the increased female labor market participation, increased life expectancy, increased labor migration (especially from less economically developed to more economically developed countries), and changes in values are inevitably changing applied psychology.

2.2 The Field Becomes Established

Cross-cultural psychology did not emerge as a self-conscious discipline separate from anthropology and

psychology and yet linked to both until about 1967. An important turning point was a conference held in Ibadan, Nigeria, which exposed psychologists to the need to avoid 'intellectual colonialism' (collecting data in different countries without sensitivity to the local culture, i.e. without the help from or giving credit to local psychologists). By the early 1970s, the use of translated Western instruments to collect data in non-Western cultures was discredited among sophisticated researchers, yet widely done because of the impracticalities of careful cross-cultural work.

The leading cross-cultural researchers argued that ideally, the instruments that are used in this field should include two aspects (or factors after factor analysis): one aspect should go to the heart of the way the culture operates in the specific domain, and consist of emic, i.e., culture-specific items. The other aspect should include etic items (i.e., items that have universal meaning). The first aspect can provide an optimal description of a phenomenon in a specific culture; the second aspect can provide comparisons across cultures.

Indeed, one of the purposes of this field is to discover what aspects of work and organizational behavior are universal (etic) and what aspects are culture-specific (emic). Humans have a lot in common. We share 99 percent of our DNA with some of the higher primates, so in many ways we are the same. Yet different cultures emerge because of different ecologies (resources, geography) and different intergroup influences (cultural diffusion, historical influences, such as wars). For example, if we were to study which aspects of different kinds of work are most valued by humans, we are likely to find more enjoyment of fishing in an ecology that has fish than in an ecology that does not. In short, liking fish has meaning only in some cultures, and is not a universal value. Other concepts (e.g., susceptibility to monotony) may be universal, and thus may permit cross-cultural comparisons.

A metaphor can make the point clearer. Suppose we are comparing apples and oranges. We can compare them on etic dimensions such as price, weight, and size, but a full description of the fruit based on such dimensions is inadequate. To capture the meaning of 'apple' one needs to measure apple flavor, an emic dimension. In short, we need to use both emic and etic concepts and dimensions for a complete description and cross-cultural examination of a phenomenon.

Triandis (1972, pp. 35–58) presented an extensive discussion of both the method and the ethics of cross-cultural research, and examples (pp. 89–263) of the use of the various methods. He advocated the inclusion of both emic and etic items, and the local standardization of scales in cross-cultural investigations. He examined the sampling of cultures, individuals, and items. He urged checks of the reliability and construct validity of the scales in each culture. He advocated controls of response sets and other rival hypotheses such as the cross-cultural equivalence of (a) the understanding of the experimental task, (b) familiarity with the method, (c) motivation, (d) response style, (e) test conditions, (f) perception of the experimenter, and (g) social desirability of the responses. He examined the role of anonymity, experimenter bias, and problems of interpretation of the data from different cultural perspectives. The chapter also discussed how cross-cultural research should be organized to avoid intellectual imperialism. Tapp, Kelman, Triandis, Wrightsman, and Coelho (1974) presented a code of ethics for such research. It advocated leaving something of value in each of the cultures studied. However, the cross-cultural community considered this code too demanding and restrictive, thus it was not adopted by the International Association of Cross-Cultural Psychology.

The avoidance of ethnocentrism, by including the perspectives of each culture under study in the research, the use of multimethod approaches (to control for the interaction between culture and method), the test of hypotheses with laboratory, survey, and ethnographic data, the testing of rival hypotheses, the checks of the reliability and validity of each method in each culture were advocated by several researchers in the 1970s, and gradually began to be used in cross-cultural research.

Another product of the Ibadan conference was the establishment of the *Cross-Cultural Newsletter* (1967), first edited by Triandis, which eventually became the *Cross-Cultural Bulletin*. In the late 1960s several journals (*International Journal of Psychology, Journal of Social Psychology*) announced that they welcomed cross-cultural data. The Directory of individuals interested in cross-cultural research was published (Berry 1968). The Human Relations Area Files established a journal which was eventually (1992) called *Cross-Cultural Research*. It is now the official organ of the Society for Cross-Cultural Research. The *Journal of Cross-Cultural Psychology* was established by Walter Lonner in 1970. It became the official journal of the International Association of Cross-Cultural Psychology (IACCP). The *Annual Review of Psychology* started chapters reviewing cross-cultural work in 1973. *Culture and Psychology* was first published in 1995.

3. Content

3.1 Handbooks Summarize the Field

The first handbook of industrial psychology was by May Smith (1944), and included no chapters with cross-cultural material. Dunnette in the *Handbook of Industrial and Organizational Psychology* (1976, reprinted in 1983) included an excellent chapter by Barrett and Bass (1976) that covered theoretical and methodological problems. This chapter examined

motivation, values, job satisfaction, managerial goals, cultural differences in attitudes toward compensation, motives and economic development. It also explored the match of organizational and cultural values. An important focus was on management and supervision (including management styles, authoritarianism), and preferences for different kinds of supervisors in different cultures. An important topic was participation of workers in job design (J. R. P. French). As an illustration of a finding of cross-cultural industrial psychology, French and others found that in the United States participation of employees in work design increases their productivity. But this was not the case in Puerto Rico or Norway. Puerto Rico is a more hierarchical culture than the United States, so that workers found it embarrassing when their supervisors asked for their ideas about how the work should be done. Norway had norms about how decisions are to be divided between labor unions and management, and asking the workers how the work should be done did not conform to those norms.

Barrett and Bass also reviewed various studies that included clusterings of countries (e.g., European countries are closer to each other in managerial attitudes than is Japan). It did an excellent job of examining factors in employee selection, and factors that increase the success of expatriates such as cross-cultural training.

Dubin's handbook (1976) included a section on work in different social systems, with chapters on labor movements (Landsberger), industrial relations in Japan (Karsh), work and management in Poland (Matejko), industrialization in Israel (Weinshall), and the self-management of Yugoslav enterprises (Jerovsek).

Drenth, Thierry, Willems, and de Wolff in the *Handbook of Work and Organizational Psychology* (1984) included one chapter on cross-cultural perspectives (Drenth and Groenendijk 1984). Bass and Drenth in *Advances in Organizational Psychology* (1987) edited chapters that included, among other parts, reports with cross-cultural data from India and Spain (Filella), decision making (Heller and Misumi), participation and industrial democracy (Wilpert), and comparative management (Ronen and Kumar).

The second edition of the Dunnette *Handbook of Industrial and Organizational Psychology* included a whole volume (Triandis, Dunnette, and Hough 1994) containing international material. It included a chapter by Triandis that provided an overview of the cross-cultural industrial and organizational psychology field, and discussed dimensions of cultural variation and the definitions of culture. This volume examined employee selection across cultures (also discussed by Levy-Leboyer), organizational cultures, motivation in different cultures (also discussed by Ronen), employee control of the organization, job design (also discussed by Hesketh and Bochner), organizational development, and conflict resolution.

This volume of the handbook also had chapters on action theory (Frese and Zapf), time and work behavior (Thierry), leadership (Graen), and aging and work (Forteza and Prieto, as well as Warr). In that volume also, Erez presented a model of industrial and organizational cross-cultural psychology. Culture-specific chapters included chapters by Kashima and Callan (the Japanese work group), Redding, Norman, and Schlander (the nature of individual attachment to the organization: a review of East Asian variations), Wang (culture, economic reform, and the role of industrial and organizational psychology in China), and Sinha (culture embeddedness and the developmental role of industrial organizations in India). Finally, there was a chapter on dealing with cultural diversity in the USA (Triandis, Kurowski, and Gelfand).

The *Handbook of Cross-Cultural Psychology* (H. C. Triandis, General Editor) was published in 1980–1. Volume 5 of that handbook included an organizational psychology chapter by A. S. Tannenbaum. The three-volume second edition of that handbook (edited by J. W. Berry) appeared in 1997. The third volume of this edition examined applications and included a chapter by Hui and Luk (industrial/organizational psychology). That volume also included some other chapters that are relevant to cross-cultural industrial and organizational psychology, such as those of Kagitcibasi (individualism and collectivism), Gudykunst and Bond (intergroup relations), Best and Williams (sex, gender, and culture), Berry and Sam (acculturation and adaptation), and Brislin and Horvath (cross-cultural training and multicultural education).

3.2 Milestones in the History of the Field

Harbison and Myers in *Management in the Industrial World* (1959) and Haire, Ghiselli, and Porter in *Managerial Thinking: An International Study* (1966) are viewed by many industrial psychologists as the first milestones of cross-cultural industrial and organizational psychology. Listed sequentially across time, Roberts in the *Psychological Bulletin* (1970) presented a critical evaluation of cross-cultural industrial psychological research. Fiedler, Mitchell, and Triandis in the *Journal of Applied Psychology* (1971) presented a method for cross-cultural training that was later shown (Black and Mendelhall 1990) to be effective in improving the performance of persons from one culture working in another culture. Inkeles and Smith in *Becoming Modern* (1974) showed that the level of modernity of people in six cultures was correlated with working in factories. Bass and Burger in *Assessment of Managers: An International Comparison* (1979) contributed a study of managers in several countries. England, Nagandhi, and Wilpert in *Organizational Functioning in Cross-Cultural Perspective* (1979) ex-

amined whether culture or other factors account for most of the variance of organizational phenomena. Hofstede in *Culture's Consequences* (1980) supplied a major dataset showing cultural differences in the values of IBM employees across a large number of countries. Sinha in the *Nurturant Task Leader* (1980) published a book that described effective leadership in India. Bhagat and McQaid in a *Journal of Applied Psychology Monograph* (1982) reviewed cross-cultural studies that used the subjective culture perspective.

3.3 The Recent Quarter Century

Nancy Adler in the *Journal of Applied Behavior Science* (1983) examined organizational development in a cross-cultural perspective. Ayman and Chemers in the *Journal of Applied Psychology* (1983) showed that Iranian workers want managers who are benevolent paternalists (warm and stern). Graham in the *Journal of International Business Studies* (1983) examined negotiation behavior in three cultures. Wilpert and Sorge (1984) in *International Perspectives on Organizational Democracy* summarized a major cross-cultural study of industrial democracy. Misumi in *The Behavioral Science of Leadership: An Interdisciplinary Japanese Research Program* (1985) presented a Japanese theory of leadership that became influential in cross-cultural studies of leadership, in many cultures. Adler in *International Dimensions of Organizational Behavior* (1986, 2nd edition 1990) published a widely used text that covered the field. A team of scholars studied the meaning of work in several cultures (MOW 1987). Smith and Peterson in *Leadership, Organizations and Culture: An Event Management Model* (1988) published a study of leadership that focused on event management. Black and Mendelhall (1990) reviewed the effectiveness of cross-cultural training programs. Hofstede in *Cultures and Organizations* (1991) contrasted national and organizational cultures, and included a methodological appendix concerned with cross-cultural research. Schwartz (1992) presented a theory of value structure and data from 20 countries. Later he published data from 50 countries. Many cross-cultural psychologists use both the Hofstede and Schwartz datasets as predictors of some organizational phenomena they happen to be working on. Earley (1993) showed that in collectivist cultures there is less social loafing than in individualist cultures when employees work with in-group members. Earley and Erez (1997) in *New Perspectives on International Industrial and Organizational Psychology* edited a collection of papers on industrial and organizational psychology that covered broad topics such as the use of theory in that field, approaches to the definition of culture, motivation, diversity in an international context, intercultural communication, decision making in multicultural teams, individual–union relationships across cultures, human resource management, leadership, negotiation and reward allocation, as well as critical commentaries by the editors. Robert House and a team of more than 100 social scientists will publish their work on the implicit meaning of leadership in over 100 cultures during the early part of the twenty-first century.

4. The Future

Predictions are hazardous, but it is likely that the major developments in this field will be in the area of dealing with diversity, especially when the diversity includes differences in culture, social class, and gender.

Industrial Ecology

1. Introduction

The words 'industry' and 'ecology' were combined to the phrasing of 'industrial ecology' in the late 1980s, when two notions gained a solid foothold in the minds and perspectives of those working for a sustainable development (see *Sustainable Development*). One notion was that the minimization of waste and emissions in individual process steps or products need not result in an overall reduced environmental impact. The other was that money could be made through a reduction of waste, emissions, or resource utilization. These two notions gave birth to a variety of concepts that renewed the debate on sustainable industrial development. Whereas some of these concepts focus on products (e.g., life cycle assessment, design for the environment) or facilities and production processes (e.g., pollution prevention), industrial ecology focuses on industrial systems. In this contribution industrial ecology is discussed as a vision for a sustainable world, as an emerging interdisciplinary research field, and how it can be made operational at different systems levels.

2. Vision

Industrial ecology finds its legitimization in the question of what the environmental impact would be when, within a period of three or four decades, with a growing world population, each individual person lives at, ideally, a standard of living common in Western industrialized countries during the 1990s (see *IPAT (Impact, Population, Affluence, and Technology)*). The amounts of natural resources required to sustain the accompanying level of consumption would probably not be available in this planet and the levels of pollution and waste generated would probably exceed the world's regenerative capacity (Frosch and Gallopoulos 1989; see *Human–Environment Relationship: Carrying Capacity*).

Such arguments have generated widespread support for the view of approaching sustainability through increased eco-efficiency (Schmidheiny 1992) and break-through innovations in technology and consumption (Von Weizsäcker et al. 1997). Industrial ecology is a perspective which helps to find 'imaginative solutions to these resource and environmental problems,' by adopting the notion that 'the industrial system ought to be modified so as to mimic the natural ecosystem in its overall operation' (Frosch and Gallopoulos 1992, p. 271). In this view, industrial ecology is the basis for a radical transformation of industrial society (Ehrenfeld 1997).

The metaphor from biology is the most important conceptual contribution of industrial ecology. In an industrial ecosystem, 'the consumption of energy and materials is optimized and effluents of one process [..] serve as the raw materials for another process' (Frosch and Gallopoulos 1989, p. 94), much like nutrients flow in biological ecosystems. The industrial network is seen as a system of mutual dependent transformation processes which is an interrelated part of a larger whole, 'analogous in its functioning to a community of biological organisms and their environment' (Frosch and Gallopoulos 1992, p. 272). Hence the fundamental importance of industrial metabolism to industrial ecology (Ayres 1989; see *Industrial Metabolism*).

Industrial ecology aims at a reduction of the environmental impact of materials and energy flows through increased resource efficiency at the systems level. Two dimensions characterize the systems thinking in industrial ecology: 'space' and 'time.' Regarding 'time,' industrial ecology has adopted life-cycle thinking. Just like concepts such as product stewardship and integrated substance chain management it takes into account the potential environmental impacts in all the stages in the life cycle of specific materials and products including design, production, use and disposal, i.e., 'from cradle to grave.' Regarding 'space,' industrial ecology has adopted different entities to delineate materials and energy flows, including the entire world, river basins such as the Rhine, the economy of a specific nation or region, industries or even companies. End-of-pipe pollution control and pollution prevention have traditionally been the guiding concepts for waste reduction in individual companies and facilities; industrial ecology extends to these concepts by stressing inter- rather than intra-firm linkages, dependencies and opportunities for waste reduction.

3. Research Field

Industrial ecology constitutes an emerging, multidisciplinary research field, whose researchers share the broad vision sketched above. They take a systems view in studying material and energy flows and their transformations into products, byproducts and wastes through industrial and natural systems (industrial metabolism), and they attempt to reduce the environmental impact of industrial systems on ecological systems by reducing the materials intensity of production and consumption. However, there is not (yet) a clear demarcation of the field. Some restrict industrial ecology to the study of biological, chemical, and

physical processes, whereas others include the study of informational, legal and economic incentives into industrial ecology, or even the study of inter- and intra-organizational structures, arrangements and coordination, and consumption (see *Consumption, Environmentally Significant*). Despite a shared unit of analysis—the flow and transformation of materials and energy—different research approaches into industrial ecology can be distinguished. The first aims at describing materials and energy flows. The second aims at their control through the traditional governance instruments of hierarchy, the market and the law. To be effective, this approach requires environmentally relevant information to be collected and processed for use in decision making. To that end, various tools are being developed. Finally, observing that the control of materials and energy flows through traditional governance instruments is not the entire story, new governance instruments are being developed.

3.1 Description of Flows and Transformations

Descriptive research into industrial ecology aims at the understanding of the flows of materials and energy both within industrial and between industrial and ecological systems, as well as their transformations in products, byproducts and effluents. For example, the industrial metabolisms of elements such as chlorine and various metals, of materials such as paper and of products such as chloro-fluoro carbons (CFCs) and polyvinyl chloride (PVC) have extensively been described (see *Industrial Metabolism*).

Such studies are criticized on various grounds. First, the choice of elements, materials, and products is biased towards those that are released as nonfugitive, nondilute, point source industrial wastes or used as nondissipative consumer products (O'Rourke et al. 1996). There is little consideration of how dissipative products such as coatings, detergents, food and pesticides would fit into an industrial ecology. To some extent, 'green chemistry' (Anastas and Breen 1997) may help reduce the environmental impact of dissipative products, but it leaves unquestioned the open-ended character of these flows. Second, the metabolism of elements, materials and products within industry requires the input of energy, as does the closing of currently open-ended flows by recycling. However, the energy component in both the current, open-ended and the future, closed flows remains largely unquestioned. Finally, in some articles systems boundaries have implicitly been defined, in most they are defined in terms of administrative boundaries (country, region). This choice of systems boundaries probably reflects the interests of the data collecting bodies which are often national or supra-national public bodies or industry associations. Cross-border material flows is one of the challenges to industrial metabolism (Rejeski 1997), yet from the industrial ecology perspective it would be more relevant to look for boundaries as defined by the area within which a material is transformed and transported by economic, physical, chemical, and biological forces. To choose natural systems boundaries does not resolve the problem since the economically motivated flow of materials and energy tends not to be restricted by oceans, watersheds, and mountain ridges.

3.2 Governance of Materials Flows: Traditional Approaches

Industrial ecology is aimed at the deliberate and rational control of materials and energy flows. Many studies share the general assumptions that decision makers—whether product developers, corporate executives, public administrators, or consumers—would take different decisions if they had the 'right information' enabling them to evaluate the environmental consequences of their decisions, if they were exposed to the 'right prices' reflecting the monetary value of the externalities of materials and energy use (O'Rourke et al. 1996), and if they were not told to do otherwise by regulators.
