Trends in membership and meetings reflect changes in AA. Membership in AA has shifted to include a larger proportion of women, members with concurrent problems with other drugs of abuse, and younger members. Reflecting these trends, the availability of 'special interest' groups has increased, particularly in the USA. The most common special meetings are gay/lesbian meetings, young people's meetings, and women's meetings.

The basic principles of AA have remained unchanged, but the implementation of AA has varied across cultures. Research by Mäkelä et al. (1996) and others has documented both the consistency and the heterogeneity in the practice of AA across AA members, AA groups, and countries. For example, cross-talk (directly commenting on another member's statements in a meeting) and negative feedback are not accepted during AA meetings, regardless of culture, and the relative importance of different steps seems similar across countries. In other ways, the practice of AA differs across cultures. For example, interpretations of the concept of a higher power vary substantially, as does the use of sponsors. Behavior during meetings also shows considerable cultural variation, particularly in the degree of physical and personal intimacy.

2. Research on Alcoholics Anonymous

2.1 Utilization of AA

AA members enter the program by a number of routes, including self-referral; referral by family, friends, or treatment centers; or through coercion from the legal system, employers, or social welfare system (Weisner et al. 1995). Surveys of the USA population reveal that almost 6 percent of US adults have attended AA at some point in their lives. Among individuals with a history of alcohol problems, more than 20 percent of men and 15 percent of women have attended AA. Less information is available about individuals who enter AA through the criminal justice system, and the practice of judicial orders to attend AA is controversial.

Epidemiological and clinical data suggest that alcoholics attending AA average just under one meeting per week. Involvement with AA varies widely, and rates of attrition are well over 75 percent in the first year. Among those who continue their involvement with AA, the probability of remaining sober and involved with AA is about 67 percent for those with one year of sobriety, 85 percent for those with two to five years sobriety, and 90 percent for those with more than five years of sobriety.

AA members are diverse in age, gender, ethnicity, severity of alcohol dependence, and a variety of other personal characteristics. Researchers have attempted to find a profile of the type of person most likely to become involved with AA. Although no one profile characterizes AA members, a large-scale review concluded that five variables were most predictive of successful AA affiliation: a history of using external supports to cope with problems, loss of control over drinking, a greater daily quantity of alcohol consumed, greater physical dependence, and greater anxiety about drinking.

2.2 AA and Population Subgroups

Two contrasting views of AA lead to different predictions about AA and different population subgroups. One perspective suggests that AA is a program

of recovery for alcoholics, and that the common experience of alcoholism should supersede superficial individual differences. An alternative perspective states that because AA was developed by educated, middle-aged, Caucasian, Christian, heterosexual males, its relevance to the young or elderly, persons of color, non-Christians, gays and lesbians, or women, is suspect. Research data about the relevance of AA to various subgroups is limited.

Recent research has examined women and AA. Women in AA tend to be older, are more likely to be employed, and have somewhat more severe drinking problems than the women in alcoholism treatment who do not attend AA. Women attending AA see the program as crucial to their sobriety, and the fellowship, support, sharing, and spirituality in AA are all seen as important as well. Women in recovery who do not attend AA feel that they do not fit in, that AA is too punitive and focused on shame and guilt; disagree with program principles related to powerlessness, surrender, and reliance on a higher power; and perceive AA as male-dominated.

Literature on cultural, ethnic, and racial subgroups and alcoholism in general is limited, and research on AA involvement for these groups is even more limited. White, Black, and Hispanic men and women all have positive views of AA, are likely to recommend AA as a treatment for alcohol problems, and recommend AA more than any other resource. There is some variability in support for AA, with fewer Asians viewing AA as a resource than individuals from other cultural groups. Among those with drinking problems, involvement with AA of different cultural and racial groups varies depending on the study population. Overall, Hispanics are more likely to have had contact with AA (12 percent) than either whites or blacks (5 percent). Among those involved with the criminal justice or welfare system, whites are most likely to have been involved with AA, but among those in primary health care settings, blacks are most likely to have been involved with AA.

No recent research has focused specifically on the experiences of either youth or the elderly in AA. Several studies of adolescent treatment, however, suggest a strong association between AA/NA involvement and abstinence. Research on the experience of gays and lesbians in relation to AA is lacking.

2.3 *The Effectiveness of AA*

One of the most consistent research findings is that there is a positive correlation between AA attendance and good outcome. Studies of treated and untreated individuals suggest that those attending AA are about 50 percent more likely to be abstinent than those not attending AA.

Evaluation studies have followed individuals receiving treatment in 12-Step-oriented treatment programs (Ouimette et al. 1999). These treatment programs have close conceptual links to AA, but are not to be confused with AA. Evaluations of individuals receiving treatment in 12-step-oriented treatment programs have found abstinence rates of 67–75 percent six months after treatment, and 60–68 percent 12 months after treatment. However, not all individuals who received treatment are reached in follow-up evaluations. If a researcher assumes that all individuals lost to follow-up have relapsed, then abstinence rates drop considerably.

A second way to study the effectiveness of AA is to randomly assign individuals to different forms of treatment that do or do not include AA. Several studies have examined the effectiveness of AA this way. These studies have not found AA or treatments designed to facilitate the involvement of AA to be more effective than other forms of treatments. However, one study found that AA involvement led to better treatment outcomes for individuals who had many friends and family members who were heavy drinkers (Longabaugh et al. 1998).

Research also has examined what aspects of AA involvement are related to drinking outcomes. Several factors predict affiliation with AA after treatment, including perceived past and future harm from alcohol use, anticipated benefits from abstinence, degree of commitment to abstinence, and drinking problem severity. There is a significant association between participation in AA activities and drinking outcomes. Aspects of participation most strongly associated with positive outcomes include increasing involvement with AA over time, leading meetings, having a sponsor, and doing 12th step work.

A final important outcome-related question is the degree to which AA involvement is associated with positive functioning in other life areas. Popular criticism of AA asserts that, although sober, AA members are psychologically dependent on AA and therefore are poorly adjusted. The research literature contradicts this perspective, with research demonstrating that those actively involved with AA have less anxiety, cope with problems more effectively, have more social support from friends, and better overall psychological adjustment.

3. *Methodological Issues in the Conduct of Research on AA*

3.1 *Sampling Issues*

Most research on AA is hampered by difficulties in accessing AA meetings and AA members. As a voluntary, anonymous organization, AA does not keep records, and does not enter into formal collaborations with researchers. Researchers, then, are faced with the challenge of developing methods to access

representative samples of AA members, or representative samples of AA groups. A number of methodologies have been suggested, but without clear data about the overall composition of the AA membership, researchers are limited in their ability to know if their samples are indeed representative.

3.2 Definitional Issues

One complex issue related to research on AA is the question: what is AA involvement? Early research classified subjects as attending AA or not. Somewhat more sophisticated studies measured attendance quantitatively, defining greater attendance as indicative of greater affiliation. More recently, researchers have approached affiliation as a multidimensional construct (e.g., Morgenstern et al. 1997) that includes attendance, endorsement of the central beliefs of AA, use of cognitive and behavioral strategies suggested by AA, degree of organizational involvement with AA, and degree of subjective sense of affiliation with AA. Although a consensus definition of AA involvement does not yet exist, there is widespread agreement that a multidimensional model is most appropriate.

3.3 Selection of Research Questions

Much of the research on AA has asked simple and relatively static questions: is AA effective; for whom; what are the characteristics of successful AA members? Involvement with AA, however, is a rich and complex experience, which varies across individual members, and varies over time within an individual member. Development of research strategies that can capture the heterogeneous nature of AA, both cross-sectionally and longitudinally, is a further challenge.

4. Future Directions

Conducting research on AA has entered the scientific mainstream. As scientists develop more sophisticated methods for accessing individuals attending and involved with AA, a number of previously unstudied issues can be examined. Longitudinal research should be conducted to study processes of involvement in AA, as well as changes in beliefs, behavior, and interpersonal relationships. Studies of constructs core to the AA program, such as spirituality, serenity, and sobriety are also of importance. Additionally, studies examining the processes of change in AA, within the context of larger models of personal change, would be important to developing more generalizable models for understanding AA. A comprehensive listing of potential topics for research on AA was generated at a recent scientific conference on AA, and is summarized in McCrady and Miller (1993). The interested reader is referred there for a fuller listing of potential directions for future research.

Alcoholism: Genetic Aspects

Humans have consumed alcoholic beverages since prehistoric times. The first source of alcoholic substances most likely was accidental fermentation of fruits or grains. Mead, a fermentation product of honey, existed in the Paleolithic age, and is typically regarded as the oldest alcoholic beverage. The process of making beer and wine from the fermentation of

carbohydrates dates back to early Egyptian times. Distilling products to obtain higher alcohol concentrations can be traced to the Arab world around 800 CE (Feldman et al. 1997). Despite widespread current use of alcoholic substances in many societies, alcoholism occurs among only a small percentage of people who drink. Alcoholism is described behaviorally, and can be characterized by excessive or compulsive use, or both, of alcohol and loss of control over drinking. It also includes drinking in an amount that leads to tolerance (need for increasing amounts in order to feel its effects), and physical dependence, a condition where symptoms such as anxiety and tremulousness (or, more seriously, seizures) occur when drinking ceases.

The prevalence of alcoholism differs from country to country. In the United States, for example, approximately 10 percent of adult males are diagnosed as alcoholics, and the annual economic costs of alcohol and drug abuse are estimated at $246 billion, with alcoholism by far the most severe substance abuse problem. The reason why only a small number of those who consume alcoholic beverages become alcoholics is unknown. It is clear, however, that determinants of alcoholism include an interaction between genetic and environmental factors. Alcoholism runs in families, with one-third of alcoholics having at least one alcoholic parent. Environmental risk factors include drug availability and low economic status. While genetic inheritance probably confers heightened vulnerability to alcoholism in some individuals, environmental manipulations may prevent or further foster the development of alcoholism, underscoring the importance of studying genetic–environmental interactions.

1. *Human Findings*

Alcoholism is a complex behavioral trait mediated by factors including socioeconomic environment, individual characteristics, and pharmacological factors. It was noted in the nineteenth century that alcoholism appeared to run in families (Vaillant 1983), and it is now clear that family history of alcoholism constitutes the strongest risk factor for the development of alcoholism. Twin studies support heritability of alcohol consumption and alcohol dependence. A monozygotic co-twin of an alcoholic (who is genetically identical) is about twice as likely to become an alcoholic as a dizygotic co-twin (who shares only 50 percent of the alcoholic co-twin's genes). Children of alcoholics raised by nonalcoholic adoptive parents also show increased susceptibility to becoming alcoholics. A Danish study found that 18 percent of 133 males with a biological paternal history of alcoholism, themselves developed alcoholism compared with only 5 percent of adoptees who did not have a positive biological family history for alcoholism (Ferguson and Goldberg 1997). Furthermore, sons of alcoholic parents who were adopted away had the same increased risk of becoming alcoholics as their biological brothers raised by their alcoholic parents.

However, a number of alcoholics do not have a family history of alcoholism, suggesting that the genetic component is not inherited in a simple fashion, and indicating that there are different forms of alcoholism. Although many physicians in the nineteenth century subtyped alcoholics, it was not until 1960 that a systematic categorization of alcoholism was developed by Jellinek (Vaillant 1983). Jellinek's types ranged from people with medical and psychological complications but not physical dependence (category 'alpha') to binge drinkers (category 'epsilon'). This classification scheme was useful for categorizing behavior of an alcoholic at a point in time, but Vaillant documented the fact that across time, alcoholics manifest different symptoms of the disease, limiting the utility of Jellinek's categories. Nonetheless, Jellinek made important contributions to the field of alcoholism typology, and some concepts in his classification scheme are still apparent in typologies of alcoholism used at the beginning of the twenty-first century.

More recently, adoption studies conducted in Scandinavia led to the postulate that there are two independently transmissible forms of alcoholism: type I and type II (Cloninger et al. 1996). Type I alcoholism is characterized by anxious personality traits, rapid development of tolerance to and dependence on the anti-anxiety effects of alcohol, typically has a late onset (after 25 years of age), and genetic predisposition seems to contribute only slightly. In contrast, type II alcoholism usually has an earlier onset, tends to predominate in men, has a high genetic predisposition, and is accompanied by antisocial personality traits and low impulse control. Other investigators have argued that typologies should distinguish severe problem drinkers from those with less severe problems. One model attempting to differentiate severity of drinking separates late-onset drinkers (type A) from affiliative/impulsive alcoholics (type B) and isolative/anxious alcoholics (type C) (Morey 1996). Late-onset drinkers demonstrate signs of alcohol abuse, but develop mild alcohol-dependence symptoms. The type B and C alcoholics are at an advanced level of alcohol dependence, and differ from each other with respect to variables such as personality traits and features of alcohol use. It seems clear now that these classification schemes represent only the extremes of a continuous spectrum of manifestations of alcoholism (Cloninger et al. 1996). In other words, an individual alcoholic may appear 'type II-like' or 'type B-like,' but in reality he or she will possess a unique developmental history and collection of diagnostically relevant traits that fits no single type perfectly. This complexity creates great difficulties for genetic analyses whose goal is to resolve 'genetic risk' into the identification of specific genes

that increase or decrease risk. Like most complex traits, many genes influence alcoholism, and each such gene is likely to increase or decrease risk very modestly.

1.1 Genome-wide Screens

In 1990 the Human Genome Project was initiated to collect genetic information on a large scale, and thus provided the basis for the field of genomics. Goals of the Human Genome Project include the identification of each of the estimated 80,000–100,000 genes in human DNA, the storage of this information in useable databases, and the development of tools for data analysis. The medical industry is using and adding to the knowledge and resources created by the Human Genome Project with the goal of understanding genetic contributions to human diseases, including alcoholism. Data from the Human Genome Project should, at least in theory, enable researchers to pinpoint alterations in specific genes that contribute to alcoholism. Although gene identification is only the first step toward understanding complete genetic contributions to alcohol abuse, there are a number of ways to identify genes provisionally that might be mediating alcoholism.

One approach to finding predisposing factors to alcoholism is to study human populations with little genetic or social/environmental variability. Using a Southwestern Native American tribe, researchers found several genetic markers linked with alcoholism (Long et al. 1998). One marker was located near a gene coding for a gamma-aminobutyric acid type A ($GABA_A$) receptor, while another was located near the dopamine D4 receptor subtype gene. Alcohol and other depressant drugs act at the $GABA_A$ receptor, which modulates inhibition in the brain by decreasing nerve cell excitability. The neurotransmitter dopamine is hypothesized to be partially responsible for mediating the reinforcing and rewarding properties of drugs of abuse, including alcohol. Thus, both of these represent plausible 'candidate genes' for alcoholism risk. Results from this study require verification, and further research will need to assess whether these candidate genes have a role in determining vulnerability to alcoholism, and to what extent these results can be generalized to other human populations.

In 1989 the National Institute on Alcohol Abuse and Alcoholism of the National Institutes of Health initiated the Collaborative Study on the Genetics of Alcoholism (COGA). This project is a multidisciplinary approach to investigating the genetic components of susceptibility to alcoholism. COGA performed a genetic linkage study on a large sample of the general population in the United States, selecting families affected by alcoholism. One of the genetic markers distinguishing alcoholics from nonalcoholics was provisionally mapped to a location near the gene coding for the alcohol metabolizing enzyme alcohol dehydrogenase (ADH). Other evidence suggests that possession of a variant of the ADH gene tends to protect against the development of alcoholism in Asian populations.

ADH metabolizes alcohol to acetaldehyde, and the acetaldehyde itself is rapidly converted to acetate in the human liver by aldehyde dehydrogenase (ALDH2). ALDH2 has also been implicated in protecting against the development of alcoholism. The normal allele is designated ALDH2*1, but a point mutation produces a mutant allele designated ALDH2*2. This mutant allele produces an enzyme with deficient activity, and is dominant over the normal allele (individuals who are both homo- and heterozygous for ALDH2*2 do not have detectable ALDH2 activity in the liver). Most individuals in Asian populations of Mongolian origin commonly have the inactive (ALDH2*2) variant. Such individuals show high acetaldehyde levels after alcohol consumption, due to changes in alcohol metabolism. High levels of acetaldehyde lead to a facial flushing response, nausea, and other subjective feelings of alcohol intoxication. Thus, it is hypothesized that it is the slow removal of acetaldehyde after alcohol consumption in individuals possessing ALDH2*2 that protects these individuals from the risk of alcohol abuse.

Among Asians, ADH and ALDH genotypes may be useful for predicting resistance to alcoholism. Little evidence, however, suggests that an inherited defect in alcohol metabolism among Caucasians differentiates those prone from those resistant to alcoholism. Among other factors, this has prompted researchers to investigate other possible genetic differences between alcoholics and nonalcoholics.

While human genome-wide scans have contributed to our knowledge of genes influencing alcoholism, results from different studies do not always agree. Some studies support an association of a dopamine D2 receptor subtype gene polymorphism with increased risk for alcoholism, while other studies do not support this claim (Goate and Edenberg 1998). One potential confound in the population-based studies investigating this polymorphism is the fact that allele frequencies range from 9–80 percent among populations. Thus, careful ethnic matching of alcoholics and controls is imperative for future human research (Goate and Edenberg 1998).

Clinical and epidemiological research over the past few decades, combined with historical evidence, has made it clear there is heterogeneity among those diagnosed as alcoholic. One of the current directions of the COGA study is to use narrower definitions of alcoholism prior to performing genetic analyses (Goate and Edenberg 1998). As discussed above, alcoholism is genetically heterogeneous. That is, two individuals classified as alcoholics may differ with respect to personality characteristics, age at alcohol abuse initiation, and the severity of alcohol-related

health problems. It is likely that performing genetic analyses on these symptomatic subgroups will identify different candidate genes. However, the fact that many genes contribute to alcoholism risk will make it very difficult to identify individual genes using a broad population-based association strategy.

1.2 Mapping Genes for Phenotypes

An alternative approach to genome-wide screens is to identify phenotypes correlated with alcohol dependence. Once these phenotypes of interest are identified, it may be easier to map genes that affect them. Characteristics present in those likely to become alcoholics may provide useful markers indicating potential risk for the development of alcoholism. These correlated traits are sometimes termed 'endophenotypes.' One such trait is brain electroencephalographic (EEG) activity. In resting humans, EEG activity is under strong genetic control. Resting-state EEGs in sober alcoholics contain greater activity in the 'beta-wave' category, and a deficiency in alpha, delta, and theta activity, as compared with nonalcoholics.

Event-Related Potentials (ERPs) are another measure of brain electrical activity that indicate brain responsiveness to a number of external stimuli. ERPs are significantly more similar in monozygotic twins than in dizygotic twins or unrelated controls, supporting a genetic influence. Event-related potentials can be useful in detecting differences in information processing, and so may be useful for identifying inherited vulnerability to alcoholism. When exposed to a novel stimulus, alcohol-naive sons of alcoholics have a pattern of brain waves (called P3 or P300 evoked potentials) resembling those measured in alcoholics. Abstinent alcoholics also show a significantly reduced P3 evoked potential compared to controls. These differences in brain activity are hypothesized to reflect a genetic vulnerability to alcoholism.

While studies in human populations have been useful in the preliminary identification of specific genes mediating alcoholism, a number of future directions are needed. First, we must develop descriptive epidemiology to understand alcoholism better. Second, we need to develop culture-specific models. Finally, we need to create a clear definition of typologies to describe different subcategories of drinkers. Because of the very limited statistical power to detect genes in human studies, the key to progress in genetic studies of complex traits (such as alcoholism) is better articulation of the exact phenotype for which genes of influence are sought.

2. Animal Models

Genetic animal models offer several advantages over studies using human subjects. For example, the experimenter is in control of the genotype being studied as well as environmental variables. In humans, only monozygotic twins have identical genotypes, and it is much more difficult to control environmental variables. Many human responses have been modeled successfully in animals, including sensitivity to the acute response to a drug, the development of tolerance, withdrawal symptoms, and voluntary intake. Numerous mouse and rat genotypes are readily available, making it possible to share information between laboratories and build a cumulative information database.

2.1 Selected Animal Lines

A powerful genetic animal method is selective breeding. Similar to how farmers use selective breeding to increase milk production, the technique has been used in alcohol research to manipulate genotypes toward a specific objective (in this case, a specific response to alcohol). By mating animals that are sensitive to a drug (for example, those that prefer alcohol solutions or exhibit severe withdrawal), after several generations, most of the genes leading to sensitivity will be captured in these mice. At the same time that sensitive animals are mated, animals that are insensitive to the same response are mated, fixing most of the genes leading to low responsiveness in the insensitive line. To the extent that genes contribute to the selected trait, the sensitive and insensitive selected lines will therefore come to differ greatly on the trait. If they also differ on behaviors other than those for which they were selected, this is evidence that the same genes are responsible for both traits. Studies utilizing this technique have increased our knowledge of which responses to alcohol share similar genetic influence.

In the 1940s, Mardones and colleagues at the University of Chile initiated the earliest selection study for drug sensitivity to develop rat lines with low (UChA) and high (UChB) alcohol consumption. To select for differences in drinking, rats were offered a choice of water or alcohol. Rats showing high alcohol preference were mated, and rats showing low alcohol preference were separately mated. The degree of alcohol preference in the UChA and UChB lines diverged across generations, indicating hereditary transmission of alcohol drinking. Many other studies since then have supported this notion. In the 1960s, a Finnish group led by Eriksson at Alko's physiological laboratory developed rat strains selected for voluntary alcohol consumption, the AA (Alko Alcohol preferring) and the ANA (Alko Non-Alcohol preferring). The AA and ANA lines also differ dramatically in voluntary alcohol intake, again supporting a genetic component to this behavior.

In the 1970s, Li, Lumeng, and their colleagues in Indiana also developed rat lines that either preferred (P), or did not prefer (NP), alcohol. This selection study was replicated by the same group in the 1980s, using the same protocol, to develop High (HAD) and

Low (LAD) Alcohol-Drinking rat lines. The existence of a number of different lines selected for and against alcohol preference has provided the opportunity to discover convergence in the genetic correlates of preference for alcohol. For example, one common result from these selected lines is that high-drinking genotypes appear to have lower brain serotonin, a neurotransmitter involved in mood and emotional responses. Furthermore, these results may relate to difference among humans, as at least some alcoholics also show lower serotonin activity.

Virtually all other responses to alcohol have demonstrated a heritable component as well, and selections have been performed for several responses in addition to drinking. In the early 1970s, Goldstein demonstrated that mice selectively bred for alcohol withdrawal symptoms developed progressively more severe withdrawal across three generations. In the late 1970s, Crabbe and his colleagues initiated an animal model of genetic sensitivity to severe and mild withdrawal after chronic alcohol exposure. Lines of mice were bred to exhibit either severe alcohol dependence measured by withdrawal symptoms (Withdrawal Seizure-Prone; WSP) or reduced response following dependence and withdrawal (Withdrawal Seizure-Resistant; WSR). The WSP and WSR strains differ dramatically in their withdrawal response, indicating that most of the genes leading to severe withdrawal are fixed in the WSP mice bred for this response. Conversely, most of the genes leading to withdrawal insensitivity are fixed in the WSR line. In addition to demonstrating a genetic component to dependence and withdrawal, differences between the WSP and WSR mice on other phenotypes suggest that alcohol withdrawal genes are also responsible for other responses. WSP mice have more severe withdrawal than WSR mice to diazepam (Valium), barbiturates, and nitrous oxide. These results suggest that similar brain substrates are mediating withdrawal severity to alcohol as well as a number of other drugs, and that some alcohol withdrawal risk-promoting genes also confer susceptibility to other drugs of abuse.

In addition to demonstrating genetic contributions to behavioral responses to alcohol, selected lines are useful for identifying differences in neural mechanisms mediating the response to alcohol. Long-Sleep (LS) and Short-Sleep (SS) mice have been selectively bred based on duration of loss of righting reflex (a measure of the sedative effects of alcohol). The LS and SS mice also differ in their response to other depressant drugs, again indicating similar brain substrates are mediating sedative responses to alcohol and other depressants. Administering drugs that activate or block activity of $GABA_A$ receptors affects alcohol sensitivity, and LS mice are more sensitive to these manipulations than SS mice. These findings indicate that selecting LS and SS mice for their behavioral response to alcohol has produced lines that differ in $GABA_A$ receptor activity.

Studies using selected lines have provided a wealth of information regarding how genes affect behaviors, and which alcohol responses share common genetic influence. However, despite the demonstration of genetic influences using this technique, it is difficult to identify specific genes mediating sensitivity or resistance to an effect of alcohol.

2.2 Quantitative Trait Loci (QTL) mapping strategies

The Human Genome Project has also led to genome mapping and DNA sequencing in a variety of other organisms including the laboratory mouse. Late twentieth-century developments in the physical mapping of the mouse make positional cloning of genes involved in various behaviors more likely. However, most behaviors (including responses to alcohol) are influenced by multiple genes. Behaviors, or complex traits, influenced by a number of genes are often termed quantitative traits. Within a population, a quantitative trait is not all-or-none, but differs in the degree to which individuals possess it. A section of DNA thought to harbor a gene that contributes to a quantitative trait is termed a quantitative trait locus (QTL). QTL mapping identifies the regions of the genome that contain genes affecting the quantitative trait, such as an alcohol response. Once a QTL has been located, the gene can eventually be isolated and its function studied in more detail. Thus, QTL analysis provides a means of locating and measuring the effects of a single gene on alcohol sensitivity.

In tests of sensitivity to convulsions following alcohol withdrawal, QTLs have been found on mouse chromosomes 1, 2, and 11. The QTL on chromosome 11 is near a cluster of $GABA_A$ receptor subunit genes. A number of subunits are needed to make a $GABA_A$ receptor, and the ability of a drug to act on the receptor seems to be subunit dependent. A polymorphism in the protein-coding sequence for *Gabrg2* (coding for the $\gamma 2$ subunit of the $GABA_A$ receptor) has been identified. This polymorphism is genetically correlated with duration of loss of righting reflex and a measure of motor incoordination following alcohol administration.

The use of QTL analysis has allowed us to begin the process of identifying the specific genes involved in alcohol related traits. Because each QTL initially includes dozens of genes, not all of which have yet been identified, it will require much more work before each QTL can be reduced to a single responsible gene. For the time being, one important aspect of QTL mapping in mice is that identification of a QTL in mice points directly to a specific location on a human chromosome in about 80 percent of cases. Thus, the animal mapping work can be directly linked to the human work in studies such as the COGA described in Sect. 1.1, which is in essence a human QTL mapping project. By using transgenic animal models (mice in

which there has been a deliberate modification of the genome), such as null mutants, QTLs can be further investigated.

2.3 Null Mutant and Transgenic Studies

Since about 1980, advances in embryology and genetic engineering have resulted in the creation of null mutant animals—mice that have a targeted deletion or over-expression of one of their own genes (and as a consequence, gene products). The use of null mutant mice is powerful in that it allows investigation into the role of the deleted gene by comparing the phenotype of the null mutant mice with normal mice. Until the development of this technology, the only way of studying the regulation and function of mammalian genes was through the observation of inherited characteristics, genetic defects, or spontaneous mutations, or through indirect manipulations such as selective breeding. There has been a rapid development in the use of null mutant mice in biological sciences. Since 1990, the number of procedures performed on transgenic animals in the United Kingdom, for example, has risen to more than 447,000.

Transgenic and null mutant mice are particularly useful in studying alcohol responses. As mentioned previously, there is evidence to suggest that alcohol affects the function of the $GABA_A$ receptor, although it is not clear how alcohol does this. By creating mice lacking a gene thought to mediate GABA function, it is possible to gather information regarding the function of a given neurotransmitter system, or function of a receptor. The γ isoform of the second messenger protein kinase C (PKCγ) has been implicated in one mechanism by which alcohol affects GABA function. Mice lacking the gene coding for this isoform are less sensitive to alcohol-induced loss of righting reflex and alcohol-induced hypothermia, suggesting that some biochemical processes in which PKCγ plays a role is a potential mechanism mediating responses to alcohol.

Null mutants have been created for a number of other neurotransmitter systems hypothesized to mediate responses to alcohol, including the dopamine D2 receptor. Mice lacking the D2 receptor gene consumed less alcohol in a free-choice situation, were insensitive to alcohol's locomotor depressant effects, and were less sensitive to the motor in coordinating effects of alcohol when compared to control mice. Differences between null mutants and control mice strongly support a role for this receptor in mediating several responses to alcohol.

Although studies using null mutant mice have provided much information regarding the role of specific genes in alcohol responses, alcohol responses are probably determined by the interaction of several genes. Thus, deletion of one gene will not provide information regarding the interaction of the deleted gene with other genes. If multiple genes are affecting a behavior, the elimination of one gene in an embryo will result in developmental compensation by other genes involved. The use of transgenics that have an inserted sequence allowing the experimenter to alter gene expression (commonly by using an antibiotic treatment) at any point in time allows control over when the gene is deleted. This permits the investigator to produce a null mutant, referred to as a conditionally regulated transgenic, after development has occurred, reducing developmental compensation. Genetic background may also influence results, because introduced genes may not exert similar effects when expressed on different genetic backgrounds.

3. Gene–Gene and Gene–Environment Effects on Alcohol Abuse

Gene–gene and gene–environment interactions are clearly prominent in alcoholism, although they are not often addressed. An important consideration is that alcoholism is multigenic, and might be polygenic (i.e., each individual gene might exert only a small effect on risk). However, a gene-by-gene analysis may not give a complete picture of how genes interact to mediate alcoholism. It is also clear that insights from the methods reviewed above are not sufficient to integrate a comprehensive understanding of alcoholism in the intact organism with environmental variables considered.

3.1 Epistasis (Gene–Gene Interaction)

Epistasis refers to the behavioral effect of interaction among gene alleles at multiple locations. Epistasis is observable when phenotypic differences among individuals with the same genotype at one locus depend on their genotypes at another locus. If adding the effects of each gene separately does not predict the effect of two genes, epistasis is most likely present. For example, assume that there are two genes leading to increased weight ('A' and 'B'). Each on its own induces a 1-pound increase in body weight. If an individual possessing both genes gained 2 pounds, this would imply a normal additive model of inheritance (no epistasis). If, however, an individual possessing both genes showed a 10-pound weight gain (or even weight loss) this would imply epistasis (example modified from Frankel and Schork 1996). As this example demonstrates, the effect of a gene may be detectable only within a setting that incorporates knowledge of epistatic interactions with other genes. A gene's effect may be undetectable because an interacting gene has an opposite effect, or because the gene's apparent effect is potentiated by another gene. Epistasis has been largely ignored in genome scans, but it is becoming increasingly evident that in order to understand genetic contributions to a complex trait fully, it

is an important consideration. Epistasis has been shown to be important in mouse models of epilepsy, and it is also likely to be critical to a thorough understanding of targeted gene deletion experiments.

3.2 Gene–Environmental Interaction

Several genes influencing behavioral traits in animals that may be homologous to aspects of human alcoholism are close to being isolated. In addition, human studies are identifying genes that might also be playing a role in alcoholism. While these experiments studied the important contributions of either genes, or experience, on the effects of drugs of abuse, few have provided any information on the important interaction between genes and environment. Gene–environment interaction simply refers to effects of environment that vary for different genotypes (or, effects of genes that vary for different environments). For example, take the adoption studies discussed above in Sect. 1. Type II alcoholism was highly heritable from father to son, regardless of environmental background (e.g., economic status of the adopted home). The risk for type I alcoholism, however, increased dramatically for individuals having both type I biological parents and low socioeconomic status in their adoptive home. Thus, the effect of environment can depend on the genotype, and vice versa.

A recent study in animals also illuminates the profound effect environment can have on the behavior of genetically identical animals (Crabbe et al. 1999). In this study, six commonly used mouse behaviors were simultaneously tested in three laboratories (two in the United States and one in Canada) using exactly the same genotypes. Stringent attempts were made to equate test apparatus, protocols, husbandry, age, and start time (of light cycle as well as time of year). Despite these rigorous controls, animals with the same genes performed differently on several of the behavioral tasks. It is important to note, however, that for a number of other behavioral tests, performance was very similar among the three sites. That genetically identical animals did not always respond the same depending on environment underscores the idea that, for behaviors like alcoholism, genes will define risk, not destiny.

Although the issue of gene–environment interaction seems a bit daunting, there are certainly ways of addressing the problem once researchers are aware of it. Testing animals using a battery of related tests is one way to approach the problem. For example, perhaps one test of memory relies heavily on locomotor performance. A genotypic difference in locomotion may be interpreted (incorrectly) as differences in memory. By testing genotypes on a battery of tests assessing memory, a clearer profile will emerge. Second, it is possible to evaluate genetic effects at different developmental stages, which would also provide information as to the ontological profile of a given behavior. Third, use of multiple genetic tools can help elucidate the generability of a genetic effect.

The issue of gene–environment interaction will be particularly relevant given the multiple forms of alcoholism, mediated by different sets of genes. Some forms are accompanied by antisocial personality traits, and others may be accompanied by depression. Dissociating the various genetic and environmental comorbidities affecting one's likelihood of being diagnosed with alcoholism will be a formidable task. It is clear that dissecting this disorder will require techniques that examine more than the effects of one gene at a time.

4. Conclusions

We now have some good clues from animal and human studies regarding specific genes involved in the response to alcohol. Late twentieth-century advances in QTL mapping strategies and the application of new molecular targeting techniques in genetic animal models are especially promising, because they suggest that a combined use of molecular biological techniques and animal behavioral genetic tools is beginning to occur. Understanding basic genetic mechanisms provides a context in which to interpret the findings using more recently developed molecular techniques. One important consideration is that while alcoholism may be partially mediated by genetic factors, the role of environment remains important. For example, environmental intervention including abstinence (before or after initial alcohol abuse) can prevent the expression of alcoholism. An individual at genetic risk may never develop alcoholism, for reasons not known. Genetic studies most likely identify an individual's lifetime risk for alcoholism, although at any given point in time an individual correctly identified as an alcoholic may not be manifesting symptoms of alcohol abuse (one reason why Jellinek's system was not useful longitudinally).

Ultimately, animal models further an understanding of human alcoholism. Thus, a comparison of animal and human results is an area of future importance. One of the goals of pharmacogenomic research is to develop agents to reduce drinking in alcoholics. As with other complex diseases, it is unlikely that one medication will be sufficient to treat a genetic disorder as complex as alcoholism. Understanding gene–gene and gene–environment interactions in conjunction with the action of alcohol in the central nervous system should provide new targets for the development of therapeutic agents.

Algorithmic Complexity

1. Introduction

In the mid 1960s, in the early stage of computer science but with the general theory of Turing machines (Turing 1936) well understood, scientists needed to measure computation and information quantitatively. Kolmogorov complexity was invented by R. J. Solomonoff (1964), A. N. Kolmogorov (1965), and G. J. Chaitin (1969), independently and in this chronological order. This theory is now widely accepted as the standard approach that settled a half-century debate about the notion of randomness of an individual object—as opposed to the better understood notion of a random variable with intuitively both 'random' and 'nonrandom' individual outcomes. Kolmogorov complexity has a plethora of applications in many areas including computer science, mathematics, physics, biology, and social sciences (Li and Vitányi 1993). This article only describes some basic ideas and some appropriate sample applications.

Intuitively, the amount of information in a finite string is the size (number of bits) of the smallest program that, started with a blank memory, computes the string and then terminates. A similar definition can be given for infinite strings, but in this case the program produces element after element forever. Thus, 1^n (a string of n ones) contains little information because a program of size about $\log n$ outputs it. Likewise, the transcendental number $\pi = 3.1415\ldots$, an infinite sequence of seemingly 'random' decimal digits, contains a constant amount ($O(1)$) of information. (There is a short program that produces the consecutive digits of π forever.) Such a definition would appear to make the amount of information in an object depend on the particular programming language used. This is the case. Fortunately it can be shown that all choices of universal programming languages (such as PASCAL, C^{++}, Java, or LISP in which we can in principle program every task that can intuitively be programmed at all) lead to quantification of the amount of information that is invariant up to an additive constant. Formally, it is best formulated in terms of 'universal Turing machines,' the celebrated rigorous formulation of 'computability' by A. M. Turing (1936) that started both the theory and practice of computation.

This theory is different from Shannon information theory that deals with the expected information in a message from a probabilistic ensemble of possible messages. Kolmogorov complexity, on the other hand, measures the information in an individual string or message. The *randomness deficiency* of a binary string n bits long is the number of bits by which the complexity falls short of n—the maximum complexity—and a string is the more random the closer the complexity is to its length.

2. Theory

The Kolmogorov complexity $C(x)$ of a string x is the length of the shortest binary program (for a fixed reference universal programming language) that prints x as its only output and then halts. A string x is incompressible if $C(x)$ is at least the length $|x|$ (number of bits) of x: the shortest way to describe x is to give it literally. Similarly, a string x is 'nearly' incompressible if $C(x)$ is 'almost as large as' $|x|$.

The appropriate standard for 'almost as large' above can depend on the context, a typical choice being $C(x) \geqslant |x| - O(|\log x|)$. Similarly, the *conditional* Kolmogorov complexity of x with respect to y, denoted by $C(x|y)$, is the length of the shortest binary program that, with extra information y, prints x. And a string x is incompressible relative to y if $C(x|y)$ is large in the appropriate sense.

Intuitively, we think of such patternless sequences as being random, and we use the term 'random sequence' synonymously with 'incompressible sequence.' This is not just a matter of naming but on the contrary embodies the resolution of the fundamental question about the existence and characterization of random individual objects (strings). Following a half-century of unsuccessful approaches and acrimonious

scientific debates, in 1965 the Swedish mathematician Per Martin-Löf resolved the matter and gave a rigorous formalization of the intuitive notion of a random sequence as a sequence that passes all effective tests for randomness. He gave a similar formulation for infinite random sequences. The set of infinite random sequences has measure 1 in the set of all sequences. Martin-Löf's formulation uses constructive measure theory and has equivalent formulations in terms of being incompressible. Every Martin-Löf random sequence is *universally* random in the sense that it individually possesses all effectively testable randomness properties. (One can compare this with the notion of intuitive computability that is precisely captured by the notion of 'computable by Turing machines,' and every Turing machine computation can be performed by a universal Turing machine.) Many applications depend on the following easy facts.

Lemma 1 *Let c be a positive integer. For every fixed y, every finite set A contains at least* $(1-2^{-c})|A|+1$ *elements x with* $C(x|A, y) \geqslant [\log|A|]-c$. (*Choosing A to be the set of all strings of length n we have* $C(x/n,y) \geqslant n-c$)

Lemma 2 *Let A be a finite set. For every y, every element* $x \in A$ *has complexity* $C(x|A, y) \leqslant \log|A|+c$. (*Choosing A to be the set of all strings of length n we have* $C(x/n,y) \leqslant n+c$)

The first lemma is proved by simple counting. The second lemma holds since a fixed program that enumerates the given finite set computes x from its index in the enumeration order—and this index has $\log|A|$ bits for a set A of cardinality $|A|$.

We can now compare Kolmogorov complexity with Shannon's statistical notion of entropy—the minimal *expected* code word length of messages from random source using the most parsimonious code possible. Surprisingly, many laws that hold for Shannon entropy (that is, on average) still hold for the Kolmogorov complexity of individual strings albeit only within a logarithmic additive term. Denote by $C(x|y)$ the information in x given y (the length of the shortest program that computes x from y), and denote by $C(x, y)$ the length of the shortest program that computes the pair x, y. Here is the (deep and powerful) Kolmogorov complexity version of the classical 'symmetry of information' law. Up to an additive logarithmic term,

$$C(x, y) = C(x)+C(y|x) = C(y)+C(x|y) \qquad (1)$$

We can interpret $C(x)-C(x|y)$ as the information y has about x. It follows from the above that the amount of information y has about x is almost the same as the amount of information x has about y: information is symmetric. This is called mutual information.

Kolmogorov complexity is a wonderful measure of randomness. However, it is not computable, which obviously impedes some forms of practical use. Nevertheless, noncomputability is not really an obstacle for the wide range of applications of Kolmogorov complexity, just like noncomputability of almost all real numbers does not impede their practical ubiquitous use.

3. *Applications*

For numerous applications in computer science, combinatorics, mathematics, learning theory, philosophy, biology, and physics, see Li and Vitányi (1993). For illustrative applications in cognitive psychology see Chater (1996) (related, more informal strains of thought are the Structural Information Theory started in Leeuwenberg (1969)), in economy see Keuzenkamp and McAleer (1995), and in model selection and prediction see Vitányi and Li (2000). Here we give three applications of Kolmogorov complexity related to social sciences, explain the novel 'incompressibility method,' and conclude with an elementary proof of Gödel's celebrated result that mathematics is undecidable.

3.1 *Cognitive Distance*

For a function $f(x, y)$ to be a proper *distance measure* we want it to be a *metric*: it has non-negative real values; it is symmetrical, $f(x, y) = f(y, x)$; it satisfies the triangle inequality, $f(x, y) \leqslant f(x, z)+f(z, y)$; and $f(x, y) = 0$ iff $x = y$. Given two objects, say two pictures, how do we define an objective measure that would define their distance that is universal in the sense that it accounts for all cognitive similarities? Traditional distances do not work. For example, given a picture and its negative (i.e., exchange 0 and 1 in each pixel), Hamming distance and Euclidean distance both fail to recognize their similarity. Let us define a new distance $D(x, y)$ between two objects x and y as the length of the shortest program that converts them back and forth (Bennett et al. 1998). It turns out that, up to a logarithmic additive term,

$$D(x, y) = \max\{C(x|y), C(y|x)\} \qquad (2)$$

This distance D is a proper metric and it is *universal* in the sense that if two objects are 'close' under any distance out of a wide class of sensible and computable metrics, then they are also 'close' under d. For example, the $D(x, y)$ distance between two black-and-white pictures x and its negative y is a small constant.

3.2 *Phylogeny of Chain Letters* (*and Biological Evolution*)

Chain letters are an interesting social phenomenon that have reached billions of people. Such letters

evolve, much like biological species (rather, their genomes). Given a set of genomes we want to determine the evolutionary history (phylogeny tree). Can we use the information distance $D(x, y)$? But then the difference in length of (especially complex) genomes implies a large distance while evolutionarily the genomes concerned can be very close (part of the genome was simply erased). We can divide $D(x, y)$ by some combination of the lengths of x and y, but this can be shown to be improper as well. As we have seen, $C(y)-C(y|x) = C(x)-C(x|y)$ within a logarithmic additive constant: it is the mutual information between x and y. But mutual information itself does not satisfy the triangle inequality and hence is not a metric and therefore clearly cannot be used to determine phylogeny. The solution is to determine closeness between each pair of genomes (or pairs of chain letters) x and y by taking the ratio of the information distance to the maximal complexity of the two:

$$d(x, y) = \frac{D(x, y)}{\max\{C(x), C(y)\}} \tag{3}$$

Note that $d(x, y)$ is always a sort of normalized dissimilarity coefficient that is at most 1. Moreover, it is proper metric. Let us look a little bit closer: suppose $C(y) \geqslant C(x)$. Then, up to logarithmic additive terms in both nominator and denominator we find (using Eqn. (2))

$$d(x, y) = \frac{C(y|x)}{C(y)} = 1 - \frac{C(y)-C(y|x)}{C(y)} \tag{4}$$

It turns out that $d(x, y)$ is universal (always gives the smallest distance) in a wide class of sensible and computable normalized dissimilarity coefficient metrics. It measures the percentage of shared information, which is a convenient way to measure English text or DNA sequence similarity. We have actually applied this measure (or rather, a less perfect close relative) to English texts. Using a compression program called *GenCompress* we heuristically approximate $C(x)$ and $C(x|y)$. With the caveat 'heuristic,' that is, without mathematical closeness-of-approximation guarantees, C. H. Bennett, M. Li and B. Ma (in an article to appear in *Scientific American*) took 33 chain letters—collected by Charles Bennett from 1980 to 1997—and approximated their pairwise distance $d(x, y)$. Then, we used standard phylogeny building programs from bioinformatics research to construct a tree of these chain letters. The resulting tree gives a perfect phylogeny for all notable features, in the sense that each notable feature is grouped together in the tree (so that the tree is parsimonious). This fundamental notion can be applied in many different areas. One of these concerns a major challenge in bioinformatics: to find good methods to compare genomes. Traditional approaches of computing the phylogeny use so-called 'multiple alignment.' They would not work here since chain letters contain swapped sentences and genomes contain translocated genes and noncoding regions. Using the chain letter method, a more serious application in Li et al. (2001) automatically builds correct phylogenies from complete mitochondrial genomes of mammals. We confirmed a biological conjecture that ferungulates—placental mammals that are not primates, including cats, cows, horses, whales—are closer to the primates—monkeys, humans—than to rodents.

3.3 Inductive Reasoning

Solomonoff (1964) argues that all inference problems can be cast in the form of extrapolation from an ordered sequence of binary symbols. A principle to enable us to extrapolate from an initial segment of a sequence to its continuation will either require some hypothesis about the source of the sequence or another method to do the extrapolation. Two popular and useful metaphysical principles for extrapolation are those of simplicity (Occam's razor, attributed to the thirteenth-century scholastic philosopher William of Ockham, but emphasized about 20 years before Ockham by John Duns Scotus), and indifference. The Principle of Simplicity asserts that the 'simplest' explanation is the most reliable. The Principle of Indifference asserts that in the absence of grounds enabling us to choose between explanations we should treat them as equally reliable. Roughly, the idea is to define the universal probability, $\mathbf{M}(x)$, as the probability that a program in a fixed universal programming language outputs a sequence starting with x when its input is supplied by tosses of a fair coin (see Kirchherr et al. 1997). Using this as a sort of 'universal prior probability' we then can formally do the extrapolation by Bayes's Rule. The probability that x will be followed by a 1 rather than by a 0 turns out to be

$$\frac{\mathbf{M}(x1)}{\mathbf{M}(x0)+\mathbf{M}(x1)}$$

It can be shown that $-\log\mathbf{M}(x) = C(x)$ up to an additive logarithmic term, which establishes that the distribution $\mathbf{M}(x)$ is a mathematical version of Occam's razor: low complexity xs have high probability ($x = 11\ldots1$ of every length n has complexity $C(x) \leqslant \log n + O(1)$ and hence universal probability $\mathbf{M}(x) \geqslant 1/n^c$ for some fixed constant c), and high complexity ys have low probability (if y is the outcome of n flips of a fair coin then for example with probability 0.9999 we have $C(y) \geqslant n-10$ and therefore $\mathbf{M}(x) \leqslant 1/2^{n-10}$). This theory was further developed in Li and Vitányi (1993), Kirchherr et al. (1997) and Vitányi and Li (2000), and relates to more

informal cognitive psychology work starting with Leeuwenberg (1969) and the applied statistical 'minimum description length (MDL)' model selection and prediction methods surveyed in Barron et al. (1998).

3.4 Incompressibility Method

Analyzing the performance of computer programs is very difficult. Analyzing the average case performance of computer programs is often more difficult since one has to consider all possible inputs and take the average. However, if we could find a typical input on which the program takes an average amount of time, then all we need to do is to find the performance of the computer program on this particular input. Then the analysis is easy. A Kolmogorov random input does exactly that: providing a typical input. Using this method, we were able to solve many otherwise difficult problems. Recent examples are average case analysis of Shellsort algorithm (Jiang et al. in press) and the average case of Heilbronn's triangle problem. A popular account about how to analyze the average-case bounds on Heilbronn's triangle problem can be found in Mackenzie (1999).

3.5 Gödel's Incompleteness Result

A new elementary proof by Kolmogorov complexity of K. Gödel's famous result showing the incompleteness of mathematics (not everything that is true can be proven) is due to Ya. Barzdin's and was later popularized by G. Chaitin, see Li and Vitányi (1993). A formal system (consisting of definitions, axioms, rules of inference) is consistent if no statement that can be expressed in the system can be proved to be both true and false in the system. A formal system is sound if only true statements can be proved to be true in the system. (Hence, a sound formal system is consistent.)

Let x be a finite binary string. We write 'x is random' if the shortest binary description of x with respect to the optimal specification method D_0 has length at least $|x|$. A simple counting argument shows that there are random xs of each length.

Fix any sound formal system F in which we can express statements like 'x is random.' Suppose F can be described in f bits—assume, for example, that this is the number of bits used in the exhaustive description of F in the first chapter of the textbook *Foundations of F*. We claim that for all but finitely many random strings x, the sentence 'x is random' is not provable in F. Assume the contrary. Then given F, we can start to exhaustively search for a proof that some string of length $n \gg f$ is random, and print it when we find such a string x. This procedure to print x of length n uses only $\log n + f$ bits of data, which is much less than n. But x is random by the proof and the fact that F is sound. Hence, F is not consistent, which is a contradiction. This shows that although most strings are random, it is impossible to effectively prove them random. In a way, this explains why the incompressibility method above is so successful. We can argue about a 'typical' individual element, which is difficult or impossible by other methods.

Algorithms

1. *Introduction*

Around the year 825 the Persian mathematician Abu Ja'far Mohammed ibn Mûsâ al-Khowârizm wrote a textbook entitled *Kitab al jabr w'al muqabala*. The term 'algorithm' is directly derived from the last part of the author's name. An algorithm is a mathematical recipe, formulated as a finite set of rules to be performed systematically, that has as outcome the solution to a well-formulated problem. In sequential algorithms these steps are ordered and should be performed one after the other. In parallel algorithms some of the rules are to be performed simultaneously. Algorithms can be graphically represented by flowcharts composed by arrows and boxes. The boxes contain the instructions and the arrows indicate transitions from one step to the next.

Algorithms were known much earlier than the eighth century. One of the most familiar, dating from ancient Greek times (c. 300 BC), is the procedure now referred to as Euclid's algorithm for finding the highest common factor of two natural numbers.

Algorithms often depend on subalgorithms or subroutines. For instance, the algorithm for obtaining the highest common factor of two numbers relies on the algorithm for finding the remainder of division for two natural numbers a and b. Dividing two numbers a and b is something we learn at school after having learnt the multiplication tables by heart. Usually we perform a division by reducing it to a sequence of multiplications and subtractions. Yet assume for the moment that to perform division we cannot rely on multiplication, nor can we express numbers in base ten. Both of these operations will require additional algorithms. We represent numbers in a very primitive form by simply writing a sequence of dots. Thus ●●●●●, for instance, represents the number 5.

The remainder algorithm works as follows (using $17 \div 5$ as an example):

(a) Write the sequence of dots for the dividend (17 in this case).
(b) Erase as many dots as correspond to the divisor (5 in this case).
(c) If the remaining number of dots is larger than or equal to the divisor go back to (a)
(d) If the remaining number of dots is smaller than the dividend print out this number
(e) STOP

The algorithm just described contains a loop. Observe that for any pair of numbers the algorithm produces the answer in a finite number of steps. Applied to our example of $17 \div 5$, the algorithm performs the following steps:

Current state	Operation
START	Write 17 dots
●●●●●●●●●●●●●●●●●	Erase 5 dots
●●●●●●●●●●●●	Erase 5 dots
●●●●●●●	Erase 5 dots
●●	Print 2 dots
STOP	

The computational algorithm for finding the remainder of a number when divided by another number can be used as a subroutine of the decision algorithm for the decidable problem 'Does b divide a?' (the answer is 'yes' if the remainder is zero). Repeated application of these algorithms produces the answer to the decidable question 'Is a a prime?' (the answer is 'no' if a is divisible by any smaller natural number besides 1).

An algorithm or machine is deterministic if at each step there is only one possible action it can perform. A nondeterministic algorithm or machine may make random choices of its next action at some steps. An algorithm is called a decision algorithm if it leads to a 'yes' or a 'no' result, whereas it is called a computational algorithm if it computes a solution to a given well-defined problem.

Despite the ancient origins of specific examples of algorithms, the precise formulation of the concept of a general algorithm dates only from the last century. The first rigorous definitions of this concept arose in the 1930s. The classical prototype algorithm is the Turing machine, defined by Alan Turing to tackle the *Entscheidungsproblem* or Decision Problem, posed by the German mathematician David Hilbert in 1900, at the Paris International Congress of Mathematicians. Hilbert's dream was to prove that the edifice of mathematics is a consistent set of propositions derived from a finite set of axioms, from which the truth of any well-formulated proposition can be established by a well-defined finite sequence of proof steps. The development and formalization of mathematics had led mathematicians to see it as the perfect, flawless science.

2. *Algorithms and the* Entscheidungsproblem

In 1931 the foundation of mathematics suffered its most crushing blow from a startling theorem proven by the Austrian logician Kurt Gödel. Gödel showed that any mathematical system powerful enough to represent arithmetic is incomplete in the sense that there must exist propositions that cannot be proven true or untrue in a finite sequence of steps. Such propositions are said to be undecidable within the given system. Turing had been motivated by Gödel's work to seek an algorithmic method of determining

whether any given proposition was undecidable, with the ultimate goal of removing undecidability as a concern for mathematics. Instead, he proved in his seminal paper 'On computable numbers, with an application to the *Entscheidungsproblem*' (1937) that there cannot exist any such universal method of determination and, hence, that mathematics will always contain undecidable propositions.

The question of establishing whether the number of steps required for a given problem is finite or infinite is called the halting problem. Turing's description of the essential features of any general-purpose algorithm, or Turing machine, became the foundation of computer science. Today the issues of decidability and computability are central to the design of a computer program—a special type of algorithm—and are investigated in theoretical computer science.

The question whether intelligent problem-solving can be described in terms of algorithms was extensively examined by Herbert Simon in the late 1940s and early 1950s. Newell and Simon proposed the first computer programs for problem-solving algorithms as well as the first programs for algorithms that prove theorems in Euclidean geometry, thus founding the new discipline of Artificial Intelligence (see *Artificial Intelligence: Genetic Programming*).

Around the same time McCulloch had developed a formal model of a neuron (McCulloch and Pitts 1943), proving that artificial neurons are capable of performing logical operations. An artificial neuron is a device that produces an output that is a function of its inputs if the sum of the inputs exceeds a threshold and otherwise produces no output. The sub-discipline of computer science known as Neural Networks deals with systems of artificial neurons firing in sequence and/or in parallel, in analogy to the operation of biological neurons.

3. *The Complexity of an Algorithm*

One important feature of an algorithm is its complexity. A number of definitions of complexity have been put forward, the most common of them being time complexity, or the length of time it takes an algorithm to be executed. Clearly, algorithms with low time complexity are to be preferred to ones with higher time complexity that solve the same problem. The question of establishing a formal definition of complexity was answered and treated formally in theoretical computer science (see *Algorithmic Complexity*).

One possibility is to count the number of operational steps in an algorithm, express this number as a function of the number of free parameters involved in the algorithm and determine the order of complexity of this function. The order of complexity of a function f is denoted by O(f), where O( ) is usually called the Landau symbol, and is defined as follows: Given two functions F(n) and G(n) defined on the set of natural numbers, we say that F is of the order of G, and write F = O(G), if there exists a constant K such that:

$$\frac{\mathrm{F}(n)}{\mathrm{G}(n)} < \mathrm{K}$$

for all natural numbers n. Thus, for instance, the function $\mathrm{F}(n) = 3n+1$ is of the order of $\mathrm{G}(n) = n$. Every polynomial in n, that is, every linear combination of powers of n, is of the order of its highest power of n. Because what is being counted is the number of steps in a sequential process it is common to view the resulting O( ) criterion as the time complexity of the algorithm, where n denotes the length of the given input.

The notion of algorithm complexity led to a fundamental classification of problems. They are classified as belonging to P or to NP, where, as we shall see, this 'or' is not exclusive. P is a shorthand for 'polynomial time' and stands for the set of all problems that can be solved by a deterministic algorithm in polynomial time, which means that the number of operations required by the algorithm can be expressed in terms of a linear combination of powers of n, where n is the number of free parameters. NP is the class of all problems that can be solved by nondeterministic algorithms in polynomial time. The strength of nondeterminism lies precisely in the machine's freedom to search through a large space of possible computations by means of a nondeterministic or stochastic process. Clearly $\mathrm{P} \subseteq \mathrm{NP}$. One of the unsolved problems in computer science is to establish whether $\mathrm{P} = \mathrm{NP}$ (Garey and Johnson 1979). Problems for which low complexity algorithms exist (i.e., problems in class P) are called tractable; other problems are called intractable.

4. *Monte Carlo Methods*

An important category of nondeterministic algorithms is the class of Monte Carlo methods. The term derives from the gambling games that are an economic mainstay of the city of that name, and originated during World War II as a code name for stochastic simulations associated with nuclear research. The most common application of Monte Carlo methods is to approximate intractable integrals. If $X_1,\ldots, X_n$ are random draws from a probability distribution with density function $f(x)$, then $S_n = \frac{1}{n}\sum_i h(X_i)$ has expected value

$$E[S_n] = \int_x h(x)f(x)\,\mathrm{d}x$$

and satisfies a central limit theorem. Thus, a difficult integral can be approximated by representing it in the

form (1) and executing the following nondeterministic algorithm:

(a) Simulate a random number X_n from the distribution $f(x)$.
(b) Compute the average $S_n = \frac{1}{n}\sum_{i=1}^{n} h(X_i)$.
(c) Estimate whether sufficient accuracy has been achieved.
(d) If yes, STOP; otherwise return to (a).

A common strategy for increasing accuracy in a problem that does not admit exact solutions is to decompose it into subproblems such that exact algorithms for tractable subproblems can be combined with Monte Carlo estimates for intractable subproblems to obtain accurate approximations to the whole problem. Monte Carlo simulations are important tools in fields such as physics, statistical analysis, stochastic neural networks, and optimization.

5. *Algorithms for Learning*

Since the inception of formal algorithms, an important question has dealt with the conditions under which algorithms can be designed to learn from experience. The idea is that an algorithm that learns from experience becomes more and more adequate for solving the problem in question. The last two decades of the twentieth century witnessed an explosion of algorithms that can perform learning tasks and a sound, theoretical understanding of learning machines is beginning to emerge. The theoretical and empirical study of learning algorithms is called Machine Learning. One type of learning is typical of neural networks that modify their weights by adapting them to feedback information on their performance. Another type of learning machine is provided by what is known as a 'genetic algorithm,' where there is a natural selection between algorithmic procedures and the most effective algorithm arises by a form of survival of the fittest.

Yet another type of learning can be materialized as a search through a large set of possible algorithms for a given problem (see *Algorithmic Complexity*). Here the type of algorithm is fixed from the beginning and what is searched for is the optimal realization of this algorithm, that is, a realization that fits the given data best. Thus learning becomes a special form of model selection. For many problems, including search across models, exact solutions are intractable, yet tractable heuristics (or rules-of-thumb) work well for a large class of problem instances. As an example, consider the problem of finding an optimal decision tree algorithm to represent a given decision rule. A decision tree is a graphical representation of a rule for making a categorization decision. The graph for a decision tree consists of nodes and arcs pointing from nodes (called parents) to other nodes (called children). One node, called the root node, has no parents. Each other node has exactly one parent. At the bottom of the tree are the leaf nodes, which have no children. With each nonleaf node is associated a rule which selects a child to visit depending on information passed from the parent node.

With each leaf node is associated a rule for computing a value for the node. The decision tree algorithm proceeds as follows:

(a) Begin at root node.
(b) Execute rule to decide which arc to traverse.
(c) Proceed to child at end of chosen arc.
(d) If child is a leaf node, execute rule to compute and print value associated with node and STOP.
(e) Otherwise, go to (b).

It is frequently desired to find an optimal decision tree for a given classification problem and a given criterion of optimality. Clearly there are exponentially many possible decision trees for a set of n pieces of information and thus, searching for optimal trees is often an intractable problem. Tractable heuristics have been suggested in machine learning that help find trees good enough for given problems. One such type of classification tree has been introduced by Breiman et al. (1993) and is known as CART, which is an abbreviation of classification and regression tree.

The study of algorithms has been highly influential in psychology. The behaviorist view, which emphasizes the relationship between sensory inputs and motor outputs, has given way to the cognitive view, which emphasizes the role of internal cognitive states in producing behavior. Information processing models of cognition have become a mainstay of cognitive psychology. Hypotheses about the manner in which cognition influences behavior are encoded as algorithms and implemented in computer software which is used to simulate behavior. Simulated results are then compared to the behavior of human or animal subjects to validate or refute the hypotheses upon which they are based. One of the important issues in cognitive psychology has been to establish how the mind deals with decisions under uncertainty. While some schools have defended the approach of classical rationality, for which the mind functions by means of probabilistic algorithms, a recent development has been to view the unaided mind as relying on simple heuristics for inference. These heuristics, as proposed by Gigerenzer et al. (1999), are actually elementary, fast, and robust algorithms. In some cases they are extremely simple classification trees (see *Heuristics for Decision and Choice*).

6. *Conclusion*

Algorithms are the core element of thinking machines. The last century witnessed the birth of highly intelligent algorithms that replicate, often with great accuracy, some of the important achievements of the human mind. Yet, one of the most important discoveries concerning algorithms is that mathematics cannot be produced by an algorithmic procedure. This discovery, which was experienced as a crisis, can be viewed as liberating because it demonstrates the limitations of a

machine. Replicating intellectual, symbolic, and even basic common-sense activities by means of algorithms turned out to be daunting tasks, still mostly exceeding the grasp of computable representations.

Alienation: Psychosociological Tradition

The concept of alienation has a long and distinguished history (see *Alienation, Sociology of*), marked at the same time by a certain elusiveness and controversy. Its elusiveness is symbolized by the fact that the concept languished with almost no attention by social scientists until its rediscovery in the 1930s when Marx's early philosophical manuscripts of 1844 became known (Marx 1964). Thus, what we take to be a classical concept in sociological analysis has, in fact, a relatively short scientific history (leaving aside its metaphysical pre-Hegelian origins).

1. Objective and Subjective Alienation

The seminal Marxian manuscripts also established the basis for much of the subsequent controversy. Marx's concept of alienation was a complex mixture of objective and subjective elements concerning the structure of social relations, estrangement from human nature, and depersonalization, especially in relation to work. The distinction between the worker's objectively defined exploitation and lack of control, on the one hand, and the worker's subjective sense of powerlessness and self-estrangement on the other, has been a constant source of debate in the alienation literature. For some, alienation is not so much a matter of the person's awareness of various deprivations, but the fundamental deprivation of awareness (i.e., false consciousness regarding one's objective domination in capitalist society).

The unclarities that inhere in these difficulties regarding alienation have led, often enough, to calls for dismissing the concept from the lexicon of analysis. It can be argued, however, that these difficulties with the concept are no greater than those which, upon reflection, obtain for other widely used concepts in psychology and sociology (e.g., 'norms,' 'attitudes,' and, indeed, the fundamental concept of 'social structure'). In the psychosocial approach, an effort has been made to provide the requisite clarity by distinguishing the several varieties of alienation that derive from the classical tradition—for example, Marx, Durkheim, Weber; Schacht (1970)—providing at the same time the basis for empirical investigation of the sources, concomitants, and consequences of alienation.

2. Dimensions of Alienation

Six dimensions of alienation have been identified (and defined below): (a) powerlessness, (b) meaninglessness, (c) normlessness, (d) social isolation, (e) cultural disengagement, and (f) self-estrangement. Scales to measure each of these have been developed (Seeman 1991), but it is important to recognize that corollary concepts (e.g., self-efficacy, mastery, reification, sense of coherence, human agency) abound in the field; thus the definitions embodied in particular scales vary widely, and the naming of measuring instruments can be the source of considerable confusion (e.g., a measure of 'reification' can readily parallel the content of scales measuring 'powerlessness' or 'self-estrangement').

Each of the varieties of alienation is defined from the actor's point of view, but it is assumed that (a) the objective structural circumstances that generate these alienations can and should be independently identified, and (b) the person's subjective report may not coincide with these objective circumstances, yielding in that case a kind of 'false consciousness.'

2.1 Powerlessness

The sense of powerlessness is the expectancy or perception that one's own behavior cannot control the occurrence of personal and social outcomes: control is vested in external forces, powerful others, luck, or fate—as in the Marxian depiction of the domination and exploitation of the worker in capitalist society.

2.2 Meaninglessness

Meaninglessness is the sense of incomprehensibility of social affairs, events whose dynamic one does not

understand and whose future course one cannot predict—as in the Weberian depiction of the complexities of secularized and rationalized bureaucratic society.

2.3 Normlessness

Normlessness is the expectancy or perception that socially unapproved means are necessary to achieve one's goals—essentially, the personalized counterpart of Durkheim's 'anomie' or breakdown of social norms, involving as well the deterioration of trust in social relations.

2.4 Social Isolation

Social isolation refers to the person's sense of exclusion or lack of social acceptance, expressed typically in feelings of loneliness or feelings of rejection or repudiation vs. belonging—as in the concern typified by Tönnies' depiction of the historical change from 'community' to 'society.'

2.5 Cultural Disengagement

Cultural disengagement refers to a different kind of separation—namely, the person's sense of removal or distance from the dominant values in the society—as in the standard depiction of the alienation of the intellectual and the avant-garde artist.

2.6 Self-estrangement

Self-estrangement is a complex and difficult version —some would say the overarching version—of alienation, embodied, for example, in the Marxian view of alienated labor as estrangement from one's creative human nature. The complexity here is suggested by the fact that there are at least three distinctive ways of conceiving of self-estrangement; in capsule form (a) the despised self (referring to negative self-esteem); (b) the disguised self (false consciousness, being as it were 'out of touch' with oneself); and (c) the detached self (engagement in activities that are not intrinsically rewarding, a derivation from Marx's emphasis on stultifying disengagement in work).

3. The Unity of Alienation

These versions of alienation do not present a theory of the phenomenon or reflect any implicit conviction about their unity (though, indeed, they may well be correlated under given circumstances). Various proposals have been made that attempt to establish the unity of the several alienations: for example, their unity is purported to lie in the fact that (a) they appear in a typical sequence; (b) they represent the fundamental components of social action (e.g., values, norms, roles, and situational facilities, Smelser 1963); (c) they exhibit a statistical coherence—that is, a generalized first factor, as it were; and (d) they express a core theme, representing various forms of fragmentation or separation in one's experience. The latter is clearly a thin reed of unity (though perhaps the most sustainable view) in which their commonality lies only in the fact that they represent classical ways of depicting the individual's sense of separation from important commonly held values: for example, powerlessness vs. mastery, normlessness vs. order and trust, social isolation vs. community.

One of the difficulties with analysis and empirical work employing the alienation concept has been its embarrassing versatility: it has too often been used to explain particular troubles and their opposites—for example, political passivity and urban riots, conformity and deviance. It needs to be recognized that the psychosocial concepts described above (or, for that matter, similar concepts such as 'relative deprivation') cannot be expected to explain very much in themselves without adequate reference to situational circumstances or to other relevant variables that need to be taken into account.

4. Empirical Studies of Alienation

In empirical terms, most of the research on alienation has focused on the ideas of powerlessness and social isolation (though not necessarily using these two concepts). In psychology, for example, an extensive literature on 'internal vs. external control' (using a 'locus of control' measure originating in Rotter 1966) has developed, exploring the ways in which the person's sense of being in personal control of events is socialized and expressed—for example, external control as a factor in deviant behavior, family planning, depression, and alcohol use. In sociology, parallel work on powerlessness and the sense of mastery has documented the impact of such alienation on a wide range of behavior, including associations between powerlessness and (a) inferior learning and achievement (e.g., the relatively poor academic performance of minority children); (b) low political engagement; (c) participation in civil disturbances; (d) unemployment; and (e) inferior health status (including disinterest in preventive health practices and mortality consequences).

One of the best documented of these studies is the work of Kohn and Schooler (1983) showing, on the one hand, the connection between the sense of powerlessness and job conditions that have the earmarks of Marxian alienated labor (i.e., work that is not creative or self-directed), and on the other hand, the psycho-

logical consequences of such work experience (e.g., diminished intellectual flexibility). Related epidemiological work on the connection between social class and health, has explored the association between low job control and health consequences such as heart disease and mortality rates.

A similarly extensive body of research bearing on social isolation and social support has developed in recent years. In a sense, the thrust of this work—the combined effort of sociologists, psychologists, and epidemiologists—has been to undermine the earlier image of urban life as a wasteland of atomized impersonal actors. It has been shown that strong interpersonal networks persist, and more important, that engagement in such social support networks has salutary effects over a wide range of life experience. Thus, for example, social ties have been demonstrated to be important for recovery from health crises (including surgery and cancer treatment), for managing response to unemployment, for overall health status (including mortality), and for sustained high performance in old age.

These remarks concerning two of the key forms of alienation illustrate the uses that have been made of the concept in empirical work. Space permitting, a similar case could be made for the other dimensions of alienation. Thus, the idea of meaninglessness has been used to explain the genesis of ethnic hostility (prejudice and discrimination as simplified answers to societal complexity); normlessness is viewed as an element in the development and rationalization of deviant behavior and response to mass persuasion; and self-estrangement (particularly in work) is used to explain a range of behavior from alcohol problems to family troubles and mass movements. Much of this, it must be said, is not well documented, however plausible the arguments may be.

5. *Physiological Concomitants of Alienation*

It is reasonable to ask whether a number of these cited consequences of alienation have a basis in physiological mediation. There are, indeed, good grounds for predicting such consequences (particularly, the wide-ranging health effects of powerlessness), since the expected biological correlates of low control have been documented—chiefly, associations between a low sense of control and high levels of damaging stress-related hormone excretion and poorer immune function (Sapolsky 1992). Furthermore, and not surprisingly, confirming evidence has developed regarding the expected physiological concomitants of social engagement—for example, better immune system performance, less hypertension, and less damaging levels of glucocorticoids which can affect memory processes are associated with greater social integration (Seeman and McEwen 1996).

6. *Conclusion: Future Prospects*

Considerable effort has been devoted to straightforward reporting on the demographics of alienation —that is, to the social location of high alienation. It seems reasonably clear, for example, that alienation is more clearly visible in less democratic societies, and among the working class and minorities. In addition, the secular trend for measures of powerlessness or mistrust has been toward increasing alienation in Western societies.

It may well be, however, that the general looseness of argument and the difficulty of documentation commented on above has led recently to a certain avoidance of the concept for social analysis. The idea of alienation was especially popular during the 1960s and 1970s—a period of societal difficulty involving student rebellions, antiestablishment movements, Vietnam protests, and the like. But the relative calm and prosperity since the 1980s have apparently dimmed the romantic ardor associated with the idea of alienation. Nevertheless, a case could be made for the view that the dimensions of alienation described here are alive and well in contemporary analysis.

The times now being more sanguine than the post-Depression and World War era, alienation appears now under other names and in more positive guise. Thus, we now see the prevalence of work on social supports (rather than social isolation), or work on mastery and efficacy (rather than powerlessness), and analysis which emphasizes the positive theme of human agency. In a way, it hardly matters what language is used, so long as at the same time the spirit and the classical significance of the idea of alienation is not lost.

M. Seeman

Alienation, Sociology of

Rather than present an overly strict definition of this rather vague umbrella concept which many would not agree with, the italics in the following five points sum up the elements that should bring the concept in sharper focus.

(a) Alienation is an *umbrella concept* that includes, but does not necessarily or logically inter-relate, the dimensions of alienation distinguished by Seeman: *powerlessness*, *meaninglessness*, *normlessness*, *social isolation*, *cultural estrangement*, *and self-estrangement* (Seeman 1959, 1976, 1989).

(b) With the obvious exception of self-estrangement, alienation always points to a *relationship between a subject and some*—real or imaginary, concrete or abstract—*aspect of his environment*: nature, God, work, the products of work or the means of production, other people, different social structures, processes, institutions, etc. Even self-estrangement could be conceived as implying a relation between subjects and their environment: the unreachable 'real self' described by Horney (1950) and others, as the product of a society still pervaded by Cartesian dualism.

(c) Since alienation is usually employed as an *instrument of polemical criticism*, *rather than as a tool of analysis and description*, this relationship can be described as one of separation—a *separation that is considered undesirable from some point of view*. Literature about the possible positive functions of alienation is very sparse indeed, probably because desired separations do not form a serious problem for anyone.

(d) Alienation always refers to a *subjective state of an individual*, or rather to a momentary snapshot of what is usually viewed, both in psychoanalytic and Marxist theory, as a *self-reinforcing inner process*. Societies, institutions, large-scale societal processes, etc. can most certainly be alienating, but to describe them as alienated would endow them with an awareness they do not have.

(e) *Viewing alienation as a subjective individual state or process implies nothing yet about its causation*: It may either be largely brought about by another preexistent subjective, 'reified' state of the same individual, as psychoanalytic theory would hold (although admittedly, such a state would ultimately be environment-induced, e.g., by neuroticizing parents, traumatic early-life experiences, etc., but not directly environment-caused in the present), or by factors having an 'objective' existence in the individual's present environment (e.g., the Marxist and non-Marxist approaches regarding alienating work situations).

1. *A Short History of the Concept*

Alienation is a venerable concept, with its roots going back to Roman law, where *alienatio* was a legal term used to denote the act of transferring property. St. Augustine described insanity as *abalienatio mentis*; Ludz (1975) has discussed its use among the early Gnostics.

In modern times, the concept surfaced again in the nineteenth century and owes its resurgence largely to Marx and Freud, although the latter did not deal with it explicitly. After World War II, when societal complexity started its increasingly accelerated rate of change, and the first signals of postmodernity were perceived by the intellectual elite, alienation slowly became part of the intellectual scene; Srole (1956) was one of the first in the 1950s to develop an alienation scale to measure degrees and varieties of alienation. Following the 1968 student revolutions in Europe and the USA, alienation studies proliferated, at least in the Western world.

In Eastern Europe, however, even the possibility of alienation was denied; theoretically, it could not exist, since officially the laborers owned the means of production. However, the existence of alienation in the 'decadent, bourgeois' societies of the West was gleefully confirmed, as it was supposed to herald the impending demise of late capitalism.

In the Western world, and especially the USA, empirical social psychological research on alienation rapidly developed. Several alienation scales were developed and administered to college students (even national samples) and especially to different disadvantaged minority groups which, not surprisingly, tended to score high on all these scales. On the other hand, much of the theoretical work was of a Marxist persuasion and largely consisted of an exegesis of especially the young Marx's writings and their potential applicability to all kinds of negatively evaluated situations in Western society: the alienation of labor under capitalism, political alienation and apathy, suppression of ethnic or other minority groups, and so forth.

Thus, the 1970s were characterized by a great divide with, on the one hand, the empirical researchers—often, though not exclusively, non-Marxist—administering their scales and charting the degree of alienation among several subgroups, and, on the other hand, the (generally neo-Marxist) theoreticians, rarely engaging in empirical research at all.

During the 1980s, as the postwar baby boomers grew older, and perhaps more disillusioned, and willy-nilly entered the rat race, interest in alienation sub-

sided. The concept definitely became less fashionable, although a small but active international core group continued to study the subject in all its ramifications, since the problems denoted by alienation were certainly far from solved.

Maturing in relative seclusion, this core group, the Research Committee on Alienation (Geyer 1996, Geyer and Heinz 1992, Geyer and Schweitzer 1976, 1981, Kalekin-Fishman 1998, Schweitzer and Geyer 1989) of the International Sociological Association (ISA), managed to narrow the hitherto existing gap between empirical and theoretical approaches and between Marxist and non-Marxist ones. The empiricists basically knew by now who were the alienated and why, and they realized the near-tautology inherent in discovering that the (objectively or subjectively) disadvantaged are alienated. Moreover, many Marxist theoreticians had exhaustively discussed what Marx had to say on alienation, commodity fetishism, and false consciousness and were ready to engage in empirical research along Marxist lines.

It is in the work going on in alienation research since the 1990s that two developments converge: While 'classical' alienation research is still continuing, the stress is now, on the one hand, on describing new forms of alienation under the 'decisional overload' conditions of postmodernity, and on the other hand on the reduction of increasingly pervasive ethnic alienation and conflict. Summarizing, one could say that attention has shifted increasingly to *theory-driven* and *hypothesis-testing* empirical research and to attempts at discovering often very pragmatic *strategies for dealienation*, as manifested by research on Yugoslav self-management and Israeli kibbutzim.

2. *Changes in the Nature of Alienation During this Century*

To oversimplify, one might say that a new determinant of alienation has emerged, in the course of the twentieth century, which is not the result of an insufferable lack of freedom but of an overdose of 'freedom,' or rather, unmanageable environmental complexity. Of course, the freedom-inhibiting classical forms of alienation certainly have not yet been eradicated, and they are still highly relevant for the majority of the world's population. Freud and Marx will continue to be important as long as individuals are drawn into freedom-inhibiting interaction patterns with their interpersonal micro- or their societal macro-environment. However, at least for the postmodern intellectual elite, starting perhaps with Sartre's wartime development of existentialist philosophy, it is the manifold consequences of the knowledge- and technology-driven explosion of societal complexity and worldwide interdependence that need to be explained.

Perhaps this started out as a luxury problem of a few well-paid intellectuals and is totally irrelevant even now for the majority of the world's inhabitants, as it is, certainly, under the near-slavery conditions still existing in many parts of the Third World. Nevertheless, in much of the Western world, the average person is increasingly confronted, on a daily basis, with an often bewildering and overly complex environment, which promotes attitudes of political apathy, often politically dangerous oversimplification of complex political issues, and equally dysfunctional withdrawal from wider social involvements.

Postmodern philosophy has largely been an effort at explaining the effects of this increased complexity on the individual, but while it is largely a philosophy about the fragmentation of postmodern life, it often seems somewhat fragmented itself. What else can one expect perhaps, given Marx's insight that the economic and organizational substructure tends to influence the ideological superstructure? However, while postmodern philosophy certainly draws attention to a few important aspects of postmodern living, it will be argued elsewhere that modern second-order cybernetics can offer a much more holistic picture of societal development over the past few decades (see *Sociocybernetics* and Geyer 1989–98), and provides a metalevel linkage between the concepts of alienation, ethnicity, and postmodernism discussed here.

3. *Changing Emphasis Towards Problems of Ethnicity, Postmodernism, and Increasing Environmental Complexity*

Two developments converge in the work going on in alienation research since the 1990s: while 'classical' alienation research is still continuing, the stress is now, on the one hand, on describing new forms of alienation under the 'decisional overload' conditions of postmodernity and, on the other hand, on the reduction of increasingly pervasive ethnic alienation and conflict, and on alienation as caused by high joblessness rates among uneducated and disadvantaged youth in the Western world, largely as a result of the export of cheap labor to the Third World.

Since the start of the 1990s, there has again been an upsurge of interest in alienation research, caused by different developments: First of all, the fall of the Soviet empire gave a tremendous boost to alienation research in Eastern Europe, for two reasons: (a) the population as a whole was finally free to express its long-repressed ethnic and political alienation, which had accumulated under Soviet rule, while (b) the existence of alienation was no longer denied and instead became a respectable object of study. In the 1970s only a few researchers in relatively strong social positions, could permit themselves to point to the existence of alienation under communism (Schaff 1977).

Second, though processes of globalization and internationalization tended to monopolize people's

attention during the second half of the twentieth century, the hundred-odd local wars fought since the end of World War II, increasingly covered live on worldwide TV, claimed attention for the opposing trend of regionalization and brought ethnic conflicts to the fore, as demonstrated by the battle for Kosovo.

Third, postmodernism emerged as an important paradigm to explain the individual's reactions to the increasingly rapid complexification and growing interdependence of international society. Many of the phenomena labeled as characteristic for postmodernity squarely fall under the rubric of alienation; in particular, the world of simulacra and virtual reality tends to be an alienated world, for reasons that Marx and Freud could not possibly have foreseen.

Schacht (1989) argued that in modern, complex, and highly differentiated multigroup societies the struggle against alienation should be concentrated on evitable alienations. According to Schacht, one cannot possibly be involved with 'society' as one can with 'community,' but only with some of the social formations within it: i.e., specific processes and institutions, that definitely cannot be considered to stand as parts to a whole. Such involvement is necessarily selective and limited, and depends on individual preferences, character, and possibilities, sometimes even on a random and unique series of accidents. Schacht's recipe for unalienated living in what he calls post-Hegelian society departs from Nietzsche's idea of enhanced spirituality, but without its implication of a kind of extraordinary quasi-artistic development of which only the exceptionally gifted are capable. He wants to add the egalitarian spirit of Marx, but without his emphasis upon each person's cultivation of the totality of human powers, although a certain breadth in the range of one's involvements and pursuits is desirable to prevent stunted growth.

Schacht then maintains that modern, liberal society is still the best possible one for self-realization along these lines, owing to the proliferation of structured contexts into which selective entry is possible—in spite of the limited access to some of these contexts for often large parts of the population.

4. *Methodological Issues*

While agreeing with Seeman that alienation is a subjective phenomenon, one can disagree with his methodological implication, i.e., that the individual is always fully aware of his or her alienated state, and is always able to verbalize it. In that sense, both the psychoanalytic and the Marxist approach seem more realistic with their functionally roughly equivalent concepts of *repression* and *false consciousness*, but the disadvantage of these approaches is an almost inevitable authoritarianism: the external observer decides, on the basis of the subject's inputs (class position, working conditions, life history, etc.) as compared with his or her outputs (behaviors, scores on an alienation scale) whether the subject is alienated or not. The subjects themselves unfortunately have very little say in the matter, whether lying on the analyst's couch or standing on the barricades, and may or may not be or become aware of their alienation, and may even—rightly or wrongly—deny being afflicted with it.

Of course, there are many clear-cut cases where the ascription of alienation by an external observer—even if used as a critical and normative rather than as a descriptive and merely diagnostic concept—is clearly warranted, even though the persons concerned may deny their alienation because of repression or false consciousness: childhood abuse, clearly traumatizing experiences, living under conditions of extreme economic deprivation or an abject political system, exploitative working conditions, etc. But there are many not quite so appalling, but still undesirable situations in the Western world nowadays where it seems less useful to ascribe alienation to persons or groups out of a missionary drive to cure others of something they are either blissfully unaware of, or perfectly content with.

5. *Probable Future Directions of Alienation Theory and Research*

While Marxist and Freudian situations of powerlessness and other forms of alienation still abound, and the struggle against these should certainly continue, it has become evident that one is inevitably alienated from lots of things—alienation here being defined as a subjectively undesirable separation from something outside oneself (the means of production, God, money, status, power, the majority group to which one does not belong, etc.) or even inside oneself (one's 'real' inner feelings, drives or desires, as in the concept of self-alienation).

Schacht considers this indeed inevitable, and his sober appraisal contrasts with the often highly normative and evaluative character of earlier alienation studies, the Marxist ones castigating the evil effects of late capitalism on the individual, and the psychoanalytic ones deploring the effects of early-life neuroticizing influences. While admittedly Marxist and Freudian types of alienation are still prevalent in much of the world and should certainly be combated, new types of alienation have entered the scene that are caused by the increasingly accelerating complexification of modern societies. They can only be hinted at below, and have to do with phenomena like selection and scanning mechanisms, problems of information overload as well as decisional overload, and the need to engage often in counterintuitive rather than spontaneous behavior.

These modern forms of alienation have the 'disadvantage' that they are nobody's fault. No one, not even late capitalism or insensitive parents, can be

blamed for the fact that the world is becoming more complex and interdependent, that consequently causal chains stretch further geographically and timewise, and that—if one wants to reckon with their effects—one has more than ever to 'think before one acts,' and even to engage in spontaneity-reducing and therefore alienating forms of 'internal simulation.' The process of complexification is not only nobody's fault, but it is also irreversible, and cannot be turned back in spite of proclamations that 'small is beautiful.' One tends to lose a sense of mastery over one's increasingly complex environment, but it is different from the sense of mastery the alienated laborers of Marxist studies are supposed to gain if only they owned the means of production, or the psychoanalysts's clients if their neurotic tendencies would evaporate after looking at their analyst's diploma on the ceiling for half a decade while reliving early or not so early traumas.

The result of the emergence of these modern forms of alienation is that alienation studies, at least to the extent they deal with these modern forms, are becoming more value-neutral (a dirty word since the 1970s), less normative, moralistic, and value-laden. Once more: it is not implied that moral indignation and corrective action based on that indignation are not called for as long as millions of people are exploited and subjugated, or even tortured and killed, in the countless small wars that have replaced the relatively benign Cold War.

What is clear is that modern forms of alienation are emerging and will affect increasing numbers of people in the developed world, and soon also in the developing world. Several authors have hinted at this development. Lachs (1976) spoke of a *mediated world*, where the natural cycle of planning an action, executing it, and being confronted with its positive or negative consequences is broken, and where one is less and less in command of more and more of the things that impinge on one's life, without being able to impute blame on anyone or anything. Etzioni (1968) likewise saw alienation as resulting from nonresponsive social systems that do not cater to basic human needs. Toffler (1970, 1990) vividly described how change is happening not only faster around us, but even through us.

The alienated used to blame their woes on the wicked capitalist or their unsatisfactory parents, even though that was an obvious oversimplification. The common point in all these modern alienation forms is that they result from the increasing complexification of modern world society that we have brought about, reinforced by the aggregated individual and group reactions to this very complexification. One has to find ways of adapting to this irreversible process, since one cannot 'undo' the products, processes, and institutions that have emerged since the middle of the twentieth century. One cannot function adequately or participate fully in a world characterized by information overload without developing efficient selection mechanisms to select quickly what may be useful from the often unwanted information deposited at one's doorstep, and without developing effective mechanisms to scan the environment for information one needs to further one's goals. Moreover, if one tries to keep an open mind, the chance that one changes one's goals before having had the time to realize them is greater than ever before in history. Our civilization stresses the importance of learning; but has not yet sufficiently stressed the importance of *unlearning*, as Toffler (1970) has stressed; the 'halving time' of knowledge is far shorter than that of uranium.

The individual living in a world saturated with communication media is offered the possibility of thoroughly identifying with different alternative life scenarios, and at least in much of the Western world many of these scenarios can be realized if one is willing to pay the inevitable price. But a lifetime is limited, and so are the scenarios one can choose and try to realize. One of the consequences of this media-driven conscious awareness of alternative life scenarios—coupled with the freedom but also the lack of time to realize them all—is that the percentage of unrealized individual possibilities is greater than ever before, which certainly contributes to a diffuse sense of alienation: 'I'm living this life, but could have lived so many other ones.' Unlike Abraham, one cannot anymore die 'one's days fulfilled.'

Naturally, it can be maintained this is a spoilt-child syndrome, induced by the infantilizing influence of the media: fantasies are stimulated without parents telling the ever more insecure child 'this is impossible.' This accords with Schacht, who favors limited and selective involvement with the world; one cannot be involved with society as one could with community, let alone with primary group contacts.

As the development of the information society further continues, alienation towards the interpersonal environment and alienation towards the societal environment may well turn out to be inversely related. Many of those who have a high capacity for dealing with societal complexity (the educated and the academics among others), especially when they make much use of this capacity in their daily lives (the 'organization men and women,' the managers and planners), tend to generalize their 'planning attitudes,' probably due to the visible success of the associated operating procedures in the societal sphere, to encompass their interpersonal contacts. Consequently, they may become interpersonally alienated, and often see simple interpersonal relations as more complex than they actually are. They are insufficiently involved in the present, being used to internally simulate every move, to constantly think and plan ahead.

Conversely, those who have a low capacity for dealing with environmental complexity (the uneducated, especially those living in still relatively simple societies, amongst others), especially when their lowly position in complex hierarchical structures does not

require much planning regarding their wider societal environment (e.g., the unskilled), on the contrary tend to generalize their 'involvement attitudes' to include whatever societal interaction loops they are engaged in. The societally alienated tend to see complex societal relations as less complex than they actually are. They are, in direct opposition to the first group, insufficiently involved in the future, not because they cannot kick the habit of being involved in the here-and-now, but because they never developed the 'broadsight' and 'long-sight' (Elias 1939) that often characterizes the interpersonally alienated.

If it is indeed true that the interpersonally nonalienated tend to be the societally alienated, who clamor for a larger share of the societal pie, while the societally nonalienated tend to be in the power positions because they are best able to reduce societal complexity, and consequently have a fair chance of being interpersonally alienated, then the question becomes: Can a complex society ever be a nonalienating society, if it is led by those who score highest on interpersonal alienation? Or, as Mannheim asked: 'who plans the planners?' Alienation will certainly never disappear, whether in politics or in work situations, whether in interpersonal or societal interactions, but it may be considerably reduced by de-alienating strategies based on social science research.

Alliances and Joint Ventures: Organizational

1. Introduction

Cooperative arrangements between organizations date back to those between merchants in ancient Babylonia, Egypt, Phoenicia, and Syria who used such arrangements to conduct overseas commercial transactions. Since the 1980s, there has been a dramatic growth in the use of various forms of cooperative arrangements such as joint ventures between organizations. Several reasons have been offered for this unprecedented growth in alliances: greater internationalization of technology and of product markets, turbulence in world markets and higher economic uncertainty, more pronounced cost advantages, and shorter product life cycles. A noteworthy feature accompanying this growth in alliances has been the tremendous diversity of national origins of partners, their goals and motives for entering alliances, as well as the formal legal and governance structures utilized. The increase in cooperative arrangements has generated a renaissance in the scholarly study of alliances

(Gulati 1998). Researchers in several disciplines, including economics, sociology, social psychology, organization behavior, and strategic management, have sought answers to several basic questions: What motivates firms to enter into alliances? With whom are they likely to ally? What types of contracts and other governance structures do firms use to formalize their alliances? How do alliances themselves and firm participation patterns in alliances evolve over time? What factors influence the performance of alliances and the benefits partners receive from alliances?

We define an alliance as any voluntarily initiated and enduring relationship between two or more organizations that involves the sharing, exchange, or codevelopment of resources (e.g., capital, technology, or organizational routines). Joint ventures are a subset of alliances and typically entail the creation of a new entity by two or more partners who retain equity in the new entity. Alliances can be classified in numerous ways. They can be either horizontal or vertical, depending on the relationship of the alliance partners across the value chain. They can also be classified according to the motivations of the partners entering them (e.g., reducing costs vs. excluding potential competitors vs. developing new products) and according to the governance structure utilized (e.g., joint venture vs. minority equity position vs. licensing arrangement). The wide range of analytically useful distinctions between alliances reflects the complexity and diversity across the vast range of cooperative arrangements entered by firms.

2. *Theoretical Perspectives*

While alliances have been examined from a variety of theoretical perspectives, two disciplines have been particularly influential: economics and sociology. Within economics, there have been several approaches to the study of alliances including industrial economics, game theory, and transaction cost economics (Kogut 1988). The industrial economics perspective suggests that a firm's relative position within its industry structure is critical and that alliances can be used to increase this position relative to other rivals or consumers (Porter 1990). Industrial economists have studied how firms use alliances and other hybrid arrangements to enhance market power, maximize parent firm profits, acquire capabilities and competencies, and enhance their strategic position (Berg et al. 1982, Vickers 1985, Porter and Fuller 1986, Ghemawat et al. 1986).

Recently, scholars have extended earlier research and used insights from game theory to illuminate some of the process dynamics within alliances and their impact for firms (Gulati et al. 1994, Khanna et al. 1998). Some of the key elements have been to model the interdependence between alliance partners in terms of varying payoffs under differing scenarios. This provides a useful window into the dynamics that unfold in alliances based upon some of the ex ante conditions in the alliance.

Transaction cost economists have examined alliances and considered how transactional hazards may influence the extent to which firms use alliances as opposed to market transactions or internal production. Furthermore, scholars have also examined the formal structure of alliances and considered the extent to which transaction costs influence the governance arrangement firms use to formalize their alliances (Pisano 1990, Gulati 1995a, Gulati and Singh 1998, Oxley 1998).

A recent critique of much of the research on strategic alliances is that it has presented an undersocialized account of firm behavior (Gulati 1998). Thus, industrial economics and transaction cost economics in particular, have focused typically on the influence of structural features of firms and industries, neglecting the history and process of social relations between organizations. Sociologists have suggested that economic action and exchange operate in the context of historical structures of relationships constituting a network that informs the choices and decisions of individual actors (Granovetter 1985, Burt 1992). A network is a form of organizing economic activity that involves a set of nodes (e.g., individuals or organizations) linked by a set of relationships (e.g., contractual obligations, trade association memberships, or family ties).

The network approach to analyzing key questions about alliances builds on the idea that economic actions are influenced by the context in which they occur and that actions are influenced by the position actors occupy within a network. Organizations are treated as fully engaged and interactive with the environment rather than as an isolated atom impervious to contextual influences. Several recent scholars have followed a network approach and studied how preexisting interfirm relationships can cumulate into a network and thus influence fundamental dynamics associated with alliances (Kogut et al. 1992, Gulati 1995a, 1995b, Gulati and Gargiulo 1999, Gulati and Westphal 1999). This is based on the premise that, through their network positions, firms have differential access to information about current and potential alliance partners. Researchers have examined the role of relational embeddedness, which emphasizes the role of direct close ties as a mechanism for facilitating exchange, and also structural embeddedness, which emphasizes the structural positions of alliances partners with a network.

In the remainder of this article we shall discuss some of the new insights emerging from a network perspective on alliances for three core issues that are critical for the study of alliances (adapted from Gulati 1998): (a) formation—which firms enter alliances and with whom do they ally, (b) governance—what factors influence the governance structure firms use to for-

malize their alliances, and (c) performance—what factors influence the performance of alliances and of the firms entering alliances.

3. Formation of Alliances

Some of the key questions regarding the formation of alliances include: Which firms enter alliances and whom do firms choose as alliance partners? Instead of focusing on the factors that may motivate firms to seek alliances, we focus here on the factors that both predispose firms to enter into alliances with greater or lesser frequency and also influence their choice of alliance partners. These questions are examined at the firm and dyad level, respectively. Among the studies that have considered the factors that influence the alliance proclivity of firms, the focus has remained on some of the economic and strategic determinants of tie formation such as the customer bargaining power, market standardization, degree of asset configuration, and degree of product substitutability (Harrigan 1988). Follow-up research has remained focused on looking at the influence of firm-level attributes such as age, size, competitive positions, financial resources, and product diversity (as proxies for economic and strategic determinants) on the propensity of firms to enter alliances. This work has been extended recently to suggest that beyond the strategic imperatives, the proclivity of firms to enter alliances is also influenced by the available amount of 'network resources,' which is a function of the firm's position in its interfirm network of prior alliances (Gulati 1999).

Another line of inquiry from a transaction cost economics perspective has examined the alliance formation question as one of a choice between 'make, buy, or ally.' Since the 1980s there has been resurgence of research on the economic theory of the firm, with a particular emphasis on the 'make or buy' decision of firms (for a review, see Klein and Shelanski 1995). The key finding of this research is that the observed firm choice between these alternative governance forms (e.g., in-house production vs. outsourcing) that firms use to procure requisite goods and services is determined by the transactional hazards associated with them. The greater the transactional hazards associated with a commodity, the more likely are firms to use hierarchical governance arrangements. The logic for hierarchical controls as a response to appropriation concerns is based on the ability of such controls to assert control by fiat, provide monitoring, and align incentives. This basic premise has been considerably refined with new and detailed measures of the potential transactional hazards that could influence governance choice by firms (e.g., Masten et al. 1991). The operation of such a logic originally was examined in the classic make-or-buy decisions that were cast in Coasian terms as a question of the boundaries of the firm (e.g., Monteverde and Teece 1982, Walker and Weber 1984, Masten et al. 1991).

While there is widespread recognition that the original bipolar choice of governance arrangements examined by transaction cost theorists is no longer valid, there have been only limited inquiries into enlarging the original question and a direct consideration of the 3-way choice between make, ally, and buy (Gulati and Lawrence 1999). The same logic by which firms choose between the extremes of make or buy is also expected to operate now that firms face an enlarged choice between make, ally, and buy: the greater the transactional hazards, the more hierarchical the governance structure. While all these studies have advanced our understanding of some of the factors that influence the creation of alliances as opposed to alternative governance structures, their primary focus on transactional characteristics as determining factors has led them to incompletely examine the role of the interorganizational networks in influencing this choice. This remains an exciting arena for future research.

The two approaches to alliance formation outlined above have focused on individual firms and on individual transactions respectively. Yet another approach is to consider this issue at the dyad level and assess the factors that influence who partners with whom in an alliance. Due to the paucity of information on the reliability and competencies of potential alliance partners, there is often uncertainty over the likely behavior of the contracting parties. Network connections and third-party referrals can play an important in role in reducing such uncertainty. As a result, they may influence the availability of and access to alliance opportunities that firms may perceive. Recent empirical research corroborates these claims and suggests that the choice of partners for alliances is influenced by strategic interdependence and also the network antecedents of the partners (Gulati 1995b, Gulati and Gargiulo 1999, Gulati and Westphal 1999).

4. Governance of Alliances

A key question regarding the governance structure of alliances is: Which ex ante factors affect the choice of alliance governance structure? Cooperative interorganizational relationships such as strategic alliances and joint ventures require negotiation of property rights governing the long-term resources invested in the arrangement. The essence of cooperative strategy is achievement of an agreement and a plan to work together such that each partner essentially becomes an agent for the other(s). Firms face numerous choices in structuring their alliances. The governance structure must include a variety of components: planning and control systems, incentive systems, information systems, and partner selection systems. Property rights

cannot always be controlled fully or specified in advance, so in part, governance of joint ventures operates by firms being placed into mutual hostage positions as they commit financial capital, real assets, and other resources to the venture (Kogut 1988).

One basic governance question concerns whether the cooperative arrangement does or does not involve equity. Questions about governance structure have been examined in depth by transaction cost economists. Pisano and co-workers (Pisano et al. 1988, Pisano 1989) found that the greater the potential transaction costs, the more likely parties are to design a hierarchical contractual arrangement and to use equity alliances rather than nonequity alliances. They argue that equity alliances are an effective governance structure for mitigating transaction costs because each partner's concern for its investment reduces opportunistic behavior (i.e., there is a 'mutual hostage' situation) and because equity partners establish hierarchical supervision through their service on the board of directors. Gulati (1995a) extended this work by suggesting that such an approach erroneously treats each transaction independently and ignores the crucial role of the history of prior transactions between partners. He found that prior alliances between firms engenders interorganizational trust that reduces the likelihood of using equity arrangements in future ties. Gulati and Singh (1998) have gone a step further and found that the use of hierarchical arrangements such as equity alliances is influenced not only by appropriation concerns but also by anticipated coordination concerns that were highlighted originally by organization design theorists but have not been the focus of recent research.

5. *Performance of Alliances*

Key questions regarding the performance of alliances include: How can we measure the performance of alliances? Which factors affect the performance of alliances? Do firms receive economic and social benefits from participating in alliances? Due to onerous research obstacles related to establishing criteria for measuring performance and the logistical challenges of collecting the detailed data necessary, the performance of alliances and of alliance partners remains an exciting but underexplored area. This is especially relevant since several anecdotal accounts suggest that the failure rate of alliances may be as high as 50 to 80 percent. Scholars suggest that alliances are often difficult to manage, taxing of top management's cognitive resources, and limiting of the partners' organizational autonomy, and thus prone to failure. They have identified several factors that could influence the success rate of alliances: building interfirm trust, continuity in interface personnel, management flexibility, proactive conflict resolution mechanisms, and regular information exchange (e.g., Kanter 1989, Bleeke and Ernst 1991). The primary approach taken by empirical studies of alliance performance has been to examine factors affecting the termination of alliances such as: industry concentration and growth rates, partners' country of origin, duration of the alliance, competitive overlap between partners, and alliance governance structure (Beamish 1985, Harrigan 1986, Kogut 1989, Levinthal and Fichman 1988). However, these studies typically are limited in two respects: (a) failure to distinguish natural vs. untimely deaths of alliances and (b) an inability to distinguish gradations of alliance performance because of the consideration of all performance dichotomously as either survival or death.

A basic and particularly vexing question is how to measure alliance success (Anderson 1990). Given the multifaceted objectives of alliances, focusing on technical efficiency and financial outcomes (e.g., return on assets) often does not offer an adequate evaluation of performance and determination of antecedents. Management and strategy scholars have begun to use extensive surveys and more longitudinal data to examine performance (Harrigan 1986, Heide and Miner 1992, Parkhe 1993). One area of inquiry however that has not been pursued by such scholars has been to consider the impact of social networks and embeddedness on the relative performance of alliances. This is especially important since there is some preliminary empirical evidence that alliances embedded in social networks are less likely to terminate and are more effective in situations of high uncertainty (Kogut 1989, Levinthal and Fichman 1988, Seabright et al. 1992). A related direction for future research would be to examine the simultaneous and potentially conflicting influence of multiple social networks on alliance performance. As more and more organizations enter multiple cooperative arrangements, with some finding themselves in hundreds of alliances (e.g., General Electric, Hewlett-Packard, and IBM), a portfolio perspective is needed to examine the degree to which multiple alliance participation generates both conflicting demands and productive synergies.

Do organizations benefit from entering strategic alliances? This question is distinct from the previous issue of the alliance's overall performance. Given that many other factors besides an alliance influence an organization's performance, it can be difficult to establish a causal link between alliance participation and organizational benefit. Consequently, researchers have looked to a variety of direct and indirect measures, including stock market effects (e.g., Koh and Venkatraman 1991, Anand and Khanna 1997) and the likelihood of organizational survival (e.g., Baum and Oliver 1991, 1992). The results of these studies have been mixed but generally suggest that alliances are beneficial for organizations. Once again, there have been only few efforts to link the social structural context of alliances with the performance

benefits that are likely to ensue from them (e.g., Gulati and Wang 1999).

An important lacuna in much of the research on alliances has been insufficient attention to the dynamics of such ties. A few studies that have focused on process issues suggest that alliances are subject to dynamic evolutionary processes that cause significant transformations beyond their original designs and mandates (Hamel 1991, Larson 1992, Ring and Van de Ven 1994, Doz 1996). Change can occur at the intrafirm, interfirm, network, industry, and societal levels. At the firm level, as the pay-offs for an alliance or at least each partner's perception of those pay-offs changes, the incentives for cooperation can change (Gulati et al. 1994, Khanna et al. 1998). Key changes also takes place at the network level, as a firm's social network (the main source of its current and potential alliance partners) evolves, which changes the structural positions of organizations within the network and affects the pattern of future ties. Even more profound dynamics can operate on the industry and national levels. In this article, we have tried to outline the importance of the social network and structural embeddedness perspectives for the study of alliances. We believe that it is particularly valuable in informing scholars and managers on 'how' (as opposed to why) dyadic, network, and societal level dynamics affect the evolution and eventual performance of alliances. This perspective also opens up new critical questions for future research on the dynamics of alliances such as how firms manage a portfolio of alliances, how firms position themselves optimally within a network, and how social network membership affects alliance performance.

Alliances: Political

Alliances are formal agreements, open or secret, between two or more nations to collaborate on national security issues. They have been variously considered as techniques of statecraft, international organizations, or regulating mechanisms in the balance of power. This article addresses several of the enduring concerns about alliances, including alliance formation, their performance and persistence; their effects on the international system and domestic politics; and their prospects in the new millennium.

1. *Alliance Formation*

Among the oldest explanations of alliances are those derived from balance-of-power theories in which the emphasis is on the external environment, including the structure, distribution of power, and state of relations among units of the system. These are often closely linked to the 'realist' approach to international politics (Morgenthau 1959, Waltz 1979, Gilpin 1981). Nations join forces as a matter of expediency in order to aggregate sufficient capabilities to achieve certain foreign policy goals, to create a geographically advantageous position, or to prevent any nation or combination of countries from achieving a dominant position. Alliance partners are thus chosen on the basis of common goals and needs, not for reasons of shared values, shared institutions, or a sense of community. According to balance-of-power theories, nations should be more likely to join the weaker coalition to prevent formation of a hegemonic one ('balancing') rather than join the dominant one in order to increase the probability of joining the winning side ('bandwagoning') (Waltz 1979). Several case studies found support for the 'balancing' hypothesis: that nations form alliances to balance threats rather than power (Walt 1987).

The 'size principle,' according to which 'coalitions will increase in size only to the minimum point of subjective certainty of winning,' is drawn deductively from 'game theory' (Riker 1962, pp. 32–3). Coalition theories share a number of characteristics with balance-of-power models, but whereas an important goal of 'ideal' balance-of-power systems is to prevent the rise of a dominant nation or group of nations, the primary motivation in game approaches is to form just such a coalition, with enough partners to ensure victory but without any additional ones who would claim a share of the spoils. Although intuitively appealing, a number of difficulties arise when this approach is applied to international politics. If war offers the prospect of winning territories or other divisible rewards, there are advantages to forming an alliance no larger than is necessary to gain victory, but even in redistribution alliances the interests of partners

may be complementary, permitting a non-competitive division of rewards. Moreover, when an alliance is formed for purposes of defense or deterrence, its success is measured by its ability to prevent conflict, not by the territorial or other gains derived from successful prosecution of a war. Another potential difficulty is the demanding requirement that leaders be able to measure capabilities with sufficient precision to define a minimum winning coalition. Any propensity to use 'worst case scenario' reasoning will likely result in a much larger alliance.

In contrast to the balance-of-power and minimum winning coalition theories are those that emphasize national attributes other than power. These approaches do not deny that calculations of national interest or power influence alliance formation, but they also emphasize that we cannot treat nations as undifferentiated units if we wish to understand either their propensity to use alliances as instruments of foreign policy, as opposed to such alternatives as neutrality, or in their choice of alliance partners. Political stability is sometimes associated with a propensity to join alliances, and instability has been seen as an impetus to go beyond non-alignment and pursue a policy of 'militant neutralism;' leaders faced with domestic instability may actively court allies in the hopes of gaining external support for a tottering regime. By utilitarian criteria, small, poor, or unstable nations are relatively unattractive alliance partners, but such nations have often been sought as allies, and they have even become the focal point of acute international crises; twentieth-century examples include Bosnia from 1908 to 1909, Serbia 1914, Cuba from 1961 to 1962, and Vietnam from 1965 to 1973.

Given a propensity to seek allies, does the choice of partners reflect a discernible pattern of preferences? Affinity theories focus on the similarities among nations as an element in their propensity to align. The premise that nations are likely to prefer partners with whom they share common institutions, cultural and ideological values, or economic interests is intuitively appealing, and NATO can be cited as an example, but it has received limited support in studies of pre-1945 alliances.

2. *Alliance Performance*

Palmerston once noted that nations have neither permanent enemies nor allies, only permanent interests. Although the longevity of most alliances can be measured better in years than decades or centuries, these observations do not explain why some alliances are cohesive and effective whereas others are not. To some, open polities are inferior allies on two counts: they experience more frequent changes in ruling elites, with the consequence that commitments to allies may also change, and the demands of domestic politics may take precedence over alliance requirements. But when democracies are under attack they are more likely to expand alliance functions and to turn alliances into communities of friendship; they are also less likely to renege on commitments by seeking a separate peace (Liska 1962, pp. 50, 52, 115).

Political instability is often associated with poor alliance performance. Unstable regimes may experience radical changes in elites, which in turn result in shifting patterns of alignment, and they may also be more willing to run high risks on behalf of their own interests but not those of allies. Differences in national bureaucratic structures and processes may be an important barrier to coordination of alliance strategies. If national security policy is the product of constant intramural conflict within complex and varied bureaucracies, even close allies may fail to perceive accurately the nuances in the bureaucratic politics 'game' as it is played abroad, and how the demands of various constituents may shape and constrain alliance policies (Neustadt 1970, Allison 1971).

Alliances differ in many ways, including the circumstances under which their provisions become operative, the type of commitment, the degree of cooperation, geographical scope, ideology, size, structure, capabilities, and quality of leadership. Presumably all nations prefer to join alliances that offer them an effective role in determining goals, strategy, and tactics; a 'fair' share of the rewards without undue costs; and the maximum probability of success in achieving their goals.

Redistribution alliances might be expected to achieve fewer successes and to break up more easily than those whose primary motives are deterrence and defense. Failure to achieve goals has a disintegrative effect and, other things being equal, it is easier for an alliance of deterrence to succeed because it is sufficient to deny the enemy a victory or to maintain the status quo. A redistribution alliance, on the other hand, must not only be able to avert defeat; it must also achieve victory if it is to be successful.

Ideology may play a role in sustaining or dissolving alliance bonds. Even those who minimize the importance of ideology in alliance formation tend to agree that a shared ideology may ensure that issues are defined similarly and facilitate intra-alliance communication. A common ideology may sustain alliances, but only as long as its tenets do not themselves become an issue.

Large alliances are usually less cohesive than small ones. The larger the alliance, the smaller the share of attention that nations can give to each ally, and as the size of the alliance increases, the number of relationships within the alliance rises even faster. Problems of coordination increase and so do opportunities for dissension. Finally, the larger the alliance, the less important the contributions of any single member, and the easier it is for any partner to become a 'free rider' by failing to meet alliance obligations.

Alliances differ widely in the kinds of political and administrative arrangements that govern their activities. Allies may undertake wide-ranging commitments to assist each other and yet fail to establish institutions and procedures for communication and policy coordination. Some suggest that hierarchical and centralized alliances are likely to be more cohesive and effective because they can mobilize their resources better and can respond more quickly to threats and opportunities. According to others, pluralistic and decentralized alliances are likely to enjoy greater solidarity and effectiveness. In pluralistic alliances, even differences on central concerns are likely to remain confined to the single issue rather than all issues (Holsti et al. 1973).

The proposition that influence within an alliance is proportional to strength may not always be valid. Under some circumstances, weakness may actually be a source of strength in intra-alliance diplomacy. The stronger nation is usually the more enthusiastic partner, it has less to gain by bargaining hard, and it can less credibly threaten to reduce its contributions. The weaker nation may also enjoy disproportionate influence within an alliance because it can commit its stronger ally, which may be unable to accept losses resulting from the smaller partner's defeat (Olson and Zeckhauser 1966).

Each state brings both assets and liabilities to the alliance. The conventional manner of assessing capabilities is to sum the assets of the members. The more realistic view is that the capabilities of an alliance rarely equal the sum of its parts. Given close coordination, similar equipment, skillful leadership, and complementary needs and resources, economies of scale may be achieved. This may sometimes be the case for alliances of deterrence, but if it becomes necessary to carry out military operations, alliance capabilities are probably less than those of the individual nations combined. Wartime operations may reveal or exacerbate problems arising from poor staff coordination, mistrust, incompatible goals, logistical difficulties, dissimilar military equipment, and organization.

The capabilities of alliance leaders are important. A powerful and wealthy bloc leader can offer side payments–private goods to supplement public ones–to smaller partners, which may in turn render the alliance more effective. According to the economic theory of 'collective action,' alliances that supplement public benefits (those that are shared by all members) with private or non-collective ones are more cohesive than alliances that provide only collective benefits (Olson and Zeckhauser 1966). Except in a pure conflict situation, there are always some tensions between the requisites of alliance cohesion and broader global concerns. If the alliance is to cope effectively with these tensions, it requires effective leadership from its leading member or members. Alliance relationships involve other kinds of tensions and fears. Members face the fears of abandonment when their own interests are at stake, and of entrapment when those of others are threatened (Snyder 1997). The ultimate test of alliance leadership comes during an international crisis when the leading partner may be forced to resolve serious tensions between alliance management (intra-alliance diplomacy) and crisis management (inter-alliance diplomacy).

Virtually every alliance faces the problem of ensuring the credibility of its commitments. The problem is most serious for alliances of deterrence. If adversaries possess serious doubts on this score, the alliance may serve as an invitation to attack. Equally important, if members have doubts about the assurances of their partners, the coalition is unlikely to be effective. 'Irrational' alliance commitments may be undertaken as part of an overall strategy of increasing the credibility of deterrence by conveying to the adversary–and to other allies–that if the alliance leader is willing to expend vast resources to protect areas of little strategic value, then it should be clear that an even greater effort will be made to defend other allies (Maxwell 1968, p. 8). Buttressing credibility by 'irrational' commitments may also entail risks, forcing the alliance leader to choose between two unpalatable alternatives: reducing the commitment under threat, thereby seriously eroding one's credibility in the future; or backing the promise to the hilt, with the possibility of becoming a prisoner of the ally's policies.

Although it is widely asserted that alliance cohesion depends upon an external threat and that it declines as the danger is reduced, this generalization must be qualified. Such a threat may give rise to divisions if only part of the alliance membership feels threatened, if the threat strikes at the basis of alliance consensus, or if it offers a solution that sets off the interests of one ally against those of another. Similarly, unless the external danger creates an equitable division of labor among alliance members, cohesion and effectiveness are likely to suffer. Although wartime alliances face considerable external threat, they may sometimes experience tensions because military operations rarely result in equal burdens. As long as the threat calls for a cooperative solution, cohesion will probably be enhanced, but should a solution which favors one ally at the expense of others appear, the alliance may lose unity or disintegrate. Finally, an alliance confronting an external threat for which there is no adequate response may also experience reduced cohesion or dissolution.

Most analysts stress the negative effects of nuclear weapons for alliances. One reason is that contemporary military technology has permitted some nations to gain preponderant power without external assistance. Another strand of the argument is that nuclear deterrence will be less than credible if it takes the form of one alliance member providing a 'nuclear umbrella' (extended deterrence) for the others. Put in its starkest form the question is: what nation will risk

its own annihilation by using its nuclear capabilities as a means of last resort to punish aggression against its allies? The other side of the argument is the fear that one may unwittingly become a nuclear target as a result of an ally's quarrels.

3. International Effects of Alliances

Alliances are intended to play a central role in maintaining the balance of power. They provide the primary means of deterring or defeating nations or coalitions that seek to destroy the existing balance by achieving a position of hegemony. Even advocates of balance-of-power diplomacy attach a number of important qualifications. Alliances among great powers contribute to instability if they are strong enough to destroy the existing balance; or if they reduce the number of nations that may act in the role of 'balancers,' which, according to the theory, are supposed to remain uncommitted until there is a threat to the balance.

Alliance critics assert that they merely breed counter-alliances, thereby leaving no nation more secure, while at the same time contributing to polarization and international tensions. A further criticism is that alliances are incompatible with collective security, which requires every nation automatically to assist the victim of aggression; alliance commitments can thus create a conflict of interest. It does not necessarily follow, however, that in the absence of alliances nations will develop an effective collective security system. Indeed, alliances may arise from disappointed hopes for collective security. Elimination of alliances may be a necessary condition for collective security, but it is not sufficient. Critics of alliances also suggest that they act as conduits to spread conflict to regions previously free of it, but Liska (1962) has come to the conclusion that alliances neither cause nor prevent conflict, nor do they expand or limit it.

Another strand of theory, not necessarily incompatible with either of the above, sees alliance as a possible step in the process of more enduring forms of integration. The premise is that effective cooperation among units in one issue area gives rise to collaboration in others and, in the long run, to institutionalization of the arrangements.

4. National Effects of Alliances

Alliance benefits may include enhanced security, reduced defense expenditures, and possible side benefits such as economic aid and prestige. A strong ally may be a necessary condition for survival. But alliances may be a net drain on national resources, they may distort calculations of national interest if allies become wedded to 'inherent good faith' models of each other, and they may lead to a loss of decision-making independence.

5. Prospects

The third quarter of the twentieth century, 'the age of alliances,' was ushered in by the formation of NATO in 1949 and the Sino-Soviet Security Treaty in 1950. Within a half-decade the Warsaw Pact, SEATO, CENTO, and a multitude of other alliances were formed, but many of them had dissolved before the end of the Cold War. Contrary to the expectations of some realists, however, NATO has outlived the threat that brought it into existence. Although many Cold War alliances failed to survive the new millennium, as long as the international system is characterized by independent political units, alliances are likely to persist as a major instrument of statecraft.

Allport, Gordon W (1897–1967)

Gordon W. Allport (1897–1967) was a leading American personality theorist and social psychologist throughout the mid-twentieth century. His two major works—*Personality: A Psychological Interpretation* (1937) and *Pattern and Growth in Personality* (1961)—stand as landmarks in the development of personality psychology. His *The Nature of Prejudice* (1954) remains one of the most cited applied works in social psychology.

The son of a Scottish-American medical doctor, Allport was born November 11, 1897 in Montezuma, Indiana, USA and grew up in Cleveland, Ohio. His half-century affiliation with Harvard University began in 1915 when he enrolled as an undergraduate. His student career foretold his adult interests in science and social issues. He majored in both psychology and social ethics and was impressed by his first teacher in psychology, Hugo Muensterberg. He spent much of his spare time in social service activities. This convergence of interests took institutional form later when he helped to establish both the Society for the Psychological Study of Social Issues and Harvard's Department of Social Relations.

Upon graduation in 1919, Allport taught English and Sociology at Robert College in Constantinople (then part of Greece, now Bogazici University in Istanbul, Turkey). In addition to German, he remained fluent in modern Greek throughout his life. Returning to Harvard in 1920, he completed his Ph.D. in psychology in two years. His dissertation title again reflected his dual commitment to science and social concerns: *An Experimental Study of the Traits of Personality: With Special Reference to the Problem of Social Diagnosis*. In addition, he assisted his older brother, Floyd, in editing the *Journal of Abnormal and Social Psychology*, the start of over four decades of association with the publication.

Harvard then awarded him a coveted Sheldon Travelling Fellowship. He spent the first year in Germany, where the new *Gestalt* school and its emphasis on cognition fascinated him. Indeed, he became a partial Gestaltist—partial because he could not accept the Gestaltists' assumptions about the inflexible genetic basis of cognitive processes (Pettigrew 1979). He spent his second Sheldon year at Cambridge University, where the psychologists coolly received his reports on *Gestalt* developments.

In 1924, Allport became a Harvard instructor in social ethics and taught what may have been the first personality course offered by a North American university. Two years later he temporarily severed his connection with Harvard to accept an assistant professorship in psychology at Dartmouth College. Yet, even during his brief four years away, he returned repeatedly to Harvard to teach in summer school. In 1930 he came back to Harvard to stay.

Allport's unique contributions to psychology are best described by three interwoven features of his work. First, he offered a broadly eclectic balance of the many sides of the discipline—holding to William James's contention that there were 'multiple avenues to the truth.' Second, he formulated the central future problems of the discipline and proposed original approaches to them. Finally, his entire body of scholarly work presents a consistent, seamless, and forceful perspective.

1. *Broadly Eclectic Balance*

Allport sought an eclectic balance for both methods and theory. His famous volumes on personality illustrate this dominant feature of his work (Pettigrew 1990). He urged, for example, the use of both ideographic (individual) and nomothetic (universal) methods. Since he thought the discipline relied too heavily on nomothetic approaches, he sought greater use of ideographic techniques. In an age of indirection, Allport insisted, 'If you want to know something about a person, why not first ask him?' Considered scandalously naive when he introduced it, his position helped to right the balance in assessment.

Typically, this was an expansionist, not an exclusionist, view. He simply sought a reasonable trade-off between accuracy and adequacy. He thought the two approaches together would make for 'a broadened psychology.' Indeed, his own empirical efforts ranged from personal documents, such as *Letters From Jenny* (1965), to two popular nomothetic tests on ascendance-submission and personal values. He also developed ingenious experimental procedures to study eidetic imagery, expressive movement, radio effects, rumor, the trapezoidal window illusion, and binocular rivalry.

His theoretical efforts also sought a balance. He vigorously advocated an open-system theory of personality with emphases on individuality, proaction, consciousness, maturity, and the unity of personality. As such, in Rosenzweig's (1970, p. 60) view, Allport served as the field's 'ego' in contrast to Henry Murray's

'id' and Edwin Boring's 'super-ego.' Yet Allport did not hold his emphases to be the only matters of importance for a psychology of personality. Rather, it was because he believed the discipline was granting these important ego-concerns too little attention.

In this sense, Allport was, to borrow from boxing, a counterpuncher. He opposed what he regarded as excessive trends in psychology that threatened his conception of an open, balanced discipline. In 1937, in his first personality book, he saw as the major threat the too-rigid applications of experimental psychology. By 1961, in his second personality volume, he saw as the major threat the too-loose applications of psychoanalysis. 'Although much of my writing is polemic in tone,' he confessed in his autobiography, 'I know in my bones that my opponents are partly right.' The key word is *partly*. Allport opposed excess, 'the strong aura of arrogance found in … fashionable dogmas' (1968, pp. 405–6). So he held fast to the open middle ground as he perceived it, and aimed his punches at the 'fashionable dogmas' that existed in each period. Modern readers may miss the significance of his arguments if they are unaware of which dragons he is attempting to slay.

2. *Formulating Central Problems and Offering Original Solutions*

Psychology recognized Allport throughout his career as a source for specifying the discipline's central problems. Typically his initially proposed solutions to the problems—such as functional autonomy—won limited acceptance. Nonetheless, many of Allport's initial proposals for addressing basic problems now exist in psychology with new labels and enlarged meanings. Allport only loosely sketched out his innovative ideas. Later work accepted the problem and expanded the ideas. Consider the much derided concept of functional autonomy. The notion that motives can become independent of their origins was considered heretical in 1937. Slowly, psychology came to accept the phenomenon if not the formulation. Today social psychologists reconceptualize the process in interactionist terms. Motives, established and functional in one situation, help lead individuals to new situations where the same motives persist but assume new functions.

Similarly, Allport's conception of personality traits has often been criticized. What critics attack is the mistaken notion that he held a static view of traits as pervasive, cross-situational consistencies in behavior. But Zuroff has shown that Allport advanced a far more dynamic conception of traits. In fact, he was 'an interactionist in the sense that he recognized behavior is determined by the person and situation' (Zuroff 1986, p. 993).

Indeed, Allport broke early ground for many ideas now fully developed and accepted. Thus, he provided in his 1937 volume a social constructionist interpretation of identity. His insistence on multiple indicators and methods offered an initial statement of Campbell and Fiske's (1959) multitrait–multimethod approach.

3. *A Consistent, Forceful Perspective*

Above all, Allport's contributions to psychology flowed from a consistent and forceful perspective presented in graceful prose. One reviewer of his 1937 *Personality* book wrote, 'One has all the way through it a distinct feeling that "This is Allport"' (Hollingworth 1938, p. 103). This pointed observation holds true for all his writing.

Allport's perspective remained consistent but not static throughout his career. He acquired a comprehensive knowledge of the psychological literature from his long years as a meticulous editor. Quite literally, a large proportion of North America's personality and social psychological literature crossed his editor's desk. His mastery of the literature also reflected his open-ended view of theory—a view more Popperian than the strict Vienna-circle positivism that held sway throughout most of his career.

Yet Allport held to his perspective forcefully. His writing conveyed this forcefulness. Blunt prose and forthright critiques characterize his style. As one disgruntled reviewer of an Allport book put it, 'There is something in it to irritate almost everyone' (Adelson 1956, p. 68). Hall and Lindzey (1957) suggest that Allport's many years of teaching led to his expressing his views in a uniquely salient and provocative style.

4. *Allport on Prejudice*

This directness is also apparent in his applied volume, *The Nature of Prejudice*. This influential book again brought together Allport's two sides—science and social action. He deemed it his proudest achievement because he thought it 'had done some good in the world.' Indeed, in its paperback edition, it became one of the best selling social psychological books in publishing history.

The Nature of Prejudice displays the special characteristics of Allport's contributions to psychology. The volume offers a broad, eclectic perspective with a lens model that ranges from history to the psychological effects of prejudice on its victims. Its open view of the many sides of the phenomenon again demonstrates the distinctive quality of Allport's wide-ranging thought.

The Nature of Prejudice is another seamless work that is 'Allportian' from start to finish. Deftly crafted in a simpler style than his other writings, Allport strove to make it accessible to a wider, nonacademic audience. In addition, it served to structure the entire study of prejudice in social psychology for the next

four decades. This is true for intergroup research in North America. In its many translated versions, it has proven highly influential in other parts of the world as well. Indeed, the volume's many predictions, though shaped by American intergroup data, have typically been confirmed in studies of intergroup prejudice throughout much of the world.

The Nature of Prejudice's useful definition of prejudice—'an antipathy based upon a faulty and inflexible generalization' (1954, p. 9)—stressed both affective and cognitive components, but it wisely left the complex link between prejudice and behavior an open, empirical question. This definition has served the field well, and only recently have social psychologists advanced expansions of its terms.

To attain his distinctive quality of balance, Allport again assumed the role of counterpuncher against prevailing dogmas. He gave full recognition to the importance of the psychoanalytically inspired authoritarian personality syndrome, which he also had uncovered during the 1940s. But he challenged the Freudian formulation of aggression with a rival theory. Instead of the psychoanalytic steam boiler model of aggression and catharsis, Allport proposed a feedback model with dramatically different implications for prejudice and its remediation. Aggression, he argued, feeds on itself. That is, the acting out of aggression, rather than leading to less aggression, actually increases the probability that further aggression will be expressed. Armed with this insight, *The Nature of Prejudice* proceeds to advocate policies that have indeed reduced levels of prejudice in the United States and elsewhere.

Allport also challenged the central assumption of one of his own favorite groups. The Human Relations Movement developed after World War II to improve America's intergroup relations. With Brotherhood Weeks and Dinners, the well-meaning movement hoped to combat prejudice and discrimination through formal intergroup contact. But Allport, in the book's most important theoretical contribution, questioned this assumption with his intergroup contact hypothesis. Contact alone, he argued, only set the scene for change; what mattered were the situational conditions of the intergroup interaction. The four conditions he listed—equal status in the situation, common goals, no intergroup competition, and authority sanction—have repeatedly been supported in research around the globe (Pettigrew 1998).

His treatment of prejudice also countered the then-fashionable assumption that group stereotypes were simply the aberrant cognitive distortions of prejudiced people. Advancing the view now universally accepted, Allport held that the cognitive components of prejudice were natural extensions of normal processes. Stereotypes and prejudgment, he concluded, were not aberrant at all, but unfortunately all too human.

Allport's foresight into the many advances, especially in research on group stereotypes, that this field has achieved over recent decades can be traced to his early *Gestalt* leanings (Pettigrew 1979). He devoted 10 of *The Nature of Prejudice*'s 31 chapters to cognitive factors. Psychology joined the cognitive revolution just after the volume was published. In social psychology, social cognition veered in a largely *Gestalt* direction that had molded Allport's perspective on prejudice. Thus, the same influences that shaped the study of prejudice in general and stereotypes in particular from 1960 on had earlier guided Allport's thought.

The Nature of Prejudice also presents a host of original hypotheses on specific topics that have stood the test of time. For instance, one popular theory of prejudice reduction emphasizes recategorization through identity with larger, more inclusive groups. Allport (1954) advocated precisely the same mechanism. Drawing concentric circles with family in the center and humankind at the periphery, he argued that 'concentric loyalties need not clash' and that prejudice is minimized by inclusive group membership.

The volume also devotes an entire chapter to the link between religion and prejudice. A religious man himself, Allport was disturbed that research routinely finds nonbelievers far less prejudiced on average than members of organized religions. He proposed a critical distinction between an 'institutionalized' religious outlook and an 'interiorized' one. The more numerous institutionally religious, he argued, are the highly prejudiced. Those of the interiorized type, who have deeply internalized their religious beliefs, are far less prejudiced. In his last empirical publication (Allport and Ross 1967), Allport presented additional evidence in support of his hypothesis and later research provides additional support.

Allport addressed the book primarily to his own ingroup—White, Protestant, American males. The examples of prejudice cited throughout involve anti-Black, anti-Jewish, anti-Catholic, and antifemale sentiments. He was clearly lecturing to 'his own kind.' It is safe, easy, and politically expedient to attack the prejudices of outgroups who hold negative views of our ingroup. It is quite a different matter to attack the prejudices of our own ingroup toward others. So yet another remarkable feature of *The Nature of Prejudice* is its target audience.

5. *Allport as Teacher and Mentor*

Though intellectually confident, Allport was actually a shy and modest man—though his manner was sometimes mistaken for aloofness. In his gentle and supportive way, he was a master teacher and mentor. He held to his conception of the uniqueness of personality and encouraged students to follow their own interests. Hence, though he produced dozens of well-known psychologists, he never developed a 'school' of followers.

One way Allport handled his social shyness was to prepare carefully for occasions in advance. Before giving his Hoernle Lecture at South Africa's leading Afrikaner University at Stellenbosch in 1956, he studied Afrikaans with a tutor for six months. He then skillfully gave the introduction to his lecture in Afrikaans, gracefully apologizing for not delivering his entire address in Afrikaans. The Afrikaner audience, accustomed to even other South Africans not knowing their language, reacted with surprise and delight. The audience arose as one with applause.

6. *The Lasting Contribution*

Allport's professional honors were many. He was elected president of both the American Psychological Association (1939) and the Society for the Psychological Study of Social Issues (1944). He received the Gold Medal of the American Psychological Foundation in 1963. He died October 9, 1967 in Cambridge, Massachusetts. His legacy in psychology is twofold. He helped to establish personality psychology as a science and as an integral part of the discipline of psychology. In addition, his applied work in social psychology, particularly on intergroup prejudice, furthered the practical value of the discipline's work for important social issues.

Alternative and Complementary Healing Practices

Complementary medicine (CAM) has become increasingly popular in the Western world since about 1975 and has excited much research (Eisenberg et al. 1998). Paradoxically, this increase of interest in and the use of complementary medicine (CAM) comes at a time when the successes of the scientifically based contemporary biomedicine or orthodox medicine (OM) have never been greater.

Perhaps the different terminologies used over the years to describe complementary medicine therapies best indicate its greater acceptance both in the orthodox and medical community and also among the lay public. Thus the term 'fringe' medicine developed into 'alternative,' then 'unconventional' and finally 'complementary' medicine. Since about 1980 there has also been an enormous growth of, and interest in, all forms of CAM (Vincent and Furnham 1997, 1999). Demand for CAM has been matched by supply, and there is now a substantial list of CAM therapies available to Western metropolitan citizens (Ernst et al. 1997).

1. *Fundamental Differences Between CAM and OM*

Aakster (1986) made the following five distinctions.

(a) Health

Whereas conventional medicine sees health as an absence of disease, alternative medicine frequently mentions a balance of opposing forces (both external and internal).

(b) Disease

The conventional medicinal interpretation sees disease as a specific, locally defined deviation in organ or tissue structure. CAM practitioners stress many wider

signs, such as body language indicating disruptive forces and/or restorative processes.

(c) Diagnosis

Regular medicine stresses morphological classification based on location and etiology, while alternative interpretations often consider problems of functionality to be diagnostically useful.

(d) Therapy

Conventional medicine often aims to destroy, demolish or surpress the sickening forces, while alternative therapies often aim to strengthen the vitalizing, health-promoting forces. CAM therapies seem particularly hostile to chemical therapies and surgery.

(e) Patient

In much conventional medicine the patient is the passive recipient of external solutions, while in CAM the patient is an active participant in regaining health.

The history, philosophy, and methods of treatment of even the main forms of complementary therapy are extremely diverse. The origins of some, for example acupuncture, are ancient, while osteopathy and homeopathy date from the nineteenth century. Some (acupuncture, homeopathy) are complete systems of medicine, while others are restricted to diagnosis alone (iridology) or to a specific therapeutic technique (massage). The range of treatments is equally varied: diet, plant remedies, needles, miniscule homeopathic doses, mineral and vitamin supplements, and a variety of psychological techniques. The theoretical frameworks and underlying philosophy vary in coherence, complexity, and the degree to which they could be incorporated in current scientific medicine.

Complementary practitioners vary enormously in their attitude to orthodox medicine, the extent of their training, and their desire for professional recognition. However, there are within this diversity, some broad common themes: a vitalistic philosophy embracing the idea of an underlying energy or vital force; a belief that the body is self-healing, and so a respect for minimal interventions; general, all-encompassing theories of disease, and a strong emphasis on the prevention of disease and the attainment of positive health. While in much conventional medicine the patient is the passive recipient of external solutions, in complementary medicine the patient is more likely to be an active participant in regaining health (Vincent and Furnham 1997).

2. *The Popularity of CAM*

Surveys indicate that between 1986 and 1991 the proportion of the British population using CAM increased by 70 percent (British Medical Association 1993, Fulder and Munro 1985). A similar trend has also been noted in other parts of Europe as well as Australia and New Zealand. The same trend has been recorded in the USA. Eisenberg et al. (1998) found, by extrapolating from their survey to the population as a whole, a 47.3 percent increase in total visits to American CAM practitioners from 427 million in 1990 to 629 million in 1997, actually exceeding visits to primary-care physicians.

In Europe, surveys suggest that a third of people have seen a complementary therapist or used complementary remedies in any given year. The popularity of CAM in Europe is growing rapidly. In 1981, 6.4 percent of the Dutch population attended a therapist or doctor providing CAM, and this increased to 9.1 percent by 1985 and 15.7 percent in 1990. The use of homeopathy, the most popular form of complementary therapy in France, rose from 16 percent of the population in 1982 to 29 percent in 1987 and 36 percent in 1992.

CAM includes a wide range of therapeutic practices and diagnostic systems that stand separate from, or in some cases opposed to, conventional scientifically based modern medicine. Working definitions of CAM often rest on the fact that complementary medicines do not exert their legitimacy with reference to scientific claims and empirical regularity. Many types of CAM work within their own philosophical paradigms using alternative models to explain health and illness and thus often remain resistant to testing within the biomedical paradigm in order to prove their effectiveness (Vincent and Furnham 1997).

A British Medical Association report (1986) listed 116 different types of complementary therapy and diagnostic aids. It is possible to classify the specialties along a number of dimensions: their history; the extent to which they have been professionalized; whether or not they involve touch; and the range and type of disorders/problems they supposedly cure. The list of recognized CAM therapies continually grows.

3. *Different Perspectives on CAM*

Gray (1998, p. 55) argues that 'the topic of unconventional therapies can no longer be ignored or marginalized because, for better or worse, each seriously ill person cannot help but be confronted with choices about their possible usage.' He believes there are currently four quite different and debatable perspectives on complementary medicine. The 'Biomedicine perspective' which is concerned with the curing of disease and the control of symptoms where the physician-scientist is a technician applying high level skills to physiological problems. This approach is antagonistic toward and skeptical of CAM, believing many claims to be fraudulent and many practitioners unscrupulous. Physicians and medical scientists within this camp often believe CAM patients are naïve, anxious, and neurotic. However, the competitive health care market place has seen a shift even in the attitudes of 'hardliners' to being more interested in, and sympathetic to, unconventional therapies.

The 'Complementary perspective,' though extremely varied, those with this perspective do share certain ideas, such as: (a) rating the importance of

domains other than the physical for understanding health; (b) viewing diseases as symptomatic of underlying systemic problems; (c) a reliance on clinical experience to guide practice; and (d) a cogent critique of the limits of the biomedical approach. Interventions at the psychological, social, and spiritual level are all thought to be relevant and important, supporting the idea of a biopsychosocial model. Many advocates of this perspective believe the body has powerful natural healing mechanisms that need to be activated. They are critical of biomedicine's harsh and often unsuccessful treatments, especially with cancer. They attack biomedicine for not having most of its own interventions based on 'solid scientific evidence.'

The 'Progressive perspective' is prepared to support either of the biomedicine or complementary perspectives, mentioned previously, depending on the scientific evidence in favor. They are hardened empiricists who believe it is possible to integrate the best of biomedicine and unconventional approaches. Like all other researchers their approach is not value free—the advocates of this approach welcome the scientific testing of all sorts of unconventional therapies.

The 'Postmodern perspective' enjoys challenging those with absolute faith in science, reason, and technology, and deconstructing traditional ideas of progress. Followers are distrustful of, and cynical toward, science, medicine, the legal system, and institutionalized religion, and even parliamentary democracy. Postmodernists abandon all worldviews and see truth as a socially and politically constructed issue. Many believe orthodox practitioners to be totalitarian persecutors of unconventional medicine. They rejoice in, and welcome multiple perspectives and 'finding one's own voice.' However, because many CAM practitioners can be theoretically convinced of their position and uncompromising, they can also be subject to postmodern skepticism. Proponents of this position argue: (a) to have a complementary perspective in any debate is healthy; (b) that CAM practitioners are also connected to particular economic and theoretical interests; (c) that the variety of values and criteria for assessing success is beneficial; and (d) that the ill people themselves should be the final arbitrators of the success of the therapy.

4. *Research into CAM*

The use of alternative models, which seem incompatible with the scientific model, is one of the main sources of controversy. The effectiveness of a medicine is usually assessed using double-blind randomized-controlled trials (RCT) to prove its efficacy beyond a placebo effect (nonspecific healing mechanism) (Ernst et al. 1997). However, scientific criteria often fail to validate complementary medicines in terms of reliable and predictable outcomes, which have withstood rigorous clinical trials. Although some clinical studies do provide strong evidence for the effectiveness of some complementary therapies, the evidence is not always enough to prove their efficacy. Some have questioned the methodology of these studies, others suggest a revision of the biomedical paradigm, and most recognize this area of research is in need of more attention and resources.

Despite the lack of conclusive evidence for the efficacy of CAM, it undoubtedly remains perceived as effective, indicated by the high levels of consumer satisfaction. The efficacy of complementary medicine from a biomedical point of view, and from a lay person's point of view is, to a very large extent, two different matters. Hence research interest into the perceived efficacy of CAM and OM by members of the general public.

Furnham and Vincent (2000) have argued that there are two fundamental scientific questions concerning CAM: first, does it work? Second, why do people choose it? The first question is concerned with the quality and quantity of disinterested evidence that CAM therapies cure or 'manage' physical and psychological illnesses by the processes and mechanisms they maintain (and not by placebo effects). Second, if the evidence is limited and highly equivocal, why do so many people seek it out and pay for it?

Because of the expense and difficulty of doing scientifically satisfactory research to answer the former question, much more attention has been paid to why patients choose CAM. Various specific hypotheses have been tested, some to do with the pull of CAM (health beliefs and circumstances) and some with the push of OM (dissatisfaction with GPs). Sociologists have stressed the importance of post-modernist beliefs (reflexivity), consumer and patient rights, and holistic movements to explain the attraction of CAM. Economists have tried to account for it in terms of costs to patients, doctors, and health insurance companies. Psychologists and psychiatrists have preferred interpersonal and intrapsychic explanations while medical practitioners have focused on the flight from science beliefs as well as the benefits of longer consultations.

The growth in the USA of CAM has been paralleled by an increase in multidisciplinary research in the area. The whole question of scientific proof, as well as the pathways to care and cure, certainly merits good interdisciplinary and international research.

Alternative Media

The designation 'alternative' is vague because it covers so many different formats and only defines these media by their difference from others. The definition used here is of small-scale, politically radical media, occupying a technological spectrum from fliers to the Web, from video to graffiti, from political song to satirical cartoons. Much of what follows will offer an historical and international survey of their roles. The review will conclude by very briefly considering the relation of these media to mainstream media, the relation between them and social movements, and the argument that they are significant in any sociological approach to media.

1. Alternative Media in History and Across the Planet

As contrasted with typical dismissal of this category of media as evanescent, petty, and ultimately irrelevant, reflection on their long and varied history in many nations and situations suggests quite otherwise. Consideration of their roles will be divided in what follows into (a) the Protestant Reformation, the English Civil War, and the American and French revolutions; (b) the US abolitionist, suffragist and labor movements; (c) Leninist political movements; (d) *samizdat* and Western shortwave radio in the later decades of the former Soviet bloc; (e) rightwing extremist alternative media; (f) 'nonmedia' alternative communication forms; and (g) the energetic attempts by state and religious authorities to suppress alternative media.

1.1 From the Reformation to the French Revolution

Martin Luther's 95 theses are only the best known example today of the 'pamphlet war' that raged in some German territories in the early 1500s. His was certainly not the most radical; one Leipzig printer, Hans Hergot, was executed for his 1527 pamphlet urging that land be held in common. But following upon the printing of the vernacular Bible, these pamphlets, many (though not all) urging religious change, played a considerable part in extending and strengthening movements of opposition to papal authority.

In the English Civil War of the 1640s, the subversive influence of the vernacular Bible and its empowerment of popular readings of the scriptures could be seen in the flood of publications by Ranters, Levelers, Diggers and other movements that claimed divine authority for their revolution against common land enclosures, despotic royal power, and Cromwell's repression. The overthrow of the monarchy and the establishment of a republic that lasted over a decade, the only one in the last 1000 years of British history, were partial echoes of these upsurges. But the media dimension of these movements was central to their impact.

In the US revolution, not only Tom Paine's famous *Common Sense* pamphlet attacking 'the Royal Brute of Great Britain,' but also a plethora of others, made their contribution to the Declaration of Independence and its armed defense. As in the German Pamphlet War, the publications took both sides in the conflict, but those that expressed the new voice of the colonists had the advantage of freshness and anger.

In the buildup to the French revolution, similarly, radical print publications played a very visible role. In order to escape the censor and the monarchy's police agents, their printing often took place just outside France's borders and then the works themselves were smuggled into the country. The content was antimonarchical and often anticlerical, sometimes expressed in ribald satirical depictions of those in power.

1.2 Media of the Abolitionist, Suffragist and Labor Movements

Focusing on the nineteenth century USA, the roles of media in these three highly influential movements are conspicuous. The earliest instances of abolitionist media were generally autobiographies of formerly enslaved Africans, either escapees or freedmen, quite often former mariners whose occupation had given them scope to travel, even in some cases to independent

Haiti. This experience both enabled them to understand the Atlantic economic and political nexus, and permitted a more wide ranging communication with fellow Africans than was the rule in the Americas. Later, escapee Frederick Douglas' autobiography and the newspaper he edited, *The Northern Star*, also played a very significant role. While many other economic and political factors played their role in tandem, these alternative media exercised considerable agency in consolidating determined opposition to the institution of slavery.

The suffragist movement, beginning from the 1848 Seneca Falls convention, made consistent use of pamphlets, tracts, cartoons, and other media to propagate its cause. While some of the cartoons and some of the propaganda romanticized the civilizing impact that women's suffrage would have upon the polity, this does not detract from their political significance. Temperance movements, for example, often connected to suffragist campaigns, gave women a sense of authority and commonality that both fitted with their supposed role as exemplars of morality and enabled them to escape the mutual segregation often entailed by domesticity. Meanwhile, as Virginia Woolf once put it, it was more and more the case that 'the middle class woman began to write,' a further mediatic step in the direction of emancipation.

The labor movement was the third great matrix of alternative media in the nineteenth century. In its earlier decades, pro-labor newspapers were part of the general hubbub of a fiercely partisan press in Philadelphia, New York and other emergent industrial centers. They were sidelined during the middle of the century by the emergence of the penny newspaper and the costs of the rotary press, but then the great labor migrations from Europe of the 1880s through to the 1920s generated a huge new alternative print sector. This partly reflected the ethnic and linguistic composition of the new labor force, but a significant part simultaneously gave voice to labor's political aspirations. For the most part the English language labor press by the end of the century represented skilled labor aristocrats, often conservative in their defense of their status, while the foreign language press expressed the perspectives of the newcomers, quite often socialist or anarchist in outlook.

1.3 Leninist Political Movements of the Twentieth Century

For much of the twentieth century, especially in nations convulsed by political strife such as Russia, China, Vietnam, India, and Indonesia, but beginning in Russia, the Leninist model of alternative media has held extraordinary sway. Effectively a model devised originally to outwit and defeat the Tsar's secret police and informer network, it became for many decades the 'scientific' procedure to organize effective oppositional media (and, in nations that experienced a Communist regime, a postrevolution media template as well).

The essential character of the Leninist media strategy was one in which alternative media were purely the transmission belt for the Communist Party leadership to diffuse its views downwards and outwards. These views might be on revolutionary tactics and strategy, on current political crises, on the global economy, on literature, in as much as Marxism always had totalizing pretensions. The notion of such media forming a general public forum in which different political viewpoints could be assigned the same moral status, was absolutely foreign to this vision. The more open the procedures, the more 'liberal' the debate, the more tactical political confusion would reign and the more vulnerable would be the newspaper's distributors and editors to police raids, exile and imprisonment.

It has to be said that this vision of alternative media as an organizational weapon was a remarkably effective survival strategy in highly polarized and repressive situations. It also helped lend Leninist political groups a hard-headed image that, faced with the menace of fascism, say, seemed tremendously attractive in contrast to endlessly debating 'academic' circles. Paradoxically, in sovietized Poland, Catholic parishes ran similarly tightly hierarchical parish organizations, for fear that more open ones would lend themselves to infiltration by the secret police. The tragic impact of Leninist media lay overwhelmingly in their perpetuation after state power had been grasped.

1.4 Samizdat and Clandestine Radio in the Collapse of Soviet Power

Samizdat literally means 'self-published' and begins to make more sense if we contrast it with the standard printed notice in any Soviet book, magazine or newspaper. This notice read '*gosizdat*,' state-published. In that tiny change of letters was concealed a radical switch of realities, the assertion of citizens' right to create their own media independently of Soviet control.

This was not an easy, or safe, process. Not easy, because even the simplest reproductive print machines such as typewriters, and later photocopiers, were licensed by the state. Typing paper was hard to come by, and large purchases, if they could be made, attracted unwanted police attention. It was also unsafe, because while legally up to nine carbon-paper copies were allowed to be made of any document, the Soviet penal code had many other clauses that gave the KGB, the political police, every rationale to repress either the author, the reader or the carrier of *samizdat*.

Russian *samizdat* publications began as a desperate response to the 1960s crackdown on Soviet dissidents, and especially after the climactic 1968 Soviet invasion of Czechoslovakia and repression of the Prague reformers. They consisted initially of typed sheets of

paper, with no margins and no blank space. Most people read blurry carbon copies. The price for being allowed to read one was to agree to retype it with another nine copies. Hardly a designer's dream, but they were generally snapped up eagerly because there was nothing else except *gosizdat*. The bulk were either nationalist—i.e., from Ukraine and the other (then) Soviet republics—or religious in character, sometimes both. The *samizdat* best known outside the USSR, though, was mostly secular and non-nationalist, dealing with other banned topics, or permitted topics in banned ways.

The second phase of *samizdat* came in the shape of whole books printed outside the USSR and smuggled back (*tamizdat*), and in forbidden cassette tapes, first audio and later video (*magnitizdat*). The audiotapes were particularly easy to hide, and the most popular in this phase reproduced the banned lyrics of Russia's dissident guitar poets.

The third phase was the expansion of *samizdat* in Eastern European Soviet bloc countries. Especially in Poland, the most populous and restive nation in the bloc, with its huge Solidarity labor movement of the 1980s, these underground media were very prevalent, despite all the government's attempts to repress them. Even when in panic in 1981 the government declared martial law, jailed many activists, and tracked down a lot of underground printing equipment, the production of *samizdat* continued regardless. By the mid-1980s, with the Gorbachev reform faction in charge in Moscow, bloody repression receded without retiring altogether, and conditions matured for Poles once again to assert themselves against Soviet domination. On the northern Polish border was Lithuania, historically united with Poland, which became the first republic to break away from the USSR. The steady spread of Polish *samizdat* media and the growth of independence expression in both nations was clearly linked, and bore fruit in Poland's election of its first postwar non-Communist government in 1989, and Lithuania's secession in 1991. The mighty Soviet empire buckled, and while once again, many economic and other factors played their part, *samizdat* media were intimately interwoven in the process.

Equally involved were the West's shortwave radio stations, the BBC World Service, Voice of America, Deutsche Welle, Radio Liberty and Radio Free Europe. Not only did 'the voices,' as they were known, supply alternative news whenever the Soviet bloc did not jam them, they also broadcast *samizdat* writings, thus making them available outside the major cities where typically their distribution was most concentrated. This amplification was extremely important.

1.5 Rightwing Extremist Alternative Media

Inclusion of these media is not for some abstract political balance. It is to underscore the sociological prevalence and power of small-scale radical media. Here the focus will be on the USA, but such media are very well known in Europe, not only in the early phases of those fascist movements that later came to power in Italy, Germany and elsewhere, but also in the second half of the twentieth century after the defeat of fascism.

In the USA, however, while Father Coughlin and Gerald Smithwere noted antisemitic and antilabor radio propagandists in the 1930s and 1940s, the second half of the century saw a large expansion in rightwing extremist alternative media. Initially in the 1950s this was a response to the slow but real advance of civil rights legislation, and was organized by the Klu Klux Klan and similar bodies. By the 1980s they were among the earliest users of the Internet for internal communication and propaganda.

As time went by, white supremacist voices found themselves not the only alternative media activists on the extremist right. The growth of the Christian Right in the 1970s, in part sharing supremacist views, but with a series of fundamentalist religious and moral priorities as well (such as total opposition to abortion rights), widely expressed itself in radio and not long afterwards on television as well. By the mid-1990s, around 10 percent of US radio stations were broadcasting Christian Right programming. Televangelism became a burgeoning profession.

Close on their heels in the 1980s were those sometimes self-described as militia or patriot groups, frequently but not universally white supremacist, antisemitic and anti-immigrant, and possessed of a pathological paranoia and hatred of government institutions beyond the county level. They frequently were convinced that a One World Government, managed by the UN, had already infiltrated the US government and was on the edge of supplanting it. They justified their obsession with arming themselves to the teeth, on occasion attacking and killing local law enforcement officers, and even going so far as to blow up a Federal building in Oklahoma City, by reference to their inalienable rights as citizens guaranteed by the miraculously donated US constitution. They often used shortwave radio for communicating their poison, afraid that Internet use would enable the authorities to track them down.

Assessing the influence of these alternative media depends very much on an evaluation of the general relation between them and the more mainstream conservative Right. Mutual interdictions and contempt do not necessarily tell us very much. Weber observed how, among religious groups, those closest to each others' sectarian beliefs are often the most ready to spy betrayal of some fundamental principle. Furthermore, with the growth of the conservative Right in general and the decline of the organized Left in the last two decades of the twentieth century, any attempt to pin down an unchanging anchor point in the political spectrum by which this relationship could

be assessed seems incognizant of this secular trend toward more conservative positions. However, the closer the practical links between various conservative vantage points, the more likely are we to see the impact of rightwing extremist media in public policy.

1.6 'Nonmedia' Alternative Communication Forms

These comprise a huge array. Graffiti, murals, posters, street theatre, dance, political song, sermons, dress, lapel-pins, festivals, street demonstrations, strikes, building-occupations, funeral parades, hunger-strikes, internet flaming, and the array of semi-covert resistance tactics that political scientist (James C. Scott 1985) once termed 'the weapons of the weak' are all part of this compendium. It is important to understand their effective interaction with more conventionally 'mediatic' alternative media. In practice, opposition expresses itself culturally by all the means it can, as the full story of the Iranian revolution of the late 1970s shows very clearly (Sreberny-Mohammadi and Mohammadi 1994).

1.7 Why Do State and Religious Authorities Seek to Suppress Alternative Media?

The question is a reasonable one, since this is indeed a very familiar pattern. The answer can only be that they fear them. This then raises a further, perhaps paradoxical question: is their fear based upon paranoia, or reason? If the former, then the conventional dismissal of alternative media as of trivial import seems to have some underpinning. If however paranoia is implausible on such a widely diffused scale, then a reverse conclusion suggests itself, namely that such media may indeed be of much more significance than researchers have often ascribed them. Perhaps, for all their combined unattractiveness, Soviet conservatives and diehard Southern US white supremacists were not stupid: they knew their respective systems rested on minute and absolute compliance, and that tinkering with them was akin to the little Dutch boy of legend removing his fist from the hole in the dyke.

2. Mainstream Media and Alternative Media

Here again, the dividing lines are blurry. Where would city culture newspapers with a critical edge, such as New York's *Village Voice*, an increasingly common genre in the 1980s and 1990s, fit? What should be made of reporters who run stories in alternative media under a pseudonym because their own editors have refused to carry them? How should a newspaper be defined that begins on the radical left and then moves over to the political center, such as France's *Libération*? How should the 'accidental midwife' role be evaluated, of radical free radio stations in Italy and France in the 1970s in forcing legislative changes that, in the 1980s, opened up broadcasting to major corporations? What of a mainstream newspaper that regularly carries material made available to it by an extreme conservative foundation?

These are some of the questions of definition that make a strictly binary categorization of alternative and mainstream media difficult, and thus complicate the analysis of their inter-relation. One reading is that alternative media of the left often receive the news first, especially in politically charged situations, and effectively do the job that mainstream journalists are theoretically supposed to do. Another is that they create a lively public sphere, in Habermas' sense (see Jürgen Habermas 1989) something that in the days of a fiercely partisan press used to be quite common but is now rare in the corporate media universe.

3. Alternative Media and Social Movements

Many alternative media cannot be understood unless related to the social movement of which they are a part, or to which they are antagonistic. Social movements of many kinds both give life to such media and are often given life by them. In the nascent phase of a movement, radical small-scale media may be very influential in maintaining focus and stimulating debate among many of the movement's future leaders. During the movement's apogee, such media are often close to being its lifeblood, updating, mobilizing, debating, exposing, and ridiculing. In the aftermath, such media—not necessarily or even usually the same ones—provide scope for reflection and regroupment.

4. Alternative Media as Key Components of the Mediascape

Returning to the question of alternative media as trivial or significant, three arguments present themselves in favor of their importance. One is quite simply their historical and current ubiquity at important junctures. Second, alternative media are widely recognized to play a vital role in organizing and consolidating social movements. Social movements often have limited access to mainstream media and, operating outside of well-established institutional frameworks, depend on alternative media for their organization and coordination. The third relates to social memory. The more ephemeral the media, the argument runs, the less their impact. However, we may conclude differently, that many of these short-

lived small-scale media make a particularly explosive dent in the political culture of the moment. In this, their mnemonic function is arguably different from mainstream media, whose power consists in sedimenting stable definitional frameworks over time within which the interpretation of society and social change takes place. Both operations, which might be likened to the brilliantly colored tropical fish and to the coral reef, are sociologically significant.

Altruism and Prosocial Behavior, Sociology of

Two basic questions will be addressed in this article. One deals with the very essence of human nature, and essentially lies within the domain of philosophy: Does altruism exist? The other is an empirical social science question: How does one understand, predict, and explain positive other-oriented social action?

1. Does Altruism Exist?

Modern social science is founded mainly on the assumption that animals, including humans, are primarily motivated by egoism, that is, that each organism's basic drives involve satisfying its own needs and desires. The recognition of the importance of self-interest in human motivation goes back at least as far as the writings of Plato in the Western philosophical tradition. Various forms of this assumption are found in economic theory (e.g., classical economics), psychology (Freud's pleasure principle, Thorndike's law of effect), in social psychology (exchange theory), and in sociology (functionalism). At the dawn of the twenty-first century, the purest expression of this assumption is found in rational choice theory.

Yet many thinkers have resisted accepting the idea that all human action is selfishly motivated. Plato and Aristotle struggled to understand the source of concern for the other that is present in friendship. Even near the time of Hobbes' classic *Leviathan*, Rousseau, Hume, and Adam Smith raised doubts that egoism was the only human motivation (see Batson 1991). Smith, for example, wrote: 'How selfish soever man may be supposed, there are evidently some principles in his nature, which interest him in the fortune of others, and render their happiness necessary to him, though he derives nothing from it except the pleasure of seeing it' ([1759] 1853, I.i.1.1).

1.1 Conceptualizing Altruism

Many different definitions have been offered for the term 'altruism.' Comte, who coined the term, defined it as an unselfish desire to 'live for others' (Comte 1875, p. 556). Social psychologists have proposed that

altruism consists of helping actions carried out without the anticipation of rewards from external sources (Macaulay and Berkowitz 1970), while others suggest that altruistic helpers must incur some cost for their actions (e.g., Krebs 1982, Wispé 1978). Note in both the focus on consequences for the helper rather than on inner motivation. Batson (1991) has proposed instead that altruism be defined by the individual's motivations: 'Altruism is a motivational state with the ultimate goal of increasing another's welfare' (p. 6).

Batson's definition makes it impossible to study altruism in nonhuman species. Sober and Wilson (1998) recognized the need to make a distinction between two types of altruism, 'evolutionary altruism' and 'psychological altruism.'

The concepts of psychological egoism and altruism concern the motives that people have for acting as they do. The act of helping others does not count as (psychologically) altruistic unless the actor thinks of the welfare of others as an ultimate goal. In contrast, the evolutionary concept concerns the effects of behavior on survival and reproduction. Individuals who increase the fitness of others at the expense of their own fitness are (evolutionary) altruists, regardless of how, or even whether, they think or feel about the action (Sober and Wilson 1998, p. 6).

They stress that, 'Even if we restrict our attention to organisms that *do* have minds, we need to see that there is no one-to-one connection between egoistic and altruistic psychological motives on the one hand and selfish and altruistic fitness consequences on the other' (p. 202). They conclude:

> The take-home message is that every motive can be assessed from two quite different angles. The fact that a motive produces a behavior that is evolutionarily selfish or altruistic does not settle whether the motive is psychologically egoistic or altruistic (p. 205).

Sober and Wilson (1998) do however propose that 'an ultimate concern for the welfare of others is among the psychological mechanisms that evolved to motivate adaptive behavior' (p. 7). They believe that both egoistic and altruistic tendencies are adaptive for survival.

1.2 Evidence for the Existence of Evolutionary Altruism

Researchers have now demonstrated mathematically (Boorman and Leavitt 1980) and by means of computer simulations (Morgan 1985) that genes for evolutionary altruism can evolve and become established in populations, through one of three mechanisms. Group selection can operate if the presence of some altruists in an isolated, endogamous group leads that entire group to survive better than groups without altruists. Kin selection operates if an altruist is more likely to save kin, whose genes are shared with the altruist and thus are more likely to survive and multiply. Finally, reciprocity selection works through a mechanism in which altruists are more likely to benefit each other, even if they are not related. Such a mechanism requires that bearers of altruistic genes be able to recognize each other—presumably through observation of past behavior. Sober and Wilson (1998, pp. 149–54) also devote considerable space to the discussion of group selection of cultural practices—such as social norms—as an alternative 'evolutionary' mechanism not involving genetic transmission by which altruistic behaviors can become established in social groups.

A strong argument has been made for empathy as the prime candidate for the inherited capacity underlying psychological altruism. At least five studies going back to 1923 have demonstrated that infants as young as a few hours old are more likely to cry at the sound of another infant's cry than at the sound of equally loud and annoying noises (Martin and Clark 1982). In addition, Matthews et al. (1981) and Rushton et al. (1986), using twin methods, found significant heritability of scores on self-report scales of altruism.

1.3 Evidence for the Existence of Psychological Altruism

Sober and Wilson (1998) discuss the difficulty both of defining what psychological altruism is and of demonstrating that it exists. If an egoistic goal is defined as 'anything one wants' one has defined altruism out of existence. If, however, altruism is defined as having irreducible preferences that the welfare of another be enhanced, it is possible to demonstrate its existence. Within social psychology, Daniel Batson has tried to demonstrate that one *can* find what Sober and Wilson (1998, pp. 245–8) call 'A over E' (other over self) pluralism: that there are some people who some of the time will choose the welfare of others over their own. Batson believes this happens when they feel empathy for the other: the 'empathy–altruism hypothesis.' For over 20 years Batson has waged academic war with several other social psychologists who espouse more egoistic models. He sets his theory against the arousal/cost-reward model of Piliavin et al. (1981), which assumes that observing another's problem arouses feelings of distress and helping alleviates those feelings, and the negative-state relief model (e.g., Cialdini et al. 1987). Cialdini assumes that children learn during socialization that helping others makes them feel good and that helping is thus motivated by hedonism. The war has been fought in a series of experimental skirmishes, summarized in Batson (1991). It appears that the rather modest goal has been achieved: some people, some of the time, do help out of altruism.

2. Determinants of Prosocial Behavior

Whether or not there are innate tendencies to care about the welfare of others, people do engage in

helpful behaviors. Two terms are commonly used in the literature. 'Prosocial behavior' means any actions, 'defined by society as generally beneficial to other people and to the ongoing political system' (Piliavin et al. 1981, p. 4). This can include paying taxes, doing volunteer work, cooperating with classmates to solve a problem, giving directions on the street, or intervening in a crime. Even acts normally deemed criminal can be prosocial in context, for example, taking medicines from a drugstore destroyed by a hurricane if needed for victims of the storm. 'Helping behavior' refers to 'an action that has the consequences of providing some benefit to or improving the well-being of another person' (Schroeder et al. 1995, p. 16). Actions from which one can also benefit (such as cooperating) are not included.

How is variation in prosocial behavior to be understood? Following the Lewinian equation $B = f(P, E)$, it is assumed that prosocial behavior is jointly determined by characteristics of the person and the environment. Thus, how individual differences in prosocial tendencies arise is first examined, and then how those tendencies combine with situational factors to influence helping behavior.

2.1 The Development of Prosocial Behavior Tendencies

Hoffman (1990) believes that, initially, infants cannot differentiate self from other, and feel only 'global empathy'; what happens to others is felt as happening to them. Starting at around a year, infants can differentiate self from others, but assume that others in distress feel exactly what they would feel. By age two or three, they not only understand that others can feel something different, but that a different response may be needed. By late childhood, children can experience empathy in response to knowledge of a person's situation, without observing the distress. Zahn-Waxler et al. (1992) provide observational evidence consistent with this theorizing regarding the early stages, and Aronfreed (1970) presents evidence regarding the learning of empathy by older children.

Cialdini et al. (1982) present a stage theory in which, in the presocialization stage (before 10), children do not know that others value helping, and will help only if asked. In the second stage, awareness, they learn that there are norms about helping, and that they can be rewarded for it, so they help in order to please. By around age 15, internalization occurs; helping becomes intrinsically satisfying. Some research supports these theories, which are consistent with research by Kohlberg (1985) regarding the development of moral reasoning. Moral reasoning, like helping, is initially based on external factors; as the child matures, decisions become based on inner motivations.

Social learning theory also informs research on the process by which children develop prosocial behavior patterns. The use of direct rewards and punishments (power assertion) and love withdrawal have been found to be less effective for the development of prosocial behavior than induction, that is, reasoning with the child. Observational learning is undoubtedly more important than direct teaching; both models who are physically present and those presented in the mass media can have significant effects. 'Preaching' altruism also has some effect, as does attributing altruistic motives to the child. Prosocial socialization can continue through adulthood, and attributional processes can be important. The 'foot-in-the-door' technique— asking a small favor and then returning to ask a larger one (e.g., Freedman and Fraser 1966)—is thought to have its effect through self-attribution. Similarly, regular participation in volunteer work leads individuals to internalize the role of helper.

The relative importance of personality and situational factors differs depending upon the kind of helping. Episodic helping—responsiveness to a request or to the perception of a sudden need—is more influenced by the situation. Sustained helping, such as volunteering, is more influenced by socialization factors and by habits, values, and personality. Interactions between personality and situational factors have also been found. Schroeder et al. (1995) present a detailed discussion of the factors influencing the various forms of helping behavior.

2.2 Determinants of Episodic Helping

Most of the empirical research on helping has used experimental methodology to study situations in which someone has a sudden need for help. Factors such as clarity and urgency of the need, the race, sex, age, or handicap of the 'victim,' how many potential helpers are present, and the relationship of victim and subject are manipulated. Latané and Darley (1970) propose that the bystander goes through a five step decision process: (a) noticing something happening, (b) deciding help is needed, (c) deciding whether one personally has a responsibility to intervene, (d) choosing a course of action, and (e) executing the plan. They consistently find that the more bystanders, the lower the likelihood that any one of them will intervene (the 'diffusion of responsibility' effect). This effect can occur at two points in the decision process. If other bystanders are visible, their actions can define whether the situation requires help (step b); if they are not visible, the knowledge that they could help can influence attribution of responsibility (step c).

Others (e.g., Piliavin et al. 1981) propose that part of the decision process involves calculating the costs to bystander and victim of intervening and not intervening. The nature of the emergency, relationship to the victim, and other situational factors enter into such calculations. The bystander's personality, background, and training can also have effects, and there can be interactions of personal and situational factors.

Wilson (1976) found that safety-oriented individuals were less likely to intervene in a perceived emergency than were esteem-oriented individuals; this difference was much greater when other bystanders were present.

2.3 Determinants of Sustained Prosocial Behaviors

Only recently have investigators seriously focused on long-term, planned helping behaviors such as blood donation, charitable giving, and volunteering for nonprofit organizations. *Voluntary Sector* has carried out surveys of charitable donation and volunteering in the USA every two years since 1988. Thus much is known descriptively about participants: They are mainly white, middle class, and express altruistic motives for their actions.

Three approaches to studying long-term helping have emerged in social psychology: attempts to find 'the altruistic personality,' explorations of the functions served by volunteering, and analyses based on the concept of role identity. After an extensive investigation of gentiles who saved Jews from the Holocaust, Oliner and Oliner (1988) proposed several personality characteristics that separate them from those who did not. Penner (e.g., Penner and Finkelstein 1998) developed a personality measure with two dimensions: other-oriented empathy (feelings of responsibility and concern about others' well-being) and helpfulness (a self-reported history of helping). Both measures distinguish volunteers from nonvolunteers, and both are related to length of service in an HIV/PWA organization and to organizational citizenship (doing optional things at work that benefit the organization).

Snyder and colleagues (e.g., Clary et al. 1998) assume that altruism is only one of many motivations behind volunteering. They measure six potential motives: enhancement (to increase self-esteem), career (to increase success in one's profession), social (to enhance friendships), values (to express who one is), protective (to escape from one's troubles), and understanding (to learn about the world). They show that these motives are relatively stable over time, people with different motives are persuaded by parallel types of appeals (e.g., people high in social motives positively evaluate social appeals), and when experiences match motives, volunteers are more satisfied.

A more sociological approach, guided by Mead's (1934) conception of roles as patterns of social acts framed by a community and recognized as distinct social objects, emphasizes helping as role behavior. A series of studies of blood donors (Piliavin and Callero 1991) demonstrate that internalization of the blood donor role is more strongly associated with a history of blood donation than are personal and social norms. More research shows similar effects for identities tied to volunteering time and giving money (Grube and Piliavin 2000, Lee et al. 1999).

Finally, there are macrosociological approaches to the study of long-term helping behaviors. For example, Wilson and Musick (1997) have presented data in support of a model using both social and cultural capital as predictors of involvement in both formal and informal volunteering. Social structure also influences the distribution of resources that may be necessary for certain helping relationships. One needs money to be able to donate to a charity and medical expertise to be able to help earthquake victims.

2.4 Cross-cultural Research

Little systematic research compares helping across cultures. Beginning in the 1970s, researchers compared helping in rural and urban areas, consistently finding that helping strangers (although not kin) is more likely in less dense areas around the world. In a real sense, then, urban and rural areas appear to have different 'cultures': Small towns are more communal or collective, while cities are more individualistic. A recent review (Ting and Piliavin 2000) examined this and many other cross-cultural studies, not only of the helping of strangers but also on the development of moral reasoning, socialization of prosocial behavior, and participation in 'civil society.' Although more collective societies generally show up as 'nicer' than individualistic societies in these comparisons, these cultures also differ in the pattern of helping. More help is provided to ingroup members than strangers in most societies, but the difference between the amount of help offered to ingroup and outgroup members is greater in communal societies.

2.5 Civil Society

Although most social scientists are still skeptical of the existence of 'pure altruism,' most serious researchers agree that some of the people some of the time consider the needs of others in decision making. Game theorists have discovered that in repeated prisoner's dilemma games and public goods problems, individuals consistently behave in more co-operative or altruistic ways than expected, and some do so more than others (Liebrand 1986). Economists and political scientists, who have long believed that all motivation is selfish, have come to grips with evidence on voting and public goods behavior which indicates that this is not true (Mansbridge 1990, Clark 1998).

J. A. Piliavin

Altruism and Self-interest

Altruism was first used circa 1853 by Auguste Comte. French *altruisme*—another; Italian *Altrui*—somebody else, what is another's; Latin *alteri huic*—to this other.

1. Definition

Altruism is behavior intended to benefit another, even when this action risks possible sacrifice to the welfare

of the actor. There are several critical aspects to altruism. (a) Altruism must entail action. Good intentions or well meaning thoughts do not constitute altruism. (b) The action is goal-directed, although this may be either conscious or reflexive. (c) The goal must be to further the welfare of another. If another's welfare is merely an unintended or secondary consequence of behavior designed primarily to further the actor's own welfare, the act is not altruistic. (d) Intentions count more than consequences. If John tries to do something nice for Barbara, and it ends up badly or with long-term negative consequences for Barbara, this does not diminish the altruism of John's initial action. Motivation and intent are critical, even though motives and intent are difficult to establish, observe, and measure objectively. (e) Altruism carries some possibility of diminution in the actor's own welfare. An act that improves both the altruist's own welfare and that of another person would be considered collective welfare, not altruism. (f) Altruism sets no conditions; its purpose is to further the welfare of another person or group, without anticipation of reward for the altruist.

Analysts often introduce various conceptual subtleties into this basic definition. We might refer to the above definition as pure altruism, and distinguish it from what could be called particularistic altruism, defined as altruism limited to particular people or groups deemed worthy because of special characteristics such a shared ethnicity, religion, or family membership (Wispé 1978).

In discussing altruism, analysts often use the term interchangeably with giving, sharing, cooperating, helping, and different forms of other-directed or prosocial behavior. The problem then becomes to recognize and allow for the subtle variations in altruism while retaining the simplicity of the single term. To solve this problem, analysts often refer to acts that exhibit some, but not all, of the defining characteristics of altruism as quasialtruistic behavior. This distinction allows us to differentiate between the many acts frequently confused with altruism (such as sharing or giving) without having to lump these significant deviations from self-interest into a catch-all category of altruism (Bar-Tal 1976, Derlaga and Brzelak 1982).

Analysts also frequently further conceptualize behavior along a continuum, with pure self-interest and pure altruism as the two poles and modal or normal behavior, including quasialtruistic acts, distributed between them. This approach avoids the problem of dichotomizing behavior into only altruistic or self-interested acts. It minimizes the confusion resulting from excessive terminological intricacies. Yet it retains the advantage of allowing us to discuss quasialtruistic acts or limited versions of altruism (such as the particularistic altruism discussed above) that would be provided for by more complex definitional terminology.

2. *What Causes Altruism?*

Analysts offer a wide range of explanations, from innate predispositions to socialization and tangible rewards. The best analyses of altruism consider more than one explanatory variable, and many of the underlying influences on altruism are frequently referred to by different names, depending on the discipline or the analyst (Kohn 1990).

Thomas Hobbes, for example, suggested an explanation for altruism that emanates not from genuine concern for the needy person but rather from the so-called altruist's personal discomfort at seeing someone else in pain (Losco 1986). Economists designate such altruism a form of 'psychic utility'; psychologists identify the same general phenomenon but refer to it as 'aversive personal distress created by arousal.' This problem presents two problems for the reader. (a) Analysts refer to the same—or to vastly similar—concepts using different terminology. These terminological differences vary, more or less systematically, from discipline to discipline; in any given analysis, they may reflect deliberate choices based on important philosophical orientations toward understanding behavior or, conversely, may merely be conventionally and uncritically adopted. (b) For purposes of analysis we need to separate predictors of altruism into distinct components in order to clarify and understand their relative influences. But in reality, these various influences often blend together and are far less distinct than our analysis suggests.

Given these caveats, it is fair to say that explanations of altruism tend to cluster into four analytical categories: sociocultural, economic, biological, and psychological.

2.1 *Sociocultural Explanations*

These focus on the individual demographic correlates of altruism. These range from religion, gender, and family background to wealth, occupation, education, or political views. The basic assumption underlying sociocultural explanations is that belonging to a particular sector of the population will predispose one toward altruism. Women are frequently said to be more altruistic than men, presumably because of genetic or socialization factors. Living in a small, close-knit community or being a member of a large, communal family is also frequently cited as encouraging altruism (Oliner et al. 1992).

2.2 *Economic Explanations*

While some economists dismiss altruism as the result of an odd utility function, most economists now tend to consider altruism a good and stress the importance

of rewards for altruism. These rewards may be material (money) or psychological (praise, honors, or simply feeling good about oneself) but are always expressed in some implicit basic economic calculus in which individual costs and benefits are entered. This leads to explanations in which altruism becomes a short-term strategy designed to obtain later goods for the altruist, through reciprocated benevolent behavior or alleviation of guilt. In reciprocal altruism, for example, John gives to Mary today in the hope that she may do something nice for him tomorrow. In participation altruism, Mary wants to be the one to give to John, as opposed to Mary's simply wanting John to benefit from anyone's altruism. Economists also explain altruism through the concept of dual utilities, in which altruism is a balancing act between John's individual self-interested utility and his other-directed utility function, or resource altruism, a variant of the dual utilities explanation in which altruism is treated as a luxury good to be indulged in once the actor has obtained his more basic self-interested needs (Margolis 1982).

The central concept underpinning all economic analyses is the idea that people think in terms of costs and benefits, and that altruism can be explained through such an economic analysis (Phelps 1975).

2.3 Evolutionary Biology

Biology is built on the Darwinian concept of individual selection and survival of the fittest. Acts in which one organism takes steps to promote the survival of another organism violates this individual selection principle. Thus, altruism presents a particular challenge to evolutionary biologists. Many biologists simply write off altruism as aberrant behavior, which eventually will disappear. Those biologists who do take altruism seriously tend to explain it through explanations that favor kin or group selection (Trivers 1971).

In kin selection, the gene, not the organism, is designated the critical unit. A selfish gene then may decide to further its likelihood of survival through foregoing the host organism's ability to propagate. Mary thus may decide not to marry since her sister has already married and Mary realizes that there will be too many offspring to survive in conditions of scarcity. Mary's sacrifice as a person willing to forego the pleasure of having children, however, actually helps further the survival of the genes Mary shares with her sister, and thus the gene is said to be selfish.

Group selectionists make a similar argument but designate the group the critical unit. They argue that groups containing a few altruists do better than groups with no altruists, since the altruists may sacrifice themselves for the good of the group. It is thus in the group's interest in the long run to protect and encourage altruism. (Tax incentives for charitable contributions are a form of this.)

Such biological analyses rely heavily on in-group/out-group distinctions and on the importance of clusters or networks of altruists who are tolerated and even protected, not for themselves but rather because their altruism benefits the group that contains them. Community size is said to encourage such altruism, as are networks or clusters of altruists, in which the mere existence and visibility of a group of altruists may influence a person to engage in similarly altruistic behavior, either through sanctions or rewards.

2.4 Psychology

Psychology offers the richest and most varied analyses of altruism. Psychologists frequently consider developmental factors such as socialization or child-rearing practices and the level of sociocognitive development. Unlike economists and biologists, psychologists allow directly for norms, usually by assuming that these are values internalized through socialization and development and are at least partially cognitive in construction (Rushton and Sorrentino 1981). Culture plays an important influence insofar as these values and norms are reinforced by the society at large. But psychologists also allow for more personal construction of values by the individual (Krebs 1982).

Psychologists frequently include some of the same factors considered by other analysts, such as reciprocity (the exchange of benefits) and often build these values into complex systems of moral judgment. Characteristics of the specific situation, including the identity of the recipient, the anonymity of the helper, and the number and identity of observers of the altruistic act, play critical roles in the emergence of altruistic behavior for psychologists (Latané and Darley 1970).

Psychological discussions, and their counterparts in philosophy, touch on the category of explanation that may be most promising (Staub et al. 1984). These works emphasize empathy, views of oneself and of the world, expectations, and identity (Batson 1991, Batson and Shaw 1991, Eisenberg and Strayer 1987). They include the cognitive and emotional bases of altruism and introduce the impact of culture via the psychological process of reasoning that leads to altruism (Oliner et al. 1992). When these factors come together in a particular way, they are said to constitute what is referred to as the altruistic personality, in which the habit of giving to others becomes so ingrained in a person that the habit becomes part of the person's personality (Oliner and Oliner 1988), or the altruistic perspective, in which the fact that the actor does, or does not, see a bond between himself and the recipient of the altruistic act, becomes critical (Monroe 1996).

This emphasis on a common humanity may provide the link with biological explanations, where there is shared genetic material, or religious explanations, in which shared membership is emphasized.

3. Importance of Altruism

Although altruism is empirically rare, its mere existence can inspire and better the world. The ordinary people who risked their lives to rescue Jews during the Holocaust help restore our hope in humanity, just as Gandhi and Mother Teresa inspire us with their acts.

Beyond this, altruism is important since its very existence challenges the widespread and dominant belief that it is natural for people to pursue individual self-interest. Indeed, much important social and political theory suggests altruism should not exist at all. It thus becomes important to consider altruism not merely to understand and explain the phenomenon itself but also to determine what its continuing existence reveals about limitations in the Western intellectual canon, limitations evident in politics and economics since Machiavelli and Hobbes, in biology since Darwin, and in psychology since Freud.

Alzheimer's Disease: Antidementive Drugs

1. Introduction

Alzheimer's disease (AD) is associated with degeneration of cholinergic neurons in the basal forebrain. The resulting cholinergic deficit appears to be correlated to a certain degree with the severity of cognitive impairments, resulting in the choline-deficit hypothesis of AD (Withehouse et al. 1982, Becker and Giacobini 1988). Although it is evident that several other neurotransmitters are also involved in the pathogenesis, cholinomimetic drugs represent the only therapeutic approach with proven efficacy in mild to moderate probable AD patients (as defined by NINCDS–ADRDA (National Institute of Neurological and Communicative Disorders; Stroke/Alzheimer's Disease and Related Disorders Association) criteria (McKhann et al. 1984), Mini-Mental State Examination (MMSE, Folstein et al. 1975; usually scores of 10–26) and Clinical Dementia Rating (CDR, Hughes et al. 1982; usually 1–2). In particular, cholinesterase inhibitors (AChEI) have proven effective in stabilizing cognitive and behavioral symptoms of AD in well-designed, double-blind, placebo-controlled, clinical studies involving approximately 10,000 patients worldwide (Giacobini 2000). Tacrine, the first AChEI approved by the US Food and Drug Administration (FDA), was introduced on to the market in 1993. Its use remained limited, due to an asymptomatic elevation of liver enzymes in over a quarter of treated patients and a high frequency of cholinergic side effects. Nevertheless, tacrine prompted the development of the so-called second-generation AChEI (donepezil, rivastigmine, galantamine) that are devoid of hepatic toxicity, comparable in efficacy, and display

Table 1
Acetylcholinesterase inhibitors

Drug	Tradename	Molecule	Mechanism of action	Approval (3/2001)
Donepezil	Aricept®	Piperidine	Reversible/specific AChE > BChE	FDA, EMEA 1996
Eptastigmine	—	Carbamate	Reversible AChEI	—
Galantamine	Reminyl®	Alkaloid	Reversible/specific AChE > BChE and nicotinic receptor modulator	EMEA 2000, FDA 2001
Metrifonate	—	Dichlorvos	Pseudoirreversible AChEI	—
Physostigmine	—	Tertiary amine	Reversible/nonselective AChEI	—
Rivastigmine	Exelon®	Carbamate	Pseudoirreversible AChEI	CH 1997, EMEA 1998, FDA 2000
Tacrine	Cognex®	Acridine derivative	Reversible/nonspecific BChE > AChEI	FDA, EMEA 1993

a better risk–benefit ratio (Giacobini 1998, 2000). From eight AChEI that have been studied for use in AD, three are currently in clinical use: donepezil, rivastigmine, as well as galantamine are registered in the United States and Europe (Table 1).

2. *Efficacy*

Controlled clinical trials used standardized and validated scales as outcome measures for cognitive (Alzheimer's Disease Assessment Scale-cognitive scale, ADAS-cog, Rosen et al. 1984; Mini-Mental State Examination, MMSE, Folstein et al. 1975) and behavioral symptoms (e.g. Neuropsychiatric Inventory, NPI, Cummings et al. 1994) as well as activities of daily living or global clinical functioning (e.g. Clinician-Based Impression of Change, CIBIC; Reisberg et al. 1997). For all AChEI that are currently on the market, significant beneficial effects on various cognitive domains and behavioral function have been shown compared to placebo (Knapp et al. 1994, Ringman and Cummings 1999, Rogers et al. 1998, Wilcock 2000). The effects, however, are limited in terms of quantity and time. AD progression in mild to moderate stages of the disease (CDR stages 1–2) is assumed at a rate of approximately nine points per year on the 70 points ADAS-cog scale. According to Giacobini (2000), under current treatment conditions, AChEI may yield a maximal effect of ~ 3.6 points (ADAS-cog) compared to placebo, with an average 1.2 point difference at the end of those studies that lasted 26–30 weeks. This effect size appears to be modest and similar for all second-generation AChEI (Small et al. 1997, Giacobini 2000). Differences in clinical efficacy between the AChEI may be due to the fact that, at least for some drugs, the dose increase to reach sufficient inhibition of acetylcholinesterase of approximately 50 percent may not be achieved due to side effects.

Although most controlled clinical studies lasted only six months, open-label follow-up studies added evidence suggesting that AChEI treatment may stabilize cognitive and behavioral functioning for up to 12 months or even longer. Indeed, measures of both basic and instrumental activities of daily living tend to reach significance after 12 months of treatment, rather than after six months (Summers et al. 1996, Raskind et al. 2000). Open-label long-term studies of up to two years have shown improved activities of daily living (ADL), behavioral functioning, and social integration, suggesting that patients may profit from a long-term treatment of up to two years (Knapp et al. 1994, Morris et al. 1998, Rogers and Friedhoff 1998, Wilcock et al. 2000). Taken together, there is a growing body of evidence suggesting that the early start of treatment with a AChEI that is sustained for a longer period of time in standard dosage may yield the best results in terms of preserving functional ability. Whether tolerance to these drugs occurs during long-term administration is not known.

The percentage of patients which obviously benefit from AChEI treatment ('responders,' e.g. ADAS-cog $\geqslant 4$ points) varies from 25 percent (low-dosed rivastigmine) to 60 percent (high-dose tacrine, donepezil, galantamine) (Giocabini 2000). There are considerable interindividual variations in the degree of response: 5–10 percent of the patients show superior improvement compared to the other patients ('responder-type'), with a relevant impact on cognition, behavioral functioning, and social integration. Ten to fifteen percent of all treated patients do not improve on the ADAS-cog with any tested AChEI. The factors that influence response are not fully understood. Cholinergic brain deficit vs. other neurotransmitter imbalances, gender, APOE-4 status, or presence of other polymorphisms may play a role.

In addition to the cognitive benefit in terms of stabilization for up to 1–2 years, treatment with AChEI may have a positive socioeconomic impact, as Knopman et al. (1999) have shown that institutionalization can be delayed for up to one year. Furthermore, a reduction of caregiver burden was reported (Wimo et al. 1998; see *Gender Identity Disorders*).

3. Side Effects

Generally AChEI are well tolerated and the majority of adverse effects can be attributed to their cholinergic properties. The incidence of cholinergic side effects is dose-related and varies among the different drugs.

Adverse effects were highest in tacrine and 55 percent of the patients withdrew from the study because of adverse events vs. 11 percent of patients treated with placebo (Knapp et al. 1994). The primary reasons for withdrawal of tacrine-treated patients were asymptomatic liver transaminase elevations (28 percent) and gastrointestinal complaints (16 percent) (Knapp et al. 1994). The proportion who discontinued treatment with rivastigmine because of adverse events was significantly higher in the higher dose group (6–12 mg day^{-1}) than in the lower dose (1–4 mg day^{-1}) or placebo groups (23 percent (55/242) vs. 7 percent (18/242) and 7 percent (16/239)) (Rösler et al. 1999). Treatment discontinuation rates because of adverse events appeared to be similar between donepezil at 5 mg day^{-1} and placebo (about 4–9 percent vs. 1–10 percent) but greater with donepezil 10 mg day^{-1} (9–18 percent) compared with placebo (Dooley and Lamb 2000). Discontinuations due to adverse events occurred in 23 percent (24 mg day^{-1}) and 32 percent (32 mg day^{-1}) in galantamine treated patients (Raskind et al. 2000).

Cholinergic side effects were usually mild, transient in nature, and could be reduced by careful titration of the doses at the beginning of treatment. Most observed side effects (> 5 percent of patients) comprised the gastrointestinal system (nausea, vomiting, diarrhea, anorexia), the central nervous system (agitation, dizziness, insomnia, fatigue), and to a lesser degree peripheral symptoms like muscle cramps. The incidence of serious adverse events in the studies was not greater than in placebo (Giacobini 2000). However, some compounds derived from carbamates, such as eptastigmine, were withdrawn from clinical studies because of potential hematotoxicity. Although benefits measured by the ADAS-cog are very similar among the different drugs, there are, however, relevant differences in terms of the side effect ratio (Table 2) which may be related to the fact that the currently used compounds represent a chemically very heterogeneous group (see *Psychopharmacotherapy: Side Effects*).

4. Tacrine

Tacrine (tetrahydroaminoacridine, Cognex®), a non-selective, reversible AChEI, was FDA approved in 1993 and was the first drug on the market for the treatment of AD. With a 5.9 percent benefit vs. placebo in ADAS-cog, tacrine demonstrated the strongest acute effect on cognition compared to other AChEI during treatment of 30 weeks (Giacobini 2000). This has been attributed to additional pharmacological properties of the drug like blockade of potassium channels, inhibition of monoamine uptake, and inhibition of the monoamine oxidase (Jossan et al. 1992). Tacrine treatment appeared to delay nursing home placement for up to one year (Knopman et al. 1999). Its use, however, has been limited due to asymptomatic elevation of serum aminotransferase and a high incidence of cholinergic side effects of up to 58 percent. The most frequent observed adverse events were alanine aminotransferase elevation three times above normal in 29 percent of treated patients, nausea and vomiting in 28 percent, diarrhea in 14 percent, dyspepsia or anorexia in 9 percent, and myalgia in 7.5 percent (Wagstaff and McTavish 1994). In practice,

Table 2
Characteristics of selected acetylcholinesterase inhibitors

	Donepezil	Galantamine	Rivastigmine	Tacrine
Half-life (~ h)	70	6	1.5	2–4
Administration	oral, once/day	oral, bid	oral, bid	oral, 4 times/day
Study	Rogers et al. 1996	Tariot et al. 2000	Rösler et al. 1999	Knapp et al. 1994
Weeks	24	26	26	30
Dose (mg/d)	5–10	16–24	6–12	120–160
Treatment difference (percent) vs. Placebo (ADAS-cog, (observed cases analysis)	3.1	4.7–5.1	2.6	5.9
Patients improved (percent) (ADAS-cog ⩾ 4 points)	38–54	36–37	24	30–50
Discontinuation (percent) due to adverse events	9–18	6–10	23	55
Most common adverse events (percent)	Nausea 17	Nausea 13–17	Nausea 50	ASAT-Elevation 29/54
	Diarrhea 17	Vomiting 6–10	Vomiting 34	Nausea and/or Vomiting 35
	Vomiting 10	Diarrhea 7–9	Dizziness 20	Diarrhea 18

the unfavorable side effect profile which made liver enzyme monitoring necessary because of potential hepatotoxicity and the inconvenience of the four-times-a-day administration limited compliance and efficacy. Since second-generation AChEI have entered the market, tacrine is no longer in clinical use.

5. *Donepezil*

Donepezil (E2020, Aricept®), a reversible, CNS-selective piperidine AChEI, was the first second-generation AChEI and was FDA approved for use in 1996. Donepezil has minimal peripheral cholinesterase inhibiting activity and a long plasma half-life (70 h), allowing for once a day administration. Donepezil treatment during 24 weeks resulted in a 4.1 percent benefit vs. placebo in ADAS-cog (Giacobini 2000). Long-term efficacy data suggested that benefits in cognition and global functioning were maintained for about 21–81 weeks (Rogers and Friedhoff 1998). Donepezil was well tolerated. The most frequent adverse effects in the 10 mg day^{-1} group were nausea 22 percent, followed by diarrhea 17 percent, insomnia 18 percent, vomiting 10 percent, fatigue 8 percent, and muscle cramps 8 percent. Because of proven efficacy and a favorable side-effect profile, donepezil was considered a first-line treatment in AD (Small et al. 1997) and is widely used in patients with mild to moderate stages of the disease (Dooley and Lamb 2000) in Europe and the US.

6. *Rivastigmine*

Rivastigmine (ENA 713, Exelon®) is a relatively selective pseudoirreversible inhibitor of acetylcholinesterase with a short half-life of 1 hour and 10-hour duration of action. Studies showed a dose-dependent improvement of the ADAS-cog by 5.4 percent in a 26-week treatment trial (Giacobini 2000). The high-dose regime (6–12 mg day^{-1}) showed better effects on cognition than the 1–4 mg day^{-1} regime, but was associated with increased nausea (50 percent of treated patients) and vomiting (34 percent) (Rösler et al. 1999). Other adverse effects during treatment with 6–12 mg day^{-1} were dizziness (20 percent), headache (19 percent), and diarrhea (17 percent) (Rösler et al. 1999). Due to the short half-life it is usually administered twice a day. Rivastigmine adds to donepezil as another first-line treatment and was approved in several European countries and in the US (Spencer and Noble 1998, Rösler et al. 1999).

7. *Galantamine*

Galantamine is a natural, tertiary amarylidacea alkaloid originally isolated from the bulbs of snowdrop and Narcissus species. Recently, a synthetic version of the reversible competitive AChEI has been developed. A 'dual action' has been claimed because galantamine modulates presynaptic nicotinic receptors in addition to its AChE inhibiting properties (Fulton and Benfield 1996). Galantamin showed comparable efficacy to other AChEI (Tariot et al. 2000, Wilcock et al. 2000). The treatment effect of 24 mg day^{-1} compared to placebo was 3.9 points on the ADAS-cog/11 scale after six months (Raskind et al. 2000). Lilienfeld and Gaens (2000) reported a significant reduction of caregiver burden as evaluated by questionnaires following galantamine treatment. Reduction of time spent assisting the patient in ADL functions was calculated to be about one hour per day in comparison to placebo. Galantamine was well tolerated. As previously observed with the other AChEI, there is a dose-dependent increase of efficacy and of study dropouts due to side effects. Most of the side effects were predictably cholinergic and may be avoided by starting at a low dose and escalating the dose slowly. Among the adverse events during treatment with 24 mg day^{-1} were nausea (37.7 percent), vomiting (20.8 percent), dizziness (13.7 percent), and diarrhea (12.3 percent) (Raskind et al. 2000). Most of the side effects were predictably cholinergic and may be avoided by starting at a low dose and escalating dose slowly (in 4 weeks), as demonstrated by Tariot et al. (2000). Among the adverse effects during treatment with 24 mg day^{-1} were nausea (16.5 perceent), vomiting (9.9 percent), and diarrhea (5.5 percent). Galantamine adds to the treatment repertoire as another first-line treatment among the AchEI and was approved in European countries and in the US.

8. *Future Therapeutic Strategies*

So far, AChEI were investigated in individuals who have reached, in neurochemical and neuropathological terms, advanced stages of the disease. There is no published data regarding the efficacy of AChEI in incipient or severe AD. In the populations thus far studied, cholinomimetic treatments face obvious limitations in terms of effect size and duration of efficacy. Therefore they have to be judged as symptomatic or palliative. It is unknown, however, whether substitution of the cholinergic system is purely symptomatic or, as some authors suggest, yield certain neuroprotective properties (Giacobini 1996). The latter is supported by the fact that the stabilizing effect of AChEI is often maintained for several weeks after termination of the drug. However, significant long-term alterations of the progression of the disease have not been reported.

In summary, although of limited efficacy, the class of AChEIs represent the current treatment of choice for mild to moderate AD (Consensus statement: Small et al. 1997). Treatment effects of up to one year were shown in well-designed, controlled clinical studies. Data supporting long-term administration of chol-

inesterase inhibitors is limited to uncontrolled extension trials, but for all AChEI that have been investigated, positive effects on outcome were suggested. Thus, development of the AChEI was an important first step in the treatment of a disease that years ago appeared to be out of reach for pharmacology.

Novel treatment strategies that are currently developed address central histopathological features of AD, such as the deposition of abnormal proteins in neuritic plaques and neurofibrillary tangles. The amyloid β-peptides (Aβ) are the major constituents of brain amyloid plaques in AD. Lowering the aggregation or the production of Aβ or stimulating amyloid clearance from the brain is currently tested in model systems, e.g., transgenic mouse models or early clinical trials. Lowering Aβ production may be achieved by modulating activities of such key enzymes of amyloid precursor protein (APP) processing as α-, β-, and γ-secretases. Clearing amyloid from the brain may be achieved by means of immunization against Aβ peptides, at least in transgenic mouse models for AD. Such strategies may provide disease modifying or preventive treatments for AD in the future.

Alzheimer's Disease: Behavioral and Social Aspects

Alzheimer's disease (AD) is one of the two most common forms of *dementia* and constitutes a considerable *social problem*. It has a pathological and genetic base but produces progressive disruption of *psychological functioning* with considerable *social consequences*, especially for *carers*. Forms of intervention are being developed which so far show at least some capacity to ameliorate the consequences of the disorder.

1. Background

AD is one of the two most common dementing illnesses; the other being cerebrovascular dementia. Normally associated with *old age*, it can occur earlier although this is extremely rare. Because AD has a slow, insidious onset and can be difficult to differentiate from other dementing disorders, determining *prevalence* is not something that can be done with great reliability. One authoritative estimate indicated prevalence between the ages of 60–69 of 0.3 percent, 70–79 of 3.1 percent and 80–89 of 10.8 percent (Rocca et al. 1991). In common with other prevalence studies of dementia, this shows prevalence to be very small in the lower age ranges but to increase more-or-less exponentially as age advances. Prevalence studies on all dementia forms combined for very old age, which include a large proportion of Alzheimer's disease, found between 22.0 and 58.6 percent demented subjects in the age range of 90–94 years and between 32.0 and 54.6 percent in the age range of 95–99 years (Ritchie and Kildea 1995).

The causes of AD are, as yet, ill understood. It is associated with pathological changes in the brain (Nordberg and Winblad 1996) consisting of atrophy and the occurrence or increased manifestation of certain microscopically identifiable features such as senile plaques and neurofibrillary tangles. Biochemical analyses indicate that several neurotransmitter systems within the brain are affected and these include the cholinergic system. There are also *genetic* influences and relatives of known cases are at increased risk. For the most part, there is no clear pattern of *inheritance* but there are a few well-described families where the pattern of incidence is that of dominant inheritance (Breitner and Folstein 1984).

Certain things follow from the above. The fact that neurotransmitter systems may be involved raises the possibility of developing pharmacological treatments that may slow down or even arrest the progress of AD. A second point is that the definitive diagnosis of AD can only be done by postmortem examination of the brain. This is partly why getting accurate prevalence figures is difficult but also explains why many authorities refer to 'dementia Alzheimer type' or 'senile dementia Alzheimer type.'

AD is a slowly progressive condition that also reduces life expectancy. It has many psychological and social consequences and it is these that form the main concern of this article.

2 Psychological Manifestations

As is the case with most dementing disorders, the psychological manifestations of AD are very varied and affect almost all aspects of functioning.

2.1 Cognitive Abilities

The very term 'dementia' implies a loss of cognitive ability and it is hardly surprising that deterioration in a wide range of cognitive functions is apparent in AD. Lapses of *memory* are most commonly the first thing that alerts sufferers, or more typically their family, friends, and colleagues, to the fact that something is going wrong. Sufferers become generally forgetful and their behavior becomes disorganized as a result.

Memory disorder in dementia has been the subject of a considerable amount of research based on various models of memory developed by cognitive psychologists (Morris 1996). *Explicit memory* or the ability to acquire and remember specific items of information (e.g., the fact that a computer password is 'Victoria') has been explored in detail. A common theme running through this work is that those with AD have particular difficulty in processing incoming information and laying down new memory traces based on that information. In contrast and at least in the earlier stages, recollection of material from the distant past remains relatively well preserved.

Another aspect of memory is *implicit memory* or the ability to acquire and remember rather more general skills such as the ability to ride a bicycle. This appears relatively well preserved in AD as exemplified by the ability to learn and retain motor skills such as the pursuit rotor task. One interesting form of implicit memory task is known as '*priming*.' In priming experiments, the occurrence of a stimulus on one occasion is found to influence a second and unrelated task carried out some time later.

Participants may be presented with a list of words such as 'elephant' and 'garage' and asked to make a judgment about these words (e.g., the attractiveness of the object referred to by the word). Some time later, participants are asked to do an apparently unrelated task in which given sets of letters such as 'ELE' are presented and are asked to give a word beginning with the same letters. Normal groups are then more likely to respond with 'elephant' as compared to other possible responses such as 'element' given that the interval between the two tasks is not too great.

This phenomenon of priming is also manifested in certain groups with severe *amnesias* (such as the alcoholic *Korsakoff syndrome*) despite their extremely poor performance if asked to simply recall the words given in the first part of the task. Studies of priming in AD have given more variable results but often there is impaired priming. Whatever this means, it does indicate that there is possibly something different in the memory impairment of AD as compared to other forms of severe amnesia.

Many other aspects of cognitive functioning also deteriorate in AD (Miller and Morris 1993, Morris 1996). One aspect that merits brief comment is *language*. The first manifestation of problems with language is often a difficulty in word finding. As the condition progresses speech becomes increasingly impoverished and the ability to understand language, whether spoken or written, deteriorates.

2.2 Other Psychological Manifestations

There are also psychological changes that do not fall into the cognitive arena. A range of *psychiatric* phenomena can emerge (Miller and Morris 1993). Many people with AD are depressed and some psychotic symptoms such as hallucinations and delusions may occur. *Behavior disturbances* can also arise and it has been estimated that about a fifth will show aggression and aimless wandering. *Sexual disinhibition* is a relatively infrequent feature but raises considerable problems for carers when it does arise.

3 Social Aspects

In common with the other dementias, AD affects not only the immediate sufferer but has a wider social impact for family, friends, and the community (Miller and Morris 1993, Wilcock 1993) as well as economic implications (Wimo et al. 1998).

3.1 Impact on Carers

In most countries, the majority of people with AD and other forms of dementia are living in the community. The main burden of care, therefore, falls on relatives (usually the spouse or child). The burden of care is considerable in that carers typically report that they are unable to leave sufferers alone other than very briefly. Sufferers wander round the house, cannot hold a sensible conversation, are unsteady on their feet, and so on. Although incontinence can be a major problem, it fortunately does not usually arise until relatively late in the illness.

There is ample evidence that caring for someone with dementia results in considerable strain and distress. As far as measures of psychological distress and psychiatric symptomatology are concerned, carers typically emerge less well than comparable control groups, particularly in terms of levels of *depression*. There are also some indications that the physical health of carers can be adversely affected.

3.2 Factors Influencing Carer Well-being

It has been shown that the level of *stress or strain* in carers is not necessarily related to the degree of behavioral disturbance or physical incapacity in the sufferer although the indications are that the altered relationship with the sufferer is often a bigger source of distress than any physical burdens.

Carer distress is influenced by the quality of the past relationship with the sufferer. Where this has been high with a close, intimate relationship, carer distress and depression is lower. Another factor is gender in that it is a common finding that male carers fare better than female in terms of levels of strain and depression. Just why this should be the case is not clear. It may be the case that male carers attract more external support.

But it also may be that male carers are better able to distance themselves from the emotional aspects of the situation and adopt a practical and instrumental approach to the problems of caring. This latter form of coping style tends to be associated with lower levels of distress and depression. Finally, social support from outside the immediate household setting can be important but here it appears to be the case that the quality of support rather than its quantity is the key factor.

4 *Intervention and Management*

As indicated above, the identification of disturbed neurotransmitter systems in the brains of those with AD opens the way to pharmacological treatments that might retard or even halt the development of symptoms such as memory loss. This has been an active area of research and the development of an effective pharmacological intervention would have implications for those concerned with the psychological and social aspects of the disorder. Progress so far has been very modest but some substances such as tacrine, have been found to achieve small beneficial effects (Nordberg and Winblad 1996).

Despite marked memory impairments, those with quite advanced levels of dementia remain sensitive to environmental influences (Miller and Morris 1993, Woods 1996). In residential units, even such simple measures as grouping chairs in the dayroom round small tables rather than having them lined along the walls, has been found to increase the level of interaction between residents. Various special forms of intervention such as 'reality orientation' and 'reminiscence therapy' have been devised. These are based on discussion and the use of materials in small groups to, respectively, heighten orientation and awareness of the world around or the exploration of things from the time when sufferers were younger in order to contrast with the present. Beneficial changes have been demonstrated but again tend to be modest.

More individually based interventions have been used successfully. For example, behavior modification principles have proved of at least some value in dealing with difficult behavioral problems such as *incontinence* and aimless *wandering*. Whilst the emphasis in work on psychosocial interventions generally has been within group residential settings, some extension of interventions to the community and informal care situations has been made (Miller 1994, Miller and Morris 1993). Manuals are available offering practical advice to carers, of which one example is Hamdy et al. (1997).

E. Miller

Alzheimer's Disease, Neural Basis of

Alzheimer's disease (AD), first described by the physician Alois Alzheimer in 1906, is an insidious progressive neurodegenerative disorder which can be detected clinically only in its final phase. A definitive diagnosis based on antemortem observations is complicated and often deceptive. A major histopathological criterion of AD, and one that is decisive for its post mortem diagnosis, is the assessment of distinctive alterations within the neuronal cytoskeleton, which appear in the form of neurofibrillary tangles in specific subsets of nerve cells of the human brain (see Sect. 1.1). Accompanying pathological alterations which, as a rule, appear later than the aforementioned intra-

neuronal changes, include extracellular deposits of the pathological protein beta-amyloid (see Sect. 1.2) and the formation of neuritic plaques (see Sect. 1.3).

1. The Neurodegenerative Process

1.1 The Intraneuronal Formation of Abnormal Tau Protein

An initial turning point in the degenerative process are pathological alterations of the cytoskeleton, a kind of internal moveable 'scaffolding' occurring in every living cell, which result from the formation of an abnormal (i.e., hyperphosphorylated) tau protein in a few susceptible types of neurons (Goedert et al. 1997, Goedert 1999). In healthy nerve cells the protein tau is one of several specific cellular proteins that is associated with and stabilizes components of the cytoskeleton. The abnormal but soluble material that emerges fills the entire nerve cell. The cell body and the cellular processes of such 'pretangle phase' neurons hardly deviate from their normal shape. In a second series of steps, this material aggregates to form virtually insoluble and nonbiodegradable filaments, the neurofibrillary tangles that are the hallmarks of AD. The latter, which often have a flame or comet-like appearance, gradually fill large portions of the nerve cell and appear black after staining with special silver techniques (Fig. 1a; Braak and Braak 1994, Trojanowski et al. 1995, Esiri et al. 1997). Nerve cells containing neurofibrillary tangles may survive for years despite marked cytoskeletal alterations. They forfeit many of their functional capacities, however, long before premature cell death occurs. After deterioration and disappearance of the parent cell, a cluster of the pathological material remains visible in the surrounding brain tissue as a remnant or so-called 'tombstone' tangle where it marks the site of the neuron's demise (Fig. 1a). The fact that 'tombstone' tangles are never observed in the absence of fresh neurofibrillary tangles accounts for the absence of spontaneous remission in AD patients. In the course of the illness, all of the involved nerve cells proceed through a 'pretangle phase' before developing the nonbiodegradable filaments. The potential for reversibility of the pathological process is most probably at its peak in the 'pretangle phase.'

1.2 The Extracellular Deposition of Abnormal Beta-Amyloid Protein

Among the many ingredients of the fluid filling the small space between brain cells known as the extracellular space are soluble proteins of still unknown function. Some of them probably result from processing of a normal component of nerve cell membranes

Figure 1
The hallmark of AD is precipitation of abnormal proteins in both intraneuronal and extracellular cerebral locations. **a**. The intraneuronal deposits represent the neurofibrillary alterations of the Alzheimer type and include three distinct kinds of lesions: strands of abnormal tau protein located within affected nerve cell bodies (neurofibrillary tangles) and within their dendritic processes (neuropil threads) as well as abnormal fibrous material which accumulates in swollen cellular processes of neuritic plaques. Extracellular 'tombstone' tangles mark the sites at which the parent nerve cells perished. **b.** The plaque-like extracellular deposits are composed chiefly, but not exclusively, of beta-amyloid protein. Depending on the texture of the neuropil (i.e., brain tissue consisting of nerve cell and glial cell cellular processes; see Section 1.2) they occur in different sizes and shapes. Most cortical beta-amyloid deposits evolve as globular structures with or without a condensed core.

called the amyloid precursor protein (APP). Under certain conditions and for reasons that are little understood, abnormal processing of the APP takes place, thereby resulting in the formation of the pathological beta-amyloid protein, a hydrophobic self-aggregating peptide (Selkoe 1994, Beyreuther and Masters 1997, Esiri et al. 1997). It is unclear whether all of the nerve cell types of the human central nervous system contribute to the production of the abnormal protein to the same degree. Within the extracellular space, the beta-amyloid protein eventually builds plaque-like deposits of varying sizes and shapes (Fig. 1(b)). Globular forms predominate in the cerebral cortex and occur preferentially in the cortical layers III and V. Band-like formations are seen in layer I of the cortex, whereas layers II, IV, and VI often are exempt. In the course of the disease, the number of plaques reaches a maximum; yet, even at their greatest extent, a large amount of brain tissue remains free of these deposits. At the present time, there is no clear evidence that deposits of beta-amyloid protein are capable of inducing the formation of neurofibrillary tangles within nerve cells, nor—in contrast to the neurofibrillary pathology in Sect. 1.1—do the beta-

amyloid plaques correlate with the degree of neuronal loss and/or clinical symptoms associated with AD, although intensive research has been devoted to establishing the existence of such connections (Hyman 1997).

1.3 The Appearance and Composition of Neuritic Plaques

Neuritic plaques consist of aggregations of altered glial cells and swollen cellular processes of nerve cells which, in part, contain fibrillary masses of the abnormal tau protein (Fig. 1(a)). Taken together, the various types of glial cells in the brain outnumber nerve cells by a ratio of approximately ten to one: They are the maintenance and repair 'troops,' so to speak, for the neurons. Deposits of beta-amyloid fill the extracellular space within the reaches of neuritic plaques. Neuritic plaques are more patchily distributed than simple beta-amyloid deposits and occur at much lower densities. Factors inducing the formation of neuritic plaques and the circumstances accompanying their disappearance from the tissue are unknown. A few cortical areas remain devoid of neuritic plaques, whereas others display high densities of these lesions quite early in the disease.

2. Developmental Sequence of the Lesional Distribution Pattern of the Intraneuronal Cytoskeletal Alterations

Neurofibrillary tangles develop gradually and nearly bilaterally symmetrically at predisposed sites within the cerebral cortex, thereafter overrunning other cortical sites and select subcortical nuclei. Many neuronal types, cortical areas, and subcortical nuclei remain uninvolved, while others undergo severe damage. This sequence of encroachment is predictable and remarkably consistent across cases, exhibiting little inter patient variability. By pinpointing the locations of the involved neurons and the severity of the lesions, six neuropathological stages in the evolution of the neurofibrillary changes can be differentiated (Braak and Braak 1999, Hyman and Trojanowski 1997).

2.1 Stages I and II

The first neurons to develop the pathology are specific projection cells located in small areas of the medial temporal lobe that are important cortical components of the limbic system. Bilateral structural preservation of these nerve cells is one of the prerequisites for retaining memory and learning capacities. Deposition of beta-amyloid protein is usually absent during development of these initial stages. The negligible to mild destruction still remains below the threshold required for the manifestation of clinical symptoms (see Sect. 2.2). Stages I and II represent the preclinical period of AD (Fig. 2, second line, involved areas are indicated by shading).

Figure 2
Development of neurofibrillary pathology in a total of 3,592 nonselected autopsy cases. In the first line, the relative prevalence of cases devoid of cytoskeletal alterations is shown for various age categories. Neurofibrillary lesions of the Alzheimer type are pathological and by no means normal concomitants of aging. The second, third, and fourth lines are similarly designed so as to show the gradual and sequential appearance of AD-related changes. Some individuals develop the initial lesions surprisingly early in life. Old age in itself is not an indispensable prerequisite for the onset of the neurodegenerative process: AD is an age-related, not an age-dependent disorder (see Braak and Braak 1994).

2.2 Stages III and IV

Subsequently, the lesions reach the hippocampal formation (stage III, and see Sect. 4) and then the

more distant neocortical destinations of the basal temporal lobe (stage IV). The clinical protocols of many individuals at stages III and IV may make reference to mild cognitive impairment (e.g., difficulties solving simple arithmetical or abstract problems), slight short-term memory or recall deficits (lapses of the so-called 'working memory'), and the presence of changes in personality ranging from suspiciousness to irascible or aggressive behavior, apathy, withdrawal, and mild or severe bouts of depression. Because such initial clinical symptoms often become manifest in stages III and IV, these cases can be referred to as clinically incipient AD (Fig. 2, third line, affected areas are marked by shading). In some patients, the appearance of symptoms still is obscured by their individual cognitive reserve capacities that are subject to influence by such factors as synaptic density, age, native acumen, education, head injury, stroke, or the co-occurrence of other neurodegenerative illnesses.

2.3 Stages V and VI

The pathology spreads superolaterally (stage V) and finally breaches the primary neocortical motor and sensory fields (stage VI). With the widespread devastation of the neocortex, patients present with severe dementia (i.e., acquired loss of memory, cognitive faculties, and judgment attended by a gradual dissolution of the personality.) The final stages V and VI correspond to clinically fully-developed AD (Fig. 2, fourth line, appropriate shading indicates the involved cortical areas). These persons become completely incontinent, are unable to dress themselves properly, to speak or recognize persons once familiar to them (spouse or children), and with the passage of time can no longer walk, sit up, or hold up their head unassisted. Increasing rigidity of major joints leads to irreversible contractures of the extremities and immobility. So-called 'primitive' reflexes normally seen only in infants also reappear in the last clinical phases of the illness (Reisberg and Franssen 1999). The period of time which elapses between the onset of clinical symptoms and death averages approximately eight and a half years (Francis et al. 1999).

3. The Relationships Between Age and the Evolutionary Stages of the Cytoskeletal Alterations

The relationships between age and the AD-associated cytoskeletal pathology can be studied by staging large numbers of nonselected brains obtained at autopsy (Braak and Braak 1997): Fig. 2 shows the percentage of cases at the various stages and according to their respective age groups. It illustrates a continuum of the cytoskeletal alterations ranging from the very first tangle-bearing nerve cell (appearing at stage I) to the extensive destruction encountered in fully-developed AD (stage VI).

The figure in the first line shows the prevalence of individuals whose brains remain entirely devoid of neurofibrillary pathology. It is important to note that a certain percentage of individuals, even at a very advanced age, refrain from developing AD-related cytoskeletal alterations (Fig. 2, first line). Neurofibrillary lesions cannot be viewed as normal concomitants of aging, even though their occurrence does in fact become more prevalent with increasing age (Hyman and Trojanowski 1997, Hyman 1998). Rather, neuronal impairment and, ultimately, destruction develop in a cell-type, layer, and area-specific fashion so that the regional pattern of nerve cell loss and atrophy (i.e., volume reduction) (see Sect. 4.1) in AD is not only quantitatively but also qualitatively different from the pattern encountered in normally aging brains.

Considerable interindividual differences exist with respect to the point at which the first neurons containing tangles actually are detectable. Many cases display a startling early onset. Often, initial lesions commence development in persons under 25 years of age, thereby implying that advanced age in itself is not a prerequisite for the development of the neurofibrillary pathology (Fig. 2, second line). The earliest cytoskeletal alterations are perfectly capable of evolving in otherwise healthy and young individuals. Accordingly, the initiation of the pathological process underlying AD is by no means an age-dependent one. Rather, it is typical of this disorder that several decades elapse between the onset of the lesions and phases of the illness in which the damage is extensive and severe enough for clinical symptoms to become apparent. Once begun, however, the destruction of the nerve cells involved progresses unyieldingly. Whether or not the neurodegenerative process underlying AD becomes clinically manifest depends solely on whether a given individual's life span permits it to attain its full expression (Braak and Braak 1997).

4. Imaging Technology and AD

4.1 Structural Imaging

Magnetic Resonance Imaging (MRI) is one of several imaging tools available to radiologists and neurologists for visualizing the blood flow and anatomical structures, including anomalies, of the human brain. Both post mortem and *in vivo* structural neuroimaging with MRI, for instance, reveal the presence of progressive atrophy in the hippocampal formation, an S-shaped or seahorse-shaped anatomical structure located in the medial temporal lobe, across a spectrum of persons suffering from age-related memory and

learning deficits associated with AD (Jack et al. 1992, Jobst et al. 1994). The hippocampal formation is responsible for, among other functions, short-term memory.

The clinical value of structural MRI brain imaging either in (1) persons considered to be at increased risk for developing AD (individuals at stage III with so-called mild cognitive impairment, the harbinger of AD) or in (2) patients with clinically diagnosed early AD, both of which groups exhibit hippocampal formation atrophy, is still purely predictive since the certain diagnosis only can be established histopathologically at autopsy (see opening paragraph). Furthermore, although the hippocampal formation becomes involved in AD relatively early (see Sect. 2.2), it is very difficult to determine *in vivo* whether progressive reductions in tissue volume that are detectable there with MRI (or those in any other given region) accurately reproduce actual nerve cell impairment or loss. This means that the use of *in vivo* MRI for early detection (e.g., in stages I–II) and diagnosis of AD is still limited and not entirely unproblematic without ongoing thorough clinical correlation. Finally, although AD brains in stages V–VI (see Sect. 2.3) generally are accompanied by macroscopically (i.e., gross) detectable ventricular enlargement, atrophy of the cerebral cortex, and a corresponding loss in brain weight, these features do not constitute specific or acknowledged criteria for AD alone.

Nevertheless, the long-range goal of *in vivo* structural MRI remains the development of a routine form of screening that will lead to the earliest possible correlation between stages of the pathology (ideally, in stages I–II while the 'prospective' patients still are just that, i.e., asymptomatic) and the clinical symptoms that emerge in the course of AD. In the meantime, when performed at regular intervals, one possible strength of *in vivo* MRI may reside in its potential not only to screen AD-candidates early but also to enhance the ability of physicians to monitor the clinical course of the disease, thereby assisting patients to preserve the quality of their lives for as long as possible and their families to plan and/or care for them more effectively.

4.2 Functional Imaging

In vivo neuroimaging with MRI makes possible visualization of activated cerebral regions during the performance of specific motor tasks or in response to external sensory stimuli. Functional MRI, however, differs from structural MRI in that the information obtained goes beyond the limits of brain morphology and topography alone. The operative principle behind the technology is that, in response to increased energy demands, blood flow in stimulated cortical regions of healthy persons may be elevated by as much as 20–40 percent and oxygen consumption by 5 percent so that activated brain tissue displays greater MRI signal intensity than nonactivated or insufficiently activated areas. Two additional *in vivo* diagnostic parameters which are measurable by means of a second functional neuroimaging technique, positron emission tomography (PET), are cerebral glucose metabolism and cholinergic neurotransmission: In individuals with mild AD, cortical hypoperfusion (decreased blood flow) can be seen in the regions involved using functional MRI. PET-scanned glucose metabolic rates are lowered in both temporoparietal lobes, and reduced cholinergic activity can be traced bilaterally as well as symmetrically in the cerebral cortex, including the hippocampus, during PET.

The practical aim of functional MRI and PET neuroimaging is the determination of the degree to which neocortical hypoperfusion and hypometabolism correlate with the severity of early AD-associated deficits. Nonetheless, even proponents of functional neuroimaging caution that, insofar as AD involves multiple neuronal systems, it is imperative for clinicians to know where in the brain and at which stages the neurotransmitter-specific cortical pathologies (e.g., cholinergic, serotonergic, GABA-ergic, noradrenergic) develop. Also, and perhaps even more importantly, clinicians need to understand mutual intersystemic implications for the patient's overall prognosis before intervening therapeutically (i.e., pharmacologically) (Francis et al. 1999). Moreover, the same dilemma mentioned in connection with structural imaging applies here as well, namely: The actual extent and severity of nerve cell damage or loss only can be surmised, not necessarily deduced or inferred, based on *in vivo* MRI or PET-detectable regional hypometabolism. Whereas the neurofibrillary pathology in AD very probably correlates with synapse loss, neuronal loss, and the clinical course of the illness, the complex causal interrelationships between the selective vulnerability of specific subsets of nerve cells, neurotransmitter-induced deficits, neurofibrillary tangle and/or beta-amyloid plaque formation, and the clinical picture of AD are only just beginning to come to light.

American Revolution, The

Political philosopher Hannah Arendt wanted to reserve 'revolution' as an analytical term to constellations,

> 'where change occurs in the sense of a new beginning, where violence is used to constitute an altogether different form of government, to bring about the formation of a new body politic, where the liberation from oppression aims at least at the constitution of freedom, can we speak of revolution. …
> (Arendt 1963, p. 28)

Hence for Arendt, the American Revolution was the ideal revolution.

1. *From Resistance to Revolution*

Various acts of Parliament had restricted the colonists' trade since 1651. The stifling effect of this mercantilist policy for over a century is still a matter of debate: the prohibitions have to be weighed against the guaranteed market and the protection by the navy. The fact is that many a frustrated colonial merchant became a smuggler. However, the colonists did not rebel after 1764 against economic hardship because of severe exploitation. The war was fought to keep the future open for the economic development and self-government that many European settlers had experienced for several generations.

The annoying features of trade restrictions existed side-by-side with the strong self-government the English settlers had been allowed to develop, ever since the landowners of Virginia elected their first House of Burgesses in 1619. By the end of the French and Indian War in 1763, elected legislative assemblies balanced the power of the royal and proprietary governors, except in the newly acquired French-speaking colony of 'Canada.' The *de facto* free press mostly took the side of the local group of politicians critical of the governor's powers such as rewarding his supporters with patronage offices. A century and a half of experience with self-government in town meetings, county courts and representative assemblies had created a political class of plantation owners, yeoman farmers, merchants, master artisans, printers and writers, lawyers, clergy, and educators. They and the openness of their circles for 'new men' made the relatively smooth transition to complete self-rule possible, when imperial authority rule was toppled in 1775–76.

The battle cry 'no taxation without representation,' raised in 1764 against the Sugar Act, left room for negotiation. King George III, his Privy Council, ministers, and the majority Whigs in Parliament chose otherwise and enacted the Stamp Act in 1765. Only when organized mobs prevented the sale of the tax stamps by threatening the lives of sales agents appointed by the governor, and when the boycott of goods from England made London merchants suffer a two-thirds loss of their exports to the colonies in 1765–66, did Parliament repeal the Stamp Act. Coordination of this first stage of defying imperial rule was the work of 27 delegates from nine colonial assemblies meeting in

New York in October 1765. They reminded the king that 'it is inseparably essential to the freedom of a people, and the undoubted right of Englishmen, that no taxes be imposed on them but with their own consent, given personally or by their representatives.' From the beginning of the revolutionary discourse, the universalist natural-rights argument ('the freedom of a people') was used to justify rejecting direct taxation from London in addition to the rights the (uncodified) British constitution guaranteed British subjects. How to organize the expression of consent through fair representation on a large scale territories became the fundamental question of American federalism and was to remain a challenge until the ratification of the Constitution in 1788 and beyond. Its solution determined the success of the Revolution.

Repeal of the Stamp Act did not indicate a new pragmatism based on economic assessment and realistic political calculation. Together with the repeal, Parliament reasserted its constitutional power 'to make laws ... to bind the colonies and people of America, subjects of the crown of Great Britain, in all cases whatsoever.' (Declaratory Act, March 18, 1766). The colonial assemblies' assertion of their sole right to tax their voters and the crown's and Parliament's insistence on their all-inclusive power over the colonists clashed and could not exist side-by-side for long. To undermine the status of the colonial legislatures as providers of the governors' salaries, Parliament voted a new set of consumer taxes to fill the coffers of the Board of Trade in order to pay the governors and judges (Townshend duties, 1767). Once again, enough colonial merchants joined the non-importation movement to make the value of goods imported to the colonies from England drop from 2.1 to 1.3 million pounds Sterling in 1768 to 1769; in 1770 Parliament pulled back, but let one symbolic item stand: the duty on tea.

The final stage of escalation from resistance to revolution began when on December 16, 1773, Sons of Liberty dressed as Indian warriors dumped 342 chests of tea from anchored ships into the Boston harbor—the 'Boston tea party' of patriotic lore. (The governor had no constables to intervene.) The organizers behind the rioters wanted to prevent the regular landing of the tea through the customs office, because that would have meant recognizing the 'unconstitutional' duty on the tea and the East India Company's monopoly. After negotiations with Lt. Governor Thomas Hutchinson had failed, they resorted to violence, fully aware of the potential reaction in London. Slightly less violent opposition to the landing and distribution of the symbolically charged tea took place in New York, Philadelphia, and Charleston. Crown and Parliament reacted in May 1774 with the Coercive Acts, renamed by revolutionary propaganda the 'Intolerable Acts': (a) Boston harbor was closed until damages for the tea were paid; (b) crown officials accused of serious crimes could be tried in the UK in order to escape biased local juries; and (c) the position of the governor was greatly strengthened and the town meetings were drastically weakened. Plans to increase the military presence in all colonies could be seen behind the Quartering Act of June 1774 that allowed the billeting of troops in private homes in addition to public buildings and taverns that the Quartering Act of 1765 had permitted. Colonial opinion leaders also perceived the Quebec Act of May, 1774, as a threat to their future liberty, because it guaranteed the 70,000 Francophones cultural autonomy within the empire, i.e., the dominant position of the Catholic hierarchy in civil matters, the legal privileges of the *seigneurs*, and French civil law, were allowed to continue. None of the Anglo-Saxon bulwarks of the free British subject against arbitrary rule, such as an elected assembly and trial by jury were established. Worst of all, Quebec's boundaries were expanded southwestward to the Ohio and Mississippi. Parliament thus crushed with one stroke, the dreams of land speculators in the colonies with charters that left their western boundaries undefined.

Once again the authorities and politicians in London had miscalculated the effect of their measures. They wanted to punish Massachusetts and frighten the other colonies into submission; but they created solidarity expressed by the motto 'United we stand, divided we fall.' The legislatures from New Hampshire to South Carolina—some in illegal, revolutionary session—sent 56 delegates to the first Continental Congress in Philadelphia. On October 14 and 18, 1774, they declared the Coercive Acts and others to be unconstitutional, hence not binding, and called for the non-importation of British goods, the interruption of all exports to British ports, and ending the slave trade. These boycotts went beyond mere passive resistance, because only the threat of violence by self-appointed local 'committees' against disobeying merchants and other opponents made them effective. On February 9, 1775, the House of Lords voted down William Pitt's reconciliatory proposal and Massachusetts was declared to be in a state of rebellion. When Royal troops began marching into the countryside to empty the militia's armories, escalation to organized armed conflict was inevitable. On April 19, 1775, infantry and the farmer militias of Lexington and Concord near Boston clashed, 272 soldiers, and 93 militiamen died. The point of no return was passed. The political networks, that had articulated the colonial interests and led the resistance since 1765, allowed no power vacuum to develop. From May 1775 on, the Second Continental Congress meeting in Philadelphia was recognized as the sole decision-making body to speak for all 12 represented colonies (Georgia's assembly still hesitated). On June 15, 1775, it appointed George Washington general of an army in the making. Throughout the war and ever since, the army obeyed the elected civil authority; there was no room for a *caudillo* to stage his private revolution. Since Quebec and Montreal were of the utmost strategic importance, the Continental

Congress tried unsuccessfully to persuade the province to join the rebellion ('To the Oppressed Inhabitants of Canada,' May 29, 1775). Two military invasions in 1775–76 also failed.

2. *The War for Independence; the Loyalists*

The diplomatic and military situation in Europe at the end of the Seven Years War greatly favored the American cause. Having lost Quebec to Great Britain, France's absolutist ruler and his *conseil d'état* now saw a chance to weaken their adversary as a colonial and naval power, by making him lose his most precious colonies in North America. From 1775 on, a considerable amount of weaponry bought secretly with French public funds and traded for American goods like tobacco was smuggled into American ports. The two treaties of Alliance and of Amity and Commerce only followed in 1778, after the American forces had proven, in October 1777 with the battle of Saratoga in the Hudson valley, that they were worth supporting. Spanish and Dutch vessels also joined, and the war for American independence became an international naval war, as well as a guerrilla war on frontier and Indian territory, and in the more densely settled coastal areas from New York (the headquarters of the British Navy throughout the war) to Savannah. The final scene of the war illustrates the American–French military partnership and the close combination of war by land and by sea: On October 18, 1781, the last British army of 8,000 men under General Cornwallis capitulated in Yorktown on the coast of Southern Virginia. They were besieged by 9,000 Americans under General Washington and 7,800 Frenchmen under General Lafayette, but the trap only snapped shut when the British navy's rescue mission was intercepted by the French West Indian fleet under de Grasse.

The war divided the colonists into active 'Patriots' who joined Washington's troops directly or marched with their militia across state boundaries (which they were not obliged to do), 'Tories' or 'Loyalists' and, probably the largest group, the fence sitters. Exact numbers are not available. Military strategists in London miscalculated when they expected a significant swelling of the Redcoats' ranks by Loyalists; only about 50,000 men joined for more or less brief periods. Between 100,000 and 150,000 civilians fled the war to the peaceful part of British North America or Caribbean colonies or sailed 'home' to England. Over 5,000 of these refugees claimed partly substantial damages from a Royal commission (Breunig 1998, pp. 1–2, 8).

After months of tripartite peace negotiations in Paris, during which the humble republican citizens Benjamin Franklin, John Jay, and John Adams proved their skill as master diplomats in dealing with the advisors to the two most powerful monarchs of Europe, King George III recognized the victorious colonies as 'free, sovereign and independent States' (Treaty of Paris September 3, 1783).

3. *Revolutionary Ideology and Republican Constitutions*

The revolutionary moment in public debate occurred in January of 1776, when the Whig consensus of 1688 as formulated by John Locke evolved into American republicanism. Many colonists now recognized that they would never gain equality of rights within the empire. The advantages of complete independence and republican government were first openly discussed in Thomas Paine's incendiary pamphlet *Common Sense* (January 9, 1776). He broke with the ritualistic praise of the British constitution, demonstrated the absurdity of hereditary monarchy, and argued that the colonists could not be subdued by military force. Hundreds of newspaper articles and pamphlets by anonymous self-styled patriots followed. On July 2, 1776, the year-long power struggle in the assemblies and in the congress of their delegates in Philadelphia was decided with the vote of 12 colonies for independence. Two days later they laid their reasons before 'the opinions of mankind': the king of Great Britain 'has abdicated Government here' by violating the colonists' rights on 21 counts he has proven himself to be a 'Tyrant,' 'unfit to be the ruler of a free People.' The new nation's political creed was based on 'the Laws of Nature and of Nature's God' and was to apply to legitimate government worldwide: 'We hold these truths to be self-evident, that all men are created equal, that they are endowed by their Creator with certain unalienable Rights, that among these are Life, Liberty, and the pursuit of Happiness. That to secure these rights, Governments are instituted among Men, deriving their just powers from the consent of the Governed.' A collective right to revolution is expressed without use of the term: '… whenever any Form of Government becomes destructive of these ends, it is the Right of the People to alter or abolish it.' That the rebelling colonists constituted 'a people' who can claim this right with impunity, is laconically asserted as a result of the King's *de facto* abdication.

The Declaration of Independence was just that, and established no legal norms for citizens to appeal to in a court of law; nor did it prescribe new institutions of government. The new internal order was agreed upon in the written state constitutions that 11 states gave themselves between 1776 and 1780. Alexander Hamilton characterized the new system as 'representative democracy.' In most states a two-chamber legislature elected by male property-owners for one to four years elected the governor from out of their midst. Institutional separation of power and functional cooperation protected the citizen from arbitrary government. So did certain rights of the individual

that had been discussed in English jurists since the Puritan Revolution and were now written into the text of the state constitutions, or in distinct Declarations of Rights. No majority of voters—the 'sovereign' of republican theory of legitimate government—could disregard them. The judges soon enhanced their role by nullifying acts of the legislators because they were 'unconstitutional.' Thus, even before sovereignty had been secured by force of arms, the first American republican or 'democratical' governments had been established at the state level. When the weak single-chamber Congress under the Articles of Confederation proved unable to cope with post-war problems—between the states and with Europe—it was replaced in 1789 by a more effective tripartite, balanced government modeled on the structure of the state governments and adapted to the needs of a federal nation. In 1791, a Declaration of Rights was added in the shape of the first 10 amendments to the Constitution. Federalism was the price for nationhood as defined in 1787, and states' rights encompassed and protected slave holding.

4. Historiography and Public Memory

Because making and preserving the nation were at stake, the Revolution and the War of Secession are the two events that have received by far the greatest attention of professional and lay historians and their different publics. Gordon (1989) assesses the major trends and works and their connections to the authors' intellectual milieu, and contemporary issues ranging from the 'Progressive' historians under the leadership of Charles Beard who emphasized economic interests and class-struggle elements among the colonists themselves to the neo-whig 'consensus' seeking intellectual historians in the1960s and 1970s (Bailyn 1992, Wood 1969) some of whom discovered a new 'republican synthesis' (Shalhope 1990). Others emphasized the influence of English and continental natural and constitutional thinking since Machiavelli (Stourzh 1970). New-left historians searched for patriotic radical roots in the founding period.

The Fourth of July as the supreme national holiday merges mythologizing the Revolution with celebrating successful nation building. Hence in times of national crisis, emotional reminders of the 'Founding Fathers' were meant to have a healing effect on the public mind. A prime example was the oratory on the occasion of the centennial in 1876, which coincided with the final phase of the post-Civil War 'reconstruction' of the union. The bicentennial of the Revolution was celebrated in a series of events from 1975–1983. President Ford and President Carter used acts of public memory from the re-enactment of the first skirmish on the village green of Lexington to the capitulation of the last British army to heal the wounds American national pride had suffered from the Vietnam War, and the constitutional crisis that had culminated in President Nixon's *de facto* impeachment in 1974. A presidential committee tried to coordinate public events and to set the patriotic tone of the public debate. The American Historical Association, the Organization of American Historians, and the Library of Congress organized special symposia and publications and reached out to the press and schools across the land and scholars abroad (*Library of Congress Symposia on the American Revolution*, published since 1972). The hoped for universal appeal of the Founders to 'the opinions of mankind' was appraised in the Library of Congress symposium on *The Impact of the American Revolution Abroad* (Library of Congress, 1976).

American Studies: Culture

American culture has been a subject of continuous interest since the Revolution, when the question of how the newly independent states differed from England became a pressing concern. As an academic field, however, 'American studies' dates back only to the 1930s, when scholars of American history and literature began to develop—first at Yale and Harvard—an interdisciplinary framework for the study of American culture. In its early incarnation, American studies privileged literary analysis and the history of ideas as a means of understanding national character and culture. Since the 1960s, American studies has incorporated other traditions, subjects, and methods of inquiry—especially from the social sciences—which have moved it beyond its humanistic origins, although that early constellation of themes continues to exercise considerable influence. This diversity—some would say fragmentation—reflects an array of challenges to the concept of a singular and unified American culture. Increasingly, American studies serves less as a distinct field of inquiry than as an umbrella term for a range of topics and approaches that are only nominally and often contentiously organized by the concept of national culture.

1. *National Culture*

National culture is the pivotal and, in Wilfred Gallie's phrase, 'essentially contested' concept that until recently underwrote nearly all inquiry in this area. Did the United States have a national culture? If so, how could it be characterized? Answers to these questions tracked a number of important changes in the meaning of national identity and culture in the nineteenth and twentieth centuries.

Two general considerations are important in specifying how culture, especially, was understood in these circumstances and how it differed from other concepts that informed the study of national life—most prominently, society, civilization, history and politics. Since the early nineteenth century, culture has been conceived primarily as a realm of spirit, expression, character, or mind. In William Wordsworth's Romantic formulation, culture was the 'embodied spirit of a People'; in Ruth Benedict's classic anthropological definition it was a 'pattern of values.' Many scholars have commented on the shift from a humanistic definition of culture that privileged artistic expression (Wordsworth) to the anthropological view that emphasized culture as a complete and integrated 'way of life' or system of meaning (Benedict). With remarkable consistency, however, both paradigms distinguished culture from 'society,' understood as the actual practices and systemic relationships among individuals, groups, and institutions. Society, not culture, moreover, has most often been identified with processes of modernization—especially commerce, industrialization and the democratic leveling of social distinctions. This opposition has underwritten a long tradition of using culture as a basis for critiquing society. In the complicated sense introduced by early nineteenth century German Romanticism and Historicism, culture is both a bedrock of national 'character' that underlies society *and* a means of transcending society through expressions of 'high' culture—quintessentially art. Much the same relationship pertains to politics and history, for which culture sometimes served as an explanatory backdrop and sometimes as a refuge, means of escape, or vehicle for redemptive hopes. Culture has had an equally ambivalent relationship to the concept of 'civilization'—perhaps the most common interpretive framework for the study of the national experience before World War II. Studies of American civilization were generally structured around a belief in the progress of the nation as a collective historical project—one that embraced existing ways of life, history, and national achievements on the world stage. These tended to reproduce the distinction between society and culture, but could also recuperate that distinction, as in Lewis Mumford's seminal cultural history, *The Golden Day* (1926), which held the 'material fact' of civilization to be inextricable from the 'spiritual form' of culture.

The second consideration is that, since the early nineteenth century, the concept of culture has been shaped by both universalist and nationalist tendencies. From early use in reference to the cultivation of land, Enlightenment thinkers gradually appropriated the term to designate the broad, relatively unified field of human knowledge, as well as individual acquisition of that knowledge. In principle, culture was the labor and the product of all humankind, reflecting the Enlightenment's faith in the universality of knowledge—above all in the natural sciences and medicine, but with comparatively little difficulty extended to philosophy, law, art, and literature. This universalism is visible not only in the elitist view of culture as contained in the highest examples of human achievement—exemplified by Matthew Arnold's enormously influential late nineteenth century definition of culture as 'the best that has been thought and said in the world'—but also in much of the anthropological tradition's view of human culture as a singular achievement or a universal, if locally differentiated, human activity. The case for uniquely national culture, on the other hand, derives primarily from German Romanticism and

Historicism. It is this tradition that conceived the nation as the natural unit of culture, rooted in a strongly ethnic identification of culture with specific peoples and committed to forms of particularistic, nationally authentic cultural expression.

The universalist and nationalist approaches to culture coexisted and often competed, as evidenced by recurring debates between those who would judge cultural achievement in America by ostensibly universal principles, and those who viewed American culture as operating according to its own rules. Until quite recently, studies of American culture have belonged with few exceptions to the latter camp, implicitly accepting the nation as the appropriate frame of reference for culture even when they were highly critical of what they found. This perspective—organized especially around ideas of a unified national character, mind, or spirit—was not seriously inconvenienced by the transition from humanistic to anthropological priorities. Only recently has the fundamental assumption of the field—the coincidence of nation and culture—come under sustained scrutiny, leading to what some have described as a crisis or breakdown of American studies, and more generally to what Giles Gunn has called an 'indisposition to ask any longer certain questions having to do with…"the point of it all"' (1987).

1.1 The Cultural Problem in Early America

Early accounts of American culture came from a variety of sources, from European travelers seeking to explain the new country to home audiences (e.g., Francis Trollope, Charles Dickens, Alexis de Tocqueville) to the men and women of letters who formed a nascent cultural elite in New England and Virginia. Most of these accounts trafficked in the details of American manners, mores, and artistic accomplishments. Comparisons with Europe were common, and the United States was frequently found uncivilized and wanting. As James Fenimore Cooper (1824) argued, a great American literature was held back by a more general cultural failing—a 'poverty of materials…no annals for the historian; no follies (beyond the most vulgar and commonplace) for the satirist; no manners for the dramatist…' and above all no 'social capital' such as London or Paris which could provide 'a standard for opinion, manners, social maxims, or even language…'.

At the same time, the new nation did not lack for cultural entrepreneurs who saw in this absence a valuable new thing—a fresh start or a more natural, uncorrupted existence than was possible in Europe. Nor did it lack ideologues who could confidently predict the nation's glorious destiny. In both cases, writers fused nationalist sentiment with the millenarianism and redemptive rhetoric of the Puritan tradition, setting in place a quasi-mystical and extremely durable framework for interpreting the national experience and America's role in the world. The recurrent strain of 'exceptionalism' that runs through American cultural, social, and political analysis—sustained by faith in the unique mission or virtues of the United States—owes much to this tradition.

Whether as absent or as new, most partisans perceived the desirability of a distinctive basis for American life. Unlike in Germany, however, where claims for cultural identity paved the way for national aspirations and forged, through Romantic and Historicist writing, the 'natural' bond between nation and culture, American cultural identity was rarely presented as given: it was above all a problem and, for many, an opportunity.

Historians such as George Bancroft (1854) addressed this problem by writing American history as the ongoing expression of divine will—a civilizing errand into the wilderness shaped by the spirit of liberty. More consequential than this overt mythologizing, in many respects, was the emerging Romantic discourse of national cultural identity—delayed in America by some 20 years with respect to England and 30 with respect to Germany. Romanticism privileged artistic expression as a means of transcending society, which Romantics viewed as increasingly debased by the marketplace and other aspects of modernization. For most English romantics (e.g., Coleridge and Shelley), this transcendence was deeply rooted in the idealization of nature as a realm of wholeness and fulfillment. In the 1830s and 1840s, American literary elites reproduced much of this antimodernizing sentiment and idealization of nature, but also increasingly integrated the nationalistic dimension of Romanticism that associated artistic achievement with national character. The long established belief in America as 'Nature's Nation' facilitated this nationalist turn. Authentic American artistic achievement would express both nature and nation because for American Romantics, the two were much the same thing.

Where European romantics tended to present culture as a refuge from material society and art as a source of private epiphanies, the American tradition—especially after Ralph Waldo Emerson's work of the 1830s—focused on culture and its highest form, poetics, as a vehicle of social redemption. The rationale for these hopes lay in the Romantic philosophy of language, which viewed language as the medium of experience and poetics as the mastery of language. Properly conceived, therefore, poetry could unify art and life; it could reassert the unity of knowledge in the face of fragmented modern experience and redeem the promise of collective life from the tarnished realities of mass democracy. The difficulty was that this culture, by definition, did not exist. Romantic cultural criticism thus tended strongly toward prophecy: American culture was for the future.

This faith in the privileged relationship between literature and the nation, and in literature's power to crystallize an as yet nonexistent national culture, shaped a powerful, sometimes dominant, and usually highly critical American tradition of social thought that ran through much of the nineteenth and early twentieth centuries, connecting Emerson to Walt Whitman, Henry David Thoreau, later proponents of cultural invention such as Van Wyck Brooks, William Carlos Williams, Lewis Mumford, Frank Lloyd Wright, Alfred Steiglitz and Waldo Frank in the 1920s, and less directly to the cultural criticism of American Pragmatists such as John Dewey. Redemptive critique, in this context, represented one extreme of a more generalized view of culture associated with acts of creation and freedom from forms of social determination. As the nineteenth century drew to a close, this oppositional formulation grew sharper and more rarified. The defense of culture as transcendent expression shared ground with Arnold's view of culture as the best. Both implied a rejection of low or popular forms, and both became increasingly divorced from the modernizing forces that were transforming American society.

2. *Tradition and the Anthropological Concept of Culture*

Although the dominant nineteenth-century concept of national culture had enshrined ideas about national character and the myths that accompanied them, it had largely repudiated the question of tradition, which was viewed primarily as a form of constraint on individual freedom. The late nineteenth century, however, witnessed a remarkable fervor for tradition of all kinds—local history, ethnic heroes, nostalgia for the Old South, medievalism, vogues for colonial furniture, family genealogy, folklore and so forth. Nationalism underwrote a large share of this activity and increasingly came to be defined by it. Cultural practices and national history began to be understood as integral to national identity, and national identity came to be, in effect, the set of all sets of diverse local traditions and markers of identity. For the first time, this relationship began to be organized on a large scale—integrated into school curricula, promoted through Americanization campaigns, and built into the landscape through the proliferation of monuments, museums, and memorial events.

In many respects, the early anthropological tradition integrated and gave focus to this generalized passion for the past. In so doing, it challenged the humanistic notion of culture as creative expression in favor of a concept that took in the sum total of human activities and that embraced continuity rather than rupture. This new meaning initially referred to human culture in general, but increasingly acquired a discrete and pluralist sense that acknowledged the existence of separate and different cultures. The anthropologist Edward Tylor is usually credited with inaugurating this cultural turn in his celebrated 1871 description of 'Culture or civilization' as 'that complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities and habits acquired by man as a member of society.' Franz Boas's turn-of-the-century critique of evolutionary models such as Tylor's gave the concept its crucial pluralist inflection. Whereas for Tylor, culture referred to a singular evolutionary scale along which differen societies could be located, Boas introduced the modern sense that cultures are multiple, discrete, and derived from particular historical circumstances.

The 1920s were the watershed years for most of these intellectual and nationalist developments. The decade saw the rapid growth of social science research on American culture, especially through national character studies pursued with ethnographic methods. Boas's numerous students, including Ruth Benedict and Margaret Mead, popularized the anthropological view of culture and in many respects ensured that it would be understood in national terms. Robert and Helen Merrell Lynd's *Middletown: A Study in American Culture* (1929) showed how the new paradigm could be exploited. The 1920s also marked the high point of Progressivism as a school of historical analysis, with its signature debunking of national myths and revelations of economic interests, as well as a more general retrenchment of national identity along sharply nativist lines. It was the period in which American heritage and tradition became a veritable industry, promoted by clubs, historians, and the large-scale official sponsorship of the national past, including the construction of most of the monuments on the Washington Mall. At the same time, it was the effective end of the era in which redemptive literary ambitions in American cultural criticism could command serious attention. This was a function not only of the decline of literature as the dominant form of cultural expression, but—especially after World War Two—of the evident hegemony of American culture in the world, which brought an end to the inferiority complex that drove much of the American obsession with producing cultural achievements worthy of comparison to Europe.

2.1 *American Studies*

American studies was a product of this turmoil, but in some respects also represented a parting of the ways with developing social science approaches to culture. Strong points of commonality existed, particularly in regard to the notion of national character. Benedict's *Patterns of Culture* (1934) legitimized national character as the basis of anthropological studies of modern societies—now conceived in relation to values and psychology rather than spirit. Moreover, the critical animus of the humanist tradition remained central to

much social scientific research. Freed from the high-low dichotomy, social scientists were much more ready than their predecessors to identify American culture with the society it produced, and to see in that culture the foundation of a deeply conflicted modern life—at once materialistic and religious, individualistic and conformist, relentlessly innovative and fearful of change. Like their predecessors, nonetheless, many sought to rally the cultural resources of the nation in the name of a more genuine individualism (the Lynds), an active citizenry, or the independence of thought and action from large-scale social forces (Dewey). Reismans et al. *The Lonely Crowd* (1953) was perhaps the high point of this tradition with its indictment of modern corporate man and its nostalgia for ostensibly past values. Another symptom was the rediscovery of Tocqueville in the 1950s as a prophet of the dangers of conformity and mass society.

American studies was created in this period of popular ascendancy of the anthropological model of culture and the cult of tradition. Nonetheless, its major formulations were not greatly impacted by either. Part of the reason was professional. American literature became an acceptable topic of academic study only in the 1920s, and it quickly sought to escape the subordinate place assigned it within English departments. The new attention to American literature was directed less toward prophesizing or calling into being an American culture, however, than to confirming that search as the emblem of American culture itself. The other major force came from intellectual history—especially from the 'New History,' which focused on the role of ideas in American life and which similarly found itself marginalized in history departments.

Where earlier investments in American culture had been forward-looking, the contours of the new field were profoundly retrospective and historical. Where the cultural and historical analysis of the past decades had been largely critical in orientation—placing history in the service of reshaping American culture and debunking myths that had been honored mostly in the breach, the new scholarship tended to root American character more firmly in its faith in its myths. The monument to this new orientation was Vernon Parrington's multi-volume *Main Currents in American Thought* (1927), which went far toward establishing the operating paradigm of American studies in its first three decades. As Gene Wise (1979) has argued, this involved a loose consensual belief among scholars in the existence of a fundamental American character or 'mind' shaped by certain leading ideas and themes in American life. Individualism, Puritanism, Pragmatism, Progress, Transcendentalism, and Liberalism figured most prominently among these—though scholars could and did disagree about specifics. The humanistic ideal of high culture animated much of this work: the key national ideas, while visible in popular culture, were crystallized in the best literary and intellectual achievements. Among other virtues, this allowed intellectual historians and literary scholars to assert the privileged status of their enterprise. As an operating paradigm, this version of national culture underwrote a broad array of literary and historical work, from Perry Miller's studies of Puritan thought, to F.O. Matthiesson's account of democratic values in the American literary 'Renaissance,' to the work of the 'consensus' historians of the 1950s (Richard Hofstadter, Louis Hartz, and Arthur Schlesinger Jr., among others) who placed Lockean liberalism at the center of the American experience.

The strongest and, in many respects, field-defining version of this cultural logic belonged to the 'myth and symbol' school of the 1950s—a group that included Lionel Trilling, Henry Nash Smith, Charles Feidelson, R. W. B. Lewis, Charles Sanford, and Leo Marx. Lewis's *The American Adam: Innocence, Tragedy and Tradition in the Nineteenth-Century* (1955) and Smith's *Virgin Land: The American West as Symbol and Myth* (1950), to choose two prominent examples, worked from a widely shared but usually implicit set of assumptions about the way that forms of cultural expression—quintessentially literary texts—symbolically enacted and participated in larger national myths. The major work of the myth and symbol school fused intellectual history with the study of literature, uncovering myths of Adamic innocence, flights from civilization, the garden as a happy middle between city and wilderness, and a host of other recurrent patterns and images that allegedly defined American culture.

By the 1960s and 1970s, this work had become the establishment against which a newer generation of scholars chafed. The myth and symbol school was charged with sins of elitism and omission, with perpetuating versions of national exceptionalism and with taking an overly aestheticized view of culture that ignored power, institutions, class, gender, race and other forms of social stratification. Where myth and symbol scholars saw persistent myths, later scholars tended to see ideological formations that served particular interests, up to and including the scholarship that legitimized those ideologies as the essence of American life. But the fundamental question addressed by the myth and symbol scholars—the relationship between cultural products and larger cultural formations—did not thereby become obsolete, and their elegant if often constrained answers continued to inform a wide range of scholarship, from Sacvan Bercovitch's accounts of the Puritan intellectual legacy (1975) to Alan Trachtenburg's studies of the cultural impact of the corporation (1982).

2.2 The Pluralist Explosion

Although critics sometimes overstated the case against the myth and symbol school, there is little doubt of the magnitude of the changes in methodologies, topics

and underlying goals that reshaped the field beginning in the late 1960s. Perhaps most fundamental to this process was the contestation along multiple fronts of the idea of a singular, unified national culture. To the extent that a new consensus emerged, American culture became identified with a fundamental cultural pluralism—with a broad array of groups, traditions, and histories whose Americanness lay primarily in the acceptance of diversity as a national ideal.

The most direct of these challenges came from struggles for equality and recognition by historically marginalized groups—women, African-Americans, Native Americans, Hispanics, Asian-Americans, and later gays and other minority groups. American studies translated these social movements into as many distinct subfields, each primarily tasked with ensuring a place for its constituency in accounts of American culture. The emergence of social history or 'history from below' in the 1960s provided a methodology for many of these developments and underwrote a range of related projects of historical recovery: most prominently labor history, working-class culture, and regional studies of various kinds. They also integrated a wealth of new sources, from oral histories to folklore, popular culture, and material culture. Eugene Genovese, Sean Wilentz, and Herbert Guttman were among the pioneers in this area.

British cultural studies was another source of innovation in the 1970s. The work of Raymond Williams, E. P. Thompson, and others introduced a new style of critical and historical reflection on the concept of culture and a systematic challenge to the hierarchies of high and low culture that stratified social life. They participated in a broad groundswell of interest in how cultural products were understood and interpreted by their consumers, and helped to legitimize the study of popular and mass culture. Combined with structuralist and poststructuralist challenges to theories of interpretation (especially in regard to the primacy of authorial intention in the transmission of meaning) and the renewed influence of Marxist approaches to culture, the broad humanistic association of culture with autonomous artistic creation began to crumble.

In its place emerged a notion of culture comprised of and continuously reshaped by institutional forces. Aesthetic judgment and popular taste were now subjects with distinctive histories, and artistic creation was embedded in networks of social relations. These relations were not primarily among great artists across the generations, as in the romantic concept of tradition, but with the whole apparatus of culture: publishers, critics, buyers, technologies, opportunities for professionalization, and a range of other forces that organized cultural production into distinct fields. Although anthropological notions of culture superficially informed American studies since the 1930s—Henry Nash Smith's 1957 description of culture as 'the way in which subjective experienced is organized' was as close to a definitive statement as the field had—and although calls for greater attention to social science concepts and methods were regular features of American studies discourse, the emphasis on culture as a singular national 'pattern of values' made the specification of that culture a highly selective process and undermined the full potential of the anthropological critique. The new approaches did not dispense with the nation as a subject of analysis, but increasingly recognized national culture as a historically variable set of exclusive practices, whether built on aesthetic grounds or on compliance with certain myths, values, or exercises in national symbolism. The battles in English departments during the 1970s and 1980s over which works comprised the literary canon (and to some extent the highly politicized 'culture wars' of the late 1980s and 1990s) were symptoms of this intellectual transition.

A variety of social scientific approaches informed this transformation of the field, from the sociological accounts of culture developed by Talcott Parsons and Robert Merton, to ethnomethodological studies of everyday practices of interpretation. Thomas Berger and Peter Luckman's *The Social Construction of Reality* (1966) had a major impact on how scholars reinscribed culture within social processes and reintegrated 'high' cultural performances within the general field of cultural practice. Clifford Geertz's anthropological essays in *The Interpretation of Culture* (1973) also strongly shaped considerations of cultural practice as an inclusive but semi-autonomous system of meanings—reliant on but never reducible to social or economic life. More recently, James Clifford's textual approaches to material culture and Pierre Bourdieu's sociological histories of taste and status have proved influential. In the process, American studies became a much more self-reflective field that is aware of its history as a set of evolving interpretive paradigms and increasingly institutionalized interests.

Perhaps the most radical challenge to date has come from the recent subfield of 'border' studies, which focuses primarily on the Chicano populations of the Southwest. Although the term loosely groups together a range of perspectives and concerns, border studies scholars have consistently drawn attention to how the ideal of national culture operates as a tool of domination of the Mexican-American population. In the process, they have rejected the use of the nation as the master unit of cultural analysis. Many of the themes of border studies and related areas of transnational studies—cultural hybridity, contact zones, cultural imperialism, and the border itself as a liminal space that denies fixed identities—have entered into American studies more widely, resulting in what Carolyn Porter (1993) and others have called the 'remapping' of the field not only around cultural pluralism around cultural struggle that crosses political borders. However far this particular remapping is pursued and however useful border studies metaphors prove in

describing cultural patterns and conflict in other settings, it is clear that American studies has moved into a somewhat paradoxical post-national phase, in which most work is predicated on rejecting the institutional premises of the field. For some American studies scholars, this represents a crisis—a breakdown of the legitimating idea that gives coherence to their activity and supports their institutional identity. For others, it represents a necessary critical turn from the study of American culture to the study of culture itself as an inevitably contested field of identity and meaning.

American Studies: Education

1. The Structure of the American Educational System

Laws providing for public schooling were on the books in some of the American colonies as early as the mid-seventeenth century, but this public schooling was typically associated with aid to the poor. The schools were not well funded, and they fell into disuse or disrepute (Edwards and Richey 1963, Chaps. 1–3). Schooling during the colonial and early republican period was a patchwork of forms similar to that found in England. Some children learned the rudiments of literacy and mathematics in neighborhood 'dame schools.' Those who were wealthy enough might attend a private academy for a fee and later attend one of the few colleges then existing for preparation for one of the learned professions or cultural finishing before embarking on a career in commerce. Apprenticeships, rather than formal schooling, were a popular means for learning trades and professions.

The great majority of American revolutionary leaders were advocates of free and compulsory public schooling for the primary grades, but it was not until the 1830s and 1840s that the 'common school' movement mobilized under the leadership of educators from the most urbanized states. Men such as Massachusetts Commissioner of Education Horace Mann promoted free and compulsory public schooling as a support for good citizenship in a democratic republic. The common school movement struggled against citizens who were opposed to paying taxes for public education and against church leaders who wanted to exercise control over the curriculum. By the mid-1840s, free and compulsory public primary schools had become institutionalized in New England and the middle-Atlantic states. The spread of public primary schooling to the western and southern United States occurred primarily in the 1850s, but attendance remained spotty and facilities primitive in many communities (Edwards and Richey 1963, Chaps. 9–10).

Since the mid-nineteenth century, the American

system of education has been distinguished from schooling in the rest of the world by its inclusiveness and by the high average number of years students remain in school. Indeed, by the latter decades of the nineteenth century, American educators were arguing that all children had a right to secondary education, sentiments that would not become common in Europe for more than a half century. Where schooling in other industrialized countries was dominated by the idea of elite preparation, schooling in the United States developed as a means of nation building. Behind these ideological differences lie a number of social differences between nineteenth-century America and Europe. No well-entrenched aristocratic or quasi-aristocratic groups existed in the English-speaking democracies of North America to guard the universities and secondary schools as bastions of a status-linked high culture. The enfranchised groups were overwhelmingly small-property owners. The interests of this small-property-owning class, particularly when joined to the evangelical force of Protestant idealism, greatly encouraged use of state power for purposes of creating a 'virtuous citizenry.' The pragmatic spirit of the small-property-owning classes also encouraged the use of schooling as a means of teaching economically useful subjects. The expansion of the system was greatly encouraged by the efforts of Northern European Protestants to 'Americanize' the children of immigrants from poorer and Catholic regions of Europe. Compulsory schooling took root earliest in districts and states with high proportions of Catholics (Meyer et al. 1979).

Compared to schooling in other industrialized societies, the American system has also been distinctive in its decentralized organization. American federalism gave local communities the primary role in school financing and organization. Many Americans favor local control on the grounds that schools are more responsive to the particular interests and concerns of the communities in which they are located. Variation in curriculum and organization has been relatively minor, however, because educational professionals have organized schools throughout the country in remarkably similar ways. (Some variation does exist; sex education, for example, has never been popular in more conservative school districts.) Local control also encourages sharp disparities in per student spending between suburbs and inner cities, a phenomenon much less evident in more centralized systems. In recent years, many states have taken over a significant proportion of school funding, which has resulted in more equal funding between wealthy and poor school districts.

During the early and mid-twentieth century, most European states divided children after their few years into separate institutional tracks connected to differentiated adult occupational fates. Americans, by contrast, resisted tracking students into ability based institutional tracks. Students instead received a generally similar curriculum well into secondary school. Even secondary schooling has been relatively undifferentiated, with courses in the 'general' and 'college preparatory' tracks dominating. As compared to other industrial countries, only a small proportion of American secondary school students enroll in programs that can be described as primarily vocational.

Another distinguishing feature of the American education structure is the size and diversity of its tertiary sector. Until recently, most industrialized countries severely restricted enrollment in colleges and universities by requiring students to pass rigorous secondary school-leaving examinations. By contrast, the American structure was largely unplanned, unregulated, and market-driven. From the beginning of the American republic, weak state control over higher education made it relatively easy for a wide variety of groups to open colleges. Elite colleges educated children from the upper professional and business strata of the Northeast. Military colleges prepared men for the officer ranks. Denominational colleges attracted the children of coreligionists. Other private colleges served women and African Americans. In the mid and late nineteenth century, public universities, chartered with land grants from the federal government, opened their doors to children of the middle classes. These universities were required by law to combine liberal education with programs offering training in the industrial arts and agriculture. Beginning in the 1920s, state normal schools developed into teachers colleges. And junior colleges, another American innovation of the twentieth century, provided opportunities for students who lacked academic confidence or could not afford to enroll in a four-year school.

The combination of relatively undifferentiated primary and secondary schooling and competition for students among an unusually large number of colleges and universities led to comparatively high rates of college going and college graduation. For most of the twentieth century, American students were at least twice as likely as students in Europe to attend institutions of higher education. Today, two out of three American students continue their studies beyond the secondary level—still a significantly higher proportion than elsewhere in the industrialized world. The proportion of professional and managerial jobs in the economy cannot fully explain this high rate of college attendance. Countries such as England and Belgium have had a similar proportion of professional and managerial jobs in their occupational structures but much lower rates of college going. Rather than hire college graduates for white-collar jobs, employers in these countries were more likely to promote able workers from the shop floor. High rates of college-going and college graduation in the United States must be seen as reflecting not only occupational change but also expansionary tendencies in the educational structure itself—and in the ideology of opportunity that supports that structure.

Once students enter postsecondary education, they are decisively differentiated by the selectivity levels of the institutions they enter and, to a lesser degree, by their major fields of study. Highly selective institutions and scientific-technical disciplines confer a significant advantage in the market for educated labor (Bowen and Bok 1998). The combination of relative homogeneity at the primary and secondary level and extreme differentiation at the postsecondary level is the opposite of the historical pattern in Europe (Allmendinger 1989).

2. *Education as a Social Institution*

One puzzle explored by institutional analysts is why schools in such a thoroughly decentralized system became so similar to one another. Historians have shown that the organization of primary and secondary schooling became relatively standardized during the late nineteenth and early twentieth centuries, as reformers trained under the leading theorists of educational administration, George Strayer and Ellwood Cubberly, took control of big city school districts and sought to replace the waning power of religion as a moralizing force with organizationally based social control (Tyack 1974, Tyack and Hansot 1982). The triumph of these 'scientific managers' moved the schools out of the hands of people who were obsessed with personally rooting out evil and put them into the hands of people who favored creating an orderly and progressive environment through rationalized structures of administration, clearly enforced rules, scientifically tested curriculum, and regular evaluation of student progress.

Although historically important, themes of social control have played a secondary role in institutional analyses by social scientists. In the 1950s and 1960s, at the height of the Cold War, social scientists took it for granted that achievement norms were both the major socializing force in schools and the basis for the school's increasingly important role in social selection. Some of the more interesting analyses of this period showed the unintended consequences of achievement norms and how extracurricular activities and peer groups helped to blunt the potential psychological costs of the 'achievement regime.' Parsons (1959) argued that the schools' increasing emphasis on achievement, while valuable for American society, also created fertile grounds for the development of delinquency among those who were unwilling or unable to compete academically. Jackson (1968) showed how the schools' emphasis on academic success encouraged conformist students to resort to cheating and other means of manipulating the system for personal advantage. In this work, peer groups were often treated sympathetically as useful balances to the schools' emphasis on achievement. Parsons (1959) noted that many jobs and community roles in modern societies required high-level social interaction skills but only moderate academic skills. He argued that success in the informal social life surrounding schools helped to train potential leaders as well as those potentially suited to occupational and other roles in which social interaction skills were essential. Coleman (1961) observed that extracurricular activities and adolescent peer groups provided alternative avenues to status for many students who were less academically inclined and thereby contributed to the psychological health of many adolescents.

In the 1970s, as college attendance began to become expected for the majority of secondary school students, institutional analysts began to turn a skeptical eye on the idea that achievement played a central role in the American educational system. Collins (1979) criticized the view that higher levels of education were required in modern societies because these societies produced jobs requiring intellectual skills. He argued that most job skills were learned on the job and that a person's status characteristics and political skills figured more prominently in advancement than cognitive ability. As an alternative to the conventional wisdom linking high levels of education to high-technology economies, Collins developed a neo-Weberian analysis of the role of educational credentials in monopolizing access to desirable positions. Constant pressures for inflation of educational requirements exist in such a credential society, because students realize that educational credentials have come to play the stratifying role that family resources and reputation once played. Meyer and Rowan (1978) developed a similar position, arguing that many individual differences in performance are systematically obscured by the 'ritual categories' of schooling. These standardized membership categories allow unequal people to be treated more or less equally. The category 'high school graduate,' for example, is treated as a meaningful element of the American social structure, even though high school graduates include some people who know a great deal and some who can barely read and write.

Major contributions of institutional analysts to the understanding of classroom-level teaching and learning environments have been fewer in number. Lortie's (1975) occupational analysis of school teaching is a notable exception. Lortie began by distinguishing the types of people recruited into teaching. The profession has been attractive historically to people concerned less with ideas or monetary success than those interested in the psychic rewards of students' affection. In addition, as compared with other professions, Lortie argued, school teaching is distinguished by five structural characteristics: work with large, heterogeneous groups of 'immature workers'; work that requires high levels of group concentration but is marked by many interruptions; work that has multiple goals rather than a single overarching goal (e.g., socioemotional development as well as cognitive development); work that is generally performed in isolation from col-

leagues; and the absence of distinct ranks in the career. The structural characteristics, according to Lortie, lead to a dominant defensiveness in the culture of teachers. This culture is marked by a desire to protect the sanctity of the classroom from outside intrusions, a tendency to rely on trial and error as a guide to practice, an and a tendency to teach to the few students who provide teachers with the majority of their psychic rewards. Lortie recommended that teaching move in a clinical direction, modeling itself on medicine and psychotherapy, but this suggestion generated little enthusiasm. His suggestion for introducing hierarchical stages into the teaching profession has, however, been adopted by many states.

Over the course of the twentieth century, American teaching clearly became less authoritarian and more student-centered, charting the typical trajectory of classroom instruction as societies move from early to advanced forms of industrial organization (Brint 1998, Chap. 5). Cuban (1993) argued that teachers implicitly differentiate between an inner core of instructional authority and an outer periphery of social relations. The core includes lesson content, teaching techniques, and tasks to be accomplished; the periphery includes the arrangement of classroom space, the amount of student movement, the amount of ability and interest grouping, and the amount of classroom noise tolerated. Teachers have yielded considerable control over the periphery of social relations, while maintaining their control over the instructional core (Cuban 1993). Indeed, recent comparative work has emphasized the nurturing qualities of American primary school teachers. Stevenson and Stigler (1992) found, for example, that teachers they surveyed in Asia chose clarity and enthusiasm as the most important attributes of good teachers, whereas teachers in the United States more often chose sensitivity and patience. This solicitous outlook is undoubtedly connected to the expansive tendencies of a system in which two-thirds of students continue to attend educational institutions into early adulthood.

3. *Inequality and Achievement*

Though widely appreciated as a foundation, institutional analysis has not provided the dominant focus for social scientists studying American schooling. Instead, social and economic policy concerns have encouraged social scientists to focus on two topics: (a) the schools' role in perpetuating or ameliorating inequality in society; and (b) the school and classroom-level influences on students' cognitive achievement.

As in England, the sociology of education was almost synonymous in the years after World War II with concerns about the schools' role in perpetuating and transforming social inequalities. Two perspectives have clashed in these analyses: one perspective arguing that mass schooling is important primarily for legitimating the intergenerational transmission of privilege (see, e.g., Warner 1949, Bowles and Gintis 1976), and the other arguing that mass schooling is important primarily for its role in selecting intellectually able and motivated students from throughout the class structure for higher level positions in the occupational structure (see, e.g., Conant 1940, Wolfle 1954).

The empirical evidence collected and analyzed during the period failed to corroborate either the theory of social class reproduction or the theory of meritocracy. The studies showed that most of the variation in people's adult occupational and income status could not be predicted by characteristics like social background, cognitive ability, and educational credentials. Some of the unexplained variation in later life fates has to do with the vicissitudes of companies, industries, and regions and with more individual histories of good and bad fortune. Both social background and measured cognitive ability show up as important explanatory factors for that part of the variation in people's adult attainments that can be explained—primarily because they both influence the likelihood that a person will obtain the high-level educational credentials that, in turn, provide access to most good jobs. Grades and test scores are the best single predictors of educational attainment, but, even so, family background never disappears as an independent causal factor. Family background helps to predict test scores, and it also has a modest direct effect on how much schooling a person is likely to receive controlling for the person's measured cognitive ability (Jencks et al. 1972; Featherman and Hauser 1978, Jencks et al. 1979). Other factors bearing on educational attainment include having an intact two-parent household, having families and friends who value education highly, taking courses that are academically challenging (particularly courses in mathematics and science), and having strong personal aspirations to succeed (Sewell and Hauser 1975, Jencks et al. 1983).

Findings on the effects of race and gender on educational attainment show a complex pattern of declining and continuing inequalities. Although the black-white gap on achievement tests has narrowed somewhat over time, the gap continues to be sizable (up to eight-tenths of a standard deviation on mathematics achievement tests) (Jencks and Phillips 1998). Because of lower test scores, blacks and Latinos are disproportionately placed in lower tracks in elementary and secondary schools, and they experience greater difficulty gaining entrance into selective colleges and universities. By contrast, gender is a declining factor in educational stratification. Girls perform as well as boys in school and on the great majority of standardized tests. In the United States, women now outnumber men in colleges and universities (perhaps because few jobs for female high school graduates pay well). Levels of gender segregation have declined markedly in most major fields and professional scho-

ols, although gendered patterns of specialization continue to exist—for example, surgery in medicine continues to be male-dominated field. Women also remain significantly underrepresented in the physical sciences and engineering (Jacobs 1995). Most important, neither minorities nor women gain the benefits from educational credentials than white men can expect; at each level of education, their occupational and income prospects are lower than those of white men.

Because the individual characteristics associated with mobility are correlated with one another, another useful perspective is to use group-level data to compare the educational opportunities of socioeconomic strata at different points in time and in different countries. In most countries, correlations between social origins and high-level educational attainments have remained remarkably stable since the beginning of the twentieth century in spite of a rapid rise in the number of years most people stay in school (Blossfeld and Shavit 1993). Only the United States and a few Scandinavian countries have succeeded in significantly equalizing opportunities between classes. Between 1945 and 1980, the United States showed decreasing inequalities between classes (Hout et al. 1993). However, this trend has reversed since 1980 as the economic conditions of the working classes have lagged behind those of the middle and upper classes and as the unsubsidized costs of attending college have increased.

In the 1980s and 1990s, social scientists studying American education increasingly turned their attention to a second major topic: school-related factors bearing on cognitive achievement. This shift reflected the dissatisfaction of many school reformers of the period with the idea that schools are powerless to overcome the effects of social and economic disadvantages in the larger society. It also reflected policy makers' concerns about the potential implications of low educational standards for the country's ability to maintain its international economic strength. During this period, social scientists investigated relationships between a number of school-related factors and levels of student achievement. They showed that academically oriented leadership, highly qualified teachers, a disciplined and orderly school environment, and the sheer amount of time spent on learning can affect average achievement test scores at schools, controlling for the composition of the student body (Coleman et al. 1982, Ravitch 1995). At the same time, studies continued to confirm that the individual and family-related differences children bring to school account for the vast majority of variation in student performance. For primary school children, only about 20–25 percent of this variation in performance lies between schools; and at the secondary school level, only about 10–15 percent of this variation lies between schools. These figures set an upper bound on how much schools themselves can expect to affect achievement inequalities (Coleman et al. 1966; Entwistle et al. 1997).

American Studies: Environment

1. *The Nature of American Environmental Studies*

Environmental studies focus on interaction between ecological (ecosystems) and human societies. Ecosystems are those organized forms of natural system that integrate biotic organisms and their resource base, including air, water, and minerals. Modern scholarship notes: (a) human societies are now seen as dependent upon more features of ecosystems, and (b) ecosystems sustain human societies in ways apart from their traditional role as 'natural resources.' Natural resource views of ecosystems led to increasing pollution and depletion from societal production, exposing citizens and social institutions to new vulnerabilities from ecological scarcities. Prior to 1965, social analyses primarily traced how features of natural systems shaped the structure, location, and activities of communities, in work such as spatial ecology (Theodorsen 1961) and human ecology (Hawley 1950). Then, ecosystems were seen as autonomous from human actions.

Central problems in modern environmental studies include the complexity of relationships between social and ecological organization. It is often difficult to offer precise statements about the ecological impact of human activities, on the one hand, and the social impact of environmental disorganization, on the other. Moreover, boundaries between social scientists' and natural scientists' roles are unclear. Evaluating patterns of social impact on ecosystems and/or ecological impact on social systems does not permit the rigor of laboratory control of variables, and thus a variety of differing assessments of such impacts emerge (e.g., Dietz and Rycroft 1987, Kraus et al. 1992).

In the United States, the social science approach incorporated mainstream natural science perspectives on environmental destruction. One approach engaged in surveying American individuals, to trace how much recognition of environmental problems had emerged, and how individuals had altered their values and behaviors in the light of this recognition (Dunlap and Van Liere 1978). Another set of analyses traced the changes in twentieth-century American institutions, assessing both how they had produced negative environmental impacts (Burch 1971), and how they responded to attempts to engage in policies of managed scarcity (Schnaiberg and Gould 2000) to meliorate this impact.

2. *Individual American Responses to Environmental Challenges*

In the late 1960s and early 1970s, social surveys traced how much the public had consciousness of pollution hazards, and their attitudes towards proposed government regulation of pollution. Higher education levels predicted more concern, but later studies showed more diffused anxieties. By the late 1970s, though, individuals showed more skepticism about the implementation of new environmental protection laws through environmental agencies. More respondents were cautious about expanding government action to protect ecosystems, especially those whose livelihoods devolved around natural resource usage (Dunlap and Van Liere 1978). Better-educated Americans still expressed stronger concerns about the social impacts of pollution. More pragmatic lines of research include people's willingness to pay for hunting and fishing licenses to support conservation agencies (Heberlein 1989) and other environmental controls.

With the rise of the energy crisis in the mid and late 1970s, a variety of studies explored citizen reactions. Many citizens favored government support for broader domestic oil exploration, despite new environmental risks from drilling and transporting offshore and onshore oil. The 'problem' denoted by these segments of American society was the scarcity of petroleum products. Conversely, though, other respondents felt this was an occasion for citizens to alter their behaviors, and to engage in more energy-conserving (and resource-conserving) actions. They favored smaller cars, more public transportation, more energy-efficient appliances, and new programs of recycling social wastes (Murray et al. 1974). Middle-income respondents favored this. In contrast, low-income groups lacked the means to change their use of energy, and high-income groups resisted this decrease in their standards of living.

Towards the latter part of the 1970s, public attention was increasingly drawn to toxic-waste problems, highlighted by the problems of Love Canal in New York State, and a series of other chemical threats to human health (Levine 1982). Many social scientists began to study the emerging grass-roots social movement organizations associated with these incidents of public health (Brown and Mikkelsen 1997). Other

studies concentrated on individuals' concerns with risk (Slovic 1987), and found that individuals perceived environmental health hazards as more severe than did experts (cf. Dietz and Rycroft 1987, Kraus et al. 1992).

In the early 1980s, attention in the scientific and media circles shifted from national pollution and energy problems to new issues of global environmental change, especially ozone depletion and greenhouse gas increases that would lead to global warming. Studies of individual attitudes incorporated this new concern, adding fears about global warming and the willingness to forego some use of energy to reduce this risk. Increasingly, though, such social surveys of individuals became more problematic, as matters of environmental policy and industrial use of natural resources became more removed from individual decisions and attitudes (Buttel and Taylor 1992).

Perhaps the most recent arena in which citizen attitudes seemed to play a role was in voluntary participation in recycling their household wastes. Ironically, much less research has been addressed to this, although for some social scientists, individual recycling became a general criterion for environmentally responsible behavior (Derksen and Gartrell 1993).

3. *American Institutional Responses to Environmental Issues*

Perhaps the closest institutional analogue to the individual surveys is the studies of diverse American environmental movement organizations. Early in the modern period of environmental concern, Albrecht and Mauss (1975) reviewed the history of conservation, recreation, and environmental voluntary organizations. These citizen-based organizations sometimes predated and at other times monitored government agencies. These agencies regulated parklands, forests, and natural resources, either for purely conservationist or utilitarian purposes (Hays 1969). Most of the studies of the 1960s and 1970s focused on older and emergent national organizations, such as the Sierra Club and Environmental Defense Fund. Yet only Mitchell (1980) actually studied their members. He discovered that the bulk of these had little experience with current and previous social movements (civil rights, anti-poverty, anti-war, and feminist). Most other analysts simply traced how national organizations had brought environmental issues to the national political agenda, and to public consciousness through the use of the mass media (Mazur 1981).

In contrast, later case studies of local or grass-roots environmental organizations offered considerable insight into the motives and means of ordinary citizen-activists in these organizations (Levine 1982, Brown and Mikkelsen 1997, Szasz 1994, Gould et al. 1996). Some of these case studies treated emergent 'environmental' protest as examples of collective behavior theories, while others used the resource mobilization perspectives developed during the civil rights and other modern social movements (Turner 1981). More recent studies often focus on environmental justice movements of peoples of color, and other lower social groups. Unlike middle-class mobilization around 'protecting the environment,' these recent grass-roots organizations often dealt with members' exposure to direct health risks from local toxic waste sources, both at home (Bullard 1994) and at work (Pellow 1998).

With the political appeal of inequality-oriented movements in the US (Szasz and Meuser 1997), and the rise of concern about global inequalities (Goldman 1998), social scientists began to study the emerging web of nongovernmental organizations. In the United States, clearing-houses of local movements emerged (Brown and Mikkelsen 1997). Responding to global inequalities, multinational linkages appeared in groups protesting in Seattle and Washington, DC in the late 1990s, the World Trade Organization and the World Bank, respectively.

Beyond these studies of protest organizations, social scientists have explored the capacity of social institutions to respond to environmental problems and environmental protection. Researchers in business/management schools have stressed the motivation and capacity of economic entities to carry out environmental management (Hoffman 1997). This approach is also consonant with a Western European approach: ecological modernization (Mol and Sonnenfeld 2000). This research details how leading industrial firms have incorporated ecological criteria into their operational decision-making.

Another set of researchers has examined the prospects and limits of American and European regulatory agencies to moderate the expansionary impulses of dominant national and multinational firms (Hawkins 1984, Landy et al. 1990). These expansionary pressures have been detailed by the theory of the treadmill of production (Schnaiberg 1980, Schnaiberg and Gould 2000). Investors seeking to maximize their share values pressured managers to expand, thereby creating rising demand for natural resources, while offering fewer benefits to workers themselves from the resulting environmental exploitation.

Over the period from the mid-1960s, normative schemes have been suggested by social scientists, working with and observing social activists. These efforts focused on creating an alternative form of production and consumption. The work of E. F. Schumacher (1973) was the first approach outlining a goal of alternative or intermediate technology. Evaluating the outcomes of these programs, Schnaiberg and Gould (2000) noted how the concept had become eviscerated of its mission in most applications. Successes of these projects were only temporary, and occurred in settings which were not of interest to major investors or firms in the treadmill of production.

A second proposal was for industrial ecology (Socolow et al. 1994), in which the waste products of one firm would serve as the feedstock for another, reducing the depletion of materials, polluting wastes, and water and energy needs. Noting that examples of such projects existed in Denmark, American analysts proposed to apply these principles in the US. However, few clear examples of such systems have emerged, usually because of the limitation of capital available for the linked technologies involved, as opposed to investments in existing single-firm technologies (Weinberg et al. 2000).

More recently, much of the logic of these earlier approaches has been reconstructed in the new ideal type of sustainable development (Baker et al. 1997, PCSD 1999). Many utopian goals have been put forward by social science and activist citizen groups, despite substantial resistance from existing institutions (Daly 1996b). Paradoxically, this concept was initially proposed by natural scientists, with an aim of sustainable biodiversity. The sociopolitical reality is that most institutions seek to achieve maximal ecological protection with minimal social change (Daly 1996a). This was confirmed by recent evaluations of urban recycling as an exemplar of sustainable development policies (Weinberg et al. 2000). A related example is eco-tourism, where sustainable development is highly contingent on limiting competition for local resources (Gould 1998). Other researchers have explored existing strategies of voluntary simplicity, eco-communities, and community-based production (Shuman 1998).

Future analytic and policy studies will require far more synthetic approaches by social scientists than have been present in the distinct lines of inquiry noted above, and that is a formidable challenge for social scientists.

A. Schnaiberg

American Studies: Politics

Observers of American politics witnessed a number of extraordinary events in the final three decades of the twentieth century. Prominent among these were the resignation of President Nixon in the wake of the Watergate scandal, the end of the war in Vietnam, a tax protest movement which spread from California across the United States, the bicentennial of both American independence and the US Constitution, a foreign policy crisis triggered by US diplomats held hostage in Iran, the end of the Cold War, the Republican party winning a majority of seats in the House of Representatives after 40 years in the minority, and the impeachment of a president for only the second time in American history. Yet, for all of these remarkable occurrences, the study of American politics in this period is marked by persistent themes: a relentless questioning of the adequacy of institutional arrangements and the unresolved nature of citizenship.

1. Institutions

The last third of the twentieth century saw no major changes to US political institutions akin to the creation of the Constitution in the 1780s, the formation of mass political parties in the nineteenth century, or the development of the welfare state in the 1930s. Indeed, while this period has been marked by policy debates over the size or merit of particular government programs, there has been remarkably little fundamental disagreement over the proper role of government. The settled nature of US institutions, however, is in marked contrast to the scholarly concerns raised with respect to the performance of contemporary American institutions as well as the evidence of public dissatisfaction.

1.1 Representative Democracy in Doubt?

The US central government is not large in comparison with other advanced industrial democracies. Yet, in relative terms, the American state grew over the course of the twentieth century to become an important provider of benefits to individuals and organizations. The expansion of the state—'big government' in the political language of the US—has raised serious questions about the performance of American political institutions. One of the most sweeping criticisms has been put forth by Lowi (1979, 1985). In Lowi's view, the institutions of American politics ceased to function as intended since the advent of the New Deal when the traditional philosophy of limited government was replaced by a philosophy of 'interest-group liberalism.' Central to this critique is the view that power had shifted from the legislative branch to the executive. By delegating authority, the legislature had made itself nearly impotent, while the powers of the presidency increased not by Constitutional amendment but through public expectations. Although few scholars fully embrace Lowi's assessment, his concerns are widely evident in the study of US institutions especially with respect to the growing informal powers of the presidency (e.g., Tulis 1987).

Another manifestation of the dissatisfaction with US institutions is the concern over 'divided government.' In the US, divided government occurs when the major parties split control of the executive and legislative branches. The potential for divided party government is rooted in both the Constitutional system and the development of political parties as a mechanism for bridging the gap between the legislative and executive branches. Although divided party government has occurred throughout American history, it became the norm in the post-1945 era. The effect of divided government on institutional performance has been the subject of some debate. While some scholars and commentators regarded divided government as leading to institutional stalemate, the careful empirical

work of Mayhew (1991) offered persuasive evidence that divided government was not dramatically different from periods of unified party control. Mayhew's analysis was not the final word, however, and a number of scholars find more substantial differences between periods of unified and divided party control (e.g., Coleman 1999).

Whatever its effect on legislative productivity, divided government can be seen as symptomatic of a broader sense of dissatisfaction with American politics. This broader discomfort encompassed several related elements of change including the erosion of public support for the Democratic party and its New Deal/Great Society agenda of activist government, the decline of party organizations and their adaptation to a 'service party' role, the increased number and prominence of interest groups in American politics, and the perception that election campaigns had become increasingly vacuous. Public manifestations of dissatisfaction with American politics are evident in lower levels of public support for the various political institutions, declining levels of trust in government, and lower turnout in presidential and congressional elections.

1.2 Remedies

In response to dissatisfaction with US institutions and party politics, some scholars have advocated measures designed to enhance deliberation and participation. Barber (1984) advocates widespread public participation and deliberation over policy issues as an antidote to the flaws of representative government, but most theorists of deliberative democracy believe widescale deliberation is impractical given the size of the American polity and the complexity of contemporary policy issues. The most empirically developed models of deliberative institutions are representative rather than direct, and are not broadly participatory. Bessette (1994) and Mansbridge (1988) advocate strengthening the deliberative norms of existing legislative institutions by developing incentives and sanctions for legislators to deliberate over the merits of public policy and to seek common ground. Fishkin's (1991) deliberative poll establishes a separate forum outside government, composed of a national sample of citizens who are brought together to discuss specific policy issues. This group is immersed in balanced information and analysis of specific issues, encouraged to discuss these issues publicly, and then surveyed about their reflective opinions.

Though more realistic than widespread deliberation, representative models like Fishkin's deliberative poll are less capable of serving the practical and ethical interests that make deliberative institutions preferable to those that are only minimally deliberative. Dahl (1997) has suggested a model of deliberation that bridges the domains of the highly involved and informed representative deliberative bodies and the less involved and informed public. For significant policy problems that normal institutions have failed to solve he proposes that a nonpartisan expert commission present alternatives to representative groups of citizens in deliberative poll settings at the national and state levels; these poll results can then be used to spark a larger public debate. Dahl's proposal is creative, yet questions persist about how more active and reflective subgroups of the citizenry can communicate their deliberations effectively to the general public.

2. Citizenship and American National Identity

2.1 American Civic Culture

Since the mid-1960s there has been a shift in focus in the study of the development of American civic culture. The influential paradigm of liberal or Lockean America stemming from Hartz (1955) remains strong but has been challenged by scholarship emphasizing the civic republican intellectual roots of the founding period. Wood (1992) and others have drawn attention to this neglected republican intellectual tradition that valued civic virtue, participation in public life, and social cohesiveness, and worried about constitutional stability and corruption. These ideas waxed in the eighteenth century but waned in the nineteenth with the growth of commercial society and the growing attractiveness of market economics. Works in constitutional theory by Michelman (1988) and in political science by Dagger (1997) attempt to use elements of the civic republican perspective, such as the imperative of civic duty and deliberative public discourse, to critique and reconstruct trends in American civic culture. In contrast to its eighteenth century forebear, contemporary civic republicanism is less skeptical about market economics, more socially inclusive, and more concerned with protecting individual rights (Dzur and Leonard 1998).

The continued relevance of nationalist political movements in the twentieth century casts new light on American civic culture. In comparative and theoretical work on the subject of nationalism the American case typifies civic, as opposed to ethnic, nationalism (Greenfeld 1992). Both forms of nationalism designate political cultures that achieve coherent and unique identities. In such cultures citizens recognize a relation to each other, to previous generations, and to their territory, that distinguishes them from members of other nations (Calhoun 1997). Civic nationalism permits universal accessibility to that national identity so that race, ethnicity, creed, or previous national affiliation are not formal barriers to becoming a fully-fledged member of the nation. The features of the American case most prominent in discussions of civic nationalism are the relative importance of constitutional patriotism and the relative unimportance of

ethnic identity as binding social forces (Habermas 1992).

2.2 Rights and Duties of Citizens

The growth of the American state and its increasing regulatory, administrative, and social welfare functions was a *de facto* rejection of the Lockean model even though Lockean language remains prominent in public discourse (Skowronek 1982). Rights of American citizenship could no longer be seen simply as negative rights—rights of protection against harm or injustice by others. Rights-bearing in the social welfare state meant, for many Progressive era intellectuals, access to food, shelter, education, and other resources needed for human development. American liberalism in the thought of someone like John Dewey became a hybrid set of values. Certainly values such as equality and freedom of speech remained central, but Dewey (1935) also asserted a positive collective commitment to human development within the context of a culturally plural, participatory, and reflective public culture.

Just how expansive welfare commitments could be justified became a central question in academic and public discourse in the 1970s—a period marked by economic recession, inflation, and tax limitation revolt. Questioning of the welfare state by libertarians like Hayek (1978) was launched from the neoclassical platform of Lockean liberalism. Taxation for support of positive rights could only be justified if it had the free agreement of those taxed, otherwise one person's positive rights were another's exploitation. Two works of normative political theory, Rawls' *A Theory of Justice* (1971) and Dworkin's *Taking Rights Seriously* (1977), developed a sophisticated defense of egalitarian social policy. Rawls and Dworkin argued that at the core of a legitimate constitutional settlement was a commitment to treating all citizens with equal concern and respect, a commitment that required close attention to the worst-off members of society. These were liberal defenses of the social welfare state since they were built on the idea of individual right and freely given constitutional arrangements. Not surprisingly, like the social movements of the 1960s and 1970s, the defense of positive rights turned to the judiciary rather than to the legislative or executive branches.

The justification of social welfare on the grounds of individual right and, more generally, the dominance of 'rights talk' in public discourse, came under scrutiny in the 1980s by academics and public intellectuals with close affinity to the civic republican tradition (Glendon 1991). 'Communitarians' such as Sandel (1982) pointed to the absence of an adequate political sociology of positive rights. Positive rights, sociologically and normatively speaking, were duties grounded in shared historical experience and common values. Such duties could not be understood as matters of reciprocity or self-interested calculation. Communitarians pointed out that civic duties in a well-functioning polity sometimes demanded sacrifice, as exemplified by military service and political participation.

2.3 Multicultural Citizenship

Recognizing the relevance of cultural pluralism as a defining feature of American civic life, Progressive-era thinkers advocated a 'federated' system of cultural preservation (Kallen 1915). Opposed to nativist renderings of a monocultural America ethnically defined by early New England settlement, and critical of an emerging mass culture that threatened homogenization, these writers applauded American cultural diversity. Their America was fundamentally an immigrant country marked by geographical regions with concentrated settlements of French, Norwegian, German, Irish, and other groups. This diversity was to be preserved, as an antidote to cultural homogenization, by state and federal acts such as bilingual education. With his concept of 'double-consciousness,' du Bois (1903) contributed to the optimistic and mostly colorblind Progressive discourse a recognition of the role African-Americans played in constructing a distinctive American identity. His work brought out the suffering, as well as the pride, bound up in the hyphenated sense of self.

Both the suffering and the pride of American cultural pluralism have been strikingly important themes politically and socially since the early 1980s. This renewed cultural pluralism was sparked in part by concerns shared by Progressive era intellectuals—homogeneity and monocultural rhetoric in public discourse—but must also be attributed to the success of liberal social movements of the 1960s and 1970s. For contemporary cultural pluralists, equal treatment under law leaves unsatisfied needs for dissimilar treatment. Politically, this view has led some to argue for group vetoes or other extrarepresentational means for preserving cultural integrity and for achieving positive affirmation of difference (Young 1990). Representation is an issue too for historians and literary critics who have pressed for a reconstruction of American history and culture that attends a multiplicity of voices. Their purpose is not simply to add neglected voices—say Mexican-Americans—to the traditional historical or literary canon, but to demonstrate how American arts, letters, and politics could not have been what they were and are without the experience of such groups (e.g., Morrison 1992). For individuals, cultural pluralism reveals new complexities in the struggle to construct personal identities. This individual struggle plays out politically when, for example, government tries to classify people using the part ethnic, part racial, part political categories of the census (Hollinger 1995).

The political impact of the multileveled category of cultural identity has come under scrutiny. Some have

argued that 'identity politics' endangers the commitment to common egalitarian ideals that marked the civil rights movement, both by emphasizing differences over commonality and by targeting group-specific political goals (Gitlin 1995). These critics note that traditional cleavages in American civic culture such as race, class, and gender still mark striking differences in individual achievements and life-plans and therefore still require civic solidarity rather than a politics of group difference. Other scholars and public intellectuals note that some differences comport poorly with others and some differences are downgraded in the discourse of cultural pluralism. How well the value of group self-determination comports with the frequently tradition-threatening value of gender equality is one concern (Okin 1999). How comfortably religious faith—a traditional difference between citizens and a difference that has historically provoked discrimination—fits into the category of 'identity' is another concern (Carter 1993).

3. *The Study of America*

The study of politics remains central to any effort to understand the American experience. Despite President Clinton's bold rhetorical claim that 'the era of big government is over,' the administrative state is well entrenched. Though there have been no major changes to US political institutions in the last three decades, scholars have raised concerns with interest group pressure, divided government, and public dissatisfaction with American politics. Creative proposals for encouraging greater public participation and deliberation are possible remedies, though much work remains to be done to gauge their effectiveness. Scholars have also sought to understand the dynamics of American civic culture during a period marked by struggles to justify substantive rights of citizenship and struggles to acknowledge cultural and other significant differences between citizens. Thorny issues persist regarding American citizenship and its intellectual heritage, with considerable disagreement about how the various components of individual and group identities ought to fit with contemporary notions of citizenship. There is, however, widespread recognition that debates over the rights, obligations, and even identities of citizenship will continue to mark this vibrant civic culture.

American Studies: Religion

1. The Term 'Religion'

Because religion is a decisive element in much of American life, the nation's spiritual impulses, expression of faith, and religious embodiments are subjects of analysis in American Studies.

Defining religion is difficult in any circumstance, but it is notoriously so in a society that describes itself as religiously pluralistic. The word religion anywhere can refer to literature that points to the transcendent as well as to philosophy expressive of ultimate concern. It may mean dogma within formal religious bodies and also vague and individualized spirituality. Religion may refer to God but it may not. Normally it implies the awareness of a supernatural or suprahuman force or person that acts upon people who, in turn, respond. Scholars of religion in American studies are attentive to all this plus expressions in myth and symbol or rite and ceremony, in metaphysical concerns and behavioral correlates of faith. They may even study phenomena as concrete as church, synagogue, or mosque.

2. Earlier American Studies and Religion

Before American Studies became a formal complex of academic disciplines, and before these disciplines were professionalized, writers were emphasizing the role of religion in the nation. Clerics as early as Cotton Mather (1663–1728) were analyzing and, in his case, criticizing the cultural manifestations of religion in New England. Thus Mather's *Magnalia Christi Americana* (1702) concentrated on the pieties and religious declensions of New England. A century later Benjamin Trumbull (1735–1820) again concentrated on New England, arguing in 1797 that 'the settlement of New-England, purely for the purposes of religion, is an event which has no parallel in the history of modern ages.' He spoke of 'settlements' and 'sentiments' alike, and helped set American Studies on a path of New England concentrations.

Still an amateur at what became American Studies were figures like Edward Eggleston (1837–1902), a writer of fiction who saw the characters in his novels as 'forerunners of my historic studies.' A Methodist circuit rider turned self-described unbeliever after 1880, he transferred his curiosities from chronicling churches to pursuing new faith in science and criticizing the New England faith praised by people like Mather and Trumbull before him.

Most American Studies writers before the Civil War were amateurs who concentrated more on historical accounting than literary analysis. George H. Callcott tracked down the vocations of the 145 historians in *The Dictionary of American Biography* who did their main work between 1800 and 1860. Listing them by professional occupation he found that 34 were clergy, 32 lawyer-statesmen, 18 printers, 17 physicians, down to one historian. We stress this both to suggest how ill-defined were the means of disciplinary access to American Studies and to suggest why religion was programmed in to be such a major feature of these Studies in earlier times.

3. Professionalization of American Studies

The development of the modern university, marked as it is by differentiation and specialization, meant that professional historians and literary scholars pursued their ways rather independently of religious and theological scholars, particularly of those whose research focused on religious institutions. Such scholars tended to be segregated in divinity schools, often at the margins of universities, or in denominational theological seminaries out of range of graduate schools.

There were personal reasons for the marginalizing of religion in early American studies. The first generations of professional historians—Charles Beard, Carl Becker, Frederick Jackson Turner, James Harvey Robinson—all had intense childhood religion backgrounds, often in small towns. They moved from these to the urban and university scene, liberated from what they remembered as the confinements and low imagination of their churches. Most of them left behind, along with their faith, any positive curiosity about religion in American culture.

Meanwhile, when professional societies formed, they tended to downplay religion, so American Studies scholars preoccupied with religion went their own way. Thus shortly after the American Historical Association (AHA) was formed in 1884, an American Society of Church History (ASCH) under church historian Phillip Schaff developed rather independently of the secular organization. Schaff thought it to be an embodiment of 'the increase of rationalism.' Both societies attracted historians who also dealt with fields other than American. But when religious history did become the focus and American the topic, the AHA historians tended to dismiss religion. Mean-

while, the ASCH historians concentrated on the Christian churches, often seeing these apart from their cultural contexts.

4. American Religious Studies Outside America

The impression that religious studies were in a way parasitical, living off methodological developments in literature and history is reasonably accurate. Was there nothing that could be called religion standing independently in the academy? It happens that during the first half of the twentieth century, disciplines called History of Religion or Comparative Religion began to be imported form Europe. These were translations of what Germans called *Religionsgeschichte* or *Religionswissenschaft*. Giants such as Max Müller and Rudolf Otto had their disciples, importers, and adapters in America. Around the beginning of the twentieth century, six universities especially encouraged such religious studies: Boston University, the University of Chicago, Cornell University, Harvard Divinity School, New York University, and the University of Pennsylvania made commitments to pursue such 'scientific study of religion.'

Little came of these early efforts. There were few graduates and very few of these found academic employment. Most notably for our purposes, most of the pioneers chose to deal with what were then called 'primitive' or 'elementary' religions that were remote in space or time from the United States. James Freeman Clarke, Morris Jastrow, Jr., Louis H. Jordan, and George Foot Moore were notable scholars who flourished between the 1870s and the 1910s. None of them put energy into American Studies—including even Native American experience, which should have come into their purview. American Studies languished.

5. University Interest in America

Often seen as a time of turning came as a number of notable literary and historical scholars, most of them concentrating on New England sources, began to discern the revelatory character of religion in American culture. They concentrated chiefly on the long-discredited, even scorned New England Puritans. Far from dismissing these as idiosyncratic obscurantists, the new scholars took the Puritan metaphysic and piety seriously and suggested that these came to be suffusive elements far beyond the churches.

Thus Samuel Eliot Morison (1887–1976) admitted that he had once been derisive of these early Americans whose faith he did not share. But with Kenneth Murdock at his side he lifted up precisely the religious aspects of Puritan culture for positive viewing as intellectual forces.

The third of the rediscoverers of Puritan influence, usually regarded as the most significant shaper of American studies of religion in his generations, was Harvard's Perry Miller (1905–63). Miller was a formidable researcher who also did not share Puritan faith but argued that it was worthy of study, a major contributor to American cultural life. Miller was an intellectual historian who underplayed the social aspects of Puritan (and later early national) life. He did so while criticizing what he saw to be the reductionism of the social historians or the philosophy of history of the progressives. While Miller was to inspire reaction from both of these schools after his long prime (1933–63), he brought respectability of a new sort to religion in American Studies.

6. The Establishment of Religious Studies

The modern location of religious studies within secular, often tax-supported universities is usually traced to the interests of post-World War II citizens during a period of 'religious revival.' When the Soviet Union launched Sputnik in 1957, Americans responded by expanding universities. While this expansion naturally favored the sciences, the humanities also prospered and, with them, departments of religious studies. Through the 1960s and the 1970s the number of these burgeoned into the hundreds. The American Academy of Religion (AAR), the Society for the Scientific Study of Religion, the Society for Values in Higher Education (which had been the Society for Religion in Higher Education), the Religious Research Association, and any number of more specialized groups attracted and gave encouragement to thousands of professors.

While these religious studies departments included scholars who focused on everything from African Religions through Korean Religions to Womanist Approaches to Religion and Society—these being names of American Academy of Religion Groups—American Studies also found new subject matter. Thus the ARR hosted Afro-American Religious History; Asian North American Religion, Culture and Society; Church-State Studies; Hispanic American Religion, Culture, and Society; Native Traditions in the Americas; Pragmatism and Empiricism in American Religious Thought. These and many more provided windows on American Studies that went far beyond New England Puritanism and historical disciplines.

7. The Lie of the Land in American Studies: Religion

The most significant change over the century saw a move from ecclesiastically and confessionally-based studies, many of them having evangelistic or polemical intent, to phenomenological, either putatively disinterested or ideologically influenced accents that were not confined to particular religions (e.g., Freudian, Marxist, feminist, deconstructionist, and the like).

Some scholars, like those of a century earlier who had been in rebellion against their own youthful religious formation or who were seeking respectability in those parts of the academy and intellectual circles that are unfriendly to religion, adopted positivist stances and often expressed hostility to most religious expression.

Debates are waged as to whether religious studies should ever be pursued except through social scientific reductionist means. That is: if one 'appreciates' religion or writes with empathy as if from within the spiritual sphere, it is charged that this stance will skew scholarship and make the student of religion in America a biased agent. At the same time, others conversely suggest that religious participation may lead to an empathy that can inform inquiry without leading to distortion and bias. All the standard arguments on the old 'objectivity' and 'subjectivity' fronts get reworked in the service of various sides in these debates.

Since the religious theme in American studies is not pursued through a free-standing discipline—though with internal variety and argument—such as anthropology, but in a sense borrows from and contributes to existing disciplines and methods, religious studies is exposed to the various disputes in the disciplines, often with special intensity.

Thus the issues brought to the agenda by terms such as deconstruction and postmodernity are especially acute for those who study religion. This is partly the case because the final object of most religion—be it 'God' as in Judaism, Islam, and Christianity, 'Holy Emptiness' in Buddhism, or 'the Sacred' in general—eludes empirical analysis. Thus the scholars in the tradition of Morison, Murdock, and Miller, however congenial they be to the substance of Puritan thought, stand outside it. They are reduced to dealing with the human experience of the transcendental or supernatural, and not with the 'thing' itself. Most scholars of religion are content with this distancing from the subject, but some voices within religious communities argue that on such premises one cannot grasp the depth of religious commitment or meanings.

Similarly, in respect to deconstruction: the detachment of symbol from reality, or the rendering of connections between them as arbitrary, while it threatens all systems of meaning, appears to be most jeopardizing when these systems and symbols point to what Paul Tillich called 'ultimate concern.' Can one do justice to religion in American life while doing violence by scholarly inquiry into the attachments the religious citizens have to their objects? Conversely, ask others, can one do justice to religion in culture if one does *not* do such violence, wresting religious symbols and meanings from the privileged place adherents want to give them?

In the midst of such debates, some raise the question of the role of theology in all this. Most of the American people, movements, institutions, and forces that get categorized as religious, approach their ways of life with at least some broad and minimal set of theological affirmations. Theology in this context is not the same as faith or religious experience, but is a reflection on claims made by people of faith and piety. It is a second-order category, something that may be described as an interpretation of personal or public life, the life of a people (e.g., Hindus, lesbians, Asian-Americans) in the light of what they regard as a transcendent reference. What about the theologian who stands inside such believing communities?

There have been major students of American religion who are explicitly theologians. A prime example is H. Richard Niebuhr who wrote two classic works, *The Social Sources of Denominationalism* in 1929 and *The Kingdom of God in America* in 1937. Niebuhr belonged to a school of Protestant neo-orthodoxy that passed from vogue in the 1970s. But he used its critical yet faith-full vantage to trace several key ideas through an America that in 1937 was more decisively shaped by mainstream Protestantism than it could conceivably be construed as being thus influenced today.

Niebuhr unashamedly but with sophistication talked about how 'revelation means for us that part of our inner history which illuminates the rest of it and which is self intelligible,' over against 'external history.' He made no claims that 'truth' vs. 'falsehood' were here at stake so much as matters of perspective that illumine the scholars' subjects in contending ways. He saw his own earlier book as too strongly committed to 'external history' through social sciences and the latter as a corrective of it. Today both are seen as primary sources of historic approaches to religious studies.

Similarly, in 1955 Jewish theologian and sociologist Will Herberg (1955) wrote a determinative study of American religion during the Eisenhower religious revival, calling it *Protestant*, *Catholic*, *Jew*. It was a provocative analysis colored by all sorts of normative judgments based in the Hebrew prophetic tradition and modern existentialist interpretations. Works such as Niebuhr's and Herberg's are dated today, and exemplary of the work of few at the century's end. Yet they illustrate one end of a spectrum of options at the opposite pole from the social scientific reductive versions.

At the twentieth century's end, while historians in great numbers pursued a wide range of historical expressions of religion, literary studies came into their own in the American Academy [of Religion] and the American academy in general. This has meant a study of American classics—Melville, Hawthorne, Whitman, Adams, and the like; modern poets and novelists—Frost, Stevens, Eliot, and more. They had been long researched in American Studies for what they might disclose about American life.

In the subsequent deconstructionist and post-modern episodes there is much less belief that disclosure of

metanarratives or larger meanings is possible. By century's end the returns were not in on these debates and the scholarly commitments that led up to them or issued from them.

8. *The Special Issue of Pluralism*

It may create a false impression to speak in generic terms of 'American religion.' From some points of view all that religions and religious voices have in common is their issuance from American as a place. Gone are the days when a Perry Miller or Yale historian Sydney Ahlstorm could credibly and in sophisticated ways make the claim that American intellectual and cultural life was New England Puritanism writ large, or that H. Richard Niebuhr could talk of the Kingdom of God in America in Protestant terms as being disclosive of meaning in the larger whole.

Instead, historians and literary scholars tended to become more eclectic, to deal with national life in more piecemeal terms. Collections of American Studies essays are likely to focus on what the subheads suggest in an essay by historian Catherine Albanese—who operates at a pole opposite from that which Philip Schaff or Sydney Ahlstrom suggests: 'Indian Episodes,' 'Catholic Encounters,' 'Protestant Relations,' 'African American Ports of Call, Jewish Alliances, and Asian Junctures,' 'Contacts and Combinations.'

Whether this eclectic, post-modern, anti-metanarrative approach is or is not contributing to the formation of an altered canon with privileged texts seen as disclosive of larger stories is an issue that will animate and agitate American Studies: Religion for years to come.

M. E. Marty

American Studies: Society

When the academic discipline of 'American Studies' was developed in the course of the 1930s, it was explicitly set up as an area of studies where scholars and students of, notably, history and literature could meet and join forces in an integrated, interdisciplinary context in order to redress what was felt to be an increasingly acute challenge: how to bridge the widening gap between the literary and historical approaches to the study of American society. However, the emergence of this new, holistic approach to American society immediately created its own dialectic: between those seeing American society as a whole, and those emphasizing its plurality; between those wanting to

highlight American society's unifying myths and symbols as well as its common values and aims, and those drawing attention to its centripetal forces, sometimes identifying these as a dynamics of cultural diversity, sometimes as a tendency toward social segmentation and discontinuity. Even at the beginning of the twenty-first century—as we emerge from the 'culture wars' of the late 1980s and 1990s—it remains difficult to establish any kind of consensus among analysts about the common denominators in American society, about its inner core or even its outer boundaries.

Nevertheless, a number of recurrent themes can be identified that appear to dominate past and present debates in American studies about the nature of American society. Following that society through history, distinguishing the lasting from the transient, the center from the periphery, was one of the original drives behind the emergence of American studies, and this strategy continues to inspire and energize the discipline. Although it may never have become the holistic approach originally envisaged, few in American studies today would deny that trying to understand and describe American society is in effect an attempt to fathom what sustains that society, what forces operate it and direct its purposes. Hence, even though, as Wiebe has argued in *The Segmented Society* (1975), surveying the whole of a society always tends to emphasize social patterns rather than social processes and to subordinate 'a history of themes inside American society to a history of the society incorporating them,' one may still look meaningfully at those themes, and at the history of their emergence and development. That is what American studies, from a wide variety of disciplinary angles, continues to do.

1. Terms and Periods

Apart from qualifying the unanimity among scholars in American studies regarding the object and methodology of their inquiry, a further note of caution should be sounded concerning terminology. Within the discipline of American studies—itself an umbrella term—the term 'society' is usually taken to refer to the aggregate of the politics, history, economics, education, geography, religion, environment, and culture of the United States, as well as to the relations and tensions between these elements. However, many Americanists, especially those approaching their object from the realms of literary analysis, the history of ideas, and 'cultural studies,' would refer to the same grouping of aspects of American society and the interplay between them as American 'culture.' As Potter remarked in *History and American Society* (1973), this terminological confusion is symptomatic of 'a serious general problem in the study of societies,' viz. the lack of fixed points of similarity in different societies, and between different aspects of societies, with which to measure continuity and separateness. For the sake of clarity (and following Wiebe), 'culture' will here be defined in its more narrow sense as 'those values and habits conditioning everyday choices in such areas as family governance, work, religious belief, friendship, and casual interchange,' while 'society' will be seen as combining 'these patterns with broader and more systematic realms of behavior, such as the organization of a community's life, the structure of a profession or business or religious denomination, and the formula for apportioning economic rewards.'

Traditionally, the evolution of American society during the first two hundred years since the Revolution has been divided into three phases, each associated with a distinctive social system: from the Revolution to the 1790s; from 1830 to 1890; and from 1920 to the 1970s. The intervening years—from the 1800s to the 1830s, and from the 1890s to the 1920s—are seen as crucial periods of transition from one social system to the next: from 'eighteenth-' to 'nineteenth-,' to 'twentieth-century society.' Whether the last three decades of the twentieth century constitute a fourth phase in American society (cf. for instance Lipset 1979), or a continuation of the transitional period of the 1960s and 70s, or, indeed, the 'disuniting of America' altogether as signaled by others (cf. Schlesinger 1991), is still a moot point. In the following, aspects of American society that have dominated debates and explorations in American studies will be discussed in terms of their emergence and evolutionary history.

2. Seventeenth- and Eighteenth-century Society

American society, one often reads in accounts of the settlement and early colonization of North America, began with a dream—a vision of a morally pure, socially just New Eden, itself the reflection of a long tradition of European utopianism. European observers and settlers alike represented seventeenth- and eighteenth-century American society in terms of a transatlantic opposition that is still relevant today: an opposition between Old World corruption and New World innocence, between darkness and light, between stasis and progress. For even if the early American settlers were a motley crowd internally divided by differences of ethnicity, language, ideology, religion, politics, and commercial interest, there was always a remarkable consensus among them about what America was, or was supposed to be—a society that, defining itself against the backdrop of European wars, exploitation, inequality, and persecution, was somehow unique, whole, progressive, and civilized.

More remarkable than that, perhaps, was that, despite their differences, the various stakeholders in the new nation were all prepared, if for very disparate reasons, to rally round a symbol of American society

first provided by one radical group of early settlers, the New England Puritans. As early as 1622, Puritan leader John Winthrop labeled England as 'this sinfull land,' plagued by poverty, inequitable taxation, a bureaucratic legal system, and religious intolerance; as the first elected governor of the Massachusetts Bay Company, Winthrop set off for New England in 1630, envisioning a 'city upon a Hill' as the utopian foundation for the new society that he and his fellow Puritans would be building. The New England Puritans may have had fairly specific religious reasons for regarding their community as a model for other colonists and as the first step toward establishing a kingdom of God in the New World that would lead the world into a new millennium, but the image of America as 'a beacon upon a hill' sufficiently reflected the ambitions of other, non-Puritan settlers for it to be adopted widely as one of the most resonant and sustaining symbols of American society, both in qualitative, intrinsic terms, and in its relation to the rest of the world. Thus, long after the waning of the Puritan theocracy, the founding fathers of the 1630s continued to be ritually invoked as heroes in the cause of liberty—not just in New England, but throughout other Eastern States and the South, and as much during the Great Revival as during the French and Indian War and the Revolution. The epic of the Puritan exodus became the common property of all Anglo-American settlers, and the rhetoric and ideology of the Puritan religious errand into that 'unredeemed, unchristianized, lawless region' (as Hawthorne put it) became the rhetoric and ideology of America's cultural errand into the 'wilderness.'

As a symbol reflecting the internal dynamics of the group, the idea of America as a bridgehead of civilization beleaguered by a 'vast and desolate wilderness' (Rowlandson 1994) to an important degree determined the social mechanics of what has been termed 'the ritual of consensus' (Bercovitch 1993). Faced as they were by the challenges of survival and success, consensus filled the need felt by Puritan and non-Puritan settlers alike for a certain social order. In particular, such a ritual of consensus had to regulate the rights and responsibilities of the individual versus the group. According to Bercovitch, there were three basic tenets of Puritan consensus, which in the course of the seventeenth century transformed from a tribal ritual into a national ritual of cultural and social origins. The first tenet was migration, as a function of divine mission or prophecy—which contributed significantly toward rationalizing the expansionist and acquisitive aspects of settlement (the Puritans being as much interested in material gain as in salvation). The second tenet of consensus was related to discipline: seeing that an individual's success made visible the meaning of the errand of the group, the challenge was how to endorse individualism without promoting anarchy. The third tenet of consensus was concerned with progress: constantly affirming that it was en route from a sacred past to a sacred future, the Puritan community established institutions that were geared more toward sustaining progress and growth than toward maintaining stability. Crucially, the Puritan ritual of consensus was constantly enacted—both in the sense of established in law and in the sense of publicly performed—in a series of interlocking covenants to which individuals were invited to subscribe their names if they wanted to be regarded as members of the community. The first and most famous of such civil covenants, the 'Mayflower Compact' (which was signed in 1620 by the Pilgrim Fathers on board the ship that took them to what was to become Plymouth Plantation), reflects how these covenants were aimed at establishing a 'Civil Body Politic' by preserving individual freedom while demanding submission to 'the general good.' It is this Puritan rhetoric of voluntary compacts and consensus, of community grounded in individuals committing themselves freely to their 'common providence,' that gave American society its unique slant on the universal process of introducing systematic relationships among individuals, groups, and institutions; and it is the same rhetoric that, being both universal yet culturally specific, facilitated the transition from the Puritan to the Yankee, and from errand to manifest destiny and the American Dream. It is the legacy of the Puritan errand that lies at the basis of America's social awareness vis-à-vis the world at large: America as the 'redeemer nation,' which, according to Tuveson (1968), can be reduced to the following key elements: 'chosen race; chosen nation; millennial-utopian destiny; fighting God's war between good (progress) and evil (regression), in which the United States is to play a starring role as world redeemer.' Thus, when Woodrow Wilson said that 'America had the infinite privilege of fulfilling her destiny and saving the world,' he was not saying anything startlingly new.

In the course of the second half of the eighteenth century, the spiritual and the more secular beginnings of American society (symbolized by Plymouth Plantation and Jamestown, respectively, by the 'beacon on the hill' and the Horn of Plenty) had become sufficiently blended for Crèvecoeur to be able to pose the notorious question in his *Letters from an American Farmer* (1782), 'What, then, is the American, this new man?' and to assume—or suggest—that this was actually more than a rhetorical question: that there really was such a social subject as 'an American.' What in hindsight is perhaps even more perplexing than Crèvecoeur's question as such, is his answer to that question: Crèvecoeur's 'American' and the society he is said to have created are still by and large what we would recognize as American national identity and society today. An immigrant newly arrived in America, Crèvecoeur informs us, would find himself 'on a new continent; a *modern society* offers itself to his contemplation, different from what he had hitherto seen.' He would see a society that is egalitarian and

classless, in which individuals are 'animated with the spirit of an industry which is unfettered and unrestrained, because each person works for himself.' The world's poor, oppressed and persecuted will find safety and plenty of opportunity in 'this great American asylum.' To underline the radical modernity and uniqueness of this new society, Crèvecoeur assures us that in America 'individuals of all nations are melted into a new race of men, whose labours and posterity will one day cause great changes in the world.' The millennial dreams of the New England Puritans have in Crèvecoeur's *Letters* become America's millennial dreams—now all Americans are 'pilgrims': 'Americans are the Western pilgrims who are carrying along with them that great mass of arts, sciences, vigour and industry which began long since in the East; they will finish the great cycle.'

3. *Nineteenth-century Society*

The individual's 'self-interest' and his concomitant voluntary submission to his nation's mission form the nucleus of Crèvecoeur's America—and they still do. The American Revolution, which ended the colonial stage in the evolution of American society, did not therefore constitute that sharp, radical break it has traditionally been made out to be. Since the end of the French and Indian War, self-interest had been synonymous with (Protestant) patriotism, and it was through their appeal to this patriotic self-interest that the Revolutionary leaders managed to steer the colonies victoriously through the conflict with Britain and toward nationhood. Thus, while Crèvecoeur's distressed frontiersman announces in his final letter (burdened by his creator's nostalgia for utopian pastoralism) that in 'these calamitous times' he feels forced to flee his farm and to resettle his family 'under the wigwam' in the western wilderness, the Whig leaders succeeded in bringing the violence and disruption of the Revolution under control by turning it into a redemptive, controlling ritual of national identity. The push for independence, which elsewhere (most notoriously in subsequent years in France) often triggered a complete collapse of the social fabric as the forces of change spun out of control, in America engendered a spirit of intense nationalism and enforced the model of consensus. What the Puritan Fathers had begun—overcoming discord in society by turning anxiety into a vehicle of social control—was now finished by the Founding Fathers.

With the 'family quarrel'—so unfortunate but necessary—finally over, America was ready to enter the final phase of its evolution toward full nationhood; the Revolution having given America independence from the Old World, it was now time to complete the errand into the wilderness by going west, not to hide under a wigwam, but to conquer the continent. Space and diversity, as Madison had argued in *Federalist Number Ten*, would be the best guarantors of liberty, because a dispersed and heterogeneous nation would be able to contain more factiousness than a compact and more homogenous one. And the dangers of faction were increasing all the time in the wake of the Revolution, as the system of graded and interlinking social relationships of eighteenth-century society—marked by paternalism, the moral economy, and virtuous republicanism (or 'civic virtue')—began to give way to an increasing emphasis on personal mobility—social mobility as well as geographical.

Uncurbed social ambition and a vigorous spirit of enterprise led to a rapid crumbling of deferential restraints, and the meaning of American wholeness came under significant pressure during these years of transition. The old household economy of colonial America had gone into a complete nosedive in the 1790s; fuelled by the stirrings of industrialism, the opening up of the west, the Louisiana Purchase of 1803, and the Napoleonic Wars in Europe (which virtually eliminated mercantile competition), liberal capitalism triggered a socioeconomic revolution that transformed the United States in the course of two decades into a market economy and market society. The end of the War of 1812 gave a further boost to America's economic revolution, with a rapidly growing immigrant population, and the building of the canals and the early railways permitting the republic to enter an era of unprecedented expansion, especially toward the vast western regions.

American geopolitics in the early decades of the nineteenth-century to a large extent shaped the growing awareness of nationhood and state. This resurgence of nationalism peaked with the so-called 'Monroe Doctrine,' which basically meant that the United States declared they would not accept any future colonization by European powers of 'the American continents.' But in social terms a price had to be paid for America achieving hegemony in the Western Hemisphere, and a controversy erupted over the question of not whether, but how the nation should be allowed to expand. With the election of Jackson as President of the United States in 1829 a powerful democratic movement swept the country, paving the way for mass politics and what was called at the time 'the age of the common man.' The fight against social and economical inequality and privilege dominated the national political agenda. And although there is still considerable disagreement among historians as to how much of this drive toward democratic reform and anti-elitism can actually be attributed to Jackson and his followers, the reaction against laissez-faire capitalism from among the working classes and other exploited groups in the new industrial society was considerable. Liberty and equality became the cornerstones of the new American society—even though the veneer of egalitarianism did not affect a host of distinctions underneath (notably those of race and gender).

A tourist like the French aristocrat Alexis de Tocqueville, who came to America in the 1830s to discover why the efforts at establishing democracy in France, starting with the French Revolution, had failed while the American Revolution had produced a stable democratic republic, may not have seen far beyond the surface respectability but he did make some seminal comments on American egalitarianism. According to Tocqueville, America was 'the first new nation' in the world. In fact, it was Tocqueville who first referred to the United States as 'exceptional,' that is, as a nation qualitatively different from other nations. In his extraordinarily influential book *Democracy in America* (1835–9), Tocqueville identified five elements in the American Creed as it had emerged from the revolutionary ideology—liberty, egalitarianism, individualism, populism, and laissez-faire—but, as Tocqueville pointed out, egalitarianism in American involves an equality of opportunity and respect, not of result or condition. Therefore there is no emphasis on social hierarchy in America—no monarchies or aristocracies (which distinguishes the United States from post-feudal nations as such)—although there is social segmentation. It is this, Tocqueville noticed, and many others since him, that was central to American exceptionalism: 'What held Americans together was their ability to live apart .... From this elementary principle emerged a pattern of beliefs and behavior that was recognizably American' (Wiebe 1975).

The idea of space as a sine qua non of liberty and equality was popularized at the end of the nineteenth century by the historian Frederick Jackson Turner. At a point in America's history when, he claimed, the vast, unsettled lands were gone, Turner identified the westward expansion of the United States as the crucial formative force behind American individualism, nationalism, and democracy. Because he had to constantly reinvent himself and reconfirm his essential Americanness as he pushed further west, the frontiersman, Turner argued, had defined American civilization. With the waning of the western wilderness, a crucial period in American history had closed. In fact, Turner's concerns turned out to be rather premature as in the decades following his bemoaning of the 'passing of the frontier' the US government gave away more land from the public domain than it had done before—but the 'frontier myth' kept a romantic image of the West alive for long after.

4. *Twentieth-century Society*

If, as historian Richard Hofstadter 1948 has observed, it has been America's 'fate as a nation not to have ideologies, but to be one,' then that ideology was very much in place at the beginning of the twentieth century. But although the ideology did not change materially from that of the late nineteenth century, the face of society did. One of the most conspicuous developments was the emergence of a new social elite—the occupational elite. The end of the nineteenth century saw an explosion of the number of Americans in administrative and professional jobs. Industry and the new technologies needed managers, technicians, and accountants; cities needed professionals in the medical, commercial, legal, and educational services. By the turn of the century, these new professionals had come to constitute a distinct social group—the new middle class.

Although the new professional class enabled individuals to climb the social ladder more rapidly than in the nineteenth century, the new class was by no means any more homogeneous—the nineteenth-century segmentation of society on the basis of region, ethnic background, and access to capital was replaced by a segmentation according to professional occupation—each segment (clerks, technicians, lawyers, teachers, engineers) having its distinct identity and social awareness, and the vitality of each depending on the vitality of the whole.

While diversity remained the common denominator in society, the need for cohesion in the national society never disappeared—the ideology of consensus still being as strong as in the days of the Puritans. If in the nineteenth century the outrage of national conscience had directed itself against sloth, drunkenness, and profligacy, in the twentieth century the social hegemony aimed its arrows at the leveling left, communists, and other 'un-American' elements (descendants of Crèvecoeur's 'off-casts') that threatened to undermine the 'volutary order' (Berthoff 1971).

But the most powerful cement of the new social system was consumption. Starting hesitantly in the latter decades of the nineteenth century, accelerating in the 1920s, and exploding in the 1950s, consumption became the foundation for the modern America. By the 1960s, consumption was no longer a privilege but a right—to some extent even a civil duty. Consumption became everybody's stake in society—the ultimate equalizer. In the course of the twentieth century, Americans began to regard the meaning of work as the power to spend, and increasingly began to discover their identity and social position in their power to consume. Mass consumption became an inalienable right. Women derived their freedom from being primary consumers; consumption was an effective weapon against communism; and the urban African-Americans who looted shops during race riots thereby underlined the fact that they were still being denied their basic civic right: the right to consume.

Consumption has been regarded as the ideological twentieth-century answer to the challenges of differences of class and civil rights. The nineteenth century had failed to manage the problems of class; the economic elite of the twentieth century quite early on accepted class as a social fact. By quickly and consistently demolishing labor organizations and any

manifestations of socialism wherever they appeared, and simultaneously offering occupational segmentation as a new model of social mobility, the threat of class conflict was contained. The importance of regular employment was paramount to egalitarianism for the credit it generated: for it was the credit that made the professional or worker a consumer, and the consumer a citizen. In a similar way, twentieth-century society put paid to the issue of race conflict: the economic elite offered members of minorities as well all other Americans a passport to consumerism and a place somewhere in the great interdependency of the system of segmented wholeness. Race, like class, simply was no longer relevant from a socioeconomic point of view. Racial or other minorities can either aspire to assimilate to the segmented system, even to belong to the social elite, or they can decide to rely on such benefits as are provided within the context of social security.

The much-touted revolutionary drive of the 1960s' 'counterculture' did not materially change the system of segmented wholeness. For a while it looked as if there might be more emphasis on the common denominators in American society, as if there were an America beyond the segmented system (classless, gender-neutral, race-neutral). Indeed, changes in the overarching social fabric have occasionally been affected by pressure from within one or more of the segments (such as racial desegregation, and a more equitable job market). But, by and large, America has remained essentially a nation of segments. However, if America still subscribes to this concept of nationality, it does so voluntarily. In contrast to the rest of the world, as Gorer, 1948 has observed, Americans believe that nationality is 'an act of will, rather than of chance of destiny.'

That is what Europeans have never understood about America, according to Baudrillard (1986). He argues that the great lesson of the success of America's social formation is that 'freedom and equality, like ease and grace, only exist where they are present from the outset. This is the surprise democracy ha[s] in store for us: equality is at the beginning, not the end. That is the difference between egalitarianism and democracy: democracy presupposes equality at the outset, egalitarianism presupposes it at the end. "Democracy demands that all of its citizens *begin* even. Egalitarianism insists that they all *finish* even."' Whereas Europe has remained stuck in the old rut of social difference and is constantly dragged back into the history of its bourgeois culture, America, by contrast, has achieved a state of radical modernity, which in temporal terms can be described as a perpetual present. Having internalized democracy and technological progress, America ducks the question of originality, descent, and mythical authenticity. Everything is exactly what it appears to be in America: the real and the imaginary have been collapsed into the 'hyperreal,'—a constant state of simulation, of signs having escaped their referentials in the real. The concept of history as 'the transcending of a social and political rationality, as a dialectical, conflictual vision of societies,' is alien to Americans, Baudrillard observes: the United States is, in fact, a utopia achieved—a society which has behaved from the beginning as though it were already achieved.

5. *American Society and American Studies*

Baudrillard's incisive observations about American society are not unchallenged within the social sciences, but despite the provocative rhetoric, it cannot be denied that his concepts of the 'hyperreal' and the 'utopia achieved' are valuable tools in trying to account for some of the more paradoxical complexities of American society—its fragmented wholeness; its social stability in the face of an unequal distribution of wealth; its belief in 'a pleasing uniformity of descent' (Crèvecoeur 1782) and a 'general happy Mediocrity' (Franklin 1986) when the racial divide appears to be as wide as ever. Baudrillard's agenda—to bring the paradoxical nature of American society into a universal model while retaining the apparent incompatibility of its constituent parts—is certainly unique in the evolution of American studies. From its inception in the 1920s, the discipline of American studies has almost inescapably been concerned with the search for the common denominator in American culture and society: the very success of its mission—to establish and institutionalize a scholarly discipline whose object of study was the society of the United States—depended on the new discipline being able to achieve some sort of consensus about the nature of that object of study.

This mission first took off seriously with the publication of Vernon Parrington's *Main Currents in American Thought* (1927), and was carried further with enthusiasm by the 'consensus historians' of the 1950s (including Richard Hofstadter, Louis Hartz, Arthur Schlesinger, Jr., Daniel Boorstin) and, most importantly (in terms of its impact on the field), by the 'myth and symbol' school of the 1950s (which included intellectual historians and literary critics such as Lionel Trilling, Henry Nash Smith, R. W. B. Lewis, and Leo Marx). The 'myth and symbol' scholars had indirectly been influenced by a host of literary critics in the 1930s and 1940s who were known collectively as the 'New Critics.' Approaching the literary text as an autonomous whole, the New Critics (which included such people as John Crowe Ranson, Kenneth Burke, Yvor Winters, and R. P. Blackmur) emphasized the transcendental qualities of the text: its moral content; its symbolic meaning as a reflection of national culture and identity; and its place and contribution to a national literary 'tradition.' F. O. Matthiessen's extraordinarily influential *American Renaissance: Art and Expression in the Age of Emerson and Whitman* (1941) established a 'great tradition' of nineteenth-century

American authors that represented the 'quintessential' characteristics, concerns, and values of 'mainstream' American society. Inspired by the humanistic ideal of high culture, Matthiessen's canon of nineteenth-century American literature not only introduced a firm hierarchy of 'high' over 'low' artistic expression but also provided the raw cultural materials for the authors of the myth and symbol school. In this way Smith's thesis of the wilderness as the basic ingredient of American civilization, Lewis's insistence on tragic innocence in the myth of the 'American Adam,' and Marx's symbol of the 'machine in the garden' to account for the 'American' dichotomy of pastoralism and technological progress could become the unifying myths and symbols that dominated the study of American society during the 1950s and 1960s.

When, in the course of the 1960s, mainstream American society and culture increasingly came under attack from historically marginalized groups as part of the struggle for emancipation and recognition (women, African-Americans, Native Americans, Hispanics, gays, and other minorities), the theory and methods of American studies were also subjected to critical analysis and reappraisal. If pluralism replaced universalism as the new norm in society, so it did in American studies. Thus the new social history that emerged in the late 1960s and early 1970s began to demolish American exceptionalism, imperialism, and the consensus society, while it tried to recover or create the history of America's 'forgotten' minorities, as well as America's popular culture, and its labor and regional history. Drawing from the techniques and methods of sociology, anthropology, and other human sciences, gender, class, and race became the new 'holy trinity' of American studies.

Increasingly, also new criticism and the myth and symbol school came under attack for being ahistorical and for their philosophical idealism. With the emergence of the 'New Historicism' (ushered in by Stephen Greenblatt and the journal *Representations*) interdisciplinarity and historical contextualization were put firmly on the methodological agenda of American studies. This paradigm shift is illustrated by a seminal collection of essays edited by Sacvan Bercovitch and Myra Jehlen, *Ideology and Classic American Literature* (1988), which contains reassessments of their work by important pioneers of American Studies theory and method including Henry Nash Smith, Leo Marx, and Alan Trachtenberg, as well as essays by a younger generation of scholars, including Houston Baker, Carolyn Porter, Donald Pease, Michael Gilmore, Jane Tompkins, Jonathan Arac and Myra Jehlen—work that exemplified the scholarly output of the 1980s, blending feminist, neo-Marxist, and poststructuralist theories and methods.

However, whereas among the newly emancipated groups this pluralist approach to American society was experienced as liberating (both intellectually and politically), a growing number of scholars began to interpret the new trend toward plurality as undesirable. Christopher Lasch was one of the first to sound the alarm bell. In *The Culture of Narcissism* (1979) he argued that the 'devaluation of the past' was symptomatic of a deep 'cultural crisis,' and he accused the 'demoralization of the humanities' of having reduced American 'individualism' to 'a narcissistic preoccupation with the self.' With the publication of Allan Bloom's *The Closing of the American Mind* (1987) the 'battle of the books' erupted into an all-out 'culture war.' According to Bloom, the social/political crisis of twentieth-century America was really an intellectual crisis. Despite the use of such edifying labels as 'individual responsibility, experience, growth, development, self-expression, liberation and concern,' Bloom argued, the 1960s had 'bankrupted' American universities and destroyed 'the grand American liberal traditions of education.' The battle over the canon of American literature was now openly a battle about the canon of American culture and society, about nationality and multiculturalism, about consensus and political correctness. The 1990s saw a whole spate of books calling for a truce and reconciliation, offering a wide array of solutions to the increasingly vicious national debate and the resulting ideological stalemate. In *Beyond the Culture Wars* (1992) Gerald Graff showed how 'teaching the conflicts can revitalize American education,' while Henry Louis Gates, Jr. advocated in *Loose Canons: Notes on the Culture Wars* (1992) a new civic culture that would transcend the sharp divisions of nationalism, racism, and sexism. Schlesinger rather desperately proposed in *The Disuniting of America* (1991) that Americans should attempt 'to vindicate cherished cultures and traditions without breaking the bonds of cohesion—common ideals, common political institutions, common language, common culture, common fate—that hold the republic together'; this appeal was picked up by David Hollinger, who argued in his *Postethnic America* (1995) that Americans should form 'voluntary' rather than 'prescribed affiliations' to bridge the ethnic and multicultural gaps in society.

There are no clear signs that the latest models of reconciliation have effected any kind of movement on the battleground of nationality and multiculturalism—which perhaps is not surprising since the majority of them propose as the solution to the threat of the radical implosion of the consensus model of American society a return to the very neo-humanist, essentialist ideals that are so vehemently being contested in the multiculturalism/pluralism debate. In the meantime, the discipline of American studies is as divided as the various participants in this debate. However, although there has been some degree of disciplinary backlash (with some academic programs having been reduced or cut from university calendars), most working in the field would concede that the questions about the future of American culture and society have never been as open as they are at the

beginning of the twenty-first century, and that this in itself more than legitimizes the continuing study of American society within the interdisciplinary framework of American studies.

Amnesia

1. *Introduction*

The term *amnesia*, as a description of a clinical disorder, refers to a loss of memory for personal experiences, public events, or information, despite otherwise normal cognitive function. The cause of amnesia can be either primarily *organic*, resulting from neurological conditions such as stroke, tumor, infection, anoxia, and degenerative diseases that affect brain structures implicated in memory; or it can be primarily *functional or psychogenic*, resulting from some traumatic psychological experience (see *Amnesia: Transient and Psychogenic*). This article will focus on organic amnesia. The following questions are addressed: What are the characteristics of amnesia? What structures are involved in forming memories (and whose damage causes amnesia) and what function does each serve in the process? Does amnesia affect recent and remote memories equally and, by implication, are memory structures involved only in memory formation and shortly thereafter, or are they also implicated in retention and retrieval over long intervals? Are all types of memory impaired in amnesia or is amnesia selective, affecting only some types of memory and not others? What implication does research on amnesia have on research and theory on normal memory?

2. *Characteristics of Organic Amnesia*

The typical symptoms of organic amnesia are the opposite of those of functional amnesia: old memories and the sense of self or identity are preserved but the ability to acquire new memories is severely impaired. Though capturing an essential truth about organic amnesia, this statement needs to be qualified in important ways in light of new research.

The scientific investigation of organic amnesia effectively began with Korsakoff's (1889) description of its symptoms at the turn of the century, during what Rozin (1976) called the 'Golden Age of Memory Research.' Likewise, it can be said that the modern era of neuropsychological research on memory and amnesia was ushered in by Scoville and Milner's (1957) publication of the effects of bilateral medial temporal

Amnesia

1. Introduction

The term *amnesia*, as a description of a clinical disorder, refers to a loss of memory for personal experiences, public events, or information, despite otherwise normal cognitive function. The cause of amnesia can be either primarily *organic*, resulting from neurological conditions such as stroke, tumor, infection, anoxia, and degenerative diseases that affect brain structures implicated in memory; or it can be primarily *functional or psychogenic*, resulting from some traumatic psychological experience (see *Amnesia: Transient and Psychogenic*). This article will focus on organic amnesia. The following questions are addressed: What are the characteristics of amnesia? What structures are involved in forming memories (and whose damage causes amnesia) and what function does each serve in the process? Does amnesia affect recent and remote memories equally and, by implication, are memory structures involved only in memory formation and shortly thereafter, or are they also implicated in retention and retrieval over long intervals? Are all types of memory impaired in amnesia or is amnesia selective, affecting only some types of memory and not others? What implication does research on amnesia have on research and theory on normal memory?

2. Characteristics of Organic Amnesia

The typical symptoms of organic amnesia are the opposite of those of functional amnesia: old memories and the sense of self or identity are preserved but the ability to acquire new memories is severely impaired. Though capturing an essential truth about organic amnesia, this statement needs to be qualified in important ways in light of new research.

The scientific investigation of organic amnesia effectively began with Korsakoff's (1889) description of its symptoms at the turn of the century, during what Rozin (1976) called the 'Golden Age of Memory Research.' Likewise, it can be said that the modern era of neuropsychological research on memory and amnesia was ushered in by Scoville and Milner's (1957) publication of the effects of bilateral medial temporal lobectomy to control intractable epilepsy in a single patient, H.M. (see Fig. 1.

Some aspects of the disorder Korsakoff described are peculiar to a kind of amnesia that now bears his name (amnesia related to vitamin (thiamine) deficiency typically associated with alcoholism), while others are common to all forms of amnesia, including the one described by Scoville and Milner. The symptoms are best described by contrasting impaired abilities with preserved ones. They are as follows:

(a) Memory is impaired for various types of material, which is why the amnesia is often referred to as global, though as we shall see not all memories are affected equally. Perception, intelligence, and other cognitive functions are relatively preserved. Thus, amnesic people perform normally on standard tests of intelligence, but are impaired by comparison on standard tests of memory. They can play chess, solve crossword and jigsaw puzzles, comprehend complex instructions, and reason logically.

(b) The memory that is impaired is only *long-term* or *secondary memory*; that memory which lasts long after the information has been received and registered, and not *short-term or primary memory* which is used to hold information briefly in mind. Unaffected also is *working memory* (Baddeley 1986) which is used to operate on the information held in mind. As an example, amnesic people have a normal digit span which refers to the number of digits one can repeat immediately in sequence (typically seven, plus or minus two) and even a normal backward digit span in which the digits must be recalled in reverse order. They are impaired, however, at retaining and recalling even a sub-span list of words after a short interval that is filled with distracting activity, even if given ample opportunity to rehearse the material before. In a more ordinary life example, amnesic people can remember sentences well enough to respond to them, but cannot follow a conversation to the end if reference is made to utterances that occurred at the beginning. The same dissociation between long- and short-term memory holds for words, stories, complex visual patterns, faces, melodies, and some esthetic stimuli (Kolb and Whishaw 1996).

(c) Long-term memory loss in amnesia is most noticeable for events and information acquired after the onset of the disorder and into the future as well as in the period immediately preceding it, but not for information acquired long before that. That is, they have an *anterograde amnesia* that extends into the future but a *retrograde amnesia* limited to the time preceding the onset of the disorder. Thus, amnesic people have difficulty remembering what they learned or experienced since the onset of the disorder, even their current address and neighborhood if they had moved to a new place, but they can remember their old home and neighborhood, and some old experiences and events (Milner 1966, Squire and Alvarez 1995). Retention of such old memories, however, may be more selective and not as well-preserved as had once been believed (see below).

(d) Anterograde long-term memory loss in amnesia applies only to information that can be recollected consciously or *explicitly*. Acquisition, retention, and recovery of memory without awareness or *implicitly*

is normal. For example, having studied a set of words or pictures, amnesic patients perform poorly when their memory is tested explicitly with recognition (Which of the following items do you recognize as having been presented to you?) or recall (Tell me the items you had studied). Their memory for studied items is normal if they are tested implicitly by seeing how performance is altered by the study experience

Figure 1
A recreation of H.M.'s lesion from the surgeon's report (left drawings A, B, C, D) and from a recent MRI scan (see bottom panels) of the lesion (right drawings, A, B, C, D). The surgeon overestimated the posterior extent of the lesion. The right side of each drawing is intact for comparison purposes. The two MRI scans labeled B are of H.M.'s brain, and the remaining one is of a control's brain. MMN = Mammilary bodies; A = Amygdala; H = Hippocampus; CS = collateral sulcus; PR = Perirhinal cortex; EC = Entorhinal cortex

without making any explicit reference to the study episode. Thus, though they cannot recall or recognize the items they studied, amnesic people will perceive them more quickly and accurately than items they did not study, or complete them better when they are degraded, such as by filling in the missing letters in a word or completing the lines in a picture. Performance on these implicit tests of memory indicates that information about the studied items is held in memory though they are not aware of that (Tulving and Schacter 1990, Schacter and Buckner 1998).

These characteristics will serve as the foundation for later discussion of empirical and theoretical investigations of amnesia, normal memory, and brain function. Indeed, research on amnesia, fascinating in its own right, has had a powerful impact on memory research and theory, especially since the landmark discovery of Scoville and Milner. This research can be divided into two interacting streams: a *functional neuroanatomical* one, concerned with identifying the neuroanatomical substrates of memory and determining their precise function; and a *(neuro)psychological* one, concerned with the implication that amnesia has for understanding normal memory at a functional level. Each is dealt with in turn.

3. Neuroanatomy of Amnesia

Amnesia is caused by bilateral damage to structures in the limbic system and to adjacent cortex in the medial temporal lobes (see Figs. 2 and 3). The hippocampal formation, in the medial temporal lobes, is the most prominent of the memory structures. It consists of the hippocampus proper with its various subfields and regions, plus the dentate gyrus and the subilculum. Communication between the hippocampus and neocortex occurs thorough a series of relays. The hippocampus is connected directly to the entorhinal cortex which in turn is connected to the parahippocampal gyrus and

Figure 2
The limbic system and memory circuit (from Hamilton, 1976)

Figure 3
The hippocampal-diencephalic systems (modified from Aggleton and Brown 1999). There are two inter-related systems: The *hippocampal-fornix-anterior thalamic system* indicated by solid lines and the *perirhinal-medial dorsal thalamic system* indicated by dashed lines

perirhinal cortex which project bidirectionally primarily to the temporal and parietal lobes of neocortex, respectively. There are also projections from the hippocampus and perirhinal cortex via the fornix and anterior cingulate to the mammillary bodies and the dorsomedial nucleus of the thalamus, which are in the diencephalon. The loop of medial temporal and diencephalic structures constitute the limbic system. The hippocampus is thus ideally situated to collate information both about the cognitive (neocortex) and emotional (limbic) state of the organism and bind that information into a memory trace that codes for all aspects of a consciously experienced event (Moscovitch 1995).

3.1 Functions of the Neuroanatomical Substrates of Memory

There is considerable debate about the role that each of the components of the memory system have and how they interact with one another. Korsakoff's amnesia is associated with damage to the diencephalon whereas amnesia caused by anoxia, encephalitis, and some degenerative disorders such as Alzheimer's Disease is associated most often with medial temporal lobe damage. Although close inspection reveals differences in memory loss among the various conditions, some have not been substantiated reliably

and others could not be attributed with certainty to differences associated with diencephalic and medial temporal lobe damage, as compared to damage to other structures that often accompanies the various disorders. For example, it had been proposed that the medial temporal lobes were necessary for consolidation and retention of new information whereas the diencephalon was needed for encoding. Investigators claimed that people with diencephalic amnesia had difficulty acquiring information, but once they did so they retained it normally. People with medial temporal damage, however, showed abnormally rapid forgetting. Other investigators, however, found no difference in forgetting rates between amnesic groups, or even between them and controls (see review in Aggleton and Brown 1999).

Others noted that people with Korsakoff's, but not medial temporal, amnesia showed a number of memory deficits in addition to loss of memory for the content of an experienced event. These included confabulation, poor memory for the source and temporal order of events, susceptibility to interference, and poor meta-memory (knowledge about memory) (Moscovitch and Wincour 1992). These deficits, all of which involve strategic aspects of memory, were shown to be related more to frontal dysfunction that often accompanies Korsakoff's amnesia, rather than to diencepahlic damage *per se*.

Influenced by research on animal models of memory, investigators focused on differences among the structures in the medial temporal lobe itself, and its projections to the diencephalon. O'Keefe and Nadel (1978) proposed that the hippocampus is needed for representing allocentric spatial information, or cognitive maps but not for representing egocentric representations, routes and landmarks. While acknowledging the role of the hippocampus in allocentric spatial memory, other investigators disputed that its only function is spatial. Instead, they claimed that the hippocampus is needed for memory for all types of relational information, whether it be among spatial elements, among objects, or among words (Cohen and Eichenbaum 1993). In support of the latter idea, investigators working with animal models showed that memory for single objects is affected little, if at all, by hippocampal lesions, but is disrupted severely by lesions to the perirhinal cortex, whereas memory for the association between objects and locations is affected by parahippocampal lesions (Murray 1996, Aggleton and Brown 1999). This division of labor is consistent with the connection these regions have to neocortex. The perirhinal cortex is connected primarily to the temporal lobes which are concerned with processing objects, whereas the parahippocampus is connected to the parietal lobes which specialize in processing spatial information.

Aggleton and Brown (1999) proposed that the functional differentiation among medial temporal lobe structures extends to the diencephalon, thus forming two integrated medial–temporal–diencephalic memory systems. One system, consisting of the hippocampus and its connections to the mamillary bodies and anterior thalamic nuclei, mediates memory for recall which relies on relational information; the other, consisting of the perirhinal cortex and its connections to the dorsomedial nucleus of the thalamus, is necessary for item recognition which depends on familiarity judgments.

The lesion evidence in humans is roughly consistent with these proposals based on animal models where dissociations of function are observed along the lines predicted by the models (but see commentary in Aggleton and Brown 1999). Because amnesic people with circumscribed lesions are rare, investigators have turned to neuroimaging studies in normal people to test the hypothesis that different aspects of memory are mediated by different regions of the medial temporal lobe. In general, the evidence has been supportive of the hypotheses that have been advanced here, with greater activation in the right hippocampus on tests of spatial (Maguire et al. 1998) and relational memory (Henke et al. 1999) and in the parahippocampal gyrus (possibly entorhinal cortex) on tests of object-location memory (Milner et al. 1997) and navigation (Agguire and D'Esposito 1999).

Whatever the final verdict is regarding the role of the various regions of the medial temporal lobe and diencephalon, the evidence indicates that the type, extent, and severity of anterograde amnesia is a function of the size, side, and location of the lesion. This rule applies as well to the deficits indicative of retrograde amnesia.

4. *Retrograde Amnesia and Memory Consolidation: Where and When Are Memories Stored?*

Whereas studies of anterograde amnesia tell us about memory acquisition, studies of retrograde amnesia provide clues about the time course involved in consolidating long-term memories and the physiological processes and neural substrates which contribute to consolidation and storage. Until recently, it was widely believed that retrograde amnesia associated with medial temporal and diencephalic damage was short-lasting and temporally graded, such that memory loss was more severe for information acquired near the time of amnesia onset than for that which was acquired long before (see Sect. 2.2 above). Accordingly, the medial temporal lobes, particularly the hippocampus, and possibly the diencephalon, were considered to be temporary memory structures, needed only for memory retention and retrieval until memories were consolidated in neocortex and other structures. They were then permanently stored there and could be retrieved directly from those regions.

Nadel and Moscovitch (1997) and Nadel et al. (2000) noted a number of problems with the accepted view. Though the duration of retrograde amnesia sometimes is short, more often retrograde amnesia for details of autobiographical events after large medial temporal (or diencepahlic) lesions can extend for decades, or even a lifetime (Warrington and Sanders 1971), far longer than it would be biologically plausible for the consolidation process to last. Retrograde amnesia for public events and personalities, however, is less extensive and often is temporally graded; this is truer still of semantic memory which includes knowledge of new vocabulary and facts about the world and ourselves (our address, the names of our friends, our job), what some have called *personal semantics* to distinguish them from autobiographical episodes (see Fig. 4). The distinction between temporally extensive and temporally limited retrograde amnesia also applies to spatial memory. Schematic cognitive maps of old neighborhoods that are adequate for navigation are retained but they lack topographical details and local environmental features, such as the appearance and location of particular homes, that would allow the person to have detailed cognitive maps of their locale (see Nadel et al. 2000).

Based on this evidence, Nadel and Moscovitch concluded, contrary to the traditional consolidation model, that the function of the medial temporal system is not temporally limited but that it is needed to represent even old memories in rich, multifaceted detail, be it autobiographical or spatial, for as long as the memory exists. Neocortical structures, on the other hand, are sufficient to form domain-specific and semantic representations based on regularities extracted from repeated experiences with words, objects, people, environments, and even of autobiographical episodes that one recollects repeatedly, creating a gist of each episode. The medial temporal lobe system may aid in the initial formation of these neocortical representations, but once formed they can exist on their own. Recent evidence from studies of children whose hippocampus was damaged at birth or shortly thereafter supports this view. Vargha-Khadem et al. (1997) found that they acquired sufficient general knowledge (semantic memories) to complete high school even though their memory for autobiographical episodes was impaired. Corroborating evidence is also provided by neuroimaging studies of recent and remote autobiographical and semantic memory. These studies found that the hippocampus is activated equally during retrieval of recent and remote autobiographical memories, but not of memory for public events or personal semantics (Ryan et al. in press, Maguire 2001) (see Fig. 5).

To account for this evidence, Nadel and Moscovitch (1997) and Nadel et al. (2000) proposed a Multiple Trace Theory (MTT) according to which a

Figure 4
Example of (a) temporally-graded retrograde amnesia and (b) temporally-extended retrograde amnesia for autobiographical incidents and personal semantics in patients with bilateral medical temporal-lobe, hippocampal, and other lesions (modified from Kopelman et al. 1999 and Cipilotti et al. 2001)

Figure 5
Hemodynamic response of the hippocampus during recall of recent and remote memories, and two baseline conditions (rest and sentence completion) (Ryan et al. in press)

memory trace of an episode consists of a bound ensemble of neocortical and hippocampal/medial temporal lobe (and possibly diencephalic) neurons which represent a memory of the consciously experienced event. Formation and consolidation of these traces, or cohesion (Moscovitch 1995), is relatively rapid, lasting on the order of seconds or at most days. Each time an old memory is retrieved, a new hippocampally mediated trace is created so that old memories are represented by more or stronger traces than are new ones, and therefore are less susceptible to disruption from brain damage than more recent ones. With respect to autobiographical episodes, the extent and severity of retrograde amnesia and perhaps the slope of the gradient are related to the amount and location of damage to the extended hippocampal complex. Remote memories for the gist of events, and for personal and public semantics, are not similarly dependent on the continuing function of the hippocampal complex (see McClelland et al. 1995 for a computational account for the usefulness of having complementary hippocampal and neocortical learning and memory systems).

Proponents of the standard consolidation model, however, argue that severe and temporally extensive retrograde amnesia is observed only when the lesion extends beyond the hippocampus to include neocortical structures where remote memories, both autobiographical and semantic, are represented (Squire and Zola 1998, but see Cipilotti et al. 2001). It remains to be determined what specific contributions the different regions of the medial temporal lobes and diencephalon make, and how they act in concert with the neocortex and other brain areas, to form and retain both detailed, contextually rich representations and context-independent knowledge (McDonald et al. 1999, Rosenbaum et al. in press).

5. *Amnesia and Neuropsychological Theories of Normal Memory: Which Types of Memory Are Affected?*

Research on amnesia and other memory disorders has influenced theories of normal memory at least since the end of the nineteenth century (Rozin 1976), but at no time has this been more apparent than in the last quarter of the twentieth century. Because amnesia is selective, affecting some memories and not others, research on amnesia has been used to promote the view that memory is not unitary, but rather consists of dissociable components, each governed by its own principles and mediated by different structures. For example, evidence showing that retrograde amnesia affects detailed autobiographical memory more than semantic memory supports the idea that episodic and semantic memory are distinct both

functionally and neurologically (Tulving 1983, Kinsbourne and Wood 1975, but see Squire and Zola 1998).

One of the characteristics of amnesia is that it affects long-term or secondary memory more than short-term or primary memory. This observation was one of the crucial pieces of evidence used in the 1960s and early 1970s to argue for a functional separation of memory into at least these two major components. The idea has since become almost universally accepted and opened the field to investigation of the functional differences between the two major components, to development of the concept of working memory (Baddeley 1986), and to identification of the mechanisms supporting working and primary memory in frontal and posterior neocortex (Smith and Jonides 1999, Petrides 2000).

Beginning in the late 1960s, research on animal models and humans indicated that the formation and retention of some types of long-term memory are spared in amnesia though there is continuing debate on how best to characterize them. Generally it is accepted that only conscious recollection is affected by amnesia. Memory retrieval without awareness seems to be intact. For example, it was noted that people with bilateral medial temporal lobe lesions, such as the patient H.M., could learn and retain motor skills for months or years, though he had no memory of the learning episode minutes after it was over. The same was true of perceptual skills involved in reading mirror-reversed words or in identifying degraded or fragmented pictures and words. That more than just a skill was involved became apparent when patients could complete or identify items to which they had been exposed more accurately and more quickly than new items, suggesting that they stored information peculiar to that item even though at a conscious level they could not recall or recognize that they had studied it (Warrington and Weiskrantz 1970) (Fig. 6). At the same time, similar phenomena were reported in normal people for material they could not consciously recollect, suggesting that the dissociation between memory with and without awareness was not peculiar to amnesia but was indicative of something fundamental about the organization of memory (see reviews in Cermak 1982, Cohen and Eichenbaum 1993, Kolb and Whishaw 1996, Tulving and Schacter 1990, Schacter and Buckner 1998, Squire and Knowlton 1999). These observations not only had a major impact on our understanding of normal memory, but also were instrumental in revitalizing research on unconscious processes in cognition and emotion, an area of investigation that had been abjured by mainstream experimental psychology for almost a century.

A number of terms have been used to refer to memory with and without awareness, including declarative and nondeclarative (or procedural memory), direct and indirect memory, memory and habit,

Figure 6
Example of amnesic and control performance on two implicit (stem completion and perceptual identification) and two explicit (forced choice and yes–no recognition) tests of memory (from Squire and Knowlton 1999)

controlled and automatic. We prefer the terms explicit and implicit memory because they are descriptively accurate, refer to the types of tests used to assess memory, and are close to theoretically neutral as to the processes and mechanisms involved.

Since the 1980s, research on normal people and on people with amnesia has identified a number of characteristics of implicit memory. The structures implicated in amnesia, the medial temporal lobes and diencephalon, are not needed for normal implicit memory. Instead, performance is mediated by a variety of structures, depending on the type of implicit memory that is being tested. Like explicit memory, implicit memory is not unitary and consists of a variety of different subtypes. Although a detailed description of all them is not possible, we mention three types that have been identified and about which we know a great deal: *perceptual implicit memory or priming, conceptual implicit memory, and procedural memory* (Knowlton and Squire 1999, Moscovitch 1992, Moscovitch et al. 1993, Schacter and Buckner 1998, Tulving and Schacter 1990).

On tests of perceptual implicit memory, the test stimulus resembles the studied target perceptually (e.g., a perceptually degraded version of it, or even an identical repetition of it) whereas on tests of conceptual implicit memory, the test stimulus resembles the target semantically (e.g., having studied the word 'horse,' the participant may be asked to make a semantic decision to the word at test, or asked to produce it in response to the word 'animal'). Performance is measured by speed or accuracy of

the response to the test stimulus, without explicit reference to the studied items. The implicit nature of the test is corroborated if the person is not aware that the response or test item refers to a studied stimulus. Increases in accuracy or decreases in response latency to old studied items as compared to new ones are indicative of implicit memory for the studied items.

Research on perceptual implicit memory suggests that performance is mediated by the same perceptual modules or representation systems in posterior neocortex that are involved in perceiving the stimuli. These modules are modified by the act of processing some given material, leaving behind a record of that process. As a result, processing is faster and more accurate when the system is re-exposed to that material as compared to new material (Wiggs and Martin 1998). The modules are domain specific, in that separate ones exist for objects, faces, words, and possibly places. They are also presemantic in that they do not represent the meaning of the item but only its structure. Thus, performance on perceptual implicit tests is sensitive to changes in perceptual or structural aspects of the stimulus but not to changes in semantic aspects.

The opposite holds for performance on conceptual implicit tests which is mediated by conceptual systems in the lateral temporal lobe and inferior frontal cortex (for reviews on implicit memory see Moscovitch et al. 1993, Gabrieli 1998, Schacter and Buckner 1998). As with perceptual modules, improvement in performance results from modifications in the conceptual systems themselves.

Tests of procedural implicit memory involve learning rules, motor sequences, conditioned responses, and subjective probabilities of stimulus–response associations without explicit memory for any of them. The structures that have been identified as crucial for procedural learning are the cerebellum for classical conditioning, and the basal ganglia for the others, with some indication of prefrontal involvement if learning rules or motor sequences involve strategic, sequential, or inhibitory components (Moscovitch et al. 1993, Squire and Knowlton 1999). Changes in these structures during execution of procedures underlies the changes in performance observed on implicit tests of procedural memory.

In studying implicit memory, great care must be taken to insure that performance on tests of memory that are ostensibly implicit are not contaminated by explicit components, such as might occur when asking participants to identify degraded stimuli they had studied earlier. It is for this reason that studies of amnesic patients is so useful. Because their explicit memory is so poor, equivalent performance between amnesic and normal people on an implicit test is taken as evidence that the test in question was not contaminated by explicit memory.

6. *Amnesia and Beyond: A Neuropsychological Component Process Model of Memory*

Studies of memory in amnesia have indicated that memory is not unitary but rather consists of a variety of different forms, each mediated by different component processes which in turn are subserved by different neural mechanisms. Because neither short-term or working memory, nor implicit memory is impaired in amnesia, it can be concluded that these types of memory are not dependent on the medial temporal lobes and diencephalic structures which are damaged in amnesia. The latter structures, however, are necessary for conscious recollection of long-term, episodic memories. It has been proposed that any information that is consciously experienced is picked up obligatorily and automatically by the hippocampus and related structures in the medial temporal lobes and diencephalon. These structures bind into a memory trace those neural elements in neocortex (and elsewhere) that mediate the conscious experience of an event. The episodic memory trace thus consists of an ensemble of hippocampal and neocortical neurons. The hippocampal component of the trace acts as an index or file entry pointing to the neural elements in neocortex that represent both the content of the event and the conscious experience of it. 'Consciousness' is, therefore, part of the memory trace. Retrieval occurs when an external or internally generated cue triggers the hippocampal index which in turn activates the entire neocortical ensemble associated with it. In this way we recover not only the content of an event but the consciousness that accompanied our experience of it. In short, when we recover episodic memories, we recover conscious experiences (Moscovitch 1995).

According to this model both encoding and retrieval of consciously apprehended information via the hippocampus and related structures is obligatory and automatic, yet we know from experience and from experimental investigation that we have a measure of control over what we encode and what we retrieve from memory. Moreover, if encoding is automatic and obligatory, the information cannot be organized, yet memory appears to have some temporal and thematic organization. How can we reconcile this model of memory with other facts we know about how memory works? One solution is that other structures, particularly those in the frontal lobes, control the information delivered to the medial temporal and diencephalic system at encoding, initiate and guide retrieval, and monitor, and help interpret and organize the information that is retrieved. By operating on the medial temporal and diencephalic system, the frontal lobes act as *working-with-memory* structures that control the more reflexive medial temporal and diencephalic system and confer a measure of intelligence and direction to it (Fig. 7). Such a complementary system is needed if

Figure 7
A schematic model of hippocampal complex-neocortical-frontal interaction during encoding and retrieval (from Moscovitch 1989, See text)

memory is to serve functions other than mere retention and retrieval of past experiences (Moscovitch 1992). As invaluable as studies of amnesia have been to our understanding of memory, those studies need to be supplemented by investigations of memory in people with other types of disorders, particularly those implicating the frontal lobes, to have a full appreciation of how memory works.

Amnesia: Transient and Psychogenic

Memory is an essential feature for an integrated personality and the ability to lead a normal life. The most complete form of memory disturbance, amnesia

(see *Amnesia*), frequently is regarded as a permanent state arising from focal brain damage in bottleneck structures of the brain. This form of so-called global amnesia (Table 1) is usually caused by bilateral damage of the regions in the limbic system (see *Limbic System*), divided into the medial temporal lobe (see *Hippocampus and Related Structures*; *Temporal Lobe*), the medial diencephalon (see *Hypothalamus*), and the basal forebrain.

On the other hand, already in the nineteenth century various reports on patients with transient forms of amnesia had appeared and frequently were subsumed under the heading of hysteria. Hysteria was seen in principle as a treatable or even curable state of an individual with a personality demonstrating a deviance or discrepancy between their nonconscious presentation and their true character. In line with this view is the described selectivity of the amnesic condition which is confined to person-relevant or individual-specific episodes, implying that only the episodic memory system (see *Episodic and Autobiographical Memory: Psychological and Neural Aspects*) is affected while world or general knowledge (the semantic memory system) (see *Semantic Knowledge: Neural Basis of*) is preserved (Table 1). When the personal past is relearned, this relearning occurs usually with a reduced affect (*la belle indifference*) (Markowitsch 1999). (Episodic memory refers to the possibility of traveling back in time; that is, it allows the reinstatement of past episodes with the context of time and place; semantic memory, on the other hand, refers to a context-free instatement of general facts.)

Psychic conditions, in particular environmental stress factors (see *Stress, Neural Basis of*), may lead to a number of amnesic conditions, some of which are of a more general and others of a more specific nature. The general conditions refer to an inability to retrieve the personal past such as in psychogenic amnesia (Markowitsch et al. 1997a), or psychogenic fugues (Markowitsch et al. 1997b), conditions nowadays subsumed under the dissociative states. Furthermore, in rare cases there may be an inability to acquire new (episodic) information long-term (Markowitsch 1999). In more specific instances, the ability to retrieve episodes of a certain nature or of a limited time period may be impaired and, consequently, the respective episodes during which a person may have been sexually abused, may remain inaccessible over years and decades (Markowitsch 1999). Sometimes, somatic injuries (e.g., whiplash injury) may provoke amnesic conditions (Markowitsch 1999). From this introduction it can be inferred correctly that a strict division into brain-damage-caused ('somatic') and psychically generated amnesias is frequently not possible. In fact, there is increasing evidence for a mixture, justifying the use of the expression 'functional amnesia' which leaves the origin or etiology open (Markowitsch 1999). Nevertheless, the more homogenous form of transient global amnesia, which is considered to be a neurological disease, will first be described, and then functional amnesias will be discussed.

1. *Transient Global Amnesia*

The dimension of affect is of importance as well in a number of cases with so-called transient global amnesia (TGA) (Hodges 1991, Markowitsch 1990). TGA is a still not very well understood condition, largely because of its time-limited nature and its many

Table 1
General forms of amnesic states and their behavioral characteristics

Feature	Global amnesia	Transient global amnesia	Functional (psychogenic) amnesia
Occurrence	Usually suddenly as a consequence of focal brain damage	Suddenly, frequently after significant physical or psychic events	Suddenly, either after chronic stress or after a single major event
Duration	Frequently permanent	$\leqslant$ 24 h	Variable
Affected forms of memory	Episodic and semantic	Mainly episodic	Episodic–autobiographic
Affected time range	Anterograde and to a minor degree retrograde	Anterograde and limited retrograde	Retrograde and/or (more rarely) anterograde
Patient's behavior	Abnormal, sometimes confuse, neurological signs	Confuse, but no neurological signs	Intentional, reality-oriented
Remission/recovery	Various degrees, depending on the lesioned locus	Complete, except for the episode of the attack itself	Sometimes complete, sometimes persistent

possible etiologies. In principle, TGA refers to a sudden severe memory loss without concomitant brain damage (or epilepsy); intelligence and consciousness (see *Consciousness, Neural Basis of* and *Conscious and Unconscious Processes in Cognition*) are preserved, the duration lasts less than one day. Transient amnesias caused by specifically induced external interventions, such as electroconvulsive therapy (see, e.g., Squire and Slater 1975), also do not fit the definition of TGA.

Essential criteria for diagnosing TGA differ somewhat between authors (Caplan 1990, Hodges 1991, Frederiks 1993). In essence, the short duration ($\leqslant 24$ h) is emphasized and the predominance of its occurrence late in adulthood (usually $\geqslant 60$ yr) (Hodges 1991; Markowitsch 1990). It is characterized by a major amnesia which goes mainly in the anterograde, but also in retrograde direction (Härting and Markowitsch 1996). Though initially it was assumed that attacks rarely recur, a more thorough screening of relevant data indicates that many patients experience more than one event (Caplan 1990, Frederiks 1993). Risk factors include high blood pressure, coronary heart disease, previous strokes or transient ischaemic attacks, migraine, hyperlipidemia, smoking, diabetes, and peripheral vascular diseases (Caplan 1990, Frederiks 1993, Hodges 1991). Imaging results (see *Functional Brain Imaging*) indicated cellular edema in the anterior temporal lobe during TGA or hypometabolic zones in the memory processing regions of the limbic system.

The precipitants of TGA include physical and psychic factors; among them are emotional stress, pain, sexual intercourse, physical activity, exposure to cold or hot water (Caplan 1990, Markowitsch 1990). This list shows that various stressors (see *Stress, Neural Basis of*) and hemodynamic challenges can lead to TGA.

The TGA episodes are neuropsychologically quite uniform. There are anterograde and retrograde components to the amnesia. As the patient recovers, the retrograde amnesia shrinks and then totally disappears just as the patients gain their ability to retain new information. Following the ictus, the patient is left with a permanent island of memory loss for the period encompassed by the TGA episode. During the ictus, the patient repetitively asks questions about his or her plight, identity and location in ways that indicate an acute awareness of the amnesia.

2. *Functional Amnesias*

The spectrum of antecedents of 'functional amnesias' is quite variable; among other features minor head trauma, psychiatric disorders, depression, stress (see *Stress, Neural Basis of*), and chronic fatigue syndrome can be listed. That amnesia may follow both psychic and somatic shock conditions has been known for a long time. Already at the turn of the nineteenth century prominent scientists distinguished between four forms of shock and emphasized the existence of a psychic shock which may result in memory disturbances. The phenomenon of post-traumatic stress disorder (PTSD) can be viewed as a present-day description of such early observations. Functional amnesias may interfere with the recall of all autobiographical information (Markowitsch et al. 1997b), or may even lead to both retrograde and anterograde amnesia of a more general nature (Markowitsch et al. 2000). In the following, common forms of functional amnesias will be described.

Minor head injury (without identifiable structural brain damage) is sometimes accompanied by lasting and major retrograde amnesia for autobiographic memory. Barbarotto et al. (1996) described a woman who slipped and fell in her office. Though no brain damage was detected, she nevertheless remained retrogradely amnesic even when tested six months after the event. The authors describe a personality pattern compatible with conversion hysteria (see Table 2). Persistent anterograde amnesia with preserved retrograde memories after a whiplash injury without measurable brain damage was described for a young woman (Markowitsch 1999).

Cases with pure psychogenic amnesia (i.e., without evidence for somatic [brain] injuries) show some common features: a weak, underdeveloped personality, a problematic childhood or youth and the appearance of emotionally negative events such as sexual abuse (Markowitsch 1999) during early life. The amnesia may be interpreted as a mechanism for blocking awareness of previous traumatic events (Markowitsch 1998).

Functional brain imaging such as positron emission tomography (PET) (see *Functional Brain Imaging*) may help to obtain evidence for altered neural processing in patients with functional amnesias. Markowitsch et al. (1997b) investigated a 37-year-old man with a persistent fugue. He remained unsure of his relationship to family members and changed a number of personality traits. While having been an avid car driver prior to the fugue, he became quite hesitant to enter a car thereafter, lost his asthma, gained substantially in body weight and changed his profession. Regional cerebral blood flow was measured with PET in an autobiographic memory paradigm and revealed a mainly left-hemispheric activation instead of the usual right-hemispheric frontotemporal one found with the same paradigm by Fink et al. (1996). This result suggests that he might indeed have been unable to recall his own past and processed this information as new and unrelated to his person. Related to this finding, another functional imaging technique (single photon emitted computer tomography; SPECT) revealed in another patient with psychogenic amnesia a hypometabolic zone in exactly that frontotemporal junction area which is necessary for normal retrieval of autobiographical memories (Markowitsch et al.

1997a). A similar hypometabolic zone in the same brain region was detected after organic brain damage and retrograde amnesia (Calabrese et al. 1996). These findings suggest that there may be a block or disconnection of memory-processing neural nets, leading to both 'psychogenic' or 'organic' amnesia (Markowitsch 1999).

Related to these findings, Markowitsch et al. (2000) described a patient who at the age of four witnessed a man burn to death and then at the age of 23 had an open fire in his house. Immediately following this second exposure to a fire, the patient developed anterograde amnesia and a retrograde amnesia covering a period of six years. PET results demonstrated a severe reduction of glucose metabolism, especially in the memory-related temporal and diencephalic regions of the brain. His amnesic condition persisted for months but improved thereafter as his brain metabolism returned to normal levels after one year. Even then his long-term memory was quite poor so that he remained unable to return to his former job.

Findings of this kind indicate that psychological stress can conceivably alter the structure and function of memory-processing brain areas, perhaps through the mediation of stress-related hormones which are active through the pituitary-adrenal axis (see *Hypothalamic–Pituitary–Adrenal Axis, Psychobiology of*) (Markowitsch 1999). For example, patients with PTSD (see Table 2) are vulnerable to becoming depressed and to manifesting memory disturbances; the release of endogenous stress-related hormones is dysregulated in PTSD and this abnormality may result in altered neural function (Markowitsch 1999).

Some studies even point to hippocampal volume reductions in association with stress (Gurvits et al. 1996, Stein et al. 1997). Massive and prolonged stress might induce changes in regions with a high density of glucocorticoid receptors such as the anterior and medial temporal lobe. In animals, it was shown that stress enhances hippocampal long-term depression (see *Long-term Potentiation (Hippocampus)*) and blocks long-term potentiation (see *Long-term Depression (Hippocampus)*). Teicher et al. (1993) found that early physical or sexual abuse hinders the development of the limbic system and may therefore induce a predisposition for the outbreak of stress-related amnesia syndromes.

3. Conclusions

The possibility of a co-existence of neurological and psychiatric or psychogenic forms of amnesia in one individual is evident from the above descriptions and had been emphasized before with Mai's (1995) statement that 'the presence of a neurological abnormality does not necessarily rule out psychogenic amnesia' (p. 105). Mai (1995), who discussed the use of the term 'hysteria' in clinical neurology, pointed out that the behavioral conditions described above make it necessary to distinguish between a *disease* and an *illness*. 'Disease' being the condition associated with pathological disturbance of structure or function, and 'illness' being the experience associated with ill-health, symptoms, and suffering. Consequently, individuals may have an illness without a disease or a disease without an illness. The independence between these two states is most clearly evident in the amnesias described above and makes them particularly interesting examples for neuroscientific investigations on the representation of memory in the brain. In the search for uncovering the neural mechanisms of information processing, particular emphasis should be laid on dynamic biochemical alterations in the brain—such as the availability or block of transmitters, neuromodulators, and hormones (including stress hormones).

Amygdala (Amygdaloid Complex)

'Amygdala' and 'amygdaloid complex' are interchangeable names used today for this temporal lobe structure which has been linked to some of the most complex functions of the brain, including emotion, mnemonic processes, and ingestive, sexual, and social behavior. Not surprisingly, the underlying neuronal circuits through which the amygdala expresses such a variety of functions are exceedingly complex and highly differentiated.

1. *Location and Basic Amygdalar Divisions*

The amygdala occupies a large portion of the inferior temporal lobe, beginning just caudal to the nucleus of the diagonal band in the front, and extending almost to the end of the cerebral hemisphere. It was first identified in human brain and named by Burdach at the beginning of the nineteenth century. Starting about 70 years later, other early descriptions of the amygdala in various species followed, and the microscopic examination of histological tissue sections began to reveal structural differentiation in the amygdala. Today, more than a dozen distinct cell groups (nuclei) can be identified within the amygdala on the cytoarchitectonic, histochemical, connectional, and functional basis. Even though there are variations in the size and position of some nuclei in different species, the basic pattern of amygdalar nuclei appears to be the same in all mammals.

Johnston (1923) introduced the fundamental description of amygdalar structure in widest use today, based on detailed analysis of comparative vertebrate material. He proposed that the amygdala be divided into a primitive group of nuclei associated with the olfactory system (central, medial, and cortical nuclei, and the nucleus of the olfactory tract), and a phylogenetically new group of nuclei (basal and lateral). Many physiologists have adopted this parcellation, resulting in a large body of evidence suggesting functional differences between these two groups. For instance, the corticomedial group, which receives direct olfactory input from both the main and accessory olfactory bulbs, is involved in the expression of agonistic, and various aspects of sexual and ingestive behavior. The basolateral group, which receives most other classes of sensory information, and has widespread isocortical and hippocampal connections, is important for emotional responses as well as mnemonic processes such as learning and memory. Although this general division works reasonably well, rapidly accumulating neuroanatomical, physiological, and behavioral results have made it clear that the amygdala is divided into more than two functional groups, and its complex intrinsic connections suggest that different functional systems are highly interactive.

2. *Amygdalar Function*

At the beginning of the twentieth century it was still widely believed that the amygdala was involved primarily in olfactory functions, and that its main connections were with olfactory areas and the hypothalamus. Theories about the function of the amygdala underwent radical changes after Klüver and Bucy (1939) examined the effects of the temporal lobe lesions in monkeys. These lesions, which included the amygdala, produced severe behavioral impairments including tameness, lack of emotional responses, hypersexuality, and excessive oral tendencies. The Klüver–Bucy syndrome can be summarized as an overall inability to identify the biological significance of stimuli. A little over a decade later, Weiskrantz performed specific lesions of the amygdala alone in monkeys, and produced similar effects lending to the hypothesis that the amygdala is necessary for establishment of positive or negative reinforcing stimuli.

Since the 1950s further evidence has been provided for amygdalar involvement in circuits necessary for stimulus-reinforcement learning, and a number of theoretical models of emotion included the amygdala as a central component. The exact role of the amygdala in emotion and motivation, however, is not clear yet. The best understood amygdalar function is, arguably, its role in conditioned fear, the main research focus for the last two decades. Rapidly accumulating neuroanatomical and functional evidence strongly suggest

that the amygdala may be crucial for the acquisition and expression of conditioned fear (see *Fear Conditioning*; *Anxiety and Fear, Neural Basis of*).

In addition, the amygdala is important for other types of aversive learning, such as avoidance learning (see *Avoidance Learning and Escape Learning*). In this type of learning the amygdala is believed to be modulating learning and memory circuits elsewhere in the brain, through connections via the stria terminalis pathway. Most recently, a role in other aspects of cognition, such as attention, has been suggested for the amygdala, although considerably less is known about the exact circuitry and mechanisms of this function.

Pioneering work of Kaada (1972), together with a large body of physiological and behavioral evidence accumulated over the last 50 years, provide powerful evidence for amygdalar influence on arousal, motivation, and the expression of reproductive, ingestive, and species-specific defensive and aggressive behavior. In more recent years, amygdalar influence on circuitry mediating reward-related behaviors has been shown as well. Generally it is believed that the amygdalar role in these behaviors is modulatory, and is exercised through an extensive network of projections to other brain regions more directly involved with these functions.

Despite the literature there is no real consensus about a unifying role for the amygdala. The most widely accepted hypothesis is that the amygdala attaches motivational and emotional significance to incoming sensory stimuli through associations with rewarding or aversive events. Based on the outcome of this pairing process the amygdala modulates other functional systems including reflex circuits, as well as systems involved in learning, memory, reward, arousal, and attention. Within this context it is important to emphasize again that the amygdala is not a unified region, and that its different subsystems are likely performing distinct functions. Thus, the challenge for future research will be in identifying amygdalar functional subsystems, and the larger circuitry they form within the cerebral hemisphere.

Our understanding of amygdalar functions is based primarily on evidence provided by animal studies. Nevertheless, in recent years a number of human studies using functional magnetic resonance imaging or positron emission tomography have confirmed the findings from the animal work, and in addition, provided evidence for amygdalar role in development of various pathologies including anxiety, depression, and schizophrenia.

3. *Connections of the Amygdala*

A detailed review of the literature on amygdalar connection—which is vast, complex, and contradictory—is beyond the scope of this article. Instead, a brief summary of major amygdalar connections, with several broad generalizations, will be presented.

The basic outline of amygdalar connections was demonstrated in early studies using axonal degeneration methods, however, most of our current knowledge is based on experiments using modern neuroanatomical pathway tracing techniques. The amygdala shares connections with all parts of the forebrain including areas in the cortex and basal ganglia in the telencephalon; thalamus, and hypothalamus in the diencepahlon; and with a number of sensory, autonomic, and behavioral areas in the midbrain and brainstem.

Most amygdalar connections are bi-directional and relay information concerning virtually all sensory modalities. Amygdalar nuclei receive inputs from polymodal cortical, thalamic, and brainstem sensory areas, as well as direct input from the olfactory bulbs. Thus, sensory information arrives to the amygdala after vastly different amounts of processing. These range from relatively unprocessed sensory information arriving from the olfactory bulb, brainstem, and thalamus, to highly processed (cognitive) information from the temporal, insular, and perirhinal cortical areas, and the hippocampal formation. A complex pattern of the intrinsic connections suggest that sensory information undergoes extensive processing within the amygdala before it is relayed further to a number of distinct functional systems, which are described below.

First, there is a well-known topographically organized projection directly to the medial and lateral zone of the hypothalamus, and via the bed nuclei of the stria terminalis to the periventricular zone. This output provides a route for the amygdala to influence circuits within the hypothalamus critical for expression of goal-oriented (ingestive, sexual, aggressive, and defensive) behaviors.

Second, is the projection to the basal ganglia, which includes topographically organized inputs to the dorsal and ventral striatum, and parts of the pallidum. Within the striatum, the amygdala innervates parts of the nucleus accumbens, fundus striatum, olfactory tubercle, and the entire caudoputamen. Interestingly, most amygdalar nuclei projecting to the caudoputamen innervate specifically its medial ('limbic') region, while only one amygdalar cell group (anterior basolateral nucleus) reaches its dorsolateral (somatomotor) part. Via its striatal projections, the amygdala can influence both limbic and somato-motor processing within the caudoputamen and reward-related processing within the nucleus accumbens, as well as learning associated with both of these. In contrast, its pallidal projections end specifically in distinct regions (substantia innominata and bed nuclei of the stria terminalis) which are associated with autonomic responses.

Third, is the projection to the medial and lateral prefrontal cortical areas and to the mediodorsal

thalamic nucleus. These projections, mainly from the basolateral nuclei, enable the amygdala to influence prefrontal cortex processing, most commonly linked to learning, working memory, and decision-making.

Fourth, are projections to the brainstem sensory and motor areas, originating primarily in the central and medial amygdalar nuclei. The central nucleus is also the recipient of major sensory information arriving from the brainstem. These efferents provide a 'feedback' to the sensory areas in the brainstem, and allow the amygdala direct access to the autonomic areas necessary for the expression of emotional and motivational responses.

Fifth, the amygdala projects back to the cortical sensory areas from which it receives inputs, thus providing a route for a feedback on sensory processing. In addition, it sends substantial, topographic inputs to various regions of the hippocampal formation, which are critical for learning and memory.

Clearly, the amygdala is well placed for a critical role in the stimulus-reinforcement type of associative learning, it receives sensory information from fundamentally all sensory modalities, and in turn, is in a position to influence a variety of motor systems via its wide ranging efferents. Furthermore, it is increasingly clear that distinct functional subsystems exist within the amygdala, and they each have their unique set of projections. An understanding of the underlying principles of the functional and anatomical organization of the amygdala is one of the most challenging questions that the field is facing today.

4. *Models of Amygdalar Organization*

In the 1980s and 1990s two models of amygdalar organization have been proposed. The first model suggests that part of the amygdala (central and medial nuclei) together with the substantia innominata and the bed nuclei of the stria terminalis, form a structural and functional unit—'the extended amygdala.' This hypothesis is based on cytoarchitectural, histochemical, and connectional similarities between the three parts of the continuum (De Olmos and Heimer 1999). Although this model fosters better understanding of the organization of central and medial parts, it does not provide a place for the rest of the amygdala.

Another more comprehensive model of amygdalar organization was proposed based on current embryological, neurotransmitter, connectional and functional data. This model argues that the amygdala is neither a structural nor a functional unit, but rather an arbitrarily defined collection of cell groups in the cerebral hemispheres, originally based on cytoarchitectonics. This suggests that it is more useful to place the various amygdalar cell groups within the context of the major divisions of the cerebral hemispheres—cortex and basal ganglia—and then to define the topographical organization of functionally defined systems within these divisions. Thus, various parts of the amygdala can be classified as belonging to one of the three distinct telencephalic groups: caudal olfactory cortex, specialized ventromedial extension of the striatum, or ventromedial expanse of the claustrum. Functionally they belong to the olfactory, autonomic, or fronto-temporal cortical systems, respectively (Swanson and Petrovich 1998).

Future research hopefully will delineate how the dynamics of information flow through the different amygdalar subsystems contribute to its different functions.

Analysis of Variance and Generalized Linear Models

Analysis of variance (ANOVA) models are models that exploit the grouping structure in a set of data and lend themselves to the examination of main effects and interactions. These models are often referred to as being hierarchical in that it makes no sense to test whether main effects can be dropped from a model that includes that factor in an interaction, and it makes no sense to test whether a lower order interaction can be dropped from a model that includes any higher order interaction involving all of the same factors. The

modeling ideas also extend to generalized linear models (GLIMs).

1. One-way Analysis of Variance

One-way ANOVA models identify groups of observations using a separate mean for each group. For example, the observations can be the age of suicide categorized by mutually exclusive ethnic groups. Suppose there are a groups with N_i observations in each group. The jth observation in the ith group is written y_{ij} with expected value $E(y_{ij}) = \mu_i$. The one-way analysis of variance model is

$$y_{ij} = \mu_i + \varepsilon_{ij} \tag{1}$$

$i = 1, \ldots, a$, $j = 1, \ldots, N_i$ where the ε_{ij}s are unobservable random errors with mean 0, often assumed to be independent, normally distributed with variance σ^2, written $\varepsilon_{ij} \sim N(0, \sigma^2)$.

The ANOVA is a procedure for testing whether the groups have the same mean values μ_i. It involves obtaining two statistics. First, the mean squared error (MSE) is an estimate of the variance σ^2 of the individual observations. Second, the mean squared groups ($MSGrps$) is an estimate of σ^2 when the means μ_i are all the same and an estimate of σ^2 plus a positive number when the μ_i are different. The ratio of these two statistics, $MSGrps/MSE$ should be approximately 1 if the μ_is are all the same and tends to be larger than 1 if the μ_is are not all the same. Under the normality assumptions for the ε_{ij}s, when the μ_is are all the same the exact value of $MSGrps/MSE$ is random and follows an F distribution with $a-1$ degrees of freedom in the numerator and $n-a$ degrees of freedom in the denominator. Here $n = N_1 + \cdots + N_a$ is the total number of observations in the data. If the observed value of $MSGrps/MSE$ is so much larger than 1 as to be relatively inconsistent with it coming from the F distribution, one concludes that the μ_is must not all be the same.

In the special balanced case where $N_i = N$ for all i, the computations are particularly intuitive as analyzing variances. To find the MSE, simply find the sample variance within each group, i.e., compute the sample variance from $y_{i1}, \ldots, y_{iN}$, then average these a numbers to get MSE. This provides an estimate of σ^2. To get $MSGrps$, first compute the sample mean for each group, say $\bar{y}_i$. Then compute the sample variance of the $\bar{y}_i$s and multiply by N to get $MSGrps$. $MSGrps$ estimates $\sigma^2 + Ns_\mu^2$ where s_μ^2 is a new parameter consisting of the sample variance of the unknown parameters $\mu_1, \ldots, \mu_a$. The μ_is are all equal if and only if $s_\mu^2 = 0$. $MSGrps/MSE$ estimates $1 + Ns_\mu^2/\sigma^2$.

Terminology varies considerably for these concepts. The mean squared error is also called the mean squared residual and the mean squared within (groups). The mean squared groups is also called the mean squared treatments (because often the groups are identified as different treatments in an experiment) and the mean squared between (groups).

An alternative but equivalent model used with one-way ANOVA is

$$y_{ij} = \mu + \alpha_i + \varepsilon_{ij} \tag{2}$$

$i = 1, \ldots, a$, $j = 1, \ldots, N_i$. Here μ is a grand mean and the α_is are differential effects for the groups. The problem with this model is that it is overparameterized, i.e., the μ and α_i parameters are not identifiable. Even if you know the μ_is, there is an infinite number of ways to define the μ and α_i parameters. In fact, you can arbitrarily pick a value for any one of the μ or α_i parameters and still make them agree with any set of μ_is. Without including extraneous side conditions that have nothing to do with the model, it is impossible to estimate any of the μ and α_i parameters. It is, however, possible to estimate some functions of them, like values $\mu + \alpha_i$, or contrasts among the α_is like $\alpha_1 - \alpha_2$. Linear functions of the μ and α_i parameters for which linear unbiased estimates exist are called estimable functions. See also *Statistical Identification and Estimability*.

The F test can also be viewed as testing the full one-way ANOVA model against the reduced model

$$y_{ij} = \mu + \varepsilon_{ij}.$$

The reduced model can be viewed as either dropping the subscript i from μ_i in model (1) or as dropping the α_is from model (2). In either case, the reduced model does not allow for separate group effects. The F statistic comes from the error terms of the two models

$$F = \frac{SSE(\text{Red.}) - SSE(\text{Full})}{dfE(\text{Red.}) - dfE(\text{Full})} \Big/ MSE(\text{Full}) = \frac{MSGrps}{MSE}.$$

Extensions of ANOVA to more general situations depend crucially on the idea of testing full models against reduced models; see *Linear Hypothesis*.

2. Two-way Analysis of Variance

Two-way ANOVA can be thought of as a special case of one-way ANOVA in which the groups have a two-factor structure that we want to exploit in the analysis. For example, Everitt (1977) discusses 97 ten-year-old school children who were cross-classified by two factors, first, the risk of their home environment: not at risk (N) or at risk (R), and then the adversity of their school conditions: low, medium, or high. This defines six groups, each a combination of a home environment and a school condition. To illustrate the modeling concepts, suppose the dependent variable y

is the score on a test of verbal abilities. In general, we would write a model

$$y_{gk} = \mu_g + \varepsilon_{gk} \tag{3}$$

where $g = 1, \ldots, G$ indicates the different groups and $k = 1, \ldots, N_g$ indicates the observations within the group. In the specific example, $G = 6$ and $(N_1, N_2, N_3, N_4, N_5, N_6) = (17, 8, 18, 42, 6, 6)$.

To use the two-factor structure, we begin by identifying the factors mumerically. Let $i = 1,2$ indicate home environment: not at risk ($i = 1$), at risk ($i = 2$). Let $j = 1, 2, 3$ identify school adversity: low ($j = 1$), medium ($j = 2$), high ($j = 3$). In general, let $i = 1, \ldots, a$ denote the levels of the first factor and $j = 1, \ldots, b$ denote levels of the second factor. Without changing anything of substance in the model, we can rewrite the ANOVA model (3) as

$$y_{ijk} = \mu_{ij} + \varepsilon_{ijk} \tag{4}$$

$i = 1, \ldots, a$, $j = 1, \ldots, b$, $k = 1, \ldots, N_{ij}$. All we have done is replace the single index for the groups g with two numbers ij that are used to identify the groups. This is still a one-way ANOVA model and can be used to generate an F test of whether all the μ_{ij}s are equal. In our example, $a = 2$, $b = 3$, and $(N_{11}, N_{21}, N_{12}, N_{22}, N_{13}, N_{23}) = (17, 8, 18, 42, 6, 6)$. Note that with a two factor model the number of groups is $G = ab$ and $E(y_{ijk}) = \mu_{ij}$.

The one-way ANOVA model (4) is often rewritten in an overparameterized version that includes numerous unidentifiable parameters. The overparameterized model is called the two-way ANOVA with interaction model, and is written

$$y_{ijk} = \mu + \alpha_i + \eta_j + (\alpha\eta)_{ij} + \varepsilon_{ijk}. \tag{5}$$

Here μ is a grand mean, the α_is are differential effects for the first factor, the η_js are differential effects for the second factor, and the $(\alpha\eta)_{ij}$s are called interaction effects. In reality, all of the μ, α_i, and η_j parameters are extraneous. If we drop all of them, we get the model $y_{ijk} = (\alpha\eta)_{ij} + \varepsilon_{ijk}$, which is just the one-way ANOVA model (4) with the μ_{ij}s relabeled as $(\alpha\eta)_{ij}$s. In model (5), without the introduction of side conditions that have nothing to do with the model, it is impossible to estimate or conduct any test on any function of the parameters that does not involve the $(\alpha\eta)_{ij}$ parameters. Since main effect parameters are extraneous when interactions are in the model, computer programs that purport to give tests for main effects after fitting interactions are really testing some arcane function of the interaction parameters that is determined by a choice of side conditions used by the program.

The interesting aspect of the two-way ANOVA with interaction model is that it suggests looking at the two-way ANOVA without interaction model

Table 1
Mean verbal test scores, additive model

		j (School)		
	μ_{ij}	1 (Low)	2 (Medium)	3 (High)
i	1 (N)	110	105	95
(Home)	2 (R)	100	95	85

Table 2
Mean verbal test scores, interaction model

		j (School)		
	μ_{ij}	1 (Low)	2 (Medium)	3 (High)
i	1 (N)	110	105	95
(Home)	2 (R)	100	95	80

$$y_{ijk} = \mu + \alpha_i + \eta_j + \varepsilon_{ijk} \tag{6}$$

This model is not equivalent to the one-way ANOVA model, but it includes nontrivial group effects. It amounts to imposing a restriction on the μ_{ij}s that

$$\mu_{ij} = \mu + \alpha_i + \eta_j \tag{7}$$

for some μ, α_is, and η_js. This indicates that the group effects μ_{ij} have a special structure in which the group effect is the sum of a grand mean and differential effects for each factor, hence model (6) is referred to as an additive model. The two-way ANOVA without interaction model is still overparameterized, so none of the individual parameters are estimable, but typically contrasts in the α_is and η_js are estimable as well as values $\mu + \alpha_i + \eta_j$.

To illustrate the modeling concepts, suppose that in our example the group means for the verbal test scores take the values shown in Table 1. These μ_{ij}s satisfy the additive model (7) so they do not display interaction. For example, take $\mu = 0$, $\alpha_1 = 110$, $\alpha_2 = 100$, $\eta_1 = 0$, $\eta_2 = -5$, $\eta_3 = -15$. Note that μ, the α_is, and the η_js are not identifiable (estimable) because there is more than one way to define them that is consistent with the μ_{ij}s. For example, we can alternatively take $\mu = 100$, $\alpha_1 = 5$, $\alpha_2 = -5$, $\eta_1 = 5$, $\eta_2 = 0$, $\eta_3 = -10$. However, identifiable functions of the parameters include $\mu + \alpha_i + \eta_j$, $\alpha_1 - \alpha_2$, $\eta_1 - \eta_3$, and $\eta_1 + \eta_2 - 2\eta_3$. Identifiable functions take on the same values for any valid choices of μ, the α_is, and the η_js. For example, the effect of changing from a not at risk home situation to an at risk home situation is a decrease of $\alpha_1 - \alpha_2 = 10$ points in mean verbal test score. Similarly, the effect of changing from a low school adversity situation to a high school adversity situation is a decrease of $\eta_1 - \eta_3 = 15$ points in mean verbal test score.

The beauty of the additive model (6) is that there is one number that describes the mean difference between students having not at risk home status and students having at risk home status. The difference is a drop of 10 points *regardless* of the school adversity status. This number can legitimately be described as the effect of going from not at risk to at risk. (Note that unless the students were assigned randomly to their home conditions, this does not imply that changing a student's status from at risk to not at risk will *cause*, on average, a 10 point gain.) Similarly, the effect of school adversity does not change with the home status. For example, going from low to high school adversity induces a 15 point drop regardless of whether the students are at risk or not at risk. Statistically, tests for main effects are tests of whether any of the α_is are different from each other and whether any of the η_js are different from each other, in other words whether the home statuses are actually associated with different mean verbal test scores and similarly for the school adversities.

The existence of interaction is simply any structure to the μ_{ij}s that cannot be written as $\mu_{ij} = \mu + \alpha_i + \eta_j$ for some μ, α_is, and η_js. For example, consider Table 2. In this case, the relative effect of having at risk home status for low or medium adversity schools is a drop of 10 points in mean test score, however for highly adverse schools, the effect of an at risk home status is a drop of 15 points. Unlike cases where the additive model (7) holds, the effect of at risk home status depends on the level of school adversity, so there is no one number that can characterize the effect of at risk home status. It makes no sense to consider the effect of home conditions without specifying the school adversity. Similarly, the effects of school adversity change depending on home status. For example, going from low to high school adversity induces a 15 point drop for students whose homes are not at risk, but a 20 point drop for at risk students. Again, there is no one number than can characterize the change from low to high school adversity, so there is no point in considering this change without specifying the home risk status. One moral of this discussion is that when interaction exists, there is no point in looking at tests of main effects, because main effects are essentially meaningless. If there is no one number that describes the effect of changing from not at risk to at risk, what could $\alpha_1 - \alpha_2$ possibly mean?

In practice, analyses such as these are conducted on estimates of the μ_{ij}s, and the estimates are subject to variability.

A primary use of model (6) is to test whether this special group effects structure fits the data. Model (6) is used as a reduced model and is tested against the full model (5) that includes interaction. This test is referred to as a test of interaction. In particular, the interaction test is not a test of whether the $(\alpha\eta)_{ij}$s are all zero, it is a test of whether every possible definition of the $(\alpha\eta)_{ij}$s must be consistent with the two-way without interaction model. The easiest way to think about this correctly is to think about testing whether one can simply drop the $(\alpha\eta)_{ij}$s from model (5).

If the two-way without interaction model (6) fits the data, it is interesting to see if any special case (reduced model) also fits the data. Two obvious choices are fitting a model that drops the second factor (school) effects

$$y_{ijk} = \mu + \alpha_i + \varepsilon_{ijk} \tag{8}$$

and a model that drops the first factor (home) effects

$$y_{ijk} = \mu + \eta_j + \varepsilon_{ijk} \tag{9}$$

If model (8) fits the data, there is no evidence that the second factor helps explain the data over and above what the first factor explains. Similarly, if (9) fits the data, there is no evidence that the first factor helps explain the data over and above what the second factor explains.

Given model (8) with only the first factor effect, we can evaluate whether the data fit a reduced model without that effect,

$$y_{ijk} = \mu + \varepsilon_{ijk} \tag{10}$$

This model comparison provides a test of whether the first factor is important in explaining the data when the second factor is ignored. Similarly we can start with model (9) and compare it to model (10). If model (10) fits, neither factor helps explain the data.

Through fitting a series of models, we can test whether there is evidence for the interaction effects, test whether there is evidence for the second factor effects η_j when the first factor α_i effects are included in the model, test whether there is evidence for the second factor effects η_j when the first factor α_i effects are not included in the model, and perform two similar tests for the importance of the α_i effects. In the special case when the N_{ij}s are all the same, the test for α effects including ηs, that is, the test of model (6) vs. model (9), and the test for α effects ignoring ηs, that is, the test of model (8) vs. model (10), are identical. Similarly, the two tests for η effects are identical. While this identity greatly simplifies the analysis, it only occurs in special cases and is not generally applicable. Moreover, it does not extend to generalized linear models such as log-linear models and logistic regression. The appropriate way to think about these issues is in terms of model comparisons.

3. *Higher-order Analysis of Variance*

The groups in a one-way ANOVA can also result from combining the levels of three or more factors. Consider a three-way cross-classification of Everitt's 97 students by further classifying them into students displaying or not displaying deviant classroom behavior. This deter-

mines $G = 12$ groups. The one-way ANOVA model $y_{gm} = \mu_g + \varepsilon_{gm}$, $g = 1, \ldots, G$, $m = 1, \ldots, N_g$ can be rewritten for three factors as $y_{ijkm} = \mu_{ijk} + \varepsilon_{ijkm}$ where the three factors are identified by $i = 1, \ldots, a$, $j = 1, \ldots, b$, $k = 1, \ldots, c$ so that $G = abc$, the group sample sizes are N_{ijk}, and $\mathrm{E}(y_{ijkm}) = \mu_{ijk}$. In the example, we continue to use i and j to indicate home and school conditions, respectively, and now use $k = 1, 2$ to indicate classroom behavior with $k = 1$ being nondeviant.

In its most overparameterized form, a three-way ANOVA model is

$$y_{ijkm} = \mu + \alpha_i + \eta_j + \gamma_k + (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + (\eta\gamma)_{jk} + (\alpha\eta\gamma)_{ijk} + \varepsilon_{ijkm} \tag{11}$$

This includes a grand mean μ, main effects for each factor α_is, η_js, γ_ks, two-factor interactions $(\alpha\eta)_{ij}$s, $(\alpha\gamma)_{ik}$s, $(\eta\gamma)_{jk}$s, and a three-factor interaction $(\alpha\eta\gamma)_{ijk}$s. In model (11), dropping the redundant terms, that is, everything except the three-factor interaction terms, gives a one-way ANOVA model $y_{ijkm} = (\alpha\eta\gamma)_{ijk} + \varepsilon_{ijkm}$. The primary interest in model (11) is that it suggests a wealth of reduced models to consider.

The first order of business is to test whether the three factor interaction is necessary, i.e., test the full model (11) against the reduced model without the three-factor interaction

$$y_{ijkm} = \mu + \alpha_i + \eta_j + \gamma_k + (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + (\eta\gamma)_{jk} + \varepsilon_{ijkm} \tag{12}$$

Focusing on only the important parameters, model (12) is equivalent to $y_{ijkm} = (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + (\eta\gamma)_{jk} + \varepsilon_{ijkm}$. In fact, even this version of the model is overparameterized. Model (11) is equivalent to the one-way ANOVA model, so if the three-factor interaction test is significant, there is no simplifying structure to the treatments. Probably the best one can do is to think of the problem as a one-way ANOVA and draw whatever conclusions are possible from the groups.

If model (12) fits the data, we can seek simpler models or try to interpret model (12). Conditioning on the levels of one factor, simplifies interpretations. For example, if $i = 1$, $y_{1jkm} = \mu + \alpha_1 + \eta_j + \gamma_k + (\alpha\eta)_{1j} + (\alpha\gamma)_{1k} + (\eta\gamma)_{jk} + \varepsilon_{1jkm}$ or $y_{1jkm} = [\mu + \alpha_1] + [\eta_j + (\alpha\eta)_{1j}] + [\gamma_k + (\alpha\gamma)_{1k}] + (\eta\gamma)_{jk} + \varepsilon_{1jkm}$. This is simply a two-factor model with interaction. If we change to $i = 2$, we again get a two-factor interaction model, one that has different main effects, but has the same interaction terms as when $i = 1$. For example, in Table 3 μ_{ijk}s satisfy model (12), that is, $\mu_{ijk} = \mu + \alpha_i + \eta_j + \gamma_k + (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + (\eta\gamma)_{jk}$ for some definitions of the parameters.

The key point in Table 3 is that, regardless of school adversity, the relative effect of not being at risk is always one point higher for nondeviants than for deviants. Thus, for high adversity the nondeviant home difference is 101–99 which is one point higher than the deviant home difference 99–98.

Table 3
No three-factor interacton

μ_{ijk}		Adversity of School (j)					
		Low		Medium		High	
	Home (i)	N	R	N	R	N	R
Classroom	Nondeviant	101	100	101	99	101	99
Behavior (k)	Deviant	100	100	100	99	99	98

Table 4
Two two-factor interactions

μ_{ijk}		Adversity of School (j)					
		Low		Medium		High	
	Home (i)	N	R	N	R	N	R
Classroom	Nondeviant	101	100	101	99	100	97
Behavior (k)	Deviant	100	98	100	97	99	95

Table 5
Rearrangement of Table 4

μ_{ijk}		Home (i)					
		N			R		
	School (j)	L	M	H	L	M	H
Classroom	Nondeviant	101	101	100	100	99	97
Behavior (k)	Deviant	100	100	99	98	97	95

If model (12) is adequate, the next step is to identify which of the two factor interaction terms are important. For example, we can drop out the $(\eta\gamma)_{jk}$ term to get

$$y_{ijkm} = \mu + \alpha_i + \eta_j + \gamma_k + (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + \varepsilon_{ijkm} \tag{13}$$

Dropping unimportant parameters, this is equivalent to $y_{ijkm} = (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + \varepsilon_{ijkm}$. To interpret model (13), condition on the factor that exists in both interaction terms. In our example, this is home conditions. The resulting model for $i = 1$ is a no interaction model $y_{1jkm} = [\mu + \alpha_1] + [\eta_j + (\alpha\eta)_{1j}] + [\gamma_k + (\alpha\gamma)_{1k}] + \varepsilon_{1jkm}$ with a similar no interaction model for $i = 2$ but with different main effects. For example, suppose the m_{ij}s are given in Table 4. Rearranging Table 4 to group together categories with i fixed gives Table 5. For fixed home conditions, there is no interaction. For not at risk students, deviant behavior is associated with a one point drop and high school adversity is associated with a one point drop. For at risk students, deviant behavior is associated with a 2 point drop and, relative to low school adversity, medium and high adversities are associated with a one point and a three point drop, respectively.

Table 6
One two-factor interaction

μ_{ijk}		Adversity of School (j)					
		Low		Medium		High	
	Home (i)	N	R	N	R	N	R
Classroom	Nondeviant	101	101	101	100	101	100
Behavior (k)	Deviant	100	100	100	99	100	99

Alternatively, we could eliminate both the $(\alpha\gamma)_{ik}$s and $(\eta\gamma)_{jk}$s from model (12) to get

$$y_{ijkm} = \mu + \alpha_i + \eta_j + \gamma_k + (\alpha\eta)_{ij} + \varepsilon_{ijkm} \tag{14}$$

which is equivalent to $y_{ijkm} = \gamma_k + (\alpha\eta)_{ij} + \varepsilon_{ijkm}$. We can think of this as a model for no interaction in a two-factor analysis in which one factor is indicated by the pair ij and the other factor is indicated by k. In the example, this means there is a main effect for classroom behavior plus an effect for each of the six combinations of home and school conditions. In particular, consider Table 6. Here, deviant behavior is always associated with a one point drop but there is interaction between home and school. For low school adversity, there is no effect of home conditions but for medium or high adversity, being at risk is associated with a one point drop.

From model (14L50), we could then fit a model that involves only the main effects

$$y_{ijkm} = \mu + \alpha_i + \eta_j + \gamma_k + \varepsilon_{ijkm} \tag{15}$$

Model (15) is equivalent to $y_{ijkm} = \alpha_i + \eta_j + \gamma_k + \varepsilon_{ijkm}$. If model (15) is adequate, we could consider models that successively drop out the α_is, the η_js, and the γ_ks.

Fitting this sequence of successively smaller models, (11) then (12) then (13) then (14) then (15), then three models with the main effects successively dropped out, provides one tool for analyzing the data. There are 36 different orders possible for sequentially dropping out the two-factor interactions and then the main effects. In the balanced case of $N_{ijk} = N$ for all i, j, k, the order of dropping the effects does not matter, so one can construct an ANOVA table to examine each of the individual sets of effects, that is, main effects, two-factor interactions, three-factor interaction. For unbalanced cases, one would need 36 different ANOVA tables, one for each sequence, so ANOVA tables are almost never examined except in balanced cases. (Two-factor models only generate two distinct ANOVA tables). For unbalanced cases, instead of looking at the ANOVA tables, it is more convenient to simply report the *SSE* and *dfE* for all of the relevant models using a notation that identifies models by only their important parameters. For four or more factors, the number of potentially interesting models becomes too large to evaluate all of them.

After deciding on one or more appropriate models, the μ_{ijk}s can be estimated subject to the model and the models interpreted subject to the variability of the estimates.

To interpret a three-factor interaction, recall that just as a two-factor interaction exists when the effect of one factor changes depending on the level of the other factor, one can think of a three-factor interaction as a two-factor interaction that changes depending on the level of the third factor. However, it may be more productive to think of three-factor interaction in a three-factor model as simply specifying a one-way ANOVA. As with two-factor models, it makes little sense to test the main effects of a factor when that factor is involved in an important interaction. Similarly, it makes little sense to test that a lower-order interaction can be dropped from a model that includes a higher-order interaction involving all of the same factors.

A commonly used generalization of the ANOVA models is to allow some of the parameters to be unobservable random variables (random effects) rather than fixed unknown parameters. See *Hierarchical Models: Random and Fixed Effects*.

4. *Generalized Linear Models (GLIM)*

ANOVA is best suited for analyzing normally distributed data. These are measurement data for which the random observations are symmetrically distributed about their mean values. Generalized linear models (GLIMs) use similar linear structures to analyze other kinds of data, such as count data and time to event data.

We can rethink two-way ANOVA models as independent observations y_{ijk} normally distributed with mean m_{ij} and variance σ^2, write $y_{ijk} \sim N(m_{ij}, \sigma^2)$. The interaction model (5) has

$$m_{ij} = \mu + \alpha_i + \eta_j + (\alpha\eta)_{ij}$$

The no interaction model (6) has

$$m_{ij} = \mu + \alpha_i + \eta_j$$

Now consider data that are counts y_{ij} of some event. Assume the counts are independent Poisson random variables with means $\mathrm{E}(y_{ij}) = m_{ij}$. The use of two subscripts indicates that the data are classified by two factors. For Poisson data the m_{ij}s must be nonnegative, so $\log(m_{ij})$ can be both positive and negative. Linear models naturally allow both positive and negative mean values, so it is natural to model the $\log(m_{ij})$s with linear models. For example, we might use the log-linear model

$$\log(m_{ij}) = \mu + \alpha_i + \eta_j + (\alpha\eta)_{ij}$$

or, without interaction,

$$\log(m_{ij}) = \mu + \alpha_i + \eta_j$$

These log-linear models are also appropriate for multinomial data and independent groups of multinomial data.

Similarly, if the data y_{ij} are independent binomials with N_{ij} trials and probability of success p_{ij}, then we can analyze the proportions $\hat{p}_{ij} \equiv y_{ij}/N_{ij}$ with $\mathrm{E}(\hat{p}_{ij}) = m_{ij} \equiv p_{ij}$. Probabilities are defined to be between 0 and 1, the odds $p_{ij}/(1-p_{ij})$ take positive values, and the log-odds can take any positive or negative value. It is natural to write linear models for the log-odds such as

$$\log[p_{ij}/(1-p_{ij})] = \mu + \alpha_i + \eta_j + (\alpha\eta)_{ij}.$$

or, without interaction,

$$\log[p_{ij}/(1-p_{ij})] = \mu + \alpha_i + \eta_j$$

More generally, in GLIMs we create linear models for $g(m_{ij})$ using any strictly monotone function $g(\cdot)$, called a link function. The linear structures used for one-way ANOVA, two-way ANOVA, and higher-order ANOVA models all apply to GLIMs, and appropriate models can be found by comparing the fit of full and reduced models similar to methods for unbalanced ANOVA. In particular, cross-classified tables of counts often involve many factors.

We now examine in more depth ANOVA-type models for binomial data. Reconsider Everitt's 97 children cross-classified by the risk of their home environment and adversity of their school conditions. Rather than studying their verbal test score performance conditional on their classroom behavior as we did when discussing three-factor ANO we now examine models for whether the children display deviant or nondeviant behavior. In particular, we model the probability of a student falling into the deviant behavior category given their membership in the six home–school groups, write the probability of deviant behavior when in the *ij* group as p_{ij} and model the log-odds with analysis of variance type models,

$$\log[p_{ij}/(1-p_{ij})] = \mu_{ij}$$

The overparameterized model

$$\log[p_{ij}/(1-p_{ij})] = \mu + \alpha_i + \eta_j + (\alpha\eta)_{ij}$$

is equivalent to the original model. Neither of these models really accomplishes anything because they fit a separate parameter to every home–school category, so the models place no restrictions on the observations.

Table 7
Log-odds : additive model

		j (School)		
	μ_{ij}	1 (Low)	2 (Medium)	3 (High)
i	1 (N)	−2	−1	1
(Home)	2 (R)	0	1	3

Table 8
Log-odds : nonadditive model

		j (School)		
	μ_{ij}	1 (Low)	2 (Medium)	3 (High)
i	1 (N)	−2	−1	1
(Home)	2 (R)	−1	1	4

The additive model

$$\log[p_{ij}/(1-p_{ij})] = \mu + \alpha_i + \eta_j$$

constitutes a real restriction on the parameters.

Suppose the log-odds, the μ_{ij}s, satisfy Table 7. These have the structure of an additive model. In this case the log-odds for deviant behavior are two larger for at risk homes than for not at risk homes, e.g., $2 = 0-(-2) = 1-(-1) = 3-1$. This means that the odds are $e^2 = 7.4$ times larger for at risk homes. In particular, the log-odds of deviant behavior for low adversity schools and not at risk homes is -2 so the odds are $O_{11} = e^{-2} = 0.135$ and the probability if $p_{11} = O_{11}/[1+O_{11}] = 0.12$. Similarly, the odds and probability of deviant behavior for low adversity schools and at risk homes are $O_{21} = e^0 = 1$ and $p_{21} = 0.5$. The change in odds is $0.135 \times 7.4 = 1$. The 7.4 fold increase in odds is the same for all school conditions. Similarly, comparing low to high school adversities, the difference in log-odds is $3 = 1-(-2) = 3-0$, so the odds of deviant behavior are $e^3 = 20$ times greater in highly adverse schools, regardless of the home situation. The odds of deviant behavior in highly adverse schools and not at risk homes is $O_{13} = e^1 = 2.7$ which is 20 times greater than $O_{11} = 0.135$, the odds for low adversity schools and not at risk homes.

An example of a nonadditive model has log-odds as shown in Table 8. For low adversity schools the log-odds only differ by 1, for medium adversity schools they differ by 2, and for high adversity schools they differ by 3. Thus the effect of home conditions on the log-odds depends on the level of school adversity.

5. *Conclusions*

The fundamental ANOVA model is the one-way model. It specifies different mean values for different groups. When the groups are identified as combi-

nations of two or more factors, models incorporating main effects and interactions become a useful device for examining the underlying structure of the data. Appropriate models can be identified by fitting sequences of successively smaller models and using general testing procedures to identify the models within each sequence that fit well. Having identified a model, it is important to interpret what that model suggests about the underlying data structure. ANOVA models, the sequential model fitting procedures, and the interpretations apply to both balanced and unbalanced data and to generalized linear models. The sequential model fitting simplifies in balanced ANOVA allowing for it to be summarized in an ANOVA table.

Analytic Induction

Analytic induction (AI) is a research logic used to collect data, to develop analysis, and to organize the presentation of research findings. Its formal objective is causal explanation, a specification of the individually necessary and jointly sufficient conditions for the emergence of some part of social life. AI calls for the progressive redefinition of the phenomenon to be explained (the explanandum) and of explanatory factors (the explanans), such that a perfect (sometimes called 'universal') relationship is maintained. Initial cases are inspected to locate common factors and provisional explanations. As new cases are examined and initial hypotheses are contradicted, the explanation is reworked in one or both of two ways. The definition of the explanandum may be redefined so that troublesome cases either become consistent with the explanans or are placed outside the scope of the inquiry; or the explanans may be revised so that all cases of the target phenomenon display the explanatory conditions. There is no methodological value in piling up confirming cases; the strategy is exclusively qualitative, seeking encounters with new varieties of data in order to force revisions that will make the analysis valid when applied to an increasingly diverse range of cases. The investigation continues until the researcher can no longer practically pursue negative cases.

1. The Methodology Applied

Originally understood as an alternative to statistical sampling methodologies, 'analytic induction' was coined by Znaniecki (1934), who, through analogies to methods in chemistry and physics, touted AI as a more 'scientific' approach to causal explanation than 'enumerative induction' that produces probabilistic statements about relationships. After a strong but sympathetic critique by Turner (1953), AI shed the promise of producing laws of causal determinism that would permit prediction. The methodology subsequently became diffused as a common strategy for analyzing qualitative data in ethnographic research. AI is now practiced in accordance with Znaniecki's earlier (1928), less famous call for a phenomenologically grounded sociology. It primarily continues as a way to develop explanations of the interactional processes through which people develop homogeneously experienced, distinctive forms of social action.

The pioneering AI studies centered on turning points in personal biographies, most often the phase of commitment to behavior patterns socially defined as deviant, such as opiate addiction (Lindesmith 1968), embezzlement (Cressey 1953), marijuana use (Becker 1953), conversion to a millenarian religious sect (Lofland and Stark 1965), abortion seeking (Manning 1971), and youthful theft (West 1978, a rare study focusing more on desistance than onset). Studies at the end of the twentieth century have addressed more situationally specific and morally neutral phenomena. These include occupational perspectives exercised in

particular work settings (Katz 1982 on lawyers, Strong 1988 on doctors, and Johnson 1998 on union representatives), and distinctive moments in the course of everyday life (Flaherty 1999 the experience of time as passing slowly, and Katz 1999 laughter in a funhouse).

There is no particular analytical scale to the phenomena that may be addressed with AI. The research problem may be macro social events such as revolutionary social movements, mid-scale phenomena such as ongoing ways of being a student in a given type of educational institution, or everyday microsocial phenomena such as expressive gestures that can only be seen clearly when videotape is repeatedly reviewed.

1.1 How AI Transforms Theory

AI transforms and produces a sociological appreciation of phenomena along recurrent lines. The explanandum is often initially defined as a discrete act or event, for example the ingestion of a drug, exceeding a specific tenure on a job, or the commission of a fatal blow. The target phenomenon is progressively redefined to address a process: a persistent commitment, for example, being addicted to a drug; the maintenance of a perspective, such as a way of being involved with the challenges of a job; or a phase of personal change, as in the emotional transformation experienced when becoming enraged. Explanatory conditions, often originally defined from the outside as biographical and ecological background factors, are redefined to specify the interactions through which people, by learning, recognizing, or becoming aware of features of their pasts and circumstances, in effect set up the motivational dynamics of their own conduct. The methodology of AI thus dovetails with the theoretical perspective of symbolic interaction (SI) (Manning 1982; see *Symbolic Interaction: Methodology*), which stipulates that a person's actions are built up and evolve over time through processes of learning, trial-and-error, and adjustment to responses by others.

Although authors do not necessarily present their findings in these categories, a common theoretical result of AI is to highlight each of three types of explanatory mechanisms. One points to the practicalities of action (e.g., learning distinctive techniques for smoking marihuana). A second relates to matters of self-awareness and self-regard (e.g., attributing physical discomfort to withdrawal from opiates). The third refers to the sensual base of motivation in desires, emotions, or a sense of compulsion to act (e.g., embezzling when feeling pressured to resolve a secret financial problem). Perhaps the most ambitious long-term objective of AI is to develop the most economical set of inquiries capable of unveiling the distinctive processes that constitute any experienced moment in social life.

1.2 As Used in Ethnography

In the 1950s, reports of AI studies often took the form of tracing how negative cases led, step-by-step, to the final state of the theory. By 1980 an AI study was more likely to be presented in the style of an ethnographic text. Ethnographers find the principles of AI useful for guiding data gathering and shaping analysis. Often starting as outsiders and typically concerned to document social reality as lived by members, ethnographers redefine categories toward homogeneity 'from the inside.' When a sense of redundancy develops in interviews and observations, they commonly seek unusual data that will implicitly serve as negative cases when explicit analysis begins. Ethnographers are better positioned to trace how social life develops than to control rival variables as a means to argue why particular types of actions occur. In turn, they gravitate away from predictive theory and toward documenting regularities in the evolution of significant forms of behavior.

The methodological strategy of AI also dovetails with ethnography's narrative style. Because the logic of proof in AI relies solely on the richness or variety of cases that have been shown to be consistent with the final explanation, not on counting confirming cases, the researcher demonstrates the evidentiary strength of the theory by showing how variations of the explanans, A, B and C (A^{1-n}, etc.) fit with instances of the explanandum, X (X^{1-n}). Similarly, a common format for ethnographic writing is to entitle an article or chapter 'the career of …,' or 'doing …,' or 'becoming a …,' and then, in separate subsections, to describe the various ways that each of the explanatory conditions and the resulting phenomenon take shape. The author implicitly lays out the 'coding' or interpretive procedures that have been applied to the data set. A separate section may be devoted to cases of desistance, or transitions to non-X. For example, in a study of drivers becoming angry, a variety of cases describes how experiences of being 'cut off' emerge, how drivers come to see themselves in asymmetrical relations with other drivers, how they mobilize for revenge; and how each of these explanatory conditions is negated in cases showing anger subsiding (Katz 1999).

2. Limitations and Advantages

The logic of AI implies ideal conditions for data gathering that are rarely satisfied. The researcher should not be committed to a preset or conventional definition of the explanandum. Funding sources, however, are usually motivated by problems as defined by popular culture and as documented by official statistics. The researcher should constantly alter the data search as analysis develops. The practicalities of ethnographic projects, however, often press toward a

less flexible involvement in the field. Data should track the emergence and decline of the explanandum, the data should remain constant through repeated inspections, and there should be an inexhaustible series of instances against which to test hypotheses. Such data may be created through unobtrusive video-recordings of situated action, but the range of phenomena that can be described contemporaneously through phases of emergence and decline, in situ, in massive number, and without reactivity either during original recording or infinite reinspection, is severely limited.

2.1 Critiques and Rejoinders

Even so, an appreciation of how AI could exploit ideal evidence helps in assessing the central criticisms that have been addressed to it. One frequently cited weakness is that AI only specifies necessary but not sufficient conditions. Another is that it produces tautological explanations. If indeed the researcher only looks for factors common in the etiology of X, narrowing definitions and shedding cases when encountering negative cases, the explanation may only specify preconditions that are necessary but not particularly distinctive to X, much less sufficient to cause it. Cressey's claim that a 'nonshareable problem' and 'rationalization' explained a specified form of embezzlement was especially vulnerable on these grounds, especially since he never described the situated action of embezzlement. But if, as has often been the case, the researcher finds data describing transition points from non-X to X, as well as data describing progressions from X to non-X (e.g., desistance studies), claims of sufficiency may be precisely tested.

As to tautology, when the explanatory conditions are social-psychological matters of interactive behavior, as opposed to psychological and internal matters of thought and outlook, they can be coded independently of X. Note that any true causal explanation of behavior should turn up some potentially tautological cases. The very idea of causal sufficiency is that, with no existential break, the simultaneous presence of A, B, and C instantly produces X; in some cases there should not be any evidence that permits the coding of A, B, and C independent of data describing X. It should be expected that in some cases the development of the explanatory factors would be depicted as continuous with the emergence of the target phenomenon. But AI also leads the researcher to hunt for case histories in which, alternatively, each of A, B, or C had been absent and then came into existence, leading to X; as well as cases in which X had been present and then, alternatively, A, B, or C declined or ended, leading to non-X. AI is especially attuned to exploit contrasting states in temporal as opposed to cross-sectional data. The best examples of AI present evidence in just this sequential form, for example showing the development of addiction after an explicit and abrupt recognition that a long-standing pattern of distress has been due to repeated opiate withdrawal (Lindesmith 1968).

2.2 Generalization, Prediction and Retrodiction

Although AI studies, in order to allow the definition of explanatory elements to develop, cannot proceed from probabilistic samples and produce meaningful statistics attesting to representativeness, they are fundamentally geared toward generalization. By seeking negative cases, the researcher tests the explanation against claims that in times, places, and social circumstances other than those defining the initial collection, the explanation will not hold. As the explanation is redefined, it becomes both more nuanced and more wide-ranging in demonstrated validity. External validity depends on internal variety, not on the quantity and logically prederived uniformity of the data set. For this reason, an AI study reporting data that are monotonous, abstracted, and static will be methodologically weak.

AI cannot produce predictions in the sense of specifying the conditions at time 1 that will result in particular behaviors at time 2. The causal homogeneity that the method demands depends on subjects' defining their situation in common ways, and no study has ever found 'objective' conditions that will perfectly predict people's understandings of their biographical backgrounds and ecological contexts. The methodology does, however, support what might be called 'retrodiction': assertions that if a given behavior is observed to have occurred at time 2, specific phenomena will have occurred at time 1. While AI has never attempted to produce natural histories that specify the order of sequencing through which given social forms emerge (first condition A, then condition B, then condition C), it always makes claims of one or more, individually necessary and jointly sufficient preconditions of the explanandum. Thus, for example, AI will not attempt to predict who will become a murderer, but if one finds a case of enraged homicidal assault AI can support assertions as to what must have happened on the way to the assault: an emotional transformation from humiliation to rage, a recognition of being at a last stand for defending self-respect, and optimism about practical success (Katz 1988). Much of what is said to be valuable about prediction, such as the potential for intervention and control, remains available when results support retrodiction. Indeed, perhaps the most useful focus for policies of intervention is the identification of a narrowly defined precondition that is distinctive to a troublesome behavior, even if that single condition alone is not sufficient to cause the problem.

2.3 Unique Contributions

By redefining phenomena from the actor's perspective, and by discovering and testing an analysis of how given forms of social life come into existence, AI makes unique contributions that may be appreciated without gainsaying the contributions of statistical research. As it redefines the explanandum from a definition initially taken from conventional culture, AI typically reveals the social distance between insiders and outsiders, and the realities of culture conflict. Although rarely touted as 'policy research,' the upshot is a documented portrayal of some segment of social life that is systematically misrepresented by the culture that supports power. To the extent that social control, as influenced by populist voting and as implemented through officials' quotidian actions, is based on stereotypes about problematic behavior, AI can play a significant role in policy reform over the long term, especially if its ethnographic texts become widely used in university education. For scholars of cultural history and cultural differentiation, AI can document the changing variety of experiences in some area of social life (e.g., the variety of experiences in illicit drug use, professional acumen, or the behavior of laughter). Perhaps most generally, AI can specify the 'essence' of sociological phenomena in the sense of documenting what is entailed in a given line of action and form of social experience.

3. Prospects

Over its 75-year history, AI has shed a rhetorical claim to priority as the logic that should guide sociological data collection, metamorphosing into a pervasive, if typically implicit, strategy for analyzing qualitative data. Within the philosophy of science, the methodology's ill-considered claim of 'induction' has been replaced by a concept of 'retroduction,' or a double fitting of analysis and data collection (Ragin 1994). Similarly, it has been recognized that 'retrodiction' but not 'prediction' captures the thrust of AI's explanatory power.

The prospects for AI rest on three grounds. First, there is broad consensus that explanations, whether probabilistic or 'universal,' are likely to work better, the better they fit with subjects' perspectives. AI focuses most centrally on the foreground of social life, reaching into subjects' backgrounds to varying lengths, but always requiring careful examination of the contents of the targeted experience. It thus balances a relative indifference in much statistical research to the specific content of the explanandum, which is often left in such gross forms as 'serious' (FBI 'Part One') crime, or self-characterized 'violence.' Second, the findings of AI indicate that if social research imposes definitions on subjects regardless of the meaning that their conduct has to them, it will risk perpetuating artificial stereotypes and supporting power relations ill-suited to effective policy making. Finally, and most broadly, the utility of AI depends on two persistent features of sociological thinking. One is a fascination with the endless variety of distinctive forms into which people shape their social lives. The other is the observation that each subjectively distinctive stretch of personal experience comes with a tail of some biographical length. If one may never predict behavior with perfect confidence, still the forms that characterize small and large segments of lives are not superficial matters that emerge wholly made and with random spontaneity. Even as people constantly bootstrap the foundations for their conduct, they ground the objectives of their action in rich depths of temporal perspective; they act with detailed, often hard-won practical competence; and they consider the matter of how their conduct will appear to others with a care that is seasoned, even if it is routinely exercised in a split second of consequential behavior. AI's quest for systematic knowledge is no less secure than is the understanding that social life takes shape as people crystallize long-evolved perspectives, elaborate familiar behavioral techniques, and weave cultured interpersonal sensibilities into situationally responsive, experientially distinctive patterns of conduct.

Analytical Marxism

Analytical Marxism is a cross-disciplinary school of thought which attempts to creatively combine a keen interest in some of the central themes of the Marxist tradition and the resolute use of analytical tools more commonly associated with 'bourgeois' social science and philosophy.

Marx is often interpreted as having used a 'dialectical' mode of thought which he took over, with modifications, from Hegel, and which can be contrasted with conventional, 'analytical' thinking. Marx himself may have said and thought so. But according to analytical Marxists, one can make sense of his work, or at least of the main or best part of it, while complying with the strictest standards of analytical thought. This need not mean that all of what is usually called 'dialectics' should be abruptly dismissed. For example, the study of the typically dialectic contradictions which drive historical change constitutes a challenging area for the subtle use of analytical thought (see Elster 1978).

The resolute option for an analytical mode of thought does, however, imply that the research program stemming from Marx should by no means be conceived as the development of an alternative 'logic,' or of a fundamentally different way of thinking about capitalist development, or about social reality in general. It rather consists of practicing the most appropriate forms of standard analytical thought—using conventional conceptual analysis, formal logic and mathematics, econometric methods, and the other tools of statistical and historical research—in order to tackle the broad range of positive and normative issues broached in Marx's work. Analytical tools may have been developed and extensively used by 'bourgeois' social science and philosophy. This does not make them unfit, analytical Marxists believe, to rigorously rephrase and fruitfully develop some of the central tenets of the Marxian tradition.

Thus, the techniques characteristic of Anglo-American analytical philosophy can be used to clarify the meaning of key Marxian concepts as well as the epistemic status of the central propositions of the Marxian corpus and their logical relations with each other (see e.g., Cohen 1978). Formal models resting on the assumption of individually rational behavior, as instantiated by neoclassical economic theory and the theory of strategic games, can be used to understand the economic and political dynamics of capitalist societies (see e.g., Przeworski 1985, Carling 1991). The careful checking of theoretical conjectures against carefully collected and interpreted historical data can be used to test Marx's grand claims about transitions from one mode of production to another (see Aston & Philpin 1985). Making use of these tools does not amount to taking on board all the statements they have allegedly helped establish in the hands of conservative philosophers and social scientists. Nor is it meant to serve dogmatic defense of any particular claim Marx may have made. Rather, analytical Marxists view a competent, inventive, and critical use of these tools as an essential ingredient of any effective strategy both for refining and correcting Marx's claims and for challenging the political status quo.

The areas in which analytical Marxists have been active range from medieval history to socialist economics and from philosophical anthropology to empirical class analysis. The issues about which they have been involved in the liveliest controversies include:

(a) Are the central propositions of historical materialism to be construed as functional explanations, i.e., as explanations of institutions by references to the functions they perform? If so, are such explanations legitimate in the social as well as in the biological realm? (See Cohen 1978; Van Parijs 1981; Elster 1983.)

(b) Is it possible, indeed is it necessary, for a Marxist to be committed to methodological individualism, i.e. to the view that all social-scientific explanations should ultimately be phrased in terms of actions and thoughts by individual human beings? Or are there some admissible 'structuralist' Marxian explanations which are radically irreducible to an individualistic perspective? (See Elster 1982, Elster 1985; Roemer 1985.)

(c) Is there any way of salvaging from the ferocious criticisms to which it has been subjected the so-called theory of the falling rate of profit, i.e., Marx's celebrated claim that capitalist economies are doomed to be crisis-ridden, owing to a systematic tendency for the rate of profit to fall as a result of the very process of profit-driven capital accumulation? If the criticisms are compelling, what are the consequences both for the methodology of Marxian economics and for Marxian crisis theory? (See Roemer 1981, Elster 1985, Van Parijs 1993.)

(d) Can one vindicate the labor theory of value, i.e., the claim that the labor time required to produce a commodity is the ultimate determinant of its price, against the numerous objections raised against. If not, does this have any serious consequence for positive Marxian theory, bearing in mind that Marx himself considered this theory essential to the explanation of capitalist profits. Does it have any serious consequence for Marxian normative theory (if any), bearing in

mind that Marx's concept of exploitation is usually defined in terms of labor value? (See Roemer 1981, Cohen 1989.)

(e) Does Marx leave any room for ethical statements, i.e., statements about what a good or just or truly free society would be like, as distinct from statements about how a society could be more rationally organized or about what it will turn out to be by virtue of some inexorable laws of history? Or should one instead ascribe to him a consistently immoralist position and, if the latter, can such a position be defended? (See Wood 1981, Elster 1985, Cohen 1989.)

(f) Can the concept of exploitation—commonly defined as the extraction of surplus labor, or as the unequal exchange of labor value—be made independent of the shaky labor theory of value? Can it be extended to deal with late-capitalist or postcapitalist societies, in which the possession of a scarce skill, or the incumbency of some valued job, or the control over some organizational asset may be at least as consequential as the ownership of material means of production? Can such a more or less generalized concept of exploitation provide the basis for an empirically fruitful concept of social class? By providing a precise characterization of what counts as an injustice, can it supply the core of an ethically sensible conception of justice? (See esp. Roemer 1982, Wright 1985, Wright et al. 1989.)

(g) How can the Marxian commitment to equality (if any) be rigorously and defensibly formulated? Could the egalitarian imperative that motivates the demand for the socialization of the means of production also be satisfied by an equal distribution of the latter, or by a neutralization of the impact of their unequal distribution on the distribution of welfare? To what extent is this imperative compatible with every individual owning (in some sense) herself, as taken for granted, it would seem, in the typically Marxian idea that workers are entitled to the full fruits of their labor? (See Roemer 1994c, Cohen 1995.)

(h) After the collapse of East-European socialism, is it possible to reshape the socialist project in a way that takes full account of the many theoretical and practical objections that have been raised against it? Can a system be designed in which the social ownership of the means of production can be combined with the sort of allocative and dynamic efficiency commonly ascribed to capitalist labor and capital markets? (See Roemer 1994b.) Or should the radical alternative to capitalism as we know it rather be found in a 'capitalist transition towards communism' through the introduction and gradual increase of an unconditional basic income or in a highly egalitarian redistribution of privately owned assets? (See van der Veen and van Parijs 1986, Bowles and Gintis 1998.)

The boundaries of analytical Marxism are unavoidably fuzzy. Defined by the combination of a firm interest in some of the central themes of the Marxist tradition and the unhibited use of rigorous analytical tools, it extends far beyond, but is strongly associated with, the so-called 'September Group' founded in 1979 by the Canadian philosopher G. A. Cohen (Oxford) and the Norwegian social scientist Jon Elster (Columbia) The group has crystallized an attitude into a movement, by endowing it with a name, a focus, and a target for criticisms (see Roemer 1985, 1994a, Ware and Nielsen 1989). Having started with a critical inventory of Marx's heritage, it gradually took a more prospective turn, with a growing emphasis on the explicit elaboration and thorough defense of a radically egalitarian conception of social justice (see Cohen 1995, 1999, Van Parijs 1995, Roemer 1996) and a detailed multidisciplinary discussion of specific reforms (see Van Parijs 1992, Roemer 1998, and the volumes in the *Real Utopias Project* directed by Erik O. Wright). This development has arguably brought analytical Marxism considerably closer to left liberal social thought than to the bulk of explicitly Marxist thought.

Anaphora

The term 'anaphora' comes from the Greek word ἀναφόρα, which means 'carrying back.' In contemporary linguistics, there are three distinct senses of 'anaphora/anaphor/anaphoric': (a) as a relation between two linguistic elements, in which the interpretation of one (anaphor) is in some way determined by the interpretation of the other (antecedent), (b) as a noun phrase (NP) with the features [+anaphor, −pronominal] versus pronominal as an NP with the features [−anaphor, +pronominal] in the Chomskian tradition, and (c) as 'backward' versus cataphora/cataphor/cataphoric as 'forward,' both of which are endophora/endophor/endophoric, as opposed to exophora/exophor/exphoric.

Anaphora is at the center of early twenty-first century research on the interface between syntax, semantics, and pragmatics in theoretical linguistics. It is also a subject of key interest in psycho- and computational linguistics, and to work on the philosophy of language, and language in cognitive science. It has aroused this interest for a number of reasons. In the first place, anaphora represents one of the most complex phenomena of natural language, which, in itself, is the source of fascinating problems. Second, anaphora has long been regarded as one of the few 'extremely good probes' in furthering our understanding of the nature of the human mind, and thus in facilitating an answer to what Chomsky considers to be the fundamental problem of linguistics, namely, the logical problem of language acquisition—a special case of Plato's problem. In particular, certain aspects of anaphora have repeatedly been claimed by Chomsky to furnish evidence for the argument that human beings are born equipped with some internal, unconscious knowledge of language, known as the language faculty. Third, anaphora has been shown to interact with syntactic, semantic, and pragmatic factors. Consequently, it has provided a test bed for competing hypotheses concerning the relationship between syntax, semantics, and pragmatics in linguistic theory.

1. *Typologies of Anaphora*

Anaphora can be classified on the basis of (a) syntactic categories, (b) truth-conditions, and (c) discourse reference-tracking systems.

1.1 *Anaphora and Syntactic Categories*

In terms of syntactic category, anaphora falls into two main groups: (a) NP- (noun phrase-), including N- (noun), anaphora, and (b) VP- (verb phrase-) anaphora. In an NP-anaphoric relation, both the anaphor and its antecedent are in general NPs, and both are potentially referring expressions (1). NP-anaphora corresponds roughly to the semantically defined type of 'identity of reference' anaphora. NP-anaphora can be encoded by gaps (or empty categories), pronouns, reflexives, names, and descriptions. By contrast, in an N-anaphoric relation, both the anaphor and its antecedent are an $\bar{N}$ rather than an NP, and neither is a potentially referring expression (2). N-anaphora corresponds roughly to the semantically defined type of 'identity of sense' anaphora. Linguistic elements that can be used as an N-anaphor include gaps, pronouns and nouns.

(1) John said that he didn't know how to telnet.

(2) John's favorite painter is Gauguin, but Mary's Ø is van Gogh.

The other main category is VP-anaphora. Under this rubric, five types may be isolated: (a) VP-ellipsis, in which the VP of the second and subsequent clauses is reduced (3); (b) gapping, in which some element (typically a repeated, finite verb) of the second and subsequent conjuncts of a coordinate construction is dropped (4); (c) sluicing, which involves an elliptical construction consisting only of a wh-phrase (5); (d) stripping, an elliptical construction in which the ellipsis clause usually contains only one constituent (6); and

(e) null complement anaphora, an elliptical construction in which a VP complement of a verb is omitted (7).

(3) John adores Goya's paintings, and Steve does, too.

(4) Reading maketh a full man; conference a ready man; and writing an exact man.

(5) John donated something to Médecins Sans Frontières, but I don't know what.

(6) Pavarotti will sing 'Nessun dorma' again, but not in Hyde Park.

(7) Mary wanted to pilot a gondola, but his father didn't approve.

1.2 Anaphora and Truth-conditions

From a truth-conditional, semantic point of view, anaphora can be divided into five types: (a) referential anaphora, one that refers to some entity in the external world either directly or via its co-reference with its antecedent in the same sentence/discourse (1); (b) bound-variable anaphora, which is interpretable by virtue of its dependency on some quantificational expression in the same sentence/discourse, thus seeming to be the natural language counterpart of a bound variable in first-order logic (8); (c) E[vans]-type anaphora, one which, for technical reasons, is neither a pure referential anaphor nor a pure bound-variable anaphor, but which nevertheless constitutes a unified semantic type of its own (9); (d) anaphora of 'laziness,' so-called because it is neither a referential anaphor nor a bound-variable anaphor, but functions as a shorthand for a repetition of its antecedent (10); and (e) bridging cross-reference anaphora, one that is used to establish a link of association with some preceding expression in the same sentence/discourse via the addition of background assumption (11) (see Huang 2000a and references therein).

(8) Every little girl wishes that she could visit the land of Lilliput.

(9) Most people who bought a donkey have treated it well.

(10) The man who gave his paycheck to his wife was wiser than the man who gave it to his mistress.

(11) John walked into a library. The music reading room had just been refurbished.

1.3 Anaphora and Discourse: Reference-tracking Systems

Reference-tracking systems are mechanisms employed in individual languages to keep track of the various entities referred to in an ongoing discourse. In general, there are four major types of reference-tracking system in the world's languages: (a) gender/class, (b) switch-reference, (c) switch-function, and (d) inference.

In a gender system, an NP or (less frequently) a VP is morphologically classified for gender/class according to its inherent features, and is tracked through a discourse via its association with the gender/class assigned. This reference-tracking device is found to be present in a large variety of languages such as Archi, Swahili, and Yimas. Next, in a switch-reference system, the verb of a dependent clause is morphologically marked to indicate whether or not the subject of that clause is the same as the subject of its linearly adjacent, structurally related independent clause. Switch-reference is found in many of the indigenous languages spoken in North America, of the non-Austronesian languages spoken in Papua New Guinea, and of the Aboriginal languages spoken in Australia. It has also been found in languages spoken in North Asia and Africa. Somewhat related to the switch-reference system is the switch-function system. By switch-function is meant the mechanism that tracks the reference of an NP across clauses in a discourse by means of verbal morphology indicating the semantic function of that NP in each clause. This system is found in a wide range of languages including English, Dyirbal, and Jacaltec. Finally, there is the inference system. In this system, reference-tracking in discourse is characterized by (a) the heavy use of zero anaphors, (b) the frequent appeal to sociolinguistic conventions, and (c) the resorting to pragmatic inference. This mechanism is particularly common in East and Southeast Asian languages like Chinese, Javanese, and Tamil. Of the four reference-tracking devices mentioned above, the first is considered to be lexical in nature, the second and third, grammatical in nature, and the fourth, pragmatic in nature (Foley and Van Valin 1984, Comrie 1989, Huang 2000a).

2. Intrasentential Anaphora: Three Approaches

Anaphora can be intrasentential, that is, when the anaphor and its antecedent occur within a single sentence. It can also be discoursal, that is, when the anaphor and its antecedent cross sentence boundaries. In addition, there are anaphoric devices that lie in between pure intrasentential anaphora and pure discourse anaphora.

With regard to intrasentential anaphora, three main approaches can be identified: (a) syntactically oriented, (b) semantically oriented, and (c) pragmatically oriented. There has also been substantial research on the acquisition of intrasentential anaphora, especially within the generative framework, but I will not review it in this article.

2.1 Syntactic

Central to the syntactically oriented analyses is the belief that anaphora is largely a syntactic phenomenon, and as such references must be made to conditions and constraints that are essentially syn-

Table 1

tactic in nature. This approach is best represented by Chomsky's (1981, 1995) binding theory within the principles-and-parameters theory and its minimalist descendant.

Chomsky distinguishes two types of abstract feature for NPs: anaphors and pronominals. An anaphor is a feature representation of an NP which must be referentially dependent and which must be bound within an appropriately defined minimal syntactic domain; a pronominal is a feature representation of an NP which may be referentially dependent but which must be free within such a domain. Interpreting anaphors and pronominals as two independent binary features, Chomsky hypothesizes that one ideally expects to find four types of NP in a language—both overt and non-overt—see Table 1. Of the four types of NP listed in Table 1, anaphors, pronominals, and r[eferential]-expressions are subject to binding conditions A, B, and C respectively (see Table 2). Binding is defined on anaphoric expressions in configurational terms, appealing to purely structural concepts like c-command, government, and locality. The binding theory accounts for the distribution of anaphoric expressions in Table 3. It is also applied to empty categories: NP-trace, pro, and wh-trace. It has even been extended to analyzing VP-ellipsis and switch-reference, but that work will not be surveyed here.

There are, however, considerable problems with the binding theory cross-linguistically. The distribution of reflexives violates binding condition A in both directions: on the one hand, a reflexive can be bound outside its local domain (so-called long-distance reflexive), as in Chinese, Icelandic and Tuki; on the other, it may not be bound within its local domain, as in Dutch and Norwegian. Binding condition B is also frustrated, for in many of the world's languages (such as Danish, Gumbaynggir, and Piedmontese), a pronominal can be happily bound in its local domain. Next, given Chomsky's formulation of binding conditions A and B, it is predicted that anaphors and pronominals be in strict complementary distribution, but this predicted complementarity is a generative syntactician's dream world. Even in a 'syntactic' language like English, it is not difficult to find syntactic environments where the complementarity breaks down. Finally, even a cursory inspection of languages like English, Japanese, and Vietnamese indicates that binding condition C cannot be taken as a primitive of grammar.

2.2 *Semantic*

In contrast to the 'geometric,' syntactic approach, the semantically based approach maintains that anaphora is essentially a semantic phenomenon. Consequently, it can be accounted for in semantic terms. Under this approach, binding is frequently defined in argument-structure terms. Reinhart and Reuland's (1993) theory of reflexivity, for example, belongs to this camp (see Tables 4 and 5).

On Reinhart and Reuland's view, reflexivity is not a property of NPs, but a property of predicates. The binding theory is designed not to capture the mirror-image distribution of anaphors and pronominals, but to regulate the domain of reflexivity for a predicate. Putting it more specifically, what the theory predicts is that if a predicate is lexically reflexive, it may not be reflexive-marked by a morphologically complex SELF anaphor in the overt syntax. And if a predicate is not

Table 6
Huang's revised neo-Gricean pragmatic apparatus (simplified)

(i) The use of an anaphoric expression x I-implicates a local coreferential interpretation, unless (ii) or (iii).
(ii) There is an anaphoric Q-scale ⟨ x, y ⟩, in which case, the use of y Q-implicates the complement of the I-implicature associated with the use of x, in terms of reference.
(iii) There is an anaphoric M-scale {x, y}, in which case, the use of y M-implicates the complement of the I-implicature associated with the use of x, in terms of either reference or expectedness.

lexically reflexive, it may become reflexive only via the marking of one of its co-arguments by the use of such an anaphor.

While Reinhart and Reuland's theory constitutes an important step forward in our understanding of binding, it is not without problems of its own. First, cross-linguistic evidence has been presented that marking of reflexivity is not limited to the two ways identified by Reinhart and Reuland. In addition to being marked lexically and syntactically, reflexivity can also be indicated morphologically. Second, more worrisome is that the central empirical prediction of the reflexivity analysis, namely, only a reflexive predicate can and must be reflexive-marked, is falsified in both directions. On the one hand, a predicate that is both syntactically and semantically reflexive can be non-reflexive marked; on the other, a non-reflexive predicate can be reflexive-marked.

2.3 Pragmatic

One of the encouraging progresses in the study of anaphora in the last decade has been the development of pragmatic approaches, the most influential of which is the neo-Gricean pragmatic theory of anaphora constructed by Levinson (1987, 2000) and Huang (1991, 1994, 2000a, 2000b). The central idea underlying this theory is that anaphora is largely pragmatic in nature, though the extent of anaphora being pragmatic varies typologically. Therefore, anaphora can largely be determined by the systematic interaction of some general neo-Gricean pragmatic principles such as Levinson's Q- (Don't say more than is required.), I- (Don't say less than is required.), and M- (Don't use a marked expression without reason.) principles, depending on the language user's knowledge of the range of options available in the grammar, and of the systematic use or avoidance of particular anaphoric expressions or structures on particular occasions. Table 6 is a revised neo-Gricean pragmatic apparatus for anaphora. Needless to say, any interpretation generated by Table 6 is subject to the general consistency constraints applicable to Gricean conversational implicatures. These constraints include world knowledge, contextual information, and semantic entailments.

There is substantial cross-linguistic evidence to show that empirically, the neo-Gricean pragmatic theory of anaphora is more adequate than both a syntactic and a semantic approach. Not only can it provide a satisfactory account of the classical binding patterns (Table 2), it can also accommodate elegantly some of the anaphoric patterns that have always embarrassed a generative analysis. Conceptually, this theory also has important implications for current thinking about universals, innateness and learnability.

3. Discourse Anaphora: Four Models

One of the central issues in discourse anaphora is concerned with the problem of anaphoric distribution, namely, how to account for the choice of a particular referential/anaphoric form at a particular point in discourse. For any entity to which reference is to be made, there is a (potentially large) set of possible anaphoric expressions each of which, by a correspondence test, is 'correct' and therefore could in principle be used to designate that entity. On any actual occasion of use, however, it is not the case that just any member of that set is 'right.' Therefore, an 'appropriate' anaphoric form from that set has to be selected from time to time during the dynamic course of discourse production, but what contributes to the speaker's choice of that form? Surely anaphoric distribution in discourse is a very complex phenomenon, involving, among other things, structural, cognitive, and pragmatic factors that interact with each other. Nevertheless, currently there are four main models of discourse anaphora: (a) topic continuity or distance-interference (Givón 1983), (b) hierarchy (Fox 1987), (c) cognitive (Tomlin 1987, Gundel et al. 1993), and (d) pragmatic (Huang 2000a, 2000b). In addition, there is a formal, Discourse Representation Theory model (Kamp and Reyle 1993), but how it can be applied to real discourse data is unclear.

3.1 Topic Continuity

The main premise of this model is that anaphoric encoding in discourse is essentially determined by topic continuity. The continuity of topic in discourse is measured primarily by factors such as linear distance, referential interference, and thematic information. Roughly, what the model predicts is this: the shorter the linear distance, the fewer the competing referents, and the more stable the thematic status of the protagonist, the more continuous a topic; the more continuous a topic, the more likely that it will be encoded in terms of a reduced anaphoric expression

like pronouns and zero anaphors. Some of these ideas have recently been further developed in centering theory (Walker et al. 1997).

3.2 Hierarchy

On this model, it is assumed that the most important factor that influences anaphoric selection is the hierarchical structure of discourse. From this assumption follows the central empirical prediction of the theory, namely, mentions (initial or non-initial) at the beginning or peak of a new discourse structural unit tend to be done by an NP, whereas subsequent mentions within the same discourse structural unit tend to be achieved by a reduced anaphoric expression.

3.3 Cognitive

The basic tenet of this model is that anaphoric choice in discourse is largely dictated by cognitive processes such as activation and attention. Its central empirical claim is that NPs are predicted to be used when the targeted referent is currently not addressee-activated, whereas reduced anaphoric expressions are predicted to be selected when such a referent is estimated to be currently both speaker- and addressee-activated. A number of hierarchies have been put forward in the literature to capture this cognitive status/anaphoric form correlation.

3.4 Pragmatic

The kernel idea behind the neo-Gricean pragmatic model is that anaphoric distribution in discourse, as in anaphoric distribution in the sentence, can also be largely determined by the systematic interaction of the Q-, M-, and I-principles, mentioned above. In Huang (2000a, 2000b), it has been demonstrated that by utilizing these principles and the resolution mechanism organizing their interaction, many patterns of discourse anaphora can be given a sound explanation. Furthermore, a careful consideration of anaphoric repair systems in conversational discourse in Chinese and English shows that the neo-Gricean pragmatic analysis is consistent with what interlocutors in conversational discourse are actually oriented to.

Clearly, there are at least three interacting factors that are at work in predicting anaphoric distribution in discourse: structural, cognitive, and pragmatic. Of these factors, the structural constraint (both linear and hierarchical) seems largely to be a secondary correlate of the more fundamental cognitive and/or pragmatic constraints. However, the interaction and division of labor between the cognitive and pragmatic constraints are not well understood and need to be further studied.

Anaphora Resolution

The term *anaphora* (which comes from a Greek root meaning 'to carry back') is used to describe situations in which there is repeated reference to the same thing in a text. Sentence (2) below contains three instances of anaphora.

(1) John noticed that a window had been left open.

(2) *He* walked over to *the window* and closed *it* firmly.

He, *the window*, and *it* mentioned in (2) refer back to the previous mentions of *John* and *a window* in (1). In

general, anaphors, like those in sentence (2), refer back to previously mentioned entities. However, anaphora can also occur with temporal or spatial reference. Temporal expressions, such as *then*, *the next day*, or *the week before*, often refer back to previously established times and spatial expressions, such as *there*, often refer back to previously mentioned locations. Thus, anaphora is an important linguistic device for establishing the coherence of an extended piece of discourse.

Anaphora resolution is the process of interpreting the link between the anaphor and the previous reference, its *antecedent*. It is especially interesting because it frequently involves interpretation across a sentence boundary. Hence, despite playing a crucial role in discourse comprehension, it falls outside the scope of traditional psycholinguistic accounts of sentence processing (Kintsch and van Dijk 1978). There are two main issues that have driven the psychological research on anaphora resolution. First, there is the issue of how the resolution process relates to more basic sentence comprehension processes, such as syntactic parsing and semantic interpretation. This issue has been addressed principally by investigating the time course of anaphora resolution as compared with other sentence interpretation processes. The second issue concerns the nature of the mental representation of the discourse context that is required to support anaphora resolution. In this article these two issues are examined in turn.

1. *The Time Course of Anaphora Resolution*

Anaphora enables readers and listeners to infer links or bridges between the different sentences in a text. Thus, one of the earliest accounts, developed by Haviland and Clark (1974), characterized it as a *bridging-inference* process. It was assumed that the anaphoric expression (i.e., pronoun or definite noun phrase) triggered a search through the previous text to find something that could link anaphor to antecedent. For the anaphors shown in (2) this can be done on the basis of simple matching, but it is often more complicated. Consider for instance, the slightly different text below.

(3) John noticed it was chilly in his bedroom.

(4) He walked over to *the window* and closed it firmly.

Here the reader needs to infer that *the window* in (4) is intended as an indirect anaphoric reference to part of the bedroom mentioned in (3). Thus, he or she will have to draw an inference, based on prior knowledge of windows and rooms, to link the two together. Self-paced reading experiments clearly demonstrate that readers spend time on such bridging operations during normal reading (e.g., see *Inferences in Discourse, Psychology of*).

The special nature of this anaphoric bridging process raises questions about how it relates to other more basic sentence interpretation processes (e.g., see *Sentence Comprehension, Psychology of*). One way of addressing the issue is by investigating the time course of anaphora resolution in relation to the other processes. Are anaphors resolved as soon as they are encountered or is resolution delayed until after a local analysis of the sentence has been established? Several methods have been developed to address this question.

1.1 *Methods for Measuring Anaphora Resolution*

Methods for investigating the time course of anaphora resolution tap into the process in two ways. One approach is to record precisely when an antecedent is reactivated after encountering an anaphor. The other approach sets out to determine how soon after encountering an anaphor the information associated with the antecedent becomes incorporated into the interpretation of the rest of the sentence. The two techniques produce rather different results and this has led to the suggestion that resolution occurs in two distinct stages. First, there is a process of antecedent identification and recovery, and, then at some later point there is a process of integration of the antecedent information into the interpretation of the current sentence.

The principal technique for establishing precisely when an antecedent is reactivated during processing uses *antecedent probe recognition*. A passage containing an antecedent is presented on a computer screen one word at a time. At predetermined points in the passage a probe word is then shown and readers have to judge whether or not it matches a previous word in the text. The difference in recognition times for probes presented before and after an anaphor give a measure of the degree to which the antecedent is reactivated on encountering the anaphor. By judicious placement of the probes it is therefore possible to measure the time course of anaphora resolution. In a classic study of this kind, Dell et al. (1983) used texts like the following:

A burglar surveyed the garage set back from the street.

Several milk bottles were piled at the curb.

The banker and her husband were on vacation.

The criminal/a cat slipped away from the street lamp.

At the critical point following either the anaphor *the criminal* or the nonanaphor *a cat*, they presented the probe word *burglar* for recognition. They found that recognition was enhanced immediately following *criminal* as compared with *cat*. They also obtained a similar effect for words drawn from the sentence in which the antecedent had appeared (e.g., *garage*). This finding, together with related findings from experiments using proper-name anaphors, indicate that antecedents are reactivated almost immediately after encountering the anaphor.

However, the antecedent probe recognition technique has not been so successful in demonstrating immediate reactivation of antecedents after reading a pronoun anaphor (Gernsbacher 1989). This led to the conclusion that the antecedent recovery process depends on the degree to which the anaphor specifies its antecedent in the discourse. Repeated proper names and repeated nouns directly match their antecedents whereas pronouns do not.

The second way of investigating the time course of resolution is to examine when antecedent information is incorporated into the interpretation of the sentence containing the anaphor. This approach has been used to investigate the interpretation of both spoken and written language. A recent example with written language is an experiment by Garrod et al. (1994) which used eye movement recording to tap into the comprehension process. They presented readers with passages such as the following:

A dangerous incident in the pool
Elizabeth$_1$ was an inexperienced swimmer and would not have gone in if *the male lifeguard*$_2$ had not been standing by the pool. But as soon as she got out of her depth she started to panic and wave her hands about in a frenzy.

(a) Within seconds (she$_1$/Elizabeth$_1$) sank into the pool.

(b) Within seconds (she$_1$/Elizabeth$_1$) jumped into the pool.

(c) Within seconds (he$_2$/the lifeguard$_2$) sank into the pool.

(d) Within seconds (he$_2$/the lifeguard$_2$) jumped into the pool.

The passages introduce two characters of different gender (i.e., *Elizabeth* and *the male lifeguard*), who are subsequently referred in the target sentences (a) to (d) using either a pronoun or a repeated noun. The crucial manipulation was with the verbs in the target sentences. Each verb was chosen to make sense only with respect to one of the antecedent characters. For example, whereas *Elizabeth* might be expected to *sink* at that point in the story, she could not *jump* because she is out of her depth, whereas the *lifeguard* might be expected to *jump*, he could not *sink* because he is standing on a solid surface. Thus sentences (a) and (d) describe contextually consistent events, but sentences (b) and (c) describe contextually anomalous events. The eye-tracking procedure makes it possible to measure the point in the sentence when the reader first detects these contextual anomalies by comparing the pattern of eye movements on matched contrasting materials (e.g., (a) vs. (b) or (d) vs. (c)).

The results from this and similar studies with spoken language produce a different pattern from the earlier reactivation experiments. They show that pronouns can be resolved at the earliest point in processing just so long as they are unambiguous and refer to the principal or topic character in the discourse at that point (see Sect. 2.2). Hence, readers immediately respond to the anomaly with sentence (b) as compared with sentence (a) above. In contrast, noun anaphors or pronouns that refer to other nontopic characters lead to delayed resolution. Hence readers only detect the anomaly in (c) as compared with (d) after they have read the whole clause. This discrepancy in the findings from the two techniques leads to the conclusion that anaphora resolution is a two-stage process. In the first stage, the anaphor triggers a search for a matching antecedent, as suggested originally by Clark, and this antecedent is recovered. However, it is only at a second later stage that the anaphoric information is fully incorporated into the interpretation of the sentence. The first recovery stage is affected by the accessibility of the antecedent and the degree to which it matches the anaphor, whereas the later integration stage is affected by the topicality of the antecedent at that point in the text (for a fuller discussion, see Garrod and Sanford 1994).

In summary, evidence on the time course of anaphora resolution, both from antecedent reactivation studies and from studies that tap into the consequences of resolution, indicate that it occurs in tandem with other more basic sentence comprehension processes. However, the time course experiments also indicate that different kinds of anaphor affect resolution in different ways. This leads to the other main issue associated with anaphora resolution, which concerns the nature of the discourse representation required to support the process.

2. *Anaphora Resolution and Discourse Representation*

Although anaphors relate to antecedent mentions, their interpretation is usually based on the antecedent's reference rather than its wording or its meaning. This means that anaphora resolution depends on access to a representation of the prior discourse that records these discourse referents: the people and other entities that the discourse has referred to up to that point.

The structure of the representation has to account for how referents become more or less accessible as the text unfolds. Discourse representations are also important for explaining indirect anaphora of the kind illustrated in sentences (3) and (4) above. These issues are considered in more detail below. First, there is a discussion of referential discourse models, then a discussion of accessibility of referents in terms of their degree of *focus*, and finally a discussion of what other kinds of information might be represented in the discourse model.

2.1 *Referential Discourse Models*

Typically anaphors are coreferential with their antecedents. That is, they are interpreted in terms of what the

antecedent refers to rather than its wording or meaning. For example consider the interpretation of *it* in sentence (6).

(5) Mary painted her front door.

(6) Jill painted *it* too.

If the wording of the antecedent *her front door* were substituted for the pronoun in (6), it would be Jill's door that Jill had painted. However, that is not the interpretation readers make. Rather the pronoun is taken to refer to the original referent (i.e., Mary's door). Furthermore, not all noun phrases introduce such referents. For example, the mention of *a teacher* in sentence (7) does not license an anaphoric reference to *the teacher* in (8), because the noun phrase does not introduce a new discourse referent.

(7) Harry was *a teacher*.

(8) *The teacher* loved history.

Thus, readers construct a representation that contains a record of the referents that have been introduced into the discourse up to that point. These discourse referents then serve as antecedents for anaphora. Such representations have been described as models of the discourse world or *discourse models* (e.g., see *Mental Models, Psychology of*).

Discourse models have been discussed in detail by various semantic theorists. For example, Kamp and Reyle (1993) developed a general framework to account for the circumstances under which sentences introduce discourse referents and the degree to which the referents become accessible for subsequent anaphora. It is called *discourse representation theory* and has had a strong influence on computational modeling of anaphora. Among other things the theory explains why *her front door* in (5) introduces a discourse referent, whereas *a teacher* in (7) does not. An important aspect of such models is how they reflect the degree to which antecedents shift in and out of *focus* as a text unfolds. To illustrate this point consider a slight variant of sentences (5) and (6):

(9) Mary painted *her front door*.

(10) She planned to paint the windows next and then the walls.

(11) Jill painted *it* too.

The use of the pronoun *it* in sentence (11) is infelicitous, despite the fact that the front door is the only antecedent discourse referent that matches in number and gender. Thus, discourse referents vary in their accessibility as antecedents for pronouns as the text unfolds. This phenomenon has been called *discourse focus* and has attracted interest both in psychology and computational linguistics.

2.2 Discourse Models and Focus

There are a variety of factors that affect the degree to which an antecedent is focused at any point in a piece of discourse. In general, the more text between the antecedent and the pronoun, the less focused, and hence less accessible, the antecedent becomes. However, several other factors play an important role in discourse focus, such as the number of alternative discourse referents that have been introduced since encountering the antecedent and whether the antecedent was originally introduced as a named principal protagonist in a narrative. There is also the issue of how the antecedent was referred to in the previous sentence. This last factor has been the subject of considerable theorizing in computational linguistics in the form of *centering theory* (Walker et al. 1998). According to the theory, a sentence projects candidate antecedents for pronominal reference in the following sentence and the candidates are ranked in terms of accessibility. High-ranking antecedents are appropriately referred to with pronouns whereas low-ranking antecedents require more explicit anaphors. The theory has been used to predict when a pronoun is more acceptable than a fuller anaphor and is consistent with the findings on the time course of resolution of pronouns as compared with fuller forms of anaphora discussed in Sect. 1.

For pronouns, anaphora resolution is influenced by discourse focus. However, with noun anaphors it is more strongly influenced by other aspects of the discourse representation. This is particular true with indirect anaphora, as when the writer refers to *the window* following mention of *a room* (e.g., see sentences (3) and (4) above).

2.3 Discourse Representation and Indirect Anaphora

The prototypical noun anaphor is a definite noun phrase, such as *the window*. However, studies of text corpora indicate that the majority of such references occur in contexts that do not contain explicitly introduced antecedents, as in sentences (3) and (4) above. Thus, they only serve as indirect anaphors.

In general, indirect anaphora takes longer to resolve than direct anaphora. However, there are certain circumstances under which it does not. For instance, indirect references to *the lawyer* in the context of a court case or to *the car* in the context of driving can be resolved as quickly as direct anaphora (Garrod and Sanford 1990). This leads to the question of whether there is more in the discourse representation than discourse referents alone. One suggestion is that the discourse model is extended to also include *discourse roles*, and that they can serve as antecedents in a similar fashion to discourse referents. Roles, such as *lawyer* or *vehicle*, are represented in certain accounts of knowledge representation as essential components of knowledge of court cases or driving (e.g., see *Mental Models, Psychology of*; *Schemas, Frames, and Scripts in Cognitive Psychology*). It is an open research question as to whether they also play a key role in indirect anaphora resolution.

Ancestors, Anthropology of

The study of beliefs and rites involving ancestors has long been a central anthropological concern. Many early anthropologists suggested that ancestral worship was the forerunner of all religions and devoted much time to building conjectural religious histories. Twentieth century anthropologists have devoted attention to the working of ancestral cults as aspects of wider religious systems and to their links to rights in property, succession to office, and cohesion of descent groups. The main questions asked include how the living define ancestors, transform the dead into them, and use them as guardians of morality and agents of social continuity.

The word 'ancestor' is often used as a synonym for 'the dead': but they should be distinguished—not all the dead are remembered and defined as ancestors. Those selected as ancestors provide a history memorializing certain events of the past that give significance to claims of the present. Defined ancestors may either actually have lived at a remembered time, may be given a place in a genealogy irrespective of the date of death, or may be invented so as to provide their believed descendants with history and identity.

The status of ancestor is given by a rite of transition performed by the living descendants of the deceased. Robert Hertz (1960) listed the three components of mortuary rites: the corpse, the mourners, and the soul. The functions of the rites are to dispose of the corpse; to remove the deceased from the immediate domain of the living and to transform him or her into an ancestor; to re-form the descent group of the deceased's living kin; and to ensure the continuity of the essential element of the deceased's human identity, the soul or some similar concept. The forms the rites take reflect the importance of the deceased: those for a king may be highly elaborate and last many months or years, for a respected elder be less so and take a few days, for a child be minimal and take only a few minutes (Huntington and Metcalf 1979, Bloch and Parry 1982).

The living decide which of the dead shall be transformed into ancestors. The key criterion is the link of kinship between a living group or person and an ancestor. Without that link the deceased is not an ancestor but merely a dead person and soon forgotten. To possess recognized ancestors gives the living descendants full identity and status; to lack them (as in the case of slaves in many societies) is to lack full status.

Several ancestral categories may be defined. For example, the Lugbara of Uganda (Middleton 1960) distinguish the *ori*, a descent group's direct and renowned male patrilineal forebears, to whom are made ritual offerings; *oku-ori*, female *ori*, daughters of the patriline who, although they bore sons to other descent groups (by the rule of exogamy), are remembered as powerful women; and *a'bi*, the general mass of other dead members of a given clan. Only relatively few of the dead become *ori* and *oku-ori*, whereas the number of *a'bi* is beyond reckoning. The ancestors of other clans are of no concern and are merely *a'bi* without definition.

Ancestral categories may also depend upon the manner of death. The Akan of Ghana, for example (Fortes 1959), distinguish three kinds of death: good death, the natural death of man or woman followed by a future in the land of the ancestors; bad death, due to evil behavior during life and a double death, first that in the living world and later within the land of the ancestors, whose inhabitants refuse to accept the deceased who is returned to the land of the living to linger as a bad and dangerous specter; and sudden death, as in war, childbirth, accident, or suicide—such a person is not buried properly in a clan cemetery but in the bush land and is then 'lost' as an ancestor.

Among the Chinese, as a third example, Confucianism makes a general distinction between the ances-

tors and the non-ancestral dead (Hsu 1948, Ahern 1973, Wolf 1974). The former are men of strictly patrilineal descent groups, senior kinsmen with clearly recognized rights due from their descendants and obligations towards them. Women are not defined as ancestors, although they have been daughters, wives, and mothers to the ancestors of a particular descent group.

These cases show that whether individuals are defined as ancestors depends upon their kinship ties with their descendants, linked by mortuary rites and by inheritance of social position and property. Ancestors possess no independent status in themselves but are given it by their living kin.

Once made into ancestors, where they dwell and the nature of their relationships to their descendants vary from one society to another. Christian cultures hold that claimed ancestors and other dead dwell either with the Deity in a heaven, a place of peace without further passing of time, and/or a hell, a place of punishment and atonement. The Akan peoples of Ghana hold that ancestors dwell in a land of the dead across a river, which has the same patterns of stratification and authority as that of the living. The Lugbara of Uganda consider that they dwell underground near their descendants' settlements, where they themselves have been buried. In virtually all religions ancestors are considered to be senior kin living apart from their descendants yet still linked by spatial propinquity and kinship interdependence. They are typically believed to see and hear their living kin, who as their juniors are unable to see or hear them except in unusual circumstances, such as their appearance as specters or when people are possessed by them.

Associated with the concept of ancestor is that of soul, linked to individual morality rather than to descent and kinship. The concept of soul was of great concern to early anthropologists such as Frazer (1911–15), Lévy-Bruhl (1927) and Tylor (1871), who coined the term 'animism' for the belief in souls attributed to all living things. Their views were essentially conjecture: more recently ethnographic research, including that on religion, has become based on detailed study of the beliefs and practices of particular cultures. For example, the Lugbara word *ori* is related to the word *orindi* (literally 'the essence of the *ori*') which might be translated as 'soul,' an element of the living that is not exterminated by death but which persists into the afterlife. Only men of full adult status have what might be called full souls; women who are the first-born of a set of siblings may be attributed souls if they acquire respected status before death, and it is they who become *oku-ori*. Other men and women lack souls or, more accurately, do not realize the potentiality of developing them, and it is they who are placed in the loose category of *a'bi*. Different societies order these concepts and elements in differing ways, but the basic factor is that of an individual's moral passage through life, the soul being that element that bestows him or her with morally responsible behavior.

Ancestors have to be remembered, usually by being listed in genealogies. Evans-Pritchard (1940) showed for the Nuer of the Sudan that the generational depth of genealogies reflects the width and composition of descent groups on the ground: the wider the group the more the number of generations needed to include all its members in a single genealogy. The identity of effective ancestors usually depends upon the recognition of a particular mode of descent (patrilineal, matrilineal, or cognatic) as the basis for local social organization. Genealogies are not, or only extremely rarely, historically accurate statements. There is typically a telescoping of generations so as to maintain the same depth of a genealogy over time; and in patrilineal systems, certainly, the exclusion of most women is usual as they do not exercise the same degree of authority as do men. The situation is different in those societies in which ancestors are memorialized in writing or on tablets (e.g. China and Mormon America); here the purpose may be to include all forebears by name irrespective of their immediate and active links to their descendants.

Terms commonly used in discussions of ancestors include 'ancestral spirits,' 'ancestral worship,' and 'ancestral cults,' that refer to the relationships between the living and their own ancestors. The beliefs and practices concerning ancestors nowhere form a distinct religion but rather a religious practice within a wider societal religion. This practice typically includes lineage and family rites, periodic rites on ancestral death days, and often annual rites for collectivities of a group's ancestors. Rites linked to the non-ancestral dead in general should not be included. Ancestors are virtually everywhere held to care for and protect their descendants; they may teach, criticize, and punish them for unfitting behavior. They may send sickness or other affliction to those who disobey their rules and wishes, and they are in general held to be conservative in their views and to represent an idealized stability and moral order. They may act on their own initiative or may be evoked by their descendants. The living may consult oracles or diviners, or interpret omens, to discover the identities and motives of specific ancestors concerned.

The living may communicate with their ancestors both by making verbal requests and by offering them food (often flesh and blood) and drink, commensality being a central act of kinship bonding. Offerings may be regular or made only when the ancestors show that they wish to receive them, at shrines of many kinds, from ancestral graves to special buildings, and may be simple and cursory or elaborate and long-lasting, depending on the ancestors' remembered status.

The term 'ancestral spirit,' used for those aspects of ancestors thought to come into direct contact with the living, is clumsy: ancestors and spirits are in their

natures quite distinct. Ancestors have been among the living, who remember the more recent of them as individuals and understand their wishes and demands. Even if their individual personalities are in time forgotten, they represent human experience, skills, and sentiments, and are senior kin. They are used by the living both to maintain conservative authority and moral order and to help bring about orderly settlement of disputes. They provide and maintain the long-lasting stability of otherwise ever-changing and fluid descent groups. On the other hand, spirits are refractions of divinity, have never been living and so have no descendants: their natures and demands are different and may be beyond human understanding. The living can exercise a more immediate control over their ancestors by stressing their link as kin, than they can over spirits. Ancestors may act as unvarying custodians of order, unlike spirits which are by contrast individualistic, capricious, and unpredictable.

An important point is that of the persistence of beliefs in ancestors in the 'modern' industrialized world. The rites of invocation and appeasement of ancestors may lose importance for small-scale descent groups precisely as these lose importance in radically changing societies; ancestors are those who, when they lived, were important in the lives and continuity of their descent groups of the time. By being remembered and commemorated in ritual, they are objects of the group's memory of the past and its identity of the present. Ancestors used as mnemonic figures remain important, as do their material representations such as tombs and shrines. This is especially so in the case of those who in their lives were kings, sacred personages who embodied the identity and continuity of their kingdoms. Such royal ancestors are not only used as signs of memory by their genealogies: they are typically given royal tombs that materially represent the past in the present and so act as centers of societal identity. In societies that accept Christianity, Islam, or other world religions, greater emphasis may be given to spirits: ancestors' powers are limited to their own descendants whereas those of spirits are typically held to affect all members of a society irrespective of their descent groups.

Androgyny

Androgyny is most simply defined as the combination of masculine and feminine characteristics within a single person. It achieved widespread popularity within gender psychology beginning in the early 1970s as part of a model for conceptualizing gender that uses familiar constructs of masculinity and femininity while avoiding prescriptive, sex-specific values inherent in earlier studies. In this article the conceptualization of androgyny within gender psychology, major research findings, and current status will be discussed.

1. The Concept of Androgyny

The idea of androgyny is an ancient one, expressed in mythology and literature centuries ago. Broadly speaking, androgyny denotes any blurring of distinctions between the sexes. In this sense there can be 'androgynous' persons in physical sex characteristics (hermaphroditism), sexual preference (bisexuality), unisex dress styles, or societies providing equal economic and political rights for the sexes. Social scientists have used the term more restrictively to describe an individual who manifests in either personality or behavior a balanced combination of characteristics typically labeled as masculine (associated with men) or feminine (with women) in our society.

The characteristics traditionally associated with each sex are diverse yet recognized easily by members of a particular society. A combination of Parsons and Bales' (1953) description of familial roles and Bakan's (1966) philosophical treatise on fundamental modalities of all living organisms has been adopted widely to distill the common themes inherent in feminine/masculine trait distinctions. The core of those psychological characteristics stereotypically associated with

women concerns sensitivity, selflessness, emotionality, and relationships with others (expressive/communal). In contrast, psychological characteristics stereotypically associated with men reflect goal orientation, self-development, assertiveness, and individuation (instrumental/agentic). Androgyny essentially represents a combination of these two themes within one person.

1.1 Origins in Masculinity–Femininity Research

The modernized concept of androgyny is founded in earlier twentieth-century ideas about the nature of psychological differences between the sexes, but endorses a much broader range of gender-related behavior for individuals regardless of biological sex. Traditional models of gender psychology viewed a clear differentiation between the sexes in a wide range of characteristics to be natural, typical, and desirable. Manifestation of 'masculine' attributes by men and 'feminine' attributes by women signified fulfillment of a basic genetic destiny. Preandrogyny studies reflected researchers' conviction about the existence of a single innate psychological trait differentiating the sexes, and focused on specifying the content universe of this masculinity–femininity trait. As Constantinople (1973) discussed in her landmark review, this trait was posited to be a continuum with femininity and masculinity serving as bipolar endpoints and logical reversals of one another. Researchers considered a given masculinity–femininity measure to be valid if it reliably clustered women's and men's responses into two distinct groups, regardless of the items' content. The final item pool was frequently a melange of content sharing only an ability to distinguish between the sexes. Endorsement of the 'masculine' pole by men and the 'feminine' pole by women was considered typical, and indicative of psychological health. Individuals who failed to exhibit attributes associated with their biological sex or who endorsed attributes typical of the other sex were suspected of being sexually confused, homosexual, and/or psychologically maladjusted.

This traditional model of gender differentiation did not explain the common occurrence of similarities across the sexes; items on which the sexes gave similar responses typically were deleted from these scales. Variability within each sex in endorsement of masculine and feminine items was also ignored in favor of highlighting mean differences between the sexes. Such inconsistencies became increasingly troublesome to researchers. Also with the mid-century resurgence of the feminist movement, the gender-related values codified within the traditional model increasingly appeared to be restrictive, outdated, and harmful to individuals. The alternative of androgyny quickly became what Mednick (1989) referred to as one of feminist psychology's conceptual bandwagons of the 1970s and early 1980s.

1.2 Assumptions Underlying Androgyny Theory and Research

Proponents of androgyny typically continued the earlier focus on masculinity and femininity as trait dimensions. In androgyny theory and research, however, a unique series of assumptions are operative. Femininity and masculinity are no longer seen as opposite ends of a single dimension in which being less feminine automatically meant being more masculine. In the conceptualization of androgyny, masculinity and femininity are portrayed as independent but not mutually exclusive groups of characteristics. Individuals can be meaningfully described by the degree to which they endorse each group as self-descriptive. One can be high on both, low on both, or high on only one. Both masculinity and femininity are also hypothesized to have a unique and positive impact on a person's psychological functioning. That is, both sexes presumably benefit from being 'feminine' and 'masculine' to some degree. Possession of high levels of both sets of characteristics, or androgyny, should thus represent the most desirable gender-relevant alternative. This model ingeniously provided researchers with a virtually limitless array of researchable hypotheses, a methodology consistent with psychology's positivist tradition, and an explicit values statement comfortably fitting with the era's Zeitgeist of expanded human rights and roles.

2. Research on Androgyny

Research on androgyny can be classified loosely according to purpose: (a) to develop androgyny measures fitting these newly formulated assumptions about femininity and masculinity; (b) to determine the meaningfulness of the masculinity and femininity dimensions as represented on the androgyny measures; and (c) to explore the implications of various combinations of these femininity and masculinity dimensions within an individual.

2.1 Development of Androgyny Measures

Development of psychometrically sound masculinity and femininity scales based on the revised assumptions was an important first step for androgyny researchers. The favored scale format was paper-and-pencil self-descriptions using Likert scales. Criteria for item selection were somewhat variable. Although a (small) number of measures were eventually developed, only two achieved prominence: The Bem Sex Role Inventory (BSRI) (Bem 1974) and the Personal Attributes Questionnaire (PAQ) (Spence and Helmreich 1978). The items on the BSRI and the PAQ reflected judges' ratings of personality characteristics utilizing criteria of sex-based social desirability or of sex

typicality, respectively. The PAQ incorporated only characteristics generally seen as desirable. The BSRI included some femininity items with less positive connotations (e.g., 'childlike,' 'gullible'), a decision that complicated subsequent analyses considerably (Pedhazur and Tetenbaum 1979).

Correlations between the masculinity and femininity scales of a single androgyny measure tended to be small in magnitude as was desired, and the content of corresponding scales across androgyny measures was overlapping but not identical. Factor analyses (e.g., Wilson and Cook 1984) indicated that the content of the femininity and masculinity scales corresponded generally to theoretical definitions of femininity as representing empathy, nurturance, and interpersonal sensitivity and masculinity as representing autonomy, dominance, and assertiveness. The emergence of this factor structure is interesting in that item selection procedures did not specifically select items to be congruent with the expressive/communal and instrumental/agentic distinctions. These content distinctions appear to be central to the broad-based perceptions of the sexes' personalities and behaviors elicited by the androgyny measures (Cook 1985).

2.2 Research on Masculinity and Femininity Scales within the Androgyny Measures

Research generally has shown that each scale is related as expected to variables linked to the instrumental/agentic and expressive/communal distinctions. However, masculinity scale correlations with measures of self-esteem and psychological adjustment have typically been stronger than femininity scale correlations for both men and women, depending on measures and samples used (Taylor and Hall 1982, Whitley 1983). This pattern of findings does not support the basic hypothesis about the equal value of both dimensions for both sexes. Explanations for this pattern have variously implicated the specific content included on the androgyny measures; the adequacy or appropriateness of criterion measures; a failure of researchers to assess negative aspects of each dimension that may offset its benefits; the greater valuing of masculine attributes in society; or the multiple determined nature of gendered phenomena. Each of these explanations is likely to have some merit. Researchers did generally agree that each dimension as operationalized on the androgyny measures may be beneficial for individuals in some respects.

2.3 Androgyny as Type: Theoretical Considerations

The most provocative studies within the androgyny literature addressed the implications of various levels of masculine and feminine characteristics within an individual. These studies were based on the assumption that the self-descriptions elicited by the androgyny measures are indicative of an enduring typological differentiation of individuals. Preandrogyny gender research generally classified two types of individuals, feminine or masculine, with pervasive consequences predicted from their internalization of either own sex-typed (masculine men and feminine women) or cross sex-typed characteristics (feminine men and masculine women). Sex typing was considered normative and good, and cross-sex typing as deviant and harmful. Individuals whose responses placed them in neither group were given little attention. Within the androgyny literature, it was hypothesized that both masculinity and femininity dimensions conferred certain benefits on men and women alike. An expanded typology was needed to acknowledge a portion of the population overlooked in preandrogyny masculinity–femininity studies, and to operationalize a new gender ideal.

Androgyny researchers exploring androgyny as type accepted that the pattern of self-descriptions elicited by androgyny measures corresponded to a meaningful typology of individuals composed of different blendings of feminine and masculine attributes. The manner in which masculinity and femininity might work together to produce androgyny was variously explained. Androgyny was proposed alternatively to mean the balancing or moderating of femininity and masculinity's excesses or deficits by the other dimension; a beneficial summation of the positive qualities of each dimension; the emergence of unique, albeit vaguely defined qualities from the synergy of the femininity and masculinity dimensions; or the elimination of sex-stereotypic standards for behavior in an individual's perceptions and decisions, thus making traditional, prescriptive masculine vs. feminine distinctions irrelevant to her or him.

Bem provided the most influential and elegant renderings of androgyny as a type of individual. Her original theory (1974) contrasted sex-typed and nonsex-typed persons, a focus that was reminiscent of the preandrogyny literature's bipolar classification of individuals. According to Bem, sex-typed individuals have internalized society's sex-appropriate standards for desirable behavior to the relative exclusion of the other sex's typical characteristics. This one-sided internalization has a negative impact on the sex-typed person's view of self and others, expectations and attitudes, and behaviors. In contrast, nonsex-typed individuals are free from the need to evaluate themselves and others consistent with prescriptive sex-linked standards, and thus are able to behave more adaptively and flexibly. In her later gender schema theory, Bem (1981) proposed that sex-typed individuals cognitively process incoming information in terms of culturally-based definitions of masculinity and femininity. These definitions are effectively internalized to function as cognitive schema shaping perceptions and subsequent behavior. Gender-related

connotations are not similarly salient for nonsex-typed persons, who are able to utilize other schema as appropriate. The implication is that freedom from reliance on gender schema is likely to be preferable in many situations.

2.4 Androgyny as Type: Scoring Methods

Conflicting views about the manner in which masculinity and femininity were believed to influence each other gave rise to controversy about the best way to derive the typological classification from the femininity and masculinity scale scores. Bem (1974) first proposed *t*-ratio scoring consistent with her primary distinction between sex-typed vs. nonsex-typed persons. In *t*-ratio scoring, androgyny is defined operationally as the lack of a statistically significant difference between femininity and masculinity scale scores. Sex-typed individuals do have statistically significant scale score differences. Researchers interested in the ramifications of a balance between masculine and feminine characteristics have tended to favor *t*-ratio scoring or some variant of it.

The second dominant view of androgyny is the additive view, in which androgyny is defined as the summation of the positive and basically independent influences of the femininity and masculinity dimensions. Whereas the balance view considers as androgynous those individuals endorsing roughly comparable levels of both dimensions at any level (low–low to high–high), in the additive view only high–high scorers are considered androgynous. Early research using the androgyny measures suggested the heuristic value of distinguishing between high–high and low–low scoring individuals. Spence and Helmreich (1978) proposed a median split of each masculinity and femininity scale score distribution to yield a four-way classification: androgynous, undifferentiated (low–low), and two sex-typed groups reporting a predominance of one set of characteristics. This scoring method was adopted quickly by researchers; Bem herself used some variation of median split scoring on occasion. Variations and alternatives to these two types of androgyny scoring procedures have been proposed but not adopted widely.

The issue of what scoring procedure is preferable has generated considerable controversy but little resolution. The best method to portray the conjoint influence of masculinity and femininity may depend on the specific nature of the hypotheses used. Unfortunately, the proliferation of scoring variations has contributed to confusion in the field. Rarely have researchers explicitly justified their choice of scoring method based on theoretical grounds. Choice of scoring method affects classification of individuals using the same androgyny measure, and may thereby influence what conclusions are derived from data analyses.

2.5 Androgyny as Type: Associated Characteristics

Numerous studies were conducted to demonstrate the unique characteristics associated with each typological category. In particular, because androgyny was seen as an ideal of human functioning, androgynous persons commonly were hypothesized to demonstrate superior adaptability, flexibility, and psychological health compared with sex-typed individuals, or to undifferentiated individuals who see neither set of characteristics as particularly self-descriptive. Unfortunately, too many studies appeared to be fishing expeditions to find any conceivable pattern of relationship between the types and other measures linked loosely to gender.

The evidence delineating the types has not been as compelling as many proponents would have liked. Generally, distinctions between the categories have been irregular and modest in size, in directions predictable from simple correlations with the masculinity and femininity scales. Androgynous persons tend to be favored, although not always, and the significant effects were frequently attributed to the power of one dimension shared with sex-typed counterparts (e.g., androgynous and masculine persons both scoring high on self-esteem because of a positive correlation with masculinity scores). Individuals classified as undifferentiated (low on both masculinity and femininity) appeared typically disadvantaged to some extent.

The most serious questions about the adequacy of the androgyny model have arisen partly because the multidimensionality of gender-related variables was underestimated. The presence of numerous sex differences reported in data analyses suggested that the process, likelihood, and implications of self-descriptions into the same category may well differ substantially for men and women. For example, Spence and Helmreich (1978) documented differential relationships by sex between femininity and masculinity and respondents' perceptions of relationships with their parents. Such interactions by sex were not difficult to acknowledge in the case of the sex-typed categories (e.g., feminine women and feminine men), but contradicted the notion that androgynous persons somehow transcend sex-based distinctions. Relationships between feminine and masculine self-descriptions and other gender-relevant variables such as attitudes and stereotypes have also not been strong. For example, an individual who is androgynous in self-description could appear to be quite traditional in feminist attitudes, feminine in appearance and informal social interaction, and masculine in behaviors on the job. Research generally has contradicted assumptions about the unitary nature of gender phenomena; a single set of traits (masculinity and femininity) or process (e.g., Bem's gender schema theory) simply cannot account for the complexity of gender-related differences within and between women.

Spence, an eminent researcher in gender psychology, has repeatedly cautioned researchers to expect such apparently disconfirming findings. From the earliest androgyny studies she emphasized that traits are, at best, behavioral predispositions that may be overridden by a multitude of individually idiosyncratic or situational factors. Trait-behavior connections are likely to be further strained when the dependent measure is peripherally related to the instrumental and expressive content embodied in the androgyny measures. Gender-related attributes, beliefs, and behaviors are likely to be substantially independent from one another, yet each related to other factors that may or may not be interconnected themselves. Spence has recommended abandoning the conceptualization of pervasive gender-related typologies in favor of assessing independently the diverse factors and processes describing and maintaining sex-based differentiation.

3. *Current Status*

Androgyny research appeared to lose momentum in the late 1980s, probably because the complexities revealed in empirical research contradicted the appealingly straightforward hypotheses characteristic of its heyday. Publications in the 1990s tended to focus on applying concepts and measures to an expanded range of cultural and age groups; continued testing of hypothesized typological differences and scoring variations; and most pertinent to recent developments within gender psychology, exploration of multifactorial models (e.g., Twenge 1999) and contextual differences (e.g., Swann et al. 1999), for example, in gender-related determinants of career behavior (Eccles et al. 1999). The conceptualization of androgyny retains its appeal as an alternative to restrictive, gender-based ideologies and roles. In a society that maintains gender distinctions at every level from personal self-concepts to sociopolitical institutions, actualizing this ideal appears more elusive than once thought. The masculinity and femininity scales developed for the androgyny measures continue to be most useful to study variables conceptually linked to the instrumental/agentic and expressive/communal dimensions represented by them.

Animal Cognition

Animal cognition is that branch of the biological sciences that studies how animals perceive, learn about, remember, understand, and respond to the world in which they live. The mechanisms it investi-

gates are evolved ways of processing information that promote the fitness or survival of the organisms that possess them. A synonym for animal cognition is comparative cognition, because researchers are often interested in the different ways in which evolution has equipped different species to process information. Comparisons between the human mind and those of animals have always held a fascination for both laymen and scientists. Careful experimental research in animal cognition shows how people and different species of animals are similar and different in the ways they comprehend their environments. Interesting new findings about animal cognition have been revealed as part of the cognitive revolution in psychology of the last 30 years. Most animals show cognitive competence in three major dimensions of the natural world—time, number, and space. New discoveries and theories offer important insights into the ways animals keep track of time, count the frequency of events, and learn to navigate successfully through space.

1. *Keeping Track of Time*

Animals, like people, keep track of time using two types of clocks, a relatively coarse 'time-of-day clock' and a fine-grain 'interval-timing clock.'

1.1 *The Time-of-Day Clock*

Time of day is given by *zeitgebers* or 'time givers' provided by internal biological circadian rythms that cycle through the same stages each day. Proof that animals keep track of time of day was provided in a classic experiment carried out by Biebach et al. (1989). Garden warblers were kept in a chamber that contained a living room and four feeding rooms. Each feeding room contained a feeder that provided a bird with food at different times of day: a bird could gain access to food in Room 1 from 6.00 to 9.00 a. m.; in Room 2 from 9.00 to 12.00 noon; in Room 3 from 12.00 to 3.00 p.m.; and in Room 4 from 3.00 to 6.00 p.m. Within only a few days of experience with this schedule, warblers went to each room at the time of day when it contained food. Even when food was made available in all of the rooms throughout the day, birds still went to Room 1 first, switched to Room 2 at about 9.00 a.m., switched to Room 3 at about 12.00 noon, and switched to Room 4 at about 3.00 p.m. Thus, even in the absence of external cues for time of day, such as the sun, birds knew the time of day when food would be in different locations.

1.2 *The Interval-timing Clock*

By contrast to the time-of-day clock, the interval-timing clock tracks intervals of a few seconds to a few minutes. Suppose a rat placed in a chamber is occasionally rewarded with a food pellet for pressing a bar. Each time a tone is presented, the first bar press made after 30 seconds causes a pellet to be delivered. Notice that presses before the end of the 30-second interval are futile. After some training, the rat learns to begin pressing the bar only a few seconds before the 30-second interval elapses. In this way, it earns the reward with a minimum of effort. The rat has learned to respond only near the time when it will be rewarded. If a curve is plotted showing the rate of bar pressing against time since the tone began, the peak of the curve appears at just about 30 seconds. This experiment has been performed with many species of animals, and they all show an ability to precisely time short intervals.

1.3 *Scalar Timing Theory*

A highly successful theory of interval timing, called *scalar timing theory*, was devised by Gibbon and Church (1990). A flow of information diagram depicting this model is shown in Fig. 1. The model is based on the assumption that a pacemaker in the brain is constantly emitting pulses at a fixed rate. When a signal is presented, it activates a switch which closes and allows pulses to flow from the pacemaker to an accumulator. In the example of the rat pressing a bar for food, the tone would close the switch, and pulses would flow into the accumulator until the rat earned its reward and the tone stopped, reopening the switch 30 seconds later. Pulses in the accumulator enter a temporary working memory, and the total in the working memory at the moment of reward is sent for permanent storage to a reference memory. Over a number of trials, a distribution of pulse totals representing intervals centered around 30 seconds will be stored in reference memory. Once a set of criterion times has been established in reference memory, an animal can track time by using a comparator that compares the pulses accumulating in the working memory with a criterion value retrieved from reference memory. Importantly, this comparison is made as a ratio; the difference between the criterion value and the working memory value is divided by the criterion value. Thus if the criterion retrieved from reference memory represented 30 seconds, and only 15 seconds had elapsed since the signal began, the comparator would yield a ratio of $(30-15)/30 = 0.50$. The model assumes that once this ratio drops below a threshold, say 0.25, the organism makes the decision to begin responding. The fact that the decision to respond is based on a ratio gives the model its scalar property. The scalar property predicts that error in responding will be proportional to the length of the interval timed. Thus, if the threshold ratio is 0.25, and the interval timed is 30 seconds, an animal should start responding 7.5 seconds before the end of the interval. If the interval timed is 60 seconds, however, the animal

Figure 1
This cognitive model of timing shows how pulses produced by a pacemaker flow into an accumulator and are sent to working memory. Criterion values stored in reference memory are retrieved into a comparator that compares the criterion number with the accumulating total in working memory and makes a decision to respond (R) or not to respond (NR)

should start responding at 15 seconds before the end of the interval. Numerous experiments show that this is exactly what happens.

2. *Numerical Operations in Animals*

Can animals count? This is a highly controversial question. Although animals may not be able to perform all of the numerical operations humans can, there is good evidence that they can keep track of the frequency of events.

2.1 *Eating a Fixed Number of Food Pellets*

Based on experiments with birds first performed by the German ethologist Otto Koehler (1951), Davis and Bradford (1991) allowed rats to walk along a narrow elevated pathway from a platform to a chair in order to eat food pellets placed in a pile. There were three groups of rats, designated '3 eaters,' '4 eaters,' and '5 eaters.' The rats in each group were verbally praised if they ate their designated number of pellets and then left the chair. If a rat ate more than its group assignment, however, it was scolded and shooed back to the platform. After considerable training (200 trials), the rats in each group ate predominately the correct number of pellets assigned to their group.

2.2 *The Clever Hans Problem*

The Davis and Bradford experiment is reminiscent of one performed at the beginning of the twentieth century. A retired German school teacher named von Osten owned a horse named Clever Hans, who he claimed could not only count but could perform a number of numerical operations. When asked to add, subtract, multiply, or divide two numbers, Hans would tap his hoof on the ground and reliably stop tapping when he reached the correct number. Hans convinced many doubters by passing tests even when problems were given to him by new testers he had not worked with before. Eventually a young scientist named Oskar Pfungst (1965) tested Hans by showing him problems that could not be seen by the tester standing in front of him. Now Hans failed miserably, and it was concluded that prior successes had arisen not from the ability to perform mathematics but from cues provided unwittingly by testers, who slightly bowed their heads when Hans had reached the correct number of taps.

In order to avoid the problems raised by the Clever Hans effect, Davis and Bradford allowed their rats to be tested with no-one in the testing room and observed the rats' behavior over closed-circuit television. In the complete absence of a human tester, and thus any possible Clever Hans cues, the rats still ate the appropriate number of pellets they had been trained to eat. The rats apparently had learned a restricted eating rule based on number of pellets taken from the pile.

2.3 *Addition of Numbers*

Beyond a sensitivity to number, is any animal capable of performing numerical operations that combine numbers? Some surprising research carried out with chimpanzees suggests that they are able to add numbers. Boysen and Berntson (1989) trained a chimpanzee named Sheba to associate Arabic numbers with numbers of objects. Eventually, Sheba could be shown a number of objects, such as two oranges or five bananas, and Sheba would correctly choose a card containing the number '2' or '5' that correctly indicated the number of items shown. Different numbers of oranges then were hidden in three different locations in the laboratory, and Sheba was allowed to inspect each location. She was then allowed to select among cards containing the numbers 1–4. Sheba reliably chose the card that equalled the total number of oranges she had found. An even more impressive finding was revealed when Sheba visited the hiding places and found cards containing number symbols. Now when offered a choice among the numbers 1–4, she chose the card that represented the sum of the

numbers just encountered. The fact that Sheba chose the total of both objects and number symbols without summation training suggests that the ability to add may have been a quite natural and automatic process for her.

3. Navigating through Space

One of the most impressive cognitive abilities of animals is that of accurately navigating through their spatial environment. It is critical for an animal's survival that it knows the locations of such things as its home, water, foods of different types, mates, competitors, and other species that might prey on it. In addition, an animal must keep track of its own travel through its environment and be able to plot a course readily back to its home base. Research has shown that animals use a number of cues and mechanisms to navigate through space. The cues used are divided into two general classes, egocentric cues and allocentric cues. Egocentric cues are cues generated by an organism as it moves through space and that allow it to keep track of its own position relative to its starting location through the mechanism of deal reckoning. Allocentric cues are structures or objects external to the organism that are used as landmarks to guide travel through space. Two important allocentric cues are the geometric frame and landmarks.

3.1 Dead Reckoning

Both insects and mammals can travel long and twisting paths from their home base in total darkness and still return home along a straight-line route. A person wearing a blindfold can be led some distance from his/her starting position through several turns; when asked to return to the start, the person will walk directly to an area near the start. In all of these cases, the return route is computed by dead reckoning, also known as path integration. The return route has two components, direction and distance. As an organism moves through space, it has several sources of internal cues that are recorded and indicate position in space. In mammals, vestibular organs in the semicircular canals measure angular acceleration created by inertial forces when turns are made. In addition, distance information is provided by proprioceptive feedback from the muscles involved in locomotion and by efference copies from motor commands. These cues are integrated to plot a return vector to home that contains information about both direction and distance. Although dead reckoning is highly effective, errors arise as the number of turns in a trip increases, and the angle of the return vector may deviate progressively from the correct one. Thus, animals often use dead reckoning to return to an area near their home and then use local landmarks to find their nest or hole.

3.2 The Geometric Frame

Cheng (1986) placed hungry rats in a walled-in rectangular arena which contained loose bedding on the floor. Food was always buried under the bedding in one corner of the arena. Rats learned to dig in this location for food on repeated trials. However, they often made an interesting error; they dug in the corner diagonally opposite the correct one. The rats' mistake told Cheng something very important about the way these animals had encoded the location of food in space. They had used the entire rectangular framework of the arena and thus coded food as being in the corner with a long wall on the left and a short wall on the right. Unfortunately for the rats, this code also fit perfectly the diagonally opposite corner and thus led to frequent error. People too frequently use the geometric framework of their home or office to find important locations but are largely unaware of this cue.

3.3 Landmarks

In the open world, animals frequently use isolated landmarks, such as trees, rocks, or man-made structures, to guide their travel. Many animals use a sun compass by navigating relative to the azimuth of the sun and use celestial cues provided by the stars at night. A forager honeybee having found a source of nectar returns to the hive and performs a waggle dance that informs its hive mates about the location of the food relative to the position of the sun. If the bees are not released from the hive for some time during which the position of the sun has changed, they still accurately fly to the location of the food. They have a built in clock that allows them to correct for the change in the position of the sun.

The movement of landmarks is frequently performed by researchers to examine how animals use landmarks. If an animal learns to search for food at a fixed location relative to some rocks and logs, an experimenter may arrange a test on a given day by moving each landmark a fixed distance to the west. The animal's search location then also will be shifted this distance to the west, showing its use of landmarks. Some interesting recent experiments carried out in the laboratory with pigeons show that these birds do not always use landmarks in the same way people do. Spetch et al. (1996) trained pigeons and people to locate a hidden goal on a computer monitor touchscreen. The touchscreen automatically detects and records any place on the monitor that the pigeon pecks or a human touches. One pattern of landmarks is shown in the Control panel of Fig. 2. In order to

Figure 2
The black geometric patterns formed a landmark array on a touchscreen within which the invisible goal was located. After pigeons and humans learned to touch the screen at the goal location (Control), both species were tested with expansions of the landmark array in horizontal, vertical, and diagonal directions. The small squares show the locations where individual pigeons and humans made most of their contacts with the screen (reproduced by permission of the American Psychological Association from the *Journal of Comparative Psychology*1996, **110**: 22–8)

receive a reward (food for the pigeon and points for the human), the subject had to contact the touchscreen in an area equidistant from each of the geometric pattern landmarks. The configuration of landmarks was moved about the screen from trial to trial, so that the subjects had to learn to use the landmarks and could not always respond to a fixed location on the screen. The Control panel shows the average locations where four pigeons and four people learned to respond relative to the landmarks.

Tests then were carried out on which the landmarks were expanded, horizontally, vertically, or diagonally in both directions. Notice that all of the people continued to search in the central area, an equal distance from each landmark. When asked, each person said 'the goal was in the middle of the landmarks.' Pigeons did something quite different. The locations where pigeons searched indicated that each pigeon had coded the goal as being a fixed distance and direction from one landmark. Different pigeons used different landmarks. This experiment provides an example of a species difference in cognitive processing. Humans used all of the landmarks and coded the goal as being in the middle, but pigeons chose only one landmark and coded the position of the goal relative to that single landmark. Later research showed the same species difference when pigeons and people had to locomote across a field to find a hidden goal (Spetch et al. 1997).

4. *Advanced Processes*

Advanced processes refer to abilities once considered unique to humans. These processes typically seem to require higher level reasoning and abstraction of information beyond that which is perceptually available. Their investigation in animals sometimes provides surprising insights into animal cognition and sometimes confirms the hypothesis that an ability is unique to humans. Examples from two areas of research will be described.

4.1 *Concept Learning*

A concept refers to a common label we give to a number of objects, actions, or ideas that are not exactly alike but have some properties in common. We use concepts all the time when we give verbal labels to things. For example, we call all cats 'cat' and all flowers 'flower,' even though all cats and all flowers do not look alike. Somehow, we have learned that these things share sufficient properties in common to be given a common label. Concepts provide us with considerable cognitive economy, as it would be laborious to distinguish each cat and each flower and give it a separate name.

Can animals form concepts? The answer appears to be yes, at least for the pictorial concepts just described. Experiments originally performed by Richard Herrnstein (Herrnstein et al. 1976) at Harvard University and more recently by Edward Wasserman (1995) at the University of Iowa show that pigeons can readily distinguish between the same categories of objects that people do. A pigeon is tested in a chamber that contains a square-shaped screen on one wall, with keys placed at the four corners of the screen. The pigeon is presented with a visual slide show that consists of the successive presententation of pictures from the categories of people, flowers, cars, and chairs, with each picture containing a different example of each category. The pigeon is rewarded with food for pecking only one of the keys when a picture from a particular category is shown. For example, a peck on the key in the upper left corner might yield reward whenever a flower picture appears, but only a peck on the key in the lower right corner would yield reward when a picture of a chair is shown. Repeated experiments have shown that pigeons learn to peck the correct key with about 80% accuracy whenever a picture in any of the categories is shown. One might worry that pigeons would memorize the correct response to these pictures, since they are shown repeatedly over sessions. Memorization does not appear to be the basis for the pigeon's

ability to sort out these pictures, because the pigeons continue to respond accurately the first time they encounter new pictures from each of these categories. This demonstration is striking because it shows that in the absence of language, which humans use to label categories, a pigeon is able to sort two-dimensional pictures into the same semantic categories that are meaningful to people.

4.2 Theory of Mind

The term 'theory of mind' refers to the fact that people know about minds. Each of us knows that we have a mind of our own. Thus, you know that your mind has a memory and that that memory contains certain information you cannot retrieve at this moment but may be able to retrieve at some later time. You also know that other people have minds and that those minds know some things that your mind knows and other things your mind does not know. The inferences you make about others minds may often guide your behavior. For example, if you are a teacher, you may teach a particular lesson if you believe your students do not know it, but you will skip it if you believe it is already contained in their minds.

Researchers working with non-human primates have raised the question, 'Do apes or monkeys have a theory of mind?' (Premack and Woodruff 1978). Although this question is highly controversial, some observations of primates suggest that it is possible. Menzel (1978) kept a group of chimpanzees in an outdoor enclosure near an open field. One chimpanzee was selected and taken about the field to be shown various locations where food was hidden. This chimp then was returned to its companions, and they were all released to search for food. The chimpanzees soon learned to track the path of the one that had been shown the locations of food, often searching ahead of the knowledgeable chimp. Some of the chimps that were shown food seemed to learn to throw off their pursuers by running in a false direction and then suddenly doubling back to get the food before the others could catch up to them. One interpretation of these behaviors is that the chimps pursued the informed individual because they knew only its mind contained valid information about food locations. Similarly, the knowledgeable chimp ran in the wrong direction in order to deceive the minds of its companions.

5. Conclusion

The examples discussed are a sampler of the many problems studied by scientists interested in animal cognition. They should convey the impression that among the many species of animals that inhabit the earth, each processes information in ways that are unique to it and in ways that are common to other species. The purpose of the field of animal cognition is to understand these similarities and differences and how they were selected by the process of evolution.

Animal Rights in Research and Research Application

1. The Concept of Animal Rights

1.1 Animal Rights and Animal Welfare

In analogy to human rights, *animal rights* can be described as rights that are attributed to animals as consequence of being animal without any further condition. The term animal rights has two different

meanings: in a narrower sense it refers to a point of view that animals have an inherent right to live according to their nature, free from harm, abuse, and exploitation by the human species. This is contrasted by an *animal welfare* position, which holds to minimize animal suffering without rejecting the human practice to use animals for e.g., nutritional or scientific purposes. Animal rights in a wider sense include both positions.

Scope as well as legitimacy of animal rights is highly controversial. Among the issues under discussion is beyond the question whether animals can be attributed rights at all, the problem of drawing a boundary: do only mammals have rights, all vertebrates or even bacteria? There are also different foundations of these rights: are they to be derived from utilitarian principles or are they to be assigned on a deontological basis?

The concept of animal rights extends well beyond the field of research which is the focus of this article. Most ethical considerations discussed below apply equally to the issues of raising and killing animals for food, using animals for sport or as companion animals (e.g., pets) as well as for fighting pests (i.e., poisoning rats or pigeons in cities) most of which affect larger numbers of animals than research.

1.2 Moral Agents and Moral Patients

Ethics distinguishes between *ethical subjects* or *moral agents* on the one hand as the set of subjects who have ethical obligations, and *objects of ethics* or *moral patients* on the other hand designating the set of individuals or objects ethical obligations are owed to. Since it requires certain preconditions to act ethically, among them rationality, most ethical theories agree to equalizing mankind and the set of moral agents. Exceptions of this are slightly more controversial but usually include individuals to whom rationality cannot be attributed, for instance young children or senile and mentally ill people.

1.3 Different Realms of Moral Patients

Classical anthropocentrism is the ethical position held for centuries that takes for granted that only human beings can be the objects of ethics. This equals the set of moral agents and moral patients, except for the few cases mentioned above. In contrast to this the approach taken by many animal rightists can be described as *pathocentric*, since it defines the set of moral patients by the definition 'all that can suffer.' Thus a pathocentrist approach fits the traditional utilitarian position that aims to minimize the total amount of suffering in the world.

1.4 Deontological and Teleological Foundations of Ethics

Philosophical foundations of ethical theories can roughly be divided in two lines of reasoning: Deontological principles imply that certain actions are intrinsically bad (or good), regardless of their consequences. Philosophers or theologists arguing this way require an instance which determines the set of bad actions or at least a method or law to determine this set, like Kant proposed with his categorical imperative. Problems with this reasoning are on the one hand the establishment of the ethical instance (since there will be competing models, for example other religions) and the deduction or interpretation of ethical principles from this instance (be it religious amendments or be it 'the will of the nature').

A strict animal right view, which ascribes certain rights to all animals and the classical anthropocentric view, which disregards animals as objects of ethics are both deontological positions that may differ in the derivation of their justification.

The other way of grounding ethical principles is teleological reasoning, which judges actions by their outcome (usually disregarding the intentions). The problem here is how to determine on which dimensions which outcome of an action is to be considered as morally good (hedon) vs. bad (dolor). Different variants of utilitarianism provide different answers to what has *intrinsic value*: Jeremy Bentham named pleasure as hedon and pain as dolor, John Stuart Mill sets out for the more general happiness as primary good.

2. History

Welfarist and animal right ideas developed against the background of the Western anthropocentric ethics. Before sketching this development it should be noted, however, that there are other cultures and religions that emphasize the sanctity of all life and thus are a realization of animal rights in the narrower sense. The concept of *ahimsa* (Sanskrit for noninjury) as the standard by which all actions are to be judged for example is rooted in Hinduism as well as in Buddhism and finds its strictest interpretation by the Jains in India, where cloth mouth covers are worn to prevent the death of small organisms by inhalation.

From the beginning of philosophy there were differences among philosophers with respect to the treatment of animals. While Pythagoras was vegetarian, Aristotle performed vivisections. The right of men to use animals for their purposes was part of Christian tradition from the very beginning. Mankind, made after God's own image and superior to all other beings, should have dominion over every little thing that moveth upon the earth (see also *Research Conduct: Ethical Codes*).

A continuous development of the moral status of animals can be reconstructed since René Descartes. When he established the dualism of mind (attributed

only to men) and matter as mere spatial extension, animals were seen as devoid of *res cogitans* and hence as pure mechanical automatons without subjective experience. This position lead to the abandonment of welfarist positions especially in research. Vivisections of alive, conscious animals were common since anesthetics were not invented yet and contemporary scientists argued that an animal yelling is like a clock that also makes predictable noises when handled appropriately. These experiments however lead to the discovery of remarkable similarities between animals and humans and it might be partly their merit that the assumption of a fundamental difference between humans and animals was undermined.

During the Enlightenment it became common sense (again) that animals are sentient beings. The rising welfarist attitude might be summed up in the term 'gentle usage' used by David Hume in his *Enquiry Concerning the Principles of Morals* (1751, Chap. 3). Most philosophers did not go as far as to include animals in the set of ethical objects for their own sake. Their indirect duty positions state that we have certain obligations to animals for the sake of their owner or for the sake of 'compassion.' This aptitude was useful in respect to our behavior towards neighbors but blunted by cruelties against animals, Kant wrote in §17 of his *Metaphysik der Sitten* in 1797.

Jeremy Bentham's *An Introduction to the Principles of Morals and Legislation* (1789), which aims to derive a law system from the principles of social eudaimonism, the utilitarian principle of 'the greatest happiness for the greatest number,' does contain the footnote most often quoted in the animal right discussion. Here Bentham criticizes that the interests of animals are not included in the existent laws, compares this with juridical systems neglecting the rights of slaves, and suggests that sentience is the 'insuperable line' beyond which the interest of any being has to be recognized: 'the question is not, Can they reason? Nor, Can they talk? But, Can they suffer?' (Chap. 17).

While the first example of an anticruelty law dates back to 1641 and is to be found in the legal code of the Massachusetts Bay Colony (US), only in the nineteenth century were efforts made to implement in laws some of the new ethical intuitions regarding animals. This juridical development, e.g., the *Martin Act* in the UK (1822) and the *Law Grammont* (1840) in France, was paralleled by the foundations of societies against cruelties to animals, which often had the purpose of enforcing the newly passed laws. Darwin's theories continued to narrow the gap between humans and animals during the late nineteenth century.

3. *Contemporary Positions*

The time since the enlightenment can be reconstructed as a transition from indirect ('anthropocentric-esthetic') to direct duty positions, with welfarist positions gaining popularity. It nowadays is common sense that animals—at least starting with a given phylogenetic complexity—are sentient creatures and thus to be included in some way in the set of moral patients.

A landmark in establishing a welfarist position in animal experimentation was made with *The Principles of Human Experimental Technique*, published first 1959 by William M. S. Russell and Rex Burch which postulated that humane experimental techniques had to conform to the *3Rs: replacement* of animal experiments whenever possible, *reduction* of the numbers of animals used where animal experiments cannot be avoided (i.e., by sophisticated experimental plans that lead to significant results using less animals), and *refinements* of methods to minimize pain and distress experienced by the animals in a given experiment.

One of the most influential works with respect to the moral status of animals is *Animal Liberation* (1975) by the Australian philosopher Peter Singer. This book was written to persuade as many readers as possible to abandon the use of animals regardless of their suffering less than being a waterproof piece of academic work. Singer was extraordinarily successful in propagating his position, but at the price of the quality of argumentation.

For a critical examination of his chapter on animal experimentation see Russell and Nicoll (1996). Taking a utilitarian view, Singer claims sentience as the only dimension that defines the set of moral patients and uses the ability to suffer as a standard example. Two conclusions follow from this line of argumentation.

First, the common use of animals for human purposes, which is more or less inevitably associated with their suffering, is to be condemned, since the animal suffering outweighs by far the human pleasure in the examples given. Even in the absence of a list of hedons and dolors which would allow one to estimate quantitatively whether an act is moral or not by computing the consequences for the animal and the 'general welfare' (as Porter tried for animal experiments in 1992), most utilitarians including Singer agree on a special status of beings which are able to plan and anticipate the future. For those beings one assumes *preference utilitarianism*, which takes the satisfaction of preferences as good, whereas *hedonistic utilitarianism* is assumed for the rest of sentient beings. Because fulfillment of preferences is usually thought to have a bigger moral weight than the intrinsic values of the hedonistic utilitarianism this rules out the possibility to use these subjects against their will in ways that will harm them but will be a benefit for the rest of the moral community.

But on the other hand putting sentience as the only yardstick by which to determine moral patients has a flipside that even preference utilitarianism fails to avoid. It does not condemn sacrificing so-called *human marginal cases* like anencephalic newborns or coma-

tose patients to whom no preferences can be attributed because they lack consciousness or even sentience for purposes of the general welfare, given no other individuals like the parents would suffer from this. This obviously deviates from the ethical intuitions held by a large part of the population in the Western hemisphere. Using human marginal cases for research is thought to be immoral, while the use of animals who might suffer more is instead thought to be morally less problematic, if not sound under certain circumstances.

Well aware of this, Singer uses the notion *speciesism* in analogy to racism for this, quoting Bentham's comparison with slavery among others as examples that exclusion of a given set of (in the examples always human) subjects from the set of moral patients in a certain society is by no means a guarantee that this restriction is not recognized as inappropriate by the following generations. He pleads for using neither higher mammals nor humans in research but his position logically includes that there are circumstances that justify sacrificing men as well as other mammals.

Utilitarian positions furthermore allow each moral agent to kill moral patients in a fast and painless way, provided nobody else suffers from this ('secret killing argument'), unless an additional assumption of being alive as hedon is made, for instance grounded on possible positive experiences in the future. Besides that this is against intuition in the case of humans, it also allows so-called terminal experiments in the life sciences which put the (humanely raised) animals under anesthesia and sacrifices them after the experiment is finished, since no suffering would be induced.

There are many attempts to avoid the problems regarding the human marginal cases, among them to use a deontological corollary that human life is protected even when it fails the utilitarian criteria for being the status of a moral patient. This may mirror the ethical intuitions of at least the Western population but it is exactly the attitude criticized as speciist. At this point there is a conflict between two tasks of philosophical ethics: on the one hand it should organize the set of moral intuitions into a coherent system, while on the other hand it should be based on and reflect the grown and sometimes incoherent moral intuitions of an epoch.

In *The Case for Animal Rights* Tom Regan (1983) rejects utilitarian foundations of animal rights beyond others for the above reasons and offers a deontological alternative. Starting point is a careful derivation of criteria for moral patients. All those beings that have a psychophysical identity over time, beliefs, desires, and a sense of the future, including their own future, are defined as 'subjects-of-a-life.' Regan grounds his deontological position by trying to fulfill certain formal demands, among them conceptual clarity, rationality, impartiality, and compliance to reflected moral principles (considered beliefs). On these grounds he considers it as the best ethical position to attribute an *inherent value* to all subjects-of-a-life. This inherent value is held by the subject, whereas the utilitarian intrinsic value is held by the subject's *experiences* (hedons and dolors). Regan criticizes this as treating the subject as 'mere receptacle' of experiences.

Regan goes on to derive several principles, first of which is the *respect principle*: moral agents are obliged to treat individuals with inherent value in a way that respects this value. From this the *harm principle* is derived: each moral agent has a direct duty not to harm any moral patients, the flipside of which is the inherent right of the moral patient not to be harmed.

Harm is given by inflictions or deprivations, and since to kill a 'subject-of-a-life' is to deprive a moral patient of its future experience, all killings are explicitly condemned by Regan's view, which rules out one of the weaknesses of utilitarianism.

Regan derives more principles, showing that according to the rights view it is immoral to negate the inherent value of subjects-of-a-life by using them in medical research even in case the general welfare of future generations would be promoted for sure. Intrinsic values like the general welfare and inherent values are incommensurate and cannot be set off against each other.

While utilitarian opponents of animal research are obliged to discuss the potential benefit of the research, not only including potential results but also the benefit of the scientists, the suppliers of scientific equipment etc. Regan can avoid this discussion in the first place: 'research should take the direction away from the use of any moral agent or patient.'

While being consequent in the 'consequences aside' notion in demanding respect for the inherent value of moral patients in the above examples, the rights view has considerable weaknesses when it comes to exceptions. Regan interprets the rights view as compatible with the violation of other's values in self-defense or by punishing other moral agents besides other cases. Justification is basically drawn from our (reflected) 'moral intuitions.' These stand against declaring pacifism as moral obligatory by defining self-defense as wrong, 'consequences aside.' Since our moral intuitions, however, *do* also allow animal experiments (at least) in some exceptional cases, it is hard to see why these should not be moral on the same grounds. This turns the uncompromising rights view quite a bit towards a welfarist position. This is avoidable if no exceptions are allowed, like in the eastern philosophy of ahimsa.

4. *The Animal Rights Movement*

In addition to the established animal welfare institutions, since the 1970s a number of more radical animal rights organizations have been founded. While the latter usually define themselves as an essential comp-

lement or even replacement of the former, there is in fact a continuum in the movement's positions under which circumstances animals may be used for scientific purposes. The heterogeneity of the movement may explain the wealth of umbrella organizations like the International Fund for Animal Welfare (1969) or worldanimal.net (1997).

While at educational institutions animal rights were originally rooted in the philosophical departments, recently also law schools deal with the topic offering classes in animal rights law.

In some aspects the history of 'animal liberation' so far resembles that of other liberation movements, but one should remember the essential difference that in this case the liberated population does not participate itself. More comparable to other social movements is the following development: the less radical parts, like the animal welfarists, got integrated in society at large, which adopted some of their demands. This in turn weakens the more extreme parts of the movement and is fertile ground for radicalization.

Underground organizations like the Animal Liberation Front (ALF) use violence and terror as means to impose their views of a humane society, be it by arson to animal laboratories or by torture to their opponents. In 1999 the journalist Graham Hall was kidnapped and branded the letters 'ALF' to his back because of his prize-winning undercover documentary on the criminal violent methods of the ALF.

It should be noted, however, that there are also many groups which are radical in refusing the welfarist 'be nice to them until you kill them' approach while sticking to nonviolent (albeit not always legal) methods of fighting for their goals. The methods they use are the same as in other domains of resistance and include concerted actions to solicit publicity against special cases of animal usage, political lobbying, and fundraising. These organizations are no small 'Robin Hoods': people for the ethical treatment of animals (PETA) as the biggest group which is totally opposed to animal experimentation reported annual net assets of over $7 million in the late 1990s.

Scientists entered discussion only after having been attacked by the animal liberation movement and having been presented to the public as conscienceless monsters for quite a while. After activities of the movement finally reached the ivory tower stopping some research programs due to lobbying and when more radical activists raided laboratories and threatened scientists, eventually societies like 'Society for health and research' (GGF, Germany, 1985) or 'Americans for Medical Progress Educational Foundation' (1991) were founded. Their goals are to 'bolster public understanding and support of the humane use of animals in medical research' (AMPEF). Scientists now offensively promote the results of research by setting up websites, producing brochures aimed at special target groups, and watch and comment on the activities of the animal right groups.

Both sides seem to be aware of the fact that the most important battlefield might be education since moral intuitions are a heritage that is based more on cultural than on biological aspects. This is one of the central distinctions between human and animal behavior codes, which for example allow carnivores to kill prey, but prevents them in general from killing members of their own species. The development of human ethical intuitions has become the subject of scientific investigation in developmental psychology. Although such a complicated process can probably never be fully explained, it is obvious that it can be influenced. Thus Peter Singer demands 'animal rights' children books, and scientists strive for an intensification of education in the live sciences.

Analyses of the Animal Right movement can be found in Francione (1996) from a rightist and in Guither (1998) from a welfarist position.

5. *Juridical Implementation*

In case animal rights in a narrower sense are implemented in laws there are inevitable collisions with basic human rights such as the freedom of religion or the freedom of science. This may be among the reasons that most countries do not implement animal rights at the level of the constitution, where other basic rights are set but in special laws that do not override the constitutional rights.

The ethical intuition that animals should not suffer unnecessarily while it is morally justifiable to use animals for human purposes like research is reflected by the fact that the regulating systems for animal experiments are similar in most Western countries and consist of three columns. First, each experimenter has to have a *personal license* to ensure a quality standard of operation (for an example of educational requirements, see the guidelines of the Federation of European Laboratory Science Organizations). Second, animal experiments are only allowed within research projects, the goals of which have been reviewed and approved to guarantee that no animal experiments are conducted for trivial purposes. Third, research institutions which perform animal experiments have to be licensed and are bound to tight regulations considering animal care during, but also outside the experiments, which is important if one considers that the average laboratory animal spends much more time in the cage than in experiments.

In addition to nationwide requirements, most research institutions, especially universities, also have their own ethical guidelines, which can be more restrictive than the law and which are usually enforced by ethics committees (see also *Ethics Committees in Science: European Perspectives* and *Ethical Practices, Institutional Oversight, and Enforcement: United States Perspectives*).

While the structure of the law regarding animal experiments is very similar in most countries, the actual requirements diverge widely, as does the enforcement of laws. While the term animal as used in the US Animal Welfare Act (1966, see Animal Information Center resources) specifically excludes rats, mice, and birds, the German animal protection law protects all vertebrates and, while other laws just aim to prevent unnecessary suffering, aims also to protect the *life* of animals.

Despite the strict German law there may be a general tendency to use the smallest common denominator when putting ethical intuitions into national laws in the age of global competition, slowing down the trend to further implement animal welfare in national laws.

Anomie

'Anomie' comes from the Ancient Greek *anomia*, meaning absence of rules, norms, or laws (the adjective form *anomos* was more common). The word is still sometimes used in this highly general sense. In Greek thought it had the negative connotations of disorder, inequity, and impiety; and when it reappeared briefly as 'anomy' in English theological literature of the seventeenth century (Orru 1987), its meaning was somewhat similar to the Ancient Greek one. The term came back at the end of the nineteenth century in writings of French philosophers and sociologists, and the French spelling imposed itself in English-language sociology despite attempts to Anglicize it to 'anomy.' 'Anomie' was particularly popular among American sociologists in the 1960s. It is one of the few lexical inventions in sociology, perhaps the only one to have been specific to the sociological community. But sociologists used it with differing and even contradictory meanings—sometimes without any meaning at all—and its career eventually ended in total confusion.

1. Durkheim's Concept

'Anomie' was reinvented by Jean-Marie Guyau, a French philosopher with a sociological bent, in two books: *Esquisse d'une morale sans obligation ni sanction*, published in 1885, and *L'Irréligion de l'avenir*, published in 1887. Guyau opposed *anomie* to *autonomie* (Kantian antonomy). Because of progressive individualization of beliefs and criteria for ethical conduct, the morality of the future would be not only autonomous but anomic—determined by no universal law. For Guyau this process was both ineluctable and desirable.

After Guyau, the word appeared occasionally in late nineteenth-century writings of French philosophers and sociologists such as Gabriel Tarde. But it was Emile Durkheim who would inscribe 'anomie' in the vocabulary of sociology, the new discipline he intended to found.

Durkheim could not accept Guyau's anarchizing individualism since for him every moral fact consisted of a sanctioned rule of behavior. He therefore considered anomie a pathological phenomenon. In *De la division du travail social* (*The Division of Labor in Society*), his doctoral thesis, defended and published in 1893, Durkheim called anomie an abnormal form of

the division of labor, defining it as the absence or insufficiency of the regulation necessary to ensure cooperation between different specialized social functions. As examples of anomie he cited economic crises, antagonism between capitalists and workers, and science's loss of unity due to its increasing specialization. In all three of these cases, what was missing were continuous contacts between individuals performing different social roles, who did not perceive that they were participating in a common undertaking. At the end of his chapter on anomic form, Durkheim discussed another kind of pathology characteristic of industrial societies: the alienation of the worker performing an overspecialized task. This explains why a number of Durkheim's readers understood job meaninglessness to be an integral part of anomie. In fact, they introduced a 'parasite' connotation into his concept. Such alienation is not only different from anomie, it is in many ways its opposite.

Durkheim further developed the theme of anomie in *Le Suicide* (*Suicide*) (1897), defining anomic suicide as that resulting from insufficient social regulation of individual aspirations. In this connection he discussed economic anomie, caused by a period of economic expansion, and conjugal or sexual anomie, due to the instituting and spread of divorce. In both these cases, an opening up of the horizon of the possible brings about the indetermination of the object of desire—or unlimited desire, which amounts to the same thing. This leads to frustration. The anomie that follows a passing crisis may be acute, but Durkheim was especially interested in chronic, even institutionalized anomie. This type of anomie, the 'morbid desire for the infinite,' was an unavoidable counterpart of modern industrial society, residing simultaneously in its value system, e.g., the doctrine of constant progress; its institutions, e.g., divorce law; and its functioning, e.g., competition in an ever-expanding market. However, along with 'progressive' anomie, Durkheim also evoked a 'regressive' type, which actually pertained to 'fatalism.' This last notion, which Durkheim did not really develop, refers to the impossibility of internalizing rules considered unacceptable because unjust or excessively repressive. Here, desires and aspirations run up against new norms, deemed illegitimate; there is a closing down of possibilities. This situation is in fact the opposite of progressive—true—anomie, where the wide, open horizon of the possible leads to unlimited desires. Fatalism, then, is the opposite of anomie, just as altruism is the opposite of egoism (Durkheim's terms for the other types of suicide). In fact, this bipolar theory of social regulation of aspirations was not clearly laid out by Durkheim, and this no doubt explains the concept's peculiar later career: after Durkheim, 'anomie' underwent a complete semantic revolution.

Anomie was not a permanent theme in Durkheim's thought; he was more concerned with the question of social integration. Indeed, both word and concept disappeared from his work after 1901, and they are not to be found anywhere in that of his disciples or collaborators in the 'French school of sociology' and in *L'Année sociologique*. While in *Les Causes du suicide*, a purported continuation of Durkheim's study of suicide published in 1930, Maurice Halbwachs confirmed Durkheim's results on many points he either neglected or rejected everything that could possibly pertain to Durkheim's theory of anomie and he made no reference to conjugal anomie and refuted Durkheim's hypothesis of a progressive economic anomie.

Yet it was in the sociology of suicide, particularly American studies of the subject, that the Durkheimian notion of anomie would endure for a time, following the 1951 English translation of *Le Suicide*. In this connection mention should be made of Henry and Short's 1954 study, in which they sought to apply Durkheim's concept of anomie in their analysis of the effect of the economic cycle on suicide frequency. The largely negative results of this and other tests of Durkheim's progressive anomie hypothesis did not encourage sociologists to explore this research avenue further. Conjugal anomie, meanwhile, was left almost entirely aside in suicide studies, which gave primacy to Durkheim's egoistic suicide, reflecting a preference for his theory of integration over the less developed one of regulation.

2. *The Americanization of Anomie*

As with sociological studies of suicide, the future of 'anomie' was linked to American sociology's reception of Durkheim's work, particularly *Suicide*. Interest in Durkheim began to manifest itself only in the 1930s. With the notable exception of Parsons (1937), however, little attention was paid at first to 'anomie.' The term made no headway at the University of Chicago, where a tradition of research on social disorganization had developed in the 1920s. It was at Harvard University that 'anomie' underwent its American naturalization. Used by Elton Mayo (1933), Talcott Parsons (1937), and Robert K. Merton (1938), it appeared as a new label—and possibly a new theoretical framework—for the study of social disorganization and deviant behavior, and enabled the new department of sociology at Harvard to position itself in relation to the old Columbia–Chicago struggle for intellectual supremacy in the discipline. This strategic aspect may be seen in the young Harvard theoreticians' use of the French spelling (sociologists at Columbia, like Durkheim's translators, spelled it 'anomy'). Distinguishing themselves from the American tradition and appropriating the continental European one, that of Durkheim, Weber, and Pareto, they wrote 'anomie.'

Merton's successful *Social structure and anomie* in its various versions (1938, 1949, 1957, 1964) both

made the term familiar and metamorphosed the concept. In fact, Merton never clearly defined what he meant by anomie. We can nonetheless say that Merton's theory ultimately identified anomie as the contradiction between the culturally defined goal of success and the individual's lack of access to legitimate means of achieving this goal. To resolve this contradiction, the individual may engage in deviant behavior, one form of which is using illegitimate means. Merton called this mode of adaptation 'innovation.'

Merton's theory of anomie is fairly equivocal, but it was understood and used as a theory of differential access to the means to success, one which predicted that delinquent behavior was most likely among the least privileged social strata. This theory, which reached its apogee in the mid-1960s, has been considered the core of 'strain theory,' a major sociological approach to deviance. It should be noted that Merton's theory was only rarely tested in empirical research on delinquency and that when it was, the results were generally negative.

The Mertonian concept of anomie—to the extent that its content can be identified and such as it has been generally understood—is in many ways not only different from Durkheim's but opposed to it. The opposition was not perceived at the time because Merton never related his own use of the term to Durkheim's. Durkheim's anomie is about the lack of restriction on goals; Merton's anomie refers to restriction on means. In Merton's theory, goals are given, defined, even prescribed by the cultural system, whereas for Durkheim the central feature of anomie is indeterminacy of goals. Durkheim's anomic individual is uncertain of what he should do because the horizon of possibilities is so open, whereas for Merton that individual, with the clearest of ideas of the objective to be reached, finds the possibilities for success closed down.

This semantic revolution attained its full effect in American sociology between 1955 and 1970, in numerous sample surveys using attitude scales designed to measure the psychological counterpart of social anomie. This research in turn was based on theoretical essays in which anomie had appeared for the first time outside Harvard: at the end of the 1940s sociologists and political scientists such as David Riesman, Robert MacIver, and Sebastian De Grazia had psychologized the concept, using the word 'anomie' to designate individual feelings of anxiety, insecurity, and distrust. These feelings figured in 'anomie scales,' meant to measure degree of pessimism in world views, feelings of having no control over one's situation, and renunciation of hope. (The most famous of these was developed by Leo Srole in 1956 and called the 'anomia scale.') In Durkheim's thought, these phenomena were characteristic of fatalism—the opposite of anomie. Anomie had become interchangeable with the notion of alienation, which sociologists were trying to apply in attitude scales; normlessness had been associated with powerlessness. All these empirical studies using attitude scales were based on the (mistaken) postulate of a single unified concept of anomie, the myth of a continuous tradition of research, with Durkheim as precursor and Merton as prophet.

Anomie scales were contemporaneous with the other main usages of the term. As we have seen, it was between the mid-1950s and the late 1960s that 'anomie' was most heavily used, with its Durkheimian meaning in the sociology of suicide and its Mertonian meaning (mainly) in the sociology of deviant behavior. That contradictory meanings of one and the same term should have been successful at the same time shows that anomie's use function in sociology was more decorative than cognitive.

In the 1960s, anomie came to be considered the sociological concept par excellence, despite (or because of) the semantic confusion surrounding it. In the 1968 edition of the *International Encyclopedia of the Social Sciences*. Talcott Parsons explained that anomie was one of the few concepts truly central of contemporary social science. At that time the term had reached the peak of its glory. Because 'anomie' made possible a kind of bridge between references to classic theoretical sociology works and sample surveys using attitudes scales purporting to test hypotheses drawn from those theories, it served as the emblem of the dominant research practice of the time (opposed to the ecological analysis and fieldwork favored by the Chicago School).

Though the word 'anomie' has lost much of his attraction for sociologists, some still use it rather vaguely to mean deregulation or disorder. It would be preferable to restrict usage of the term to Durkheim's meaning of an excessive growth in aspirations or expectations. This concept refers to a paradox present in Tocqueville and in the notion of relative deprivation (and for which Raymond Boudon (1977) has constructed a model): when individual objective conditions improve, collective subjective dissatisfaction may increase.

Anthropology

Anthropology as a discipline is concerned with human diversity. In its most inclusive conception, this is what brings together the four fields of sociocultural anthropology, archaeology, biological (or physical) anthropology, and linguistics. With its formative period in the historical era when Europeans, and people of European descent, were exploring other parts of the world, and establishing their dominance over them, and when evolutionary thought was strong, it also came to focus its attention especially on what was, from the western point of view, distant in time or space—early humans or hominoids, and non-European peoples. In that early period, there was indeed a strong tendency to conflate distances in time with those in space: some living non-Europeans could be taken to be 'contemporary ancestors,' dwelling in 'primitive societies.' Understandings of the discipline have changed over time, however, and they are not now entirely unitary across the world. What is held together under one academic umbrella in one place may be divided among half a dozen disciplines somewhere else. A mapping of the contemporary state of the discipline, consequently, may usefully begin by taking some note of international variations.

1. Terminologies and Boundaries

It is particularly in North America that academic anthropology has retained what has come to be known as 'the four-field approach,' although in recent times its continued viability has come under debate. Among the founders of the discipline, some were perhaps able to work (or at least dabble) in all the main branches, but with time, in American anthropology as well, it has certainly been recognized that most scholars reach specialist skills in only one of them—even as it may be acknowledged that a broad intellectual sweep across humanity has its uses, and at the same time as it is recognized that here as elsewhere, research in the border zones between established disciplines or subdisciplines often brings its own rewards. On the whole, in any case, scholars in archaeology, biological anthropology, linguistics, and sociocultural anthropology now mostly work quite autonomously of one another, and while terminologies vary, in many parts of the world, they are understood as separate disciplines.

In Europe, varying uses of the terms 'anthropology,' 'ethnology,' and 'ethnography,' between countries and regions as well as over time, often reflect significant historical and current intellectual divides (Vermeulen and Alvarez Roldán 1995). In parts of the continent, in an earlier period, the term 'anthropology' (in whatever shape it appeared in different languages) tended to be used mostly for physical anthropology, but in the later decades of the twentieth century, it was largely taken over by what we here term sociocultural anthropology—itself a hybrid designation for what is usually referred to either as social anthropology or as cultural anthropology. (Especially in German usage, however, 'anthropology' also frequently refers to a branch of philosophy.) Physical or biological anthropology, meanwhile, was absorbed in many places by other disciplines concerned with human biology, while archaeology and linguistics maintained their positions as separate disciplines.

In some European countries, now or in the past, the term 'ethnography' has been used, unlike in present-day usage in Anglophone countries, to refer to

sociocultural anthropology as a discipline. Matters of discipline boundaries are further complicated, however, by the fact that sociocultural anthropology especially in northern, central, and eastern Europe is often itself divided into two separate disciplines, with separate origins in the nineteenth and early twentieth centuries. One, which was often originally designated something like 'folk life studies,' had its historical links with cultural nationalism, and concerned itself with local and national traditions, especially with regard to folklore and material culture. This discipline mostly did not acquire a strong academic foothold in those western European countries which were most involved in exploration and colonialism outside Europe, particularly Great Britain and France, where on the other hand, that sociocultural anthropology which focused on non-European forms of life was earliest and most securely established. The more Europe-oriented, or nationally inclined, 'folk life studies' discipline has tended, in recent decades, to redesignate itself as 'European ethnology'—or in some contexts, simply as 'ethnology,' in contrast to a rather more non-Western oriented, or at least internationalist, 'anthropology.'

In another usage, 'ethnology' has been taken to refer to a more historical and museological orientation (in contrast with what was for a time a more presentist social anthropology), while in other contexts again, it is more or less synonymous with 'sociocultural anthropology.' Yet further national variations in terminology continue to make direct transpositions of terms between languages treacherous. Meanwile, outside the heartlands of western academia, the idea that the study of non-European societies and cultures must be a separate discipline has not always been obvious and uncontroversial. In African universities, founded in the late colonial or the postcolonial period, there has often been no distinction made, at least organizationally, between anthropology and sociology—and not least in Africa, anthropology sometimes has to carry the stigma of being associated with the evils of colonialism and racism (Mafeje 1998). In India, when anthropology is recognized as a distinct discipline, it is frequently taken to be particularly preoccupied with 'tribal' populations, and perhaps with physical anthropology—while some of the scholars recognized internationally as leading Indian anthropologists, concerned with the mainstream of Indian society, may be seen as sociologists in their own country.

Back in North America and Europe, again, the framework of academic life is not altogether stable over time. 'Cultural studies,' putting itself more conspicuously on the intellectual map from the 1970s onwards, has been most successful as a cross-disciplinary movement in the Anglophone countries but has had an impact elsewhere as well. Its center of gravity may have been mostly in literary and media studies, but insofar as it has engaged with methods of qualitative field research and with issues of cultural diversity, not least in the areas of multiculturalism and diaspora studies, it has sometimes come close to sociocultural anthropology and—in certain European countries—to ethnology, as discussed above. While some anthropologists may see this as an undesirable intrusion into their disciplinary domain, others see it as a source of new stimuli (Dominguez 1996, Nugent and Shore 1997).

2. *Conceptions of the Core*

If a concern with human diversity may define anthropology as a whole, it is perhaps too airy a notion to offer a strong sense of the distinctive working realities of the anthropological practitioner. In discussing the changing assumptions of what is the core of anthropological work and thought, we will concentrate on sociocultural anthropology—by now the segment of the wider field which remains, internationally, most clearly identified as anthropology.

Obviously the tradition of studying more exotic, non-Western forms of life has remained strong, and some would still maintain that this is what a 'real anthropologist' does. Yet it is a conception of anthropology which is now, in its own way, susceptible to charges of 'Eurocentrism,' with uncomfortable and controversial links to a past in which the divide between a dominant West and a subjugated 'Rest' was more likely taken for granted, at political, intellectual, and moral levels. By the latter half of the twentieth century, past vocabulary such as 'primitive societies' had become mostly an embarrassment, and in a more egalitarian mood, some anthropologists had taken to arguing that it was quite acceptable for North American and European anthropologists to go to Africa, Asia, or Oceania, as long as anthropologists from these regions were also welcomed to do research in the Occident, in a generous worldwide intellectual exchange effort. Such a symmetrical exchange, however, has hardly occurred. The relatively small number of professional anthropologists originating in non-Western, non-Northern parts of the world have seldom had the inclination, or the funding, to do their research abroad. They have been much more likely to conduct their studies in their home countries—where they may thus sometimes share their fields with expatriate anthropologists from Europe or North America (Fahim 1982).

In the latter part of the twentieth century, moreover, the emphasis on studying exotic others—in what had now become the Third World, or the Fourth World—was weakening in American and European sociocultural anthropologies as well. In some parts of Europe where the discipline was relatively late in getting established, most anthropologists from the very beginning did their research in their own countries, even as they drew intellectual inspiration from

the classic studies of exotics imported from older national anthropologies. The growing interest in, and increasing legitimacy of, 'anthropology at home' has been based partly on a sense that humanity is indivisible, and an academic segregation of the West from the Rest indefensible. The preoccupation with exploring human diversity is to a certain extent retained by emphasizing the internal diversity of forms of life (lifestyles, subcultures, etc.) of contemporary societies. The exotic may be around the corner. Moreover, the study of one's own society is often motivated by a sense of relevance: one may be better placed to engage actively with whatever are perceived to be the wrongs of the place where one has the rights and the duties of a citizen. Of course, such a repatriation of sociocultural anthropology may blur certain disciplinary boundaries–perhaps with sociology, perhaps in some contexts with an 'ethnology' of the European type, which could also identify itself as an 'anthropology at home.'

If anthropology is no longer quite so committed to identifying itself in terms of exotic fields, its methodology appears, in some views, to offer another sense of distinctiveness. Anthropologists, since at least the early twentieth century, have typically done 'field work.' They emphasize 'participant observation,' or 'qualitative research'—in contrast with the handling of more or less impersonal statistical data—or 'ethnography,' in the sense of integrated descriptions of ways of life. In this discipline, the pure theorist is an anomaly, if not entirely nonexistent. The direct involvement with another way of life, whether it is in a village on the other side of the world, or a neighborhood across town, or another occupation, tends to become more than a methodological choice. It becomes a central personal experience, a surrender with strong moral and esthetic overtones and a potential for rich satisfaction and life-long memories.

Even so, placing field work at the core of the distinctiveness of anthropology is also problematic. In part, the problem is that 'doing ethnography' has become increasingly common in various other disciplines as well, even if anthropologists often complain that it is then done badly, superficially. It is also true that field work of the most orthodox variety does not fit readily into every setting. In all field studies, anthropologists tend to do not only participant observation, but other kinds of work as well. They talk to informants, elicit life histories, collect texts, do surveys, and engage in some variety of activities to acquire new knowledge. To what extent their observational work can really be actively participatory must depend a great deal on the contexts. But furthermore, in contemporary life observational work is sometimes not very rewarding. Following the daily round of an agricultural village is one thing; observing an office worker, or even a creative writer, at his desk, in front of his computer screen is another. On the other hand, fields in the present-day world may involve other kinds of data than those of classic anthropology—more media use, for example. Notions of 'field' and 'field work' are increasingly coming to be debated in anthropology, as the world changes and as anthropologists try to fit their pursuits into it, and there are clearly also anthropologists who prefer less distinctively anthropological methodological repertoires (cf. Gupta and Ferguson 1997, Bernard 1998).

The idea of gaining knowledge and understanding from field work is certainly not entirely separate from the issues of where, and among whom, anthropologists work either. While anthropologists have been inclined to assume, or argue explicitly, that there are special insights to be gained from combining an outsider view with immersion in another way of life, the rise of 'anthropology at home,' the increasingly frequent copresence of indigenous and expatriate anthropologists in many fields, and the growth elsewhere in academic life of more emphatically insider-oriented fields of study, such as some varieties of ethnic studies, leave assumptions and arguments of this kind more clearly open to debate. Some would question as a matter of principle what kind of validity an outsider's perspective can have. Others could argue that one can never be an anthropologist and an insider at the same time, as these are distinct intellectual stances. And then, surely, such issues are further complicated by the fact that insider and outsider are not necessarily either-or categories, and hardly altogether stable either. An outsider can perhaps become an insider—and on the other hand, one can probably start as an insider and drift away, and become an outsider. Here again is a complex of problems which remains close to the heart of anthropological work (Merton 1972, Narayan 1993).

One may wish to object to the somewhat unreflected inclination to put field work at the center of the discipline because it would tend to make anthropology primarily a methodological specialty—perhaps, because of its qualitative emphasis, the counterpart of statistics. Undoubtedly many anthropologists would prefer to identify their discipline with particular ideas, theories, and intellectual perspectives, and the history of anthropology is most often written in such terms. It may still turn out to be difficult to point to any single, uncontested, enduring central concept, or structure of concepts.

Again, however, there is the exploration of human diversity. A key idea here has obviously been that of 'culture,' not least in the plural form of 'cultures.' Most fundamentally, in its conventional but multifaceted anthropological form, 'culture' stands for whatever human beings learn in social life, as contrasted with whatever is inborn, genetically given. But with the idea that human beings are learning animals also goes the understanding that they can learn different things, so that what is cultural tends to exhibit variation within humanity. Moreover, the tendency has been to conceptualize culture at a level of

human collectivities (societies, nations, groups), so that members are held to be alike, sharing a culture, while on the other hand there are cultural differences between such collectivities. Culture, that is, has been taken to come in distinct packages—culture*s*. In the classic view of culture, there has also been a tendency to try and see each such culture 'as a whole'—to describe entire ways of life and thought, and to throw light on the varied interconnections among ideas and practices.

Such a basic notion of culture has allowed anthropologists to proceed with the task of drawing a panoramic map of human diversity. There has certainly also been a widespread preoccupation with showing how much of human thought and behavior is actually cultural (that is, learned) and thus variable, rather than altogether biologically based, and uniform. This emphasis has been visible, for example, in anthropological contributions to gender studies.

Yet culture has also been a contested concept in anthropology, not least in recent times. It is true that it was never ally central to anthropological thought in all varieties of anthropology. American sociocultural anthropology, which has more often been identified as 'cultural anthropology,' has focused rather more on it, for example, than its British counterpart, more inclined over the years to describe itself as 'social anthropology' (and perhaps now offering 'sociality' as an emergent alternative or complementary core concept). By the late twentieth century, however, critics in the United States as well as elsewhere argued that the established style of cultural thought tended to exaggerate differences between human collectivities, to underplay variations within them, to disregard issues of power and inequality and their material bases, and to offer overly static, ahistorical portrayals of human ways of life. While some anthropologists have gone as far as to argue for the abolition of the culture concept, others would be inclined to accept many of the criticisms, and yet take a more reformist line. Whichever view is taken, it seems that debates over the understanding of culture offer the discipline one of its lively intellectual foci (Hannerz 1993, Kuper 1999).

The notion of cultural translation has also had a part in defining anthropological work, and inevitably it is drawn into the arguments about the culture concept generally. Indeed, bridging cultural divides by making the ideas and expressions of one culture understandable in terms of another has been a major anthropological activity, although this linguistic analogy is certainly too limiting to describe all anthropology (Asad 1986, Pálsson 1993). In a somewhat related manner, it has gone with the interest in human diversity to describe anthropology as a discipline centrally involved with comparison. In a general way, this is clearly valid. Much of anthropology is at least implicitly comparative, in its inclination to emphasize what is somehow notably different about the ideas, habits, and relationships of some particular population. To the extent that the origins of the discipline have been European and North American, the baseline of such comparisons and contrasts has no doubt been in a general way Western. At the same time, there has been a strong tendency to use the knowledge of diversity to scrutinize Western social arrangements and habits of thought to destabilize 'common sense.' In such a way, anthropological comparison can serve the purpose of cultural critique, and this possibility has again been drawing increasing attention in recent times (Marcus and Fischer 1986). On the other hand, the form of large-scale comparative studies, focusing on correlations between particular sociocultural elements across a large number of social units, which was prominent in the discipline in some earlier periods, has not been a central feature for some time, and the intellectual and methodological assumptions underlying comparison are also a more or less continuous topic of argument (Köbben 1970, Holy 1987).

3. *Specialties and Subdisciplines*

If culture in the singular and plural forms, field work, translation, and comparison may count as ideas and practices which hold anthropology together, not in consensus but often rather more through engagement in debate, it is often suggested that the discipline also tends to be systematically segmented along various lines—not only in terms of what is understood to make up the discipline, as noted above, but also with regard to what draws together closer communities of specialists. One of the three major dimensions here is area knowledge. Anthropologists tend to be Africanists, Europeanists, Melanesianists, or members of other region-based categories. Relatively few of them ever commit themselves to acquiring specialized knowledge of more than one major region to the extent of doing field research there. It is true that if field work is often highly localized, it does not necessarily lead to a wider regional knowledge either, but as a matter of convention (perhaps at least to fit into normal job descriptions in the discipline), the tendency has been to achieve specialist status by reaching toward an overview of the accumulated anthropological knowledge of some such unit, and perhaps seeking opportunities to familiarize oneself with more of it through travel. In countries where 'area studies' have been academically institutionalized, such regional anthropologies have had a significant role in the resulting interdisciplinary structures, and generally, shared regional specialization has often been important in scholarly exchanges across discipline boundaries.

The second major dimension of specialization can be described as topical. Although anthropology has a traditional orientation toward social and cultural 'wholes,' there is yet a tendency among many anthropologists to focus their interest on particular kinds

of ideas, practices, or institutions. Frequently, such specializations have tended to follow the dominant dividing lines between other academic disciplines—there have been a political anthropology, an economic anthropology, a psychological anthropology, an anthropology of law, an anthropology of art, and an ecological anthropology, for example. Drawing on knowledge of social and cultural diversity, one aspect of such specialization has been to scrutinize and criticize concepts and assumptions of the counterpart disciplines with respect to their tendencies toward Western-based intellectual ethnocentrism; but obviously there is also a continuous absorption of ideas from these other disciplines. Here, then, are other interdisciplinary connections. It may be added that such subdisciplines often have their own histories of growth in some periods, and stagnation in others (Collier 1997).

Third, anthropologists sometimes specialize in the study of broad societal types—hunter-gatherers, peasants, pastoralists, fishermen, and so forth. In some ways urban anthropology may be seen as a similar kind of specialty. In fields like these, too, intensities of collective engagement and intellectual progress have tended to vary in time.

4. *The Practical Uses of Anthropology*

It has occasionally been argued that anthropology is less engaged with practical application than many other academic disciplines, and more concerned with achieving a somewhat lofty overview of the human condition, in all its variations. One factor underlying such a tendency may be a sort of basic cultural relativism—it may go with the acceptance, and even celebration, of human diversity to be somewhat sceptical of any attempt to impose particular arrangements of life on other people. This stance may well be supported by the fact that anthropologists have often been outsiders, working in other societies or groups than their own, and feeling that they have no mandate for meddling, or for that matter any actual realistic opportunity.

Nonetheless, there have always been a number of varieties of 'applied anthropology.' In an early period, when the study of non-Western societies was carried out in contexts of Western colonialism, it was held that anthropological knowledge could be useful in colonial administration. While some administrators had some anthropological course work before taking up their overseas assignments, and while some anthropologists did research oriented toward such goals, it seems that such connections remained rather limited, and administrators were often impatient with the anthropologists' preference for a long-term buildup of basic knowledge. Particularly toward the end of the colonial period, anthropologists also often saw such involvements as morally and politically questionable.

In the postcolonial era, anthropological knowledge has been engaged in a larger scale, and in many different ways, in development work in what had now turned into 'the Third World.' Many governments, international agencies, and international nongovernmental organizations have thus drawn on anthropological advice, and have offered arenas for professional anthropological activity outside academia. At the same time, with 'development' turning into a global key concept, around which an enormous range of activities and organizations revolve, this again has become another focus for critical theoretical scrutiny among anthropologists (Dahl and Rabo 1992, Escobar 1995).

When anthropologists work in their own countries, the range of applications may be wider, and as already noted, practical and political relevance is frequently one reason for doing anthropology 'at home.' Not least as transnational migration has made more societies increasingly ethnically and culturally heterogeneous, anthropologists have been among the social scientists engaged, in one way or other, in the handling of minority affairs and multiculturalism. Educational and medical anthropology are not always involved in practical application, and research in such fields is also carried out in other societies than the researcher's own, but often work in these subdisciplines similarly centers on the encounter between major institutional complexes and culturally heterogeneous populations. Some number of anthropologists in Europe and North America now also make use of their disciplinary perspectives as specialists on organizational culture, and as marketing analysts. A further practical field which emerged in the late twentieth century as a profession in itself is that of 'intercultural communication,' which offers training and consultancy in the handling of concrete situations of cultural difference, and, putting it somewhat dramatically, of 'culture shock.' This field has links to several academic disciplines, but to a considerable degree it draws on a more or less anthropological conception of culture—of a type, it may be added, that many anthropologists might now find rather old-fashioned and clumsy.

5. *The Future of Anthropology*

In all its varying shapes, in space and over time, anthropology has tended to straddle conventional academic classifications of disciplines. In its scope of subject matter—family and kinship, politics, market and exchange, for example, on the one side; art, music, and dance on the other—it extends across the social sciences and the humanities. Insofar as it has to take into account what are the biological givens of human thought and action, and inquires into the interactions of humankind with its natural environment, it reaches into the natural sciences as well. But its multiple affiliations are not only a consequence of its varied

subject matter. They are also implied in the variety of intellectual approaches: in field research, in theoretical work, and in styles of presentation.

In many ways the enduring characteristics of anthropology, throughout this range of forms, continue to be expressions of the concern with diversity, with the highly varied manners of being human. To the global public stock of ideas it brings such notions as taboo, witchcraft, cargo cults, totemism, or the potlatch exchange feasts of Northwest Coast American Indians. Concepts such as 'Big man' (out of Melanesia), or 'patron–client relationships' (not least out of the Mediterranean area), or 'caste' (out of India), allowed to travel out of their areas of origin, can enrich our thinking about power, politics, and inequality in many contexts. There is a rich intellectual universe here, to be drawn on within the discipline and from outside it. And anthropology has its classic preoccupations, such as ritual or kinship, concerning which new materials about yet more variations are continuously gathered worldwide, and around which theoretical debates never seem to cease.

At the same time, anthropology goes on reconfiguring itself (cf. Wolf 1964, Hymes 1972, Fox 1991, Ingold 1996). One might perhaps have thought that a discipline revolving around the diversity of human forms of life and thought would find itself in difficulty at a time when increasing global interconnectedness may lead to cultural homogenization and a loss of local or regional cultural forms. Indeed, it is true that many people in the world no longer stick to the beliefs they used to hold, and are discarding some of their past practices, ranging from spirit possession to headhunting. In part, the responsibility of anthropology here becomes one of preserving a record of the ways of being humans, past and present, and keeping that record alive by continuing to scrutinize it, interpret it, and bringing it to bear on new developments.

It is also true, however, that diversity is not diminishing as much as some, perhaps fairly superficial, views of globalization might suggest. Traditions may be remarkably resilient, adapting to new influences and absorbing them in various ways; there may be more than one 'modernity.' Moreover, new interconnections may generate their own social and cultural forms, so that there may be cultural gain as well as cultural loss. A growing interest in anthropology with such notions as hybridity and creolization bears witness to this. In addition, however, anthropology has continuously expanded the field of social and cultural variations with which it has actively engaged. As the discipline was practiced in the earlier decades of the twentieth century, one might have discerned a tension between on the one hand the ambitious claims of offering a view of humanity, and on the other hand the actual concentration on villages of horticulturalists, bands of hunter-gatherers, or other exotic and small-scale sociocultural arrangements. But then by midcentury, there was an increasing involvement with peasant societies, and the civilizations of which they were a part, and later yet urban anthropology appeared as another subdiscipline, practiced in field settings in every region. In recent times, the anthropology of science has been another growing specialization, as the practices of scientists are scrutinized as yet another kind of cultural construct, and as laboratories are added to the range of possible sites of field work (Downey and Dumit 1997). It appears, consequently, that the enduring wider claims of the discipline to an overall engagement with human modes of thought and action are increasingly being realized.

Obviously, in many of its fields of interest, anthropologists now mingle with scholars from a variety of other backgrounds, and the division of labor between disciplines here may not seem obvious. Undoubtedly there are blurred boundaries as well as cross-fertilization, but anthropologists would emphasize the intellectual potential of a conceptual apparatus trained on, and informed by a knowledge of, a great variety of cultural assumptions and institutional arrangements. There is also the commitment to close-up observation of the relationships between human words and deeds, and the strain toward understanding 'wholes' which, despite its vagueness, may usefully involve a particular commitment to contextualization as well as skills of synthesis.

Anthropologists now find themselves at work in a global ecumene of increasing, and increasingly polymorphous, interconnectedness. This is a time in which that diversity of social and cultural forms with which they are preoccupied is constantly as well as rapidly changing, and where new social, political, economic, and legal frameworks encompassing and rearranging that diversity are emerging. More people may have access to a larger part of the combined human cultural inventory than ever before; conversely, whether one likes it or not, more of that cultural diversity can also come in one's way. This is also a time when debates over the limits of diversity are coming to new prominence, for different reasons. Evolutionary biologists are setting forth new views of human nature which need to be carefully confronted with understandings of cultural variation. As people sense that they live together in one world, questions also arise over what is, or should be, shared humanity, for example in the area of human rights (Wilson 1997). There would seem to be a place in the public life of this era for a cosmopolitan imagination which both recognizes diversity and seeks for the ground rules of a viable and humane world society. For such a cosmopolitan imagination, one would hope, anthropology could continue to offer materials and tools.

Anthropology and History

For anthropology, history is not one but many things. First, it is the past, and especially the past that survives in archives and other written or oral records; 'prehistory' is its more remote counterpart. Second, it is change, diachronic as opposed to synchronic process. Third, history is a domain of events and artifacts that make manifest systems of signification, purpose, and value, the domain of human action. Fourth, it is the domain of all the diverse modes of the human experience and consciousness of being in time. Last, it is a domain encompassing all those practices, methods, symbologies, and theories that human beings—professional academic historians among them—have applied to the collection, recollection, and comprehension of the past, the present, and the relations between the two.

1. Anthropology and Natural History

At the end of the sixteenth century, anthropology emerged in Europe not in contrast to history but rather within it. Thence, and for some two and a half centuries forward, it would be understood broadly as that branch of 'natural history' that investigated the psychophysical origins and diversification of the human race—or races, as was very often the case. Demurring throughout the period to the theological calculus of the creation of Adam, it confined itself to treating developments presumed to have transpired over only a few millennia. In 1858, miners at England's Brixham cave unearthed tools and other human remains that stratigraphers could prove to be at least 70,000 years old. Theological authority suffered a blow from which it would not recover; anthropological time suddenly acquired much greater archaeological depth. Meanwhile, a growing scholarly coalition was coming together to support the doctrine that 'culture' was that common human possession which made manifest the basic psychic unity of all the putative races of mankind. In 1854, James Pritchard would accordingly launch 'ethnology,' and send the racialists

off on their separate ways (Stocking 1987). 'Cultural' and 'physical' anthropologists would never again keep their earlier company. Yet, even through the turn of the twentieth century, natural history remained the largely uncontested source of the methods and aims of both. Questions of origin and development continued to have pride of place. The 'savage' or the 'primitive' became all the more entrenched as a disciplinary preserve, but also as the rudimentary pole of any number of ambitious reconstructions of the probable steps or stages that had marked the human passage to 'civilization' or 'modernity.' Tylor's *Primitive Culture* (1871), Morgan's *Ancient Society* (1877), and the several volumes of Frazer's *Golden Bough* (1990) are classic examples of the genre.

Such far-reaching treatises would strike the more meticulous of the subsequent generation of their readers as undisciplined, even whimsical. By the 1920s, and despite all their other differences, Franz Boas, Bronislaw Malinowski, and A. R. Radcliffe-Brown were inaugurating a turn away from 'speculative history' in favor of meticulous observational attention to the 'ethnographic present.' Not even these sober empiricists were, however, opposed in principle to reconstructive or evolutionary analysis.

With due regard for rigor, the more adventurous of their colleagues would continue to pursue it; and virtually every subfield of anthropology has contributed to it ever since. Physical anthropology is now a 'genetic' science in both the larger and the stricter sense of the term. Morgan's project survives most explicitly in the US, from Leslie White to Marvin Harris, as 'cultural materialism' (see Harris 1968), but also endures implicitly in the technological determinism that informs Goody's argument in *The Domestication of the Savage Mind* (1977). Tylor and Frazer are the precursors not simply of Claude Lévi-Strauss's structuralism (see infra) but also of the burgeoning interdisciplinary and neo-Darwinist vocation known as 'evolutionary psychology.' Boas himself is among the bridges between an older 'comparative philology' and ongoing efforts to trace the family tree of all the world's languages (see Kroeber 1935).

2. *Anthropology and Ethnohistory*

A more modest anthropological tradition of diachronic research has borrowed its methods less from natural history than from empirical historiography. It has a partial foreshadowing in the particularistic study of the drift and dissemination of traits and artifacts from the centers to the peripheries of cultural production with which diffusionists in both Germany and the US were occupied between the 1890s and the 1930s. It has its more definitive commencement in the immediate aftermath of the Second World War. Its most familiar designation is still 'ethnohistory,' however misleading the suggestion of parallels with 'ethnoscience' or 'ethnomethodology' may be. In any event, the signature task of ethnohistory has always been the investigation and documentation of the pasts of those native or 'first' peoples whom anthropologists had, until recently, proprietarily or conventionally claimed as 'their own.'

In the US, its more concrete initial impetus came with the 1946 ratification of the Indian Claims Act, which soon led to anthropologists serving as expert witnesses—sometimes for the plaintiffs, sometimes for the defense—in the readjudication of the treaties of the pioneer era. In the US and elsewhere, it had a crucial catalyst in the granting of public access to the administrative archives of the pioneers, the missionaries, and the bureaucrats of European colonization. Hence, its characteristic focus: the dynamics of contact and conflict between the subaltern and their would-be overlords: pioneering, missionary, colonizing, or enslaving (Cohn 1968, 1980).

Narrowly delimited, ethnohistory remains a specialist's craft. Since the 1970s, however, its methods and its themes have met with an ever widening embrace, and if 'historical ethnography' and 'historical anthropology' are not yet synonymous with standard disciplinary practice, they are certainly of a piece with it. The anthropological gaze is now less often 'from afar' than it is longitudinal. Such a vantage has been pivotal in the renovation of political economy. It has also brought fresh and stimulating perspectives to the address of kinship, race, national and personal identity, and gender. Its deployment and its impact may or may not be indications of greater disciplinary enlightenment, but they are by no means indications of passing intellectual fashion alone. The lengthening of the anthropological gaze has rather gone hand in hand with the ascendance of a postcolonial order in which social and cultural boundaries have become increasingly permeable and structures increasingly indistinguishable from processes. It has gone hand in hand as well with the ascendance of the postcolonial demand that anthropology offer a reckoning, not simply of its relation to the colonial past but also of the status of the knowledge that it claims to produce.

3. *Anthropology and Hermeneutics*

In our postcolonial order, anthropology itself needs interpreting; so, too, do many other sociocultural phenomena. Anthropology's current troupe of interpreters espouses, however, an even stronger postulate: that sociocultural phenomena, as historical phenomena, permit only of interpretation; that they permit of contextual understanding, but not of general explanation. 'Interpretive anthropology,' thus, stands starkly at odds with the loftier versions of the natural history of culture, but also with any empirical historiography that has the inductive abstraction of general types or causal relations as its end. It now comes in many versions of its own. The most venerable

of them commences with the Boasians. In 1935, Alfred Kroeber would accordingly remark that the ethnographies that Ruth Benedict and his other colleagues were busy producing were 'historical' in type. True enough, their temporality was synchronic, not diachronic. Their mode, however, was particularistic; their method contextualist; their analyses rarely if ever causal; and their model consequently that of what Wilhelm Dilthey had defined as the *Geisteswissenschaften*—'sciences of mind,' literally, but better glossed as 'sciences of meaning' or simply 'hermeneutics.' In fact, Kroeber was quite correct; Benedict, Margaret Mead, and the other cultural anthropologists of Boas's circle were indeed hermeneuticians. They were hence establishing the methodological legacy to which Geertz is the most celebrated heir (see Geertz 1973).

The more proximate wellspring of contemporary interpretation flows out of the tumult of the later 1960s. Elaborating in 1972 upon the call for a 'critical and reflexive anthropology,' Scholte was among its earliest manifestologists, though he borrowed many of his own philosophical and methodological tenets from Johannes Fabian's slightly earlier exposition of Hans-Georg Gadamer's revision of Dilthey's thought (Scholte 1972, Fabian 1971, 1983). The channels thus opened have remained critical and reflexive, if perhaps not always so politically committed as Scholte might have hoped. Gadamer's heremeneutics has, moreover, served as only one of many subsequent grounds on which to establish interpretive license. Bypassing Gadamer, Bourdieu (1991) has found a cardinal inspiration for his own program of reflexive critique in Martin Heidegger. Walter Benjamin (see Taussig 1993) and Giambattista Vico (see Herzfeld 1987) have won admirers of their own. Among the French poststructuralists, Bourdieu himself has attracted a substantial following, especially in his own country; Michel Foucault has had the greater impact on both reflexion and critique in the US and elsewhere.

Such a well populated census might suggest that, as much now as at its beginnings, anthropology belongs to history (as a discipline) no less than in it (as contingent process). Yet, even many of those who label themselves 'historical anthropologists' or 'interpreters' of one or another stripe would object to such a subsumption. No doubt, professional territorialism plays a part in their resistance. Often very palpable differences of professional sensibility play another part. Matters more strictly intellectual, however, play a part of their own, and their stakes are no more evident than within the anthropology of history itself.

4. *The Anthropology of History*

Durkheim's *Elementary Forms of the Religious Life* (1965) opens the arena of the anthropology of history with its argument for the social causation of the experience and conceptualization of time. Halbwachs's *Collective Memory* (1980) expands it, and after many decades of neglect, has come to be among the foundational texts of a recent surge of ethnographic and comparative inquiry into the techniques, the media, and the politics of remembering—and forgetting (see, e.g., Boyarin 1994, Shryock 1997). The most imposing precedent of the broader anthropology of history is, however, Lévi-Strauss's *Savage Mind* (1966). A treatise devoted to the analysis of the analogical—and ahistorical—matrices of mythic and totemic thought, *The Savage Mind* concludes with an extended polemic against the 'historical, structural anthropology' that Jean-Paul Sartre had advocated in the introduction to his *Critique of Dialectical Reason*. Sartre had no time for totemists.

His anthropology would instead rest with the charting, and the heightening, of 'historical consciousness.' Against it, Lévi-Strauss had two general rejoinders. The first was that 'historical consciousness' was the expression not of dawning wisdom but instead of a collective devotion to 'development,' and its absence not the expression of error but instead of a collective devotion to homeostasis. Some societies ran historically 'hot'; others ran 'cold.' All were equally human. The second was that history—as narrative, as diachronic interpretation—was always 'history-for,' always biased. Stripped of its bias, it amounted to nothing more than the methodical application of temporal scales of measure to the flow of human and nonhuman events alike. If not that, then it amounted simply to the preliminary 'cataloging' with which any 'quest for intelligibility'—the anthropological quest included—had to begin. But it could be a beginning only: 'as we say of certain careers, history may lead to anything, provided you get out of it' (Lévi-Strauss 1966).

In the face of much criticism, Lévi-Strauss has granted that his division between 'hot' and 'cold' societies was in need of much refinement. He has not, however, retreated from his division between historical and properly anthropological knowledge. On the contrary: from the outset of his career, he has counted history consistently among those disciplines limited to the merely statistical representation and analysis of their objects. His anthropology is for its part a model-theoretic discipline, an axiomatic and deductive science. Its object remains what it was for Tylor: the psyche. Its quest, however, culminates not in the hypothetical reconstruction of the path toward enlightened modernity but instead in the formal exegesis of the universal 'grammar,' the structural and structuring properties, of the mind itself. 'Structuralism,' thus construed, is far less influential than it was in the 1960s, but by no means bereft. In cognitive anthropology, it has its most secure contemporary home; and there, history (as intellectual or epistemological paragon) continues to meet with a cool reception.

For Lévi-Strauss as for other philosophical and scientific rationalists, there is an insuperable gap between 'the facts' and their theoretical intelligibility. For positivists and empiricists, the relation between facts and theories is putatively more seamless. Unabashedly positivist anthropologists are a rather rare breed at present, at least in the sociocultural field, though many cultural materialists and evolutionary psychologists might quietly reckon themselves as such. The positivist anthropology of historical consciousness or the 'historical sensibility' is rare indeed, but has a singularly unabashed spokesperson in Donald Brown. In *History, Hierarchy, and Human Nature* (1988), Brown offers a cross-cultural survey of those traits—from divination to record-keeping—most suggestive of a preoccupation with the meaning and significance of events. Among literate peoples, he discerns a relatively stable correlation: between the presence and prominence of such a preoccupation and the absence of caste or other fixed hierarchies. He concludes that history (as sensibility, as worldview, and as mode of inquiry) takes its most regular nourishment from an ideology of social mobility. Whether or not correct, the conclusion is compatible with Lévi-Strauss's own considered judgments. Here, too, the anthropologist takes history as his analytical object.

Sahlins offers an alternative, which also takes history as its analytical object—but further as its analytical mode. It preserves the structuralist principle that systems of signification are never mere derivatives of their social or material environment. Yet it casts them less as revelations of the grammar of the psyche than as interfaces or differentials between the past and the future of given social practice. Their effect is threefold. First, they determine the internal historical 'temperature' of practice, which is relatively colder when governed by prescriptions, warmer when not. Second, they vary in their capacity to accommodate potentially anomalous or disruptive events. They are in other words more or less historically 'sensitive,' and the greater their sensitivity, the more the continuity of practice is itself at risk. Finally, they influence the symbolic 'weight' or import of actors and their acts. Where some men are 'kings,' and their authority unchallenged, the historian is right to monitor them with especial care; where democracy holds sway, they would do better to monitor status groups or classes or parties. Hence, the best historian should be a good anthropologist, and the best anthropologist always prepared to be a good historian as well (Sahlins 1985).

Sahlins's standard of goodness is still the standard of objective accuracy. It thus stands in partial contrast to the standard that has at least implicitly guided interpretive anthropology since the Boasian 'golden age.' Though subject to diverse formulations—some more vividly critical than others—the latter standard is practical or pragmatic, a matter of consequences. Perhaps for a majority of interpretive anthropologists, it has been nothing short of 'liberation'—whether from psycho-sexual repression, as for Benedict and Margaret Mead, or from political domination and economic exploitation, as for Scholte. Many of its prominent inflections remain reformist, though of more qualified scope. For the Geertzian, however, the pragmatic proof of an interpretation lies in its facilitating conversation, its translational efficacy.

For others, it lies in a broadening or enrichment of our imagination of the ways of being human. For a few others still, it lies in therapeutic release—perhaps from prejudice, perhaps from alienated isolation. Interpretation must in every case be informed factually; but at its best, is always also 'informative.' Its analytical mode is historical; but however much Lévi-Strauss or Sahlins might disapprove, it is always also 'history-for' and 'anthropology-for' alike. The interpretive history of anthropology and the interpretive anthropology of history must, moreover, occupy the same epistemological plane. For the interpreter, historical and anthropological knowledge are of precisely the same kind.

History, then, is not simply a thing of many refractions. It is also a thing of plural and incompatible anthropological estimations. These in turn are among the most telling indices of plural and incompatible visions of the basic enterprise of anthropology itself. One can hence condemn the discipline for its intellectual indecisiveness or incoherence. Or one can applaud it for its perspectival diversity. One can in any event note that its many byways have a common point of departure—in the question of whether human nature itself is transhistorically fixed, or instead historically variable. This is anthropology's first question, and if the past is any indication of the future, it is likely to remain so—at least until either Man, or history, comes to an end.

Anthropology, History of

Social or cultural anthropology can be defined, loosely and broadly, as the comparative science of culture and society, and it is the only major discipline in the social sciences that has concentrated most of its attention on non-Western people. Although many of the classic problems investigated by anthropologists are familiar to the European history of ideas, the subject as it is known today emerged only in the early twentieth century, became institutionalized at universities in the Western world in mid-century, and underwent a phenomenal growth and diversification in the latter half of the century.

1. Foundations and Early Schools

1.1 Proto-anthropology

Interest in cultural variation and human universals can be found as far back in history as the Greek city-state. The historian Herodotos (fifth century BC) wrote accounts of 'barbarian' peoples to the east and north of the peninsula, comparing their customs and beliefs to those of Athens, and the group of philosophers known as the Sophists were perhaps the first philosophical relativists, arguing (as many twentieth century anthropologists later did) that there can be no absolute truth because, as one would put it today, truth is contextual. Yet their interest in cultural variation fell short of being scientific, chiefly because Herodotos lacked theory while the Sophists lacked empirical material.

Centuries later, scholarly interest in cultural variation and human nature re-emerged in Europe because of the new intellectual freedom of the Renaissance and questions arising from European overseas exploits. Michel de Montaigne (sixteenth century), Thomas Hobbes (seventeenth century), and Giambattista Vico (eighteenth century) were among the thinkers of the early modern era who tried to account for cultural variability and global cultural history as well as dealing with the challenge from relativism. Eighteenth century philosophers such as Locke, Hume, Kant, Montesquieu, and Rousseau developed theories of human nature, moral philosophies, and social theories, taking into account an awareness of cultural differences. The early German romantic Herder challenged Voltaire's universalistic vision by arguing that each people (*Volk*) had a right to retaining its own, unique values and customs—in a manner reminiscent of later cultural relativism romanticism. Indeed, by the end of the eighteenth century, several of the general questions still raised by anthropologists had already been raised: Universalism versus relativism (what is common to humanity; what is culturally specific), ethnocentrism versus cultural relativism (moral judgments versus neutral descriptions of other peoples), and humanity versus the rest of the animal kingdom (culture versus nature). Twentieth century anthropology has taught that these and other essentially philosophical problems are best investigated through the detailed study of living people in existing societies through ethnographic fieldwork, and by applying carefully devised methods of comparison to the bewildering variety of 'customs and beliefs.' It would

take several generations after Montesquieu's comparative musings about Persia and France, in his *Lettres persanes*, before anthropology achieved this mark of scientific endeavor.

1.2 Victorian Anthropology

The first general theories of cultural variation to enjoy a lasting influence were arguably those of two men trained as lawyers: Henry Maine (1822–88) in Britain and Lewis Henry Morgan (1818–82) in the USA. Both presented evolutionist models of variation and change, where Western European societies were seen as the pinnacle of human development. In his *Ancient Law* (1861), Maine distinguished between *status* and *contract* societies, a divide which corresponds roughly to later dichotomies between traditional and modern societies, or, in the late nineteenth-century German sociologist Ferdinand Tönnies' terminology, *Gemeinschaft* (community) and *Gesellschaft* (society); status societies are assumed to operate on the basis of kinship and myth, while individual merit and achievement are decisive in contract societies. Although simple contrasts of this kind have regularly been severely criticized, they continue to exert a certain influence on anthropological thinking (see *Evolutionism, Including Social Darwinism*).

Morgan's contributions to anthropology were wide-ranging and, among other things, he wrote a detailed ethnography of the Iroquois. His evolutionary scheme, presented in *Ancient Society* (1877), which influenced Marx and Engels, distinguished between seven stages (from lower savagery to civilization). His materialist account of cultural change influenced Marx and Engels. His pioneering work on kinship divided kinship systems into a limited number of types, and saw kinship terminology as a key to understanding society. Writing in the same period, the historian of religion Robertson Smith and the lawyer J.J. Bachofen offered, respectively, theories of monotheistic religion and of the (wrongly assumed) historical transition from matriliny to patriliny.

An untypical scholar in the otherwise evolutionist Victorian era, the German ethnologist Adolf Bastian (1826–1905) reacted against simplistic typological schemata. Drawing inspiration from Herderian romanticism and the humanistic tradition in German academia, Bastian wrote prolifically on cultural history, avoiding unwarranted generalizations, yet he held that all humans have the same pattern of thinking, thus anticipating structuralism.

The leading British anthropologist of the late Victorian era was Edward Tylor (1832–1917), whose writings include a famous definition of culture (dating from 1871), seeing it as the sum total of collective human achievements (thus contrasting it to nature). Tylor's student James Frazer (1854–1941) published the massive and very influential *Golden Bough* (1890, rev. ed. 1911–15), an ambitious comparative study of myth and religion.

Intellectual developments outside anthropology in the second half of the nineteenth century also had a powerful impact. Charles Darwin's theory of natural selection, first presented in his *Origin of Species* from 1859, would both be seen as a condition for anthropology (positing that all humans are closely related) and, later, as a threat to it (arguing the primacy of the biological over the cultural). The emergence of classic sociological theory in the works of Comte, Marx, and Tönnies, and later Durkheim, Weber, Pareto, and Simmel, provided anthropologists with general theories of society, although their applicability to non-European societies continues to be disputed (see *Sociology, History of*).

The quality of the data used by the early anthropologists was variable. Most of them relied on written sources, ranging from missionaries' accounts to travelogues of varying accuracy. The need for more reliable data began to make itself felt. Expeditions and systematic surveys now provided researchers around the turn of the twentieth century with improved knowledge of cultural variation, which eventually led to the downfall of the ambitious theories of unilineal evolution characteristic of nineteenth-century anthropology.

An Austro-German specialty proposed both as an alternative and a complement to evolutionist thinking, was diffusionism, the doctrine of the historical diffusion of cultural traits. Never a part of the mainstream outside of the German-speaking world, elaborate theories of cultural diffusion continued to thrive, particularly in Berlin and Vienna, until after World War II. As there were serious problems of verification associated with the theory, it was condemned as speculative by anthropologists committed to fieldwork and, furthermore, research priorities were to shift from general cultural history to intensive studies of particular societies.

In spite of theoretical developments and methodological refinements, the emergence of anthropology, as the discipline is known today, is rightly associated with four scholars working in three countries in the early decades of the twentiethth century: Franz Boas in the USA, A.R. Radcliffe-Brown and Bronislaw Malinowski in the UK, and Marcel Mauss in France.

1.3 Boas and Cultural Relativism

Boas (1858–1942), a German migrant to the USA who had briefly studied anthropology with Bastian, carried out research among Eskimos and Kwakiutl Indians in the 1890s. In his teaching and professional leadership, he strengthened the 'four-field approach' in American anthropology, which still sets it apart from European anthropology, including both cultural and social anthropology, physical anthropology, archaeology,

and linguistics. Although cultural relativism had been introduced more than a century before, it was Boas who made it a central premise for anthropological research. Against the evolutionists, he argued that each culture had to be understood in its own terms and that it would be scientifically misleading to rank other cultures according to a Western, ethnocentric typology gauging 'levels of development.' Boas also promoted *historical particularism*, the view that all societies or cultures had a unique history that could not be reduced to a category in some universalistic scheme. On related grounds, Boas argued incessantly against the claims of *racist* pseudoscience (see *Race: History of the Concept*).

Perhaps because of his particularism, Boas never systematized his ideas in a theoretical treatise. Several of his students and associates nevertheless did develop general theories of culture, notably Ruth Benedict, Alfred Kroeber, and Robert Lowie. His most famous student was Margaret Mead (1901–78). Although her best-selling books on Pacific societies have been criticized for being superficial, she used material from non-Western societies to raise questions about gender relations, socialization, and politics in the West, and Mead's work indicates the potential of cultural criticism inherent in the discipline.

One of Boas' most remarkable associates, the linguist Edward Sapir (1884–1939), formulated, with his student Benjamin Lee Whorf, the Sapir–Whorf hypothesis, which posits that language determines cognition. Consistent with a radical cultural relativism, the hypothesis implies that, for example, the Hopi perceive the world in a fundamentally different way from Westerners, due to differences in the structure of their respective languages.

1.4 The Two British Schools

While modern American anthropology had been shaped by the Boasians and their relativist concerns, as well as the perceived need to record native cultures before their anticipated disappearance, the situation in the major colonial power, Great Britain, was different. The degree of complicity between colonial agencies and anthropologists is debatable, but the very fact of imperialism was an inescapable premise for British anthropology until after World War II.

The man who is often hailed as the founder of modern British social anthropology was a Polish immigrant, Bronislaw Malinowski (1884–1942), whose over two years of fieldwork in the Trobriand Islands (between 1914 and 1918) set a standard for ethnographic data collection that is still largely unchallenged. Malinowski argued the need to learn the local language properly and to engage in everyday life, in order to see the world from the actor's point of view and to understand the interconnections between social institutions and cultural notions. Malinowski placed an unusual emphasis on the acting individual, seeing social structure not as a determinant of but as a framework for action, and he wrote about a wide range of topics, from garden magic, economics, and sex to the puzzling *kula* trade. Although he dealt with issues of general concern, he nearly always took his point of departure in his Trobriand ethnography, demonstrating a method of generalization very different from that of the previous generation with its scant local knowledge.

The other major British anthropologist of the time was A.R. Radcliffe-Brown (1881–1955). An admirer of Durkheim's sociology, Radcliffe-Brown did relatively little fieldwork himself, but aimed at the development of a 'natural science of society' where universal laws of social life could be formulated. His theory, known as structural-functionalism, saw the individual as unimportant, emphasizing instead the social institutions (kinship, norms, politics, etc.). Most social and cultural phenomena were seen as functional in the sense that they contributed to the maintenance of the overall social structure (see *Functionalism in Anthropology*).

Despite their differences in emphasis, both British schools had a sociological concern in common (which they did not share with most Americans), and tended to see social institutions as functionally integrative. Both rejected the wide-ranging claims of diffusionism and evolutionism, and yet, the tension between structural explanations and actor-centered accounts remains strong in British anthropology even today.

Malinowski's students included Raymond Firth, Audrey Richards, and Isaac Schapera, while Radcliffe-Brown, in addition to enlisting E.E. Evans-Pritchard and Meyer Fortes—arguably the most powerful British anthropologists in the 1950s—on his side, taught widely, and introduced structural-functionalism to several foreign universities. British interwar anthropology was characteristically oriented towards kinship, politics, and economics, with Evans-Pritchard's masterpiece *The Nuer* (1940) demonstrating the intellectual power of a discipline combining detailed ethnography, comparison, and elegant models. Later, his models would be criticized for being too elegant to fit the facts on the ground—a very Malinowskian objection.

1.5 Mauss

No fieldwork-based anthropology developed in the German-speaking region, and German anthropology was marginalized after World War II. In France, the situation was different. Already in 1902, Durkheim had published, with his nephew Marcel Mauss (1872–1950), an important treatise on primitive classification; in 1908, Arnold van Gennep published *Les Rites de Passage*, an important analysis of initiation rites, and Lucien Lévy-Bruhl elucidated a theory, later refuted by both Evans-Pritchard, Mauss and others, on the

'primitive mind,' which he held to be 'pre-logical.' New empirical material of high quality was being produced by thorough observers such as Maurice Leenhardt in New Caledonia and Marcel Griaule in West Africa.

Less methodologically purist than the emerging British traditions and more philosophically adventurous than the Americans, interwar French anthropology, under the leadership of Mauss, developed a distinct flavor, witnessed in the influential journal *L'Année Sociologique*, founded by Durkheim and edited by Mauss after Durkheim's death in 1917. Drawing on his vast knowledge of languages, cultural history, and ethnography, Mauss, who never did fieldwork himself, wrote several learned, original, compact essays ranging from gift exchange (*Essai sur le Don*, 1924) to the nation, the body, and the concept of the person. Mauss' theoretical position was complex. He believed in systematic comparison and the existence of recurrent patterns in social life at all times and in all places, yet he often defended relativist views in his reasoning about similarities and differences between societies.

Not a prolific writer, Mauss exerted an enormous influence on later French anthropology through his teaching. Among his students and associates were most of the major French anthropologists at the time, and the three leading postwar scholars in the field—Louis Dumont, Claude Lévi-Strauss, and Georges Balandier—were all deeply indebted to Mauss.

1.6 Some General Points

The transition from evolutionist theory and grand syntheses to more specific, detailed, and empirically founded work, in reality amounted to an intellectual revolution. The work of Tylor and Morgan had been relegated to the mists of history, and the discipline had been taken over by small groups of scholars who saw intensive fieldwork, cultural relativism, the study of single societies, and rigorous comparison as its essence. Today, the academic institutions, the conferences, and the learned journals all build on the anthropology of Boas, Malinowski, Radcliffe-Brown, and Mauss. This is to a great extent also true of the anthropological traditions of other countries (Vermeulen and Roldán 1995), including India, Australia, Mexico, Argentina, The Netherlands, Spain, and Scandinavia. Soviet/Russian and East European anthropologies have followed different itineraries, retaining a connection with the German *Volkskunde* tradition.

2. Anthropology in the Second Half of the Twentieth Century

The numbers of anthropologists and institutions devoted to teaching and research in the field grew rapidly after World War II. The discipline diversified. New specializations such as psychological anthropology, political anthropology, and the anthropology of ritual emerged, and the geographical foci of the discipline multiplied: whereas the Pacific had been the most fertile area for theoretical developments in the 1920s and Africa had played a similar part in the 1930s and 1940s, while the preoccupation with North American Indians had been stable throughout, the 1950s saw a growing interest in the 'hybrid' societies of Latin America and the Caribbean as well as the anthropology of India and South-East Asia, and the New Guinean highlands became similarly important in the 1960s. Such shifts in spatial emphasis had consequences for theoretical developments, as each region posed its own peculiar problems.

From the 1950s, the end of colonialism also affected anthropology, both in a banal sense—it became more difficult to obtain research permits—and more profoundly, as the subject–object relationship between the observer and the observed became problematic as the traditionally 'observed' peoples increasingly had their own intellectuals and spokespersons who frequently objected to Western interpretations of their way of life.

2.1 Structuralism

The first major theory to emerge after World War II was Claude Lévi-Strauss' structuralism. Lévi-Strauss (1908–) developed an original theory of the human mind, drawing on structural linguistics, Mauss' theory of exchange and Lévy-Bruhl's theory of the primitive mind (which Lévi-Strauss opposed). His first major work, *Les Structures Elémentaires de la Parenté* (*The Elementary Structures of Kinship*, 1949), introduced a grammatical, formal way of thinking about kinship, with particular reference to systems of marriage (the exchange of women between groups). Lévi-Strauss later expanded his theory to cover totemism, myth, and art. Never uncontroversial, structuralism had an enormous impact on French intellectual life far beyond the confines of anthropology. In the English-speaking world, the reception of structuralism was delayed, as Lévi-Strauss' major works were not translated until the 1960s, but he had his admirers and detractors from the beginning. Structuralism was criticized for being untestable, positing as it did certain unprovable and unfalsifiable properties of the human mind (most famously the propensity to think in terms of contrasts or binary oppositions), but many saw Lévi-Strauss' work, ultimately committed to human universals, as an immense source of inspiration in the study of symbolic systems such as knowledge and myth (see *Structuralism, History of*).

A different, and for a long time less influential, brand of structuralism was developed by Louis Dumont (1911–99), an Indianist and Sanskrit scholar who did fieldwork both in the Aryan north and the Dravidian south. Dumont, closer to Durkheim than

Lévi-Strauss, argued in his major work on the Indian caste system, *Homo Hierarchicus* (1969), for a holistic perspective (as opposed to an individualistic one), claiming that Indians (and by extension, many non-modern peoples) saw themselves not as 'free individuals' but as actors irretrievably enmeshed in a web of commitments and social relations, which in the Indian case was clearly hierarchical.

Most later, major French anthropologists have been associated with Lévi-Strauss, Dumont, or Balandier, the Africanist whose work in political anthropology simultaneously bridged gaps between France and the Anglo-Saxon world and inspired both neo-Marxist research and applied anthropology devoted to development.

2.2 Reactions to Structural-functionalism

In Britain and her colonies, the structural-functionalism now associated chiefly with Evans-Pritchard and Fortes was under pressure after the war. Indeed, Evans-Pritchard himself repudiated his former views in 1949, arguing that the search for 'natural laws of society' had been shown to be futile and that anthropology should fashion itself as a humanities discipline rather than a natural science. Retrospectively, this statement has often been quoted as marking a shift 'from function to meaning' in the discipline's priorities; Kroeber expressed similar views in the USA. Others found other paths away from what was increasingly seen as a conceptual straitjacket. Edmund R. Leach, whose *Political Systems of Highland Burma* (1954) suggested a departure from functionalist orthodoxies, notably Radcliffe-Brown's dictum that social systems tend to be in equilibrium and Malinowski's view of myths as integrating 'social charters', would later be a promoter and critic of structuralism in Britain. Leach's contemporary Raymond Firth proposed a distinction between social structure (the statuses in society) and social organization, which he saw as the actual process of social life, whereby choice and individual whims were related to structural constraints. Later in the 1950s and 1960s, several younger social anthropologists, notably F.G. Bailey and Fredrik Barth, followed Firth's lead as well as the theory of games (a recent development in economics) in refining an actor-centered perspective on social life. Max Gluckman, a former student of Radcliffe-Brown and a close associate of Evans-Pritchard, also abandoned the strong holist program of the structural-functionalists, reconceptualizing social structure as a loose set of constraints, while emphasizing the importance of individual actors. Gluckman's colleagues included several important Africanists, such as A.L. Epstein, J. Clyde Mitchell, and Elizabeth Colson. Working in southern Africa, this group pioneered urban anthropology and ethnicity studies in the 1950s and 1960s.

2.3 Neo-evolutionism, Cultural Ecology and Neo-Marxism

The number of anthropologists has always been larger in the USA than anywhere else, and the discipline was always diverse there. Although the influence from the Boasian cultural relativist school remains strong, other groups of scholars have also made their mark. From the late 1940s onwards, a resurgent interest in Morgan's evolutionism led to the formulation of neoevolutionist and materialist research programs. Julian Steward, a student of Robert Redfield (who had been a student of Radcliffe-Brown), proposed a theory of cultural dynamics distinguishing between 'the cultural core' (basic institutions such as the division of labor) and 'the rest of culture' in a way strongly reminiscent of Marx. Steward led research projects among Latin American peasants and North American Indians, encouraging a focus on the relationship between culture, technology, and the environment. Leslie White held more deterministic materialist views, but also—perhaps oddly—saw symbolic culture as a largely autonomous realm. Among the major scholars influenced by White, Marvin Harris has strengthened his materialist determinism, while Marshall D. Sahlins in the 1960s made the move from neoevolutionism to a symbolic anthropology influenced by structuralism.

Cultural ecology sprang from the teachings of Steward and White, and represented a rare collaboration between anthropology and biology. Especially in the 1960s, many such studies were carried out, including, notably, Roy Rappaport's *Pigs for the Ancestors* (1968), an attempt to account for a recurrent ritual in the New Guinean highlands in ecological terms. The upsurge of Marxist peasant research, especially in Latin America, in the 1970s, was also clearly indebted to Steward.

The appearance of radical student politics in the late 1960s, which had an impact on academia until the early 1980s, had a strong, if passing, influence on anthropology. Of the more lasting contributions, the peasant studies initiated by Steward and furthered by Eric Wolf, Sidney Mintz, and others must be mentioned, along with French attempts, represented in the very sophisticated work of Maurice Godelier and Claude Meillassoux, at synthesizing Lévi-Straussian structuralism, Althusserian Marxism, and anthropological comparison. Although Marxism and structuralism eventually became unfashionable, scholars—particularly those engaged in applied work—continue to draw inspiration from Marxist thought (see *Marxist Social Thought, History of*).

2.4 Symbolic and Cognitive Anthropology

More true to the Boasian legacy than the materialist approaches, studies of cognition and symbolic systems developed and diversified in the USA. A leading theorist is Clifford Geertz, who wrote a string of

influential essays advocating hermeneutics (interpretive method) in the 1960s and 1970s (see *Hermeneutics, History of*). While his originality as a theorist can be questioned, his originality as a writer is obvious, and Geertz ranks as perhaps the finest writer of contemporary anthropology. Marshall Sahlins is, with Geertz, the foremost proponent of cultural relativism today, and has published a number of important books on various subjects (from Mauss' theory of exchange to sociobiology and the death of Captain Cook), consistently stressing the autonomy of the symbolic realm, thus arguing that cultural variation cannot be explained by recourse to ecology, technology, or biology.

In Britain, too, interest in meaning, symbols, and cognition grew after the war, especially from the 1960s (partly due to the belated reception of Lévi-Strauss). British anthropology had hitherto been strongly sociological, and two scholars who fused the legacy from structural-functionalism with the study of symbols and meaning were Mary Douglas and Victor Turner. Taking his cue from van Gennep, Turner, a former associate of Gluckman, developed a complex analysis of rituals among the Ndembu of Zambia, showing their functionally integrating aspects, their meaningful aspects for the participants, and their deeper symbolic significance. Douglas, a student of Evans-Pritchard, famous for her *Purity and Danger* (1966), analyzed the human preoccupation with dirt and impurities as a way of thinking about the boundaries of society and the nature/culture divide. Prolific and original, Douglas is a major defender of a reformed structural-functionalism.

Against all these (and other) perspectives regarding how 'cultures' or 'societies' perceive the world, anthropologists emphasizing the actor's point of view have argued that no two individuals see the world in the same way and that it is preposterous to generalize about societies. The impact of feminism has been decisive here. Since the 1970s, feminist anthropologists have identified often profound differences between male and female world-views, indicating how classic accounts of 'societies' really refer to male perspectives on them as both the anthropologist and the main informants tended to be male. For example, in a restudy of Trobriand society undertaken in the 1970s and 1980s, Annette Weiner showed that Malinowski's famous work was ultimately misleading as he had failed to observe important social processes confined to females.

2.5 Anthropology and the Contemporary World

Since the pillars of modern anthropology were erected around the First World War, the former colonies became independent, 'natives' got their own educated elites (including social scientists), economic and cultural globalization led to the spread of capitalism and consumer culture, and transcontinental migration blurred the boundaries between the traditional 'us' and 'them.' This situation entailed new challenges for anthropology, which were met in various ways—revealing continuities as well as breaks with the past.

A late field to be incorporated into anthropology, but one that became the largest single area of interest from the 1970s, was the study of identity politics, notably ethnicity and nationalism. Since the publication of several important texts around 1970 (by, *inter alia*, Barth and Abner Cohen in Europe, and George DeVos in the USA), anthropological ethnicity studies investigated the interrelationship between ethnic identity and ethnic politics, and explored how notions of cultural differences contribute to group identification. Since the publication of several important texts on nationalism in the early 1980s (by Ernest Gellner, Benedict Anderson and others), this also became an important area for anthropologists. Ethnicity and nationalism are partly or wholly modern phenomena associated with the state, and thus denote a departure from the former mainstay of anthropology, the study of nonmodern small-scale societies. While ethnicity and (especially) nationalism could not be studied through participant-observation only (other kinds of data are required), it was evident that anthropologists who engaged in this field remained committed to the classic tenets of the discipline; ethnographic fieldwork, comparison, and a systemic view of social reality. Also, the study of identity politics emerged as an interdisciplinary field where anthropologists, sociologists, historians, and political scientists profited from each other's expertise.

Other modern phenomena also received increased attention in anthropology from the 1970s, including consumption, 'subcultures,' wagework, and migration. The boundary between the 'Western self' and the 'non-Western other' became blurred. Anthropological studies of Western societies became common, and Europe was established as an ethnographic region along with West Africa, South Asia, and so on. Even anthropologists working in traditional settings with classic topics increasingly had to see their field as enmeshed, to a greater or lesser extent, in a global system of communication and exchange.

Because of the increased penetration of the formerly tribal world by capitalism and the state, and accompanying processes of cultural change, there was a growing demand for a reconceptualization of culture in the 1980s and 1990s, and scholars such as Ulf Hannerz and Marilyn Strathern developed fluid concepts of culture seeing it as less coherent, less bounded, and less integrated than the Boasian and Malinowskian traditions implied.

Some scholars saw the postcolonial situation as sounding the death knell of anthropology: Since the 'primitive' was gone, and the former informants were now able to identify and describe themselves (they no longer needed anthropologists to do it), the science of

cultural variation seemed to have lost its *raison d'être*. Following the lead of Edward Said's *Orientalism* (1978), an influential critique of Western depictions of the 'East', and often inspired by Michel Foucault, they saw anthropology as a colonial and imperialist enterprise refusing non-Western peoples a voice of their own and magnifying the distance between 'us' and 'them.' Especially in the late 1980s and early 1990s, this view had many followers, some of whom abandoned empirical research, while others tried to incorporate the autocriticism into their work. Yet others saw these pessimistic views as largely irrelevant, since anthropology had always been fraught with similar tensions, to which each new generation found its solutions. In this regard, it must be pointed out that the earlier feminist critique of anthropology, far from repudiating the subject, led to its enriching by adding new implements to its toolbox and new dimensions to its worldview. The same could be said of the reconceptualizations of culture, which arguably offered an improved accuracy of description (see *Postcoloniality*).

3. The Situation at the Turn of the Millennium

Over the course of the twentieth century, anthropology became a varied discipline with a strong academic foothold in all continents, although its centers remained in the English- and French-speaking countries. It was still possible to discern differences between American cultural anthropology, British social anthropology, and French *ethnologie*, but the discipline was more unified than ever before—not in its views, but in its approaches. Hardly a part of the world had not now been studied intensively by scholars engaging in ethnographic fieldwork, but since the world changes, new research is always called for.

Specializations proliferated, ranging from studies of ethnomedicine and the body to urban consumer culture, advertising, and cyberspace. Although the grand theories of the nineteenth and twentieth centuries—from unilinear evolutionism to structuralism—had been abandoned, new theories claiming to provide a unified view of humanity were being proposed; for example, new advances in evolutionary psychology and cognitive science offered ambitious general accounts of social life and the human mind, respectively. The problems confronting earlier generations of anthropologists, regarding, for example, the nature of social organization, of knowledge, of kinship, and of myth and ritual, remained central to the discipline although they were explored in new empirical settings by scholars who were more specialized than their predecessors.

Anthropology has thrived on the tension between the particular and the universal; between the intensive study of local life and the quest for general accounts of the human condition. Is it chiefly a generalizing science or a discipline devoted to the elucidation of the unique? The general answer is that anthropologists ultimately do study Society, Culture, and Humanity, but that in order to do so, they must devote most of their energies to the study of societies, cultures, and humans. As long as their mutual differences and similarities are not fully understood, there will be an intellectual space in the world for anthropology or, at least, a discipline like it (see *Anthropology*; *Spatial Thinking in the Social Sciences, History of*).

Antidepressant Drugs

Because of historical developments, a stringent classification for all available agents with antidepressant properties has not yet been agreed upon. Initial classificatory attempts focused on the chemical structure of the drugs. Recent classifications emphasize the pharmacological profile of the drug. This latter approach is of greater clinical relevance, because it depicts the primary target sites in the central nervous system (e.g. transporter proteins or various receptor subtypes), allowing a better prediction of the potential clinical application and the side-effect profile of the drug. As a result of both approaches, many clinicians today distinguish the following groups of antidepressants: (a) monoaminooxidase inhibitors (MAOI), (b)

tricyclic antidepressants (TCA), (c) selective serotonin reuptake inhibitors (SSRI), and (d) antidepressants with different pharmacological profiles.

1. History

1.1 MAOI

Iproniazid and its precursor isoniazid had been developed in the laboratories of the company Hoffmann-La Roche primarily as antituberculosis agents. As a consequence of casuistic observations on mood-elevating properties of iproniazid, this effect was first confirmed by Loomer and colleagues (1957) in a clinical trial. However, significant hepatotoxicity was observed during iproniazid treatment. Subsequent development of drugs inhibiting MAO systems led to the introduction of isocarboxazid, phenelzine and tranylcypromine as irreversible inhibitors of MAO. Their use has been limited because of possible hypertensive crises after ingestion of food containing large amounts of tyramine, forcing patients to follow dietary restrictions during pharmacotherapy with these drugs. This led to the development of reversible MAOI such as moclobemide, which no longer required dietary restrictions.

1.2 TCA

After the discovery of the antipsychotic effects of chlorpromazine in 1952, the compound G22355, later called imipramine, was developed in the laboratories of the company Geigy. Imipramine was a derivative of chlorpromazine and was first tested in clinical trials in schizophrenia. While no relevant antipsychotic effects were noted, mood-elevating effects in patients with a co-occurring depressive syndrome were observed. At this point, both the company and the clinical investigator Kuhn decided to test imipramine in patients with depression as a potential antidepressant. The results of the clinical trials were first published in 1957, and are still a remarkable document of skillful clinical observation, as the report contains many details about the antidepressant effects of imipramine which still hold true today (Kuhn 1957).

A variety of compounds that were chemically related to imipramine have been developed. They all shared the basic chemical structure of a tricyclus. Subsequent research revealed that in most instances, while the tricyclic basal structure was preserved, minor alterations of its side chains resulted in markedly different pharmacological profiles of the drugs. The chemically related compound maprotiline, often termed a tetracyclic, was developed as a consequence of systematic variation of the tricyclic structure.

From the 1960s to the 1980s, the TCA were the dominating group of antidepressants in clinical practice throughout the world. As many of the TCA compounds induce substantial side effects, they gradually lost their predominance with the availability of the SSRI during the 1990s.

1.3 SSRI

In the 1970s, on the basis of increasing knowledge about the mechanism of action of MAOI and TCA, pathophysiological models of depression were proposed. Consequently, potential antidepressants with more specific neurotransmitter receptor effects were developed. According to the norepinephrine depletion hypothesis of depression, drugs to selectively potentiate central noradrenergic neurotransmission were developed. On the other hand, the various available TCA were scrutinized for their potency of serotonin reuptake inhibition. Clomipramine was shown to have the strongest effects on serotonin reuptake inhibition; however, the substance does not selectively inhibit the serotonin transporter but also shows effects on norepinephrine.

Subsequently, in a collaboration between a pharmaceutical company (Astra) and the research team of Carlson in Sweden, the first SSRI zimelidine was developed. The first results from a clinical trial on zimelidine were published in 1977 (Benkert et al. 1977). However, the antidepressant had to be dropped from the market because of the emergence of neurological side effects.

In the 1980s, fluoxetine ('Prozac'), an SSRI developed by Eli-Lilly Company, was made available in the USA. The introduction of this drug represents the breakthrough of SSRIs in the treatment of depression. Successful marketing strategies and the low toxicity of fluoxetine may explain the broad spectrum of indications for this drug. The prescription of fluoxetine in patients with personality disorders and, finally, the use of Prozac by healthy people to improve their general wellbeing, led to an ongoing discussion regarding the acceptability of so-called 'life-style' drugs.

In the following years, four additional SSRIs were approved: fluvoxamine, paroxetine, sertraline, and citalopram. The latter two substances have favorable pharmacokinetics and a low risk for drug–drug interactions—an issue that became increasingly important in the 1990s.

1.4 Antidepressants With Different Pharmacological Profiles

The introduction of selective antidepressants reduced the rate of unwanted side effects. The higher selectivity of these drugs was, however, not accompanied by higher efficacy. Therefore, research and drug development focused on compounds which exerted their effects on different and interrelated neurotransmitter

receptors in the brain to enhance their benefit: risk ratio based on theoretical reasoning about the anticipated profile of effects and side effects.

The push to develop highly selective antidepressants targeting a single type of neurotransmitter receptor or transporter had ended. Highly effective and well-tolerated drugs like mirtazapine and venlafaxine are examples of the new strategy of drug design.

Rather independent from this line of progress, the herbal St. John's Wort has achieved great popularity throughout the world, based on the drug's low toxicity, its high acceptance, and a proven efficacy in the treatment of mild to moderate depression. The exact mechanism of action is not completely known.

2. *Mechanism of Action of Antidepressants*

There is considerable evidence that many antidepressants facilitate neurotransmission of one or more monoamines—serotonin, norepinephrine, or dopamine. This effect appears to be mediated by different mechanisms:

(a) blockade of one or more types of synaptic monoamine transporters;

(b) blockade of the enzymes that inactivate monoamines;

(c) stimulation and/or blockade of receptor subtypes.

2.1 *Blockade of One or More Types of Synaptic Monoamine Transporters*

Synaptic monoamine transporters are protein structures which rapidly retrieve released neurotransmitter molecules from the synaptic cleft into the originating neuron. By specifically blocking the transporter, the reuptake of the neurotransmitter is hampered, thus increasing its availability in the synapse. Examples of compounds that predominantly or selectively inhibit the reuptake of serotonin are the SSRI listed above, or the tricyclic compound clomipramine. Drugs predominantly or selectively inhibiting the norepinephrine reuptake are reboxetine, and the tricyclic compounds desipramine and nortriptyline. Many antidepressants block both the serotonin and norepinephrine transporter, more or less with the same potency, e.g. imipramine, amitriptyline, doxepine, milnacipran, or venlafaxine. Examples of dopamine reuptake inhibitors are bupropion (also affecting norepinephrine uptake), or amineptine.

2.2 *Blockade of the Enzymes that Inactivate Monoamines*

The main enzyme relevant in this context is the MAO. Its isoform MAO-A degrades mainly serotonin and norepinephrine, while MAO-B predominantly metabolizes dopamine. MAO can be blocked irreversibly and unselectively by compounds such as phenelzine or tranylcypromine. Reversible MAO-A inhibitors such as moclobemide selectively block the metabolism of serotonin and norepinephrine within therapeutic ranges. Selective MAO-B inhibitors have not consistently proved to be antidepressants.

2.3 *Stimulation and/or Blockade of Receptor Subtypes*

In this category, various compounds with different modes of action are mentioned. From the tricyclic compounds, trimipramine blocks dopamine D2, alpha-1-adrenergic H1-histaminergic and muscarinic receptors without any substantial effect on monoamine transporters. Mirtazapine blocks alpha-1 and 2-adrenergic receptors, as well as 5-HT_2 and 5-HT_3 and H1 histaminergic receptors. Nefazodone mainly blocks 5-HT_2 receptors, with weak inhibition of serotonin and norepinephrine uptake.

The pharmacological profile of most antidepressants has been well characterized, providing an explanation for some of the acute and prolonged effects of these agents. In particular, the side-effect profile of antidepressants can be readily derived from their pharmacological profile. However, the postulated enhancement of monoaminergic function may not be the only or even the crucial factor explaining why antidepressants work. The pharmacological profile of a drug does not sufficiently explain its antidepressant properties. This is borne out by the following findings:

(a) The pharmacological target sites within the CNS are affected within minutes after administration of the drug. Many side effects of these agents occur early in the course of treatment, in good time correlation with the administration of the drug. However, virtually all antidepressants need several days to weeks of regular application until their full therapeutic effect becomes clinically visible.

(b) Other pharmacological agents acting as monoamine reuptake inhibitors comparable to the above-mentioned antidepressant drugs have not been found to possess convincing antidepressant properties (e.g., cocaine, amphetamine).

(c) Drugs without primary effect on monoamine sites may also possess antidepressant effects, such as substance P antagonists or CRF antagonists.

Several hypotheses have been developed to explain the delay of full antidepressant effects. It has been postulated that the effects of antidepressants at their primary target sites (receptors or transporters as first messengers) induce secondary effects, e.g., adaptatory changes in intracellular signal transduction at the level of second messengers (such as the adenylyl cyclase system) or of gene expression. This may lead to altered receptor sensitivity (as described for beta-adrenergic receptor down-regulation or decreased sensitivity of serotonergic receptors, such as 5-HT_2 receptors).

Changes of the synthesis of brain-derived neurotrophic factor and/or alterations of the hypothalamic–pituitary axis may represent pathways by which antidepressants finally exert their therapeutic effects. Changes in synthesis of protein structures might explain the time lag needed for antidepressants to develop their full therapeutic effect on mood and affect.

3. Indications

By now, many drugs with antidepressant effects have also been evaluated as effective agents in several indications, which are briefly outlined below.

3.1 Depressive Disorders

The classical indication for TCA, MAOI, SSRI and other antidepressants is depressive episodes (e.g., major depression). Their use is the treatment of choice in moderate or severe depression. Antidepressants are effective both in acute treatment and in preventing relapse of unipolar depression during long-term treatment (continuation or maintenance phase, after the acute symptoms have been treated effectively). Several authors have found that depressive episodes with melancholic features are more likely to respond to drug treatment than to psychotherapy. So-called atypical depressive episodes are reportedly more likely to respond to MAOI (and perhaps to SSRI) than to TCA such as imipramine. In the treatment of psychotic depression, the combination of an antidepressant with an antipsychotic is warranted. Contrary to former belief, long-lasting mild to moderate depressive states, currently labeled as dysthymia, also respond well to antidepressant drug treatment in a majority of cases. In bipolar disorder, the use of antidepressants during a depressive episode may trigger a switch into a manic state; therefore their use in this indication is currently a matter of debate.

3.2 Panic Disorder

Starting with TCA such as imipramine or clomipramine, a variety of antidepressant drugs have been demonstrated to be an effective treatment in panic disorder with or without agoraphobia. Currently, SSRI are the treatment of choice in this indication, if a drug treatment with an antidepressant is established. SSRI have shown convincing anxiolytic properties in combination with a favorable side-effect profile for a majority of patients.

3.3 Obsessive–compulsive Disorder (OCD)

This often chronic and disabling disorder, characterized by intruding thoughts or repetitive compulsions that often are time-consuming and may interfere considerably with an individual's functioning, seems to respond selectively to compounds such as clomipramine or SSRI that act as predominant or selective serotonin reuptake inhibitors, because norepinephrine reuptake inhibitors or MAOIs have not consistently shown therapeutic effects in this indication.

3.4 Generalized Anxiety Disorder

In the treatment of this chronic anxiety disorder characterized by waxing and waning anxiety symptoms and excessive worrying, several antidepressants such as SSRI or venlafaxine have demonstrated beneficial effects in reducing cognitive anxiety symptoms in particular.

3.5 Social Phobia

MAOI and SSRI are effective treatments for this disorder, characterized by marked anxiety in social situations, where the individual is exposed to unfamiliar people or to possible scrutiny by others.

3.6 Bulimia Nervosa

This disorder, with recurrent episodes of binge eating, loss of control, overeating impulses, and inappropriate compensatory behavior to prevent weight gain, can also be beneficially influenced by antidepressants. Binge frequency and purging behavior in particular can be significantly reduced by regular treatment.

3.7 Premenstrual Syndrome

Symptoms of tension, dysphoria, and irritability, accompanied by various somatic complaints and occurring during the late luteal phase of the menstrual cycle, can be effectively treated by continuous or intermittent administration of SSRI or clomipramine. As in the case of OCD, there is evidence that only predominant or selective serotonin reuptake inhibitors are effective from the spectrum of antidepressant drugs.

3.8 Further Indications

Antidepressants have also been demonstrated to be of therapeutic value in the treatment of pain syndromes of various etiologies, in the prophylaxis of migraine, in the treatment of post-traumatic stress disorder, the treatment of children with enuresis or attention-deficit and hyperactivity syndrome, or in patients with narcolepsy (especially clomipramine). SSRI may also be of therapeutic value in treating premature ejacu-

lation, obesity, or anger attacks associated with mood or personality disorders. In impulsive and affectively unstable personality disorders (e.g., borderline personality disorder) SSRI may be beneficial, whereas MAOI may be helpful in avoidant personality disorder.

4. *Therapeutic Principles*

If treatment with antidepressant drugs is established, the prescribing clinician and the treated patient need to consider some general guidelines, which apply to most indications for which these agents have been evaluated:

(a) Treatment with antidepressants generally requires continuous treatment over several weeks on a regular basis; intake on an as-needed base generally is not sensible.

(b) Therapeutic effects generally develop gradually during continuous treatment with antidepressants. In a majority of cases, 2–3 weeks are needed until more than 50 percent symptom reduction is achieved.

(c) During the course of treatment, side effects usually appear before the desired therapeutic effect reaches its maximum. This particular issue needs to be clarified with the patient in order to ensure compliance with treatment up to the point of clinical remission.

(d) Antidepressants need to be given in a sufficiently high dose to achieve optimal treatment effects. Efficient doses for TCA usually lie between 100 and 300 mg/day. SSRI such as citalopram, fluoxetine, or paroxetine need 20 mg/day, sertraline or fluvoxamine at least 50 mg/day. Depending on the side-effect profile of a drug, initial treatment requires gradual dose increase until effective doses are achieved (for TCA recommended starting doses are 25–50 mg/day; SSRI can usually be started with the minimal effective dose).

After remission is reached, it is generally recommended to maintain the effective dose for at least several weeks or months in order to prevent recurrence of the symptoms or relapse. In cases of known high risk of recurrence, continued treatment over years is needed. Combining antidepressant drug treatment with psychotherapy (especially cognitive-behavioral or interpersonal therapy) usually provides additive benefit for the patient; both approaches are not contradictory.

Antidepressants do not have addictive properties.

5. *Disputable Issues: Ethical, Methodological, Clinical*

Despite the widely accepted beneficial effects of antidepressants, there is ongoing debate on how these effects and benefits can be assessed. The scientific gold standard established over a period of about 50 years, and representing the basis of approval of new antidepressant drugs by legal authorities, is to assume *efficacy* of antidepressants if they are clearly superior to placebo in at least two well-conducted randomized controlled trials. Ethical issues are primarily related to the use of placebo in such pivotal trials. A recent study has shown that suicide rates and mortality in patients treated with placebo in randomized controlled trials were not discernible from those of patients treated with an antidepressant verum (Khan et al. 2000).

The demonstration of efficacy of antidepressants in controlled clinical trials is necessary but not sufficient for evaluating the therapy of major depression and related disorders. The focus of interest is shifting from pure efficacy to *effectiveness* studies of antidepressants. This implies asking the question whether a treatment still works when used by the average clinician with the average patient in an average therapeutic setting. Additionally, *efficiency* studies are essential to assess the required level of resources to produce reasonable benefit. Research at the interface of clinical trials and effectiveness studies, including cost-utility and econometric studies, is indispensable to estimate the benefit and the shortcomings of available antidepressant drug therapy (Wells 1999).

Evidence from double-blind, placebo-controlled trials of antidepressant drugs from all classes has shown them to be effective in alleviating symptoms in approximately 60 to 75 percent of patients with major depression. In contrast, the placebo response rate averages 35 percent after one month of treatment. However, the very high variability of verum and placebo responses makes it nearly impossible to extrapolate from one study to another or from the results of a clinical trial to real clinical situations. This variability of study outcomes can be reduced by patients' selection based on DSM-IV criteria, and by clinicians trained on standard depression assessment scales. A symptom reduction of at least 50 percent, e.g., in the Hamilton Depression Rating Scale score, is widely used as an arbitrarily chosen but operational measure of treatment response. However, a 50 percent improvement may leave many patients with significant symptoms, and, paradoxically, it is more difficult to achieve a 50 percent response if the baseline severity of depression is high. As a consequence, antidepressant drug efficacy in less severely depressed patients is not easily demonstrable, although most of these patients require effective treatment.

The effects of antidepressive drugs are seen in all of the symptoms of major depression; however, vegetative symptoms, e.g., sleep disturbances and loss of appetite, are often the most rapidly improved. When only a single global measure is used to assess depression severity or improvement, differential drug effects and differential response patterns in subgroups of patients are overlooked. Thus, the methodology used for the assessment of symptoms and symptom changes, as well as the distribution of prevailing symptoms in different patients' samples, can influence

study results. There is still a lack of studies considering these issues and other factors which can potentially influence treatment response, e.g., patients' gender, age, or personality.

Furthermore, the efficacy of antidepressants is often confounded with the time course of improvement. There is still controversy over whether or not some antidepressants exert a faster onset of action. Survival–analytical approaches (Stassen et al. 1993), exponential recovery models (Priest et al. 1996), and pattern analysis (Quitkin 1999) are statistical methods to assess differential dynamics of improvement under antidepressants. There are additional important clinical and methodological issues relevant to treatment with antidepressant drugs.

One of these issues is the question whether patients with mild or moderate depression should be pharmacologically treated. This issue is linked to the issue of reliable screening and diagnosis.

There is a lack of convincing trials on the comparative and combined effectiveness of biological and psychological treatments in depression. Despite the long experience in the use of antidepressants and psychotherapy, there is no evaluation standard for these issues.

Another controversy directly related to mental health policy is the recommendation of antidepressants to prevent manifestation of major depressive disorder at an early stage, when only prodromal or single symptoms are present. This issue also includes the questionable prescription of antidepressants for children and adolescents—a generally underinvestigated field.

Secondary prevention, i.e. reducing the risk for recurrence and chronicity of depressive disorders, also raises the question of how long antidepressants should be prescribed after remission of the target symptoms. The potentially advantageous prophylactic use of antidepressants is challenged by the risk of triggering switches into manic states, particularly in bipolar disorder. Decisive studies are required to demonstrate which antidepressants have the lowest risk for mood switches and phase acceleration.

6. *Conclusion and Future Prospects*

Today, a respectable armamentarium for the treatment of depressive disorders is at hand, and antidepressants are standing in the front line. When used adequately, the available antidepressant drugs are effective in reducing an enormous burden of costs, distress, suffering, and death.

Notwithstanding the tremendous progress in the field of antidepressant drugs the ultimate goals have not yet been reached. The key objectives of antidepressive drug treatment remain as follows:

(a) to reduce and ultimately to remove all signs and symptoms of the depressive syndrome in the largest possible proportion of patients in the shortest possible time;

(b) to restore occupational and psychosocial function to that of the asymptomatic state;

(c) to attenuate and ultimately to eliminate the risk of relapse, recurrence, and chronicity.

There is still an urgent need to develop new and better treatments for depression, including drugs and other biological treatments, psychotherapeutic strategies, and combinations of some or all of these. The benefit of having a wide array of antidepressant drugs and other treatment options is based on evidence that there may be different forms of the illness, which respond to different mechanisms of action. More research is needed to develop predictors of differential responsiveness in order to tailor antidepressant treatment to the individual patient's requirement (Preskorn 1994).

Depression is—among other neurological and psychiatric disorders—at present a treatable, but still little understood, disease. From the very beginning, the history of antidepressive drug treatment was accompanied by scientists' expectation that the knowledge about the mechanism of action of antidepressants would lead to an extended insight into the biological nature of the treated illnesses. In fact, the progress in research on antidepressants had an immense impact on biological psychiatry. However, there is still a lack of knowledge concerning the molecular understanding of the etiology and pathophysiology of depression, and the complex mechanisms of action of antidepressant drugs are still enigmatic.

Despite the chemical and pharmacological diversity of the presently available antidepressant drugs, they have some properties in common. The differences between antidepressant drugs lie mainly in side effects, tolerability, and the potential for pharmacokinetic interactions. Regarding the mechanism of action of the diversity of available antidepressants, a final common pathway is likely to be involved. A modulation of a number of different types of neurotransmitter receptors seems to contribute to the long-term effects of antidepressants, in most cases irrespective of the acute effects of the diversity of available drugs on a particular system. On a higher level of action, shared effects of different antidepressants on second-messenger systems and gene expression can be assumed but specific data are not available. For instance, an active cross-talk between serotonergic and noradrenergic receptors which can be modulated by a protein kinase has been demonstrated. Furthermore, a link between central glucocorticoid receptors and neurotransmitter receptor systems is likely.

Promising new candidates of alternative mechanisms of action for antidepressive drugs include substance P (neurokinin I) receptor antagonists (Kramer et al. 1998), neuropeptide Y agonists (Stogner and Holmes 2000), and corticotropin-releasing hormone receptor (CRH-R) antagonists (Holsboer 1999). Despite encouraging initial results from animal and

human studies, a firm conclusion regarding safety and efficacy of these new therapeutic principles cannot yet be drawn.

Rational antidepressive drug development in the future will presumably be guided by the tools of modern drug discovery, which comprise:

(a) the genetic understanding of depression and environmentally influential factors;

(b) animal models that closely reflect the pathophysiology of depressive signs and symptoms;

(c) complex cellular models with cloned transmitter and neuropeptide receptors;

(d) a detailed atomic-level understanding of the target molecules where the drugs are intended to act (Cooper et al. 1996).

Brain imaging techniques and molecular genetic methodology will not only expand our knowledge about biological manifestations of depressive disorders. These techniques will also help increasingly in monitoring and understanding the biological effects of antidepressants *in vivo*.

It does not seem overoptimistic to expect that with the rapid progress of genetic and molecular research, the core pathophysiology of depressive disorders could be elucidated in the near future. This attainment alone could provide a rationale for a causal therapy of depression and related disorders, and for logically designed antidepressant drugs with a clear therapeutic superiority over those available today.

Superiority should be in future understood not only in terms of higher efficacy, but also with regard to lower toxicity, better subjective tolerability and treatment adherence, improved functional outcome, and quality of life. The increasingly available evidence should serve as the basis for the prescription of a particular drug to a given patient. Long-term mental health issues for the development of better antidepressants should be the cost-effective reduction of patients' disability, morbidity, and mortality caused by depression and related disorders.

Antiquity, History of

Antiquity is commonly understood as the history of the Mediterranean world and its neighboring regions before the Middle Ages. The concept is a legacy of the tripartite division of history which has developed since the Renaissance. There was always a tension between mere concentration on Greek and Roman history as representing 'classical' antiquity, and an approach including the high cultures of Egypt and the Near East. On the one hand, the Assyrian and Persian

empires were due to the theory of the four world monarchies (adopted from oriental sources in the Book of Daniel) part of a Christian view of history. On the other hand, there was a strong tradition (going back to Aristotle) of contrasting Western freedom with oriental despotism where subjects lived under slave-like conditions. Until the nineteenth century oriental history could only be viewed through classical and biblical sources. Since then, decipherment of hieroglyphs and cuneiform as well as excavations have led to a reconstruction based on monumental sources. Their interpretation, however, required a linguistic and archaeological specialization which led to a new departmentalization between classical and oriental studies.

1. *Early Greece*

Until the later nineteenth century, the beginnings of Greek history were equated with the first literary sources, the Homeric epics (eighth century BC). Since then excavations have enabled detection of the main structures of the Bronze Age civilizations—the 'Minoan' in Crete and the 'Mycenaean' in parts of mainland Greece, where great palaces served as centers of a redistributive economy. Those cultures were finally destroyed during the twelfth century BC by waves of invaders whose identity is far from clear, although they were probably not identical with the Dorian Greeks who afterwards settled in parts of mid-Greece, the Peloponnese, and Crete. The structures of the 'Dark Ages' up to the eighth century can only be reconstructed conjecturally. There was no need to build up greater units, since there were no attempts by foreign powers to establish control. Social life took place in village communities with some collective organization for warfare and regulation of internal conflicts. The leading part was played by well-to-do landowners, who had to rely on the support of the peasants and permanently competed for a precarious leadership within the community.

The so-called archaic age from ca. 750 BC to ca. 500 BC is the formative period of Greek culture. The adaptation of the Phoenician alphabet was a cultural breakthrough, the epics of Homer and Hesiod (ca. 700 BC) canonized the ensemble of gods and heroes, and Panhellenic festivals such as the Olympic Games presented places of contact for aristocrats from all over the Greek world. Cultural unity was also fostered by the 'colonization' which led to numerous Greek settlements on the coasts of Asia Minor, Sicily, southern Italy, North Africa, and in the Black Sea area; contacts with indigenous populations reinforced the consciousness of an ethnic homogeneity based on language, religion, and customs. Colonization reacted to population growth, aiming at occupation of arable land. Newly created settlements became independent units. Constructing a new community implied a process of rationalization by which the order at home was also understood to be subject to change by deliberative decisions.

2. *The City-state*

The city-state (*polis*), first developed in colonization areas, became the typical form of organization in most (yet not all) parts of mainland Greece. It consisted of a fortified center on a hill, a residential town at the foot of a hill, and the agricultural hinterland. Its political unity was symbolized by a meeting-place and communal temples. Collective decision making was formalized by the establishment of magistrates with defined competences and terms of office, councils with administrative functions, and assemblies which took decisions about war and peace, and the administration of justice. For a long time, public functions could only be fulfilled by well-to-do people, but they had to take into account the opinion of the peasants who made out the bulk of the military.

The development toward formalized political structures overlapped with increasing tensions between rising and declining families of the social elite on the one hand, and between the aristocracy and the peasantry on the other. Considerable parts of the peasantry were in danger of indebtedness and finally enslavement. There were demands for cancellation of debts and redistribution of land. In several cities internal tensions led to the seizure of power by a tyrant, an aristocrat who controlled the city through a mixture of military force and patronage. Tyrants improved the condition of the peasantry, developed the infrastructures of the cities, and fostered communal identity by establishing central cults. Only later were tyrants considered to be exercising arbitrary rule incompatible with the freedom of citizens. In certain cities, 'legislators' were entrusted with the formulation of rules which should stabilize the community.

At the end of the archaic age, a firm political structure was achieved in most cities, with considerable differences as to the degree of participation open to the bulk of the citizenry. Priests were responsible for the administration of cults and temples but did not dispose of political power. There were hundreds of autonomous *poleis*, most of them with a territory of 50–100 km^2 and some hundred or a few thousand (male, adult) citizens. There were, however, some exceptions, in particular Sparta and Athens.

2.1 *Sparta*

Sparta had embarked on an unparalleled expansion. During the second half of the eighth century BC, it conquered Laconia and Messenia, the southern part of the Peloponnese (a territory of ca. 8,500 km^2). The subjugated populations were treated as helots, state

serfs, or as *perioikoi* ('those who dwell about'), who lived in communities enjoying local autonomy but bound to follow Sparta's military leadership.

Uprisings among the Messenians in the late seventh century BC led to a total reorganization of Spartan society, which was achieved by a series of reforms probably completed about 550. The citizens (Spartiates, ca. 9,000) received almost equal plots of land, which were tilled by the helots, whose products enabled the Spartiates to serve as full-time hoplites. Every Spartiate underwent a public education and afterwards lived in a warrior community. Society had a uniquely militaristic character, distinguished by an austere life-style, which has provoked admiration as well as abhorrence (from antiquity until the present day). The political system was unique again: there was a hereditary kingship in the form of a dual monarchy (of unknown origin), the kings being the leaders of the army; home affairs were administered by magistrates (*ephors*) appointed every five years and a council of men over 60 elected for life (*gerousia*); decisions on foreign policy were taken by the assembly of the Spartiates. In spite of the ostentatious stress on equality within the Spartiates, there was probably an informally ruling elite, although internal politics remain obscure. During the sixth and fifth centuries BC, Sparta enjoyed remarkable stability, and the strength of its army was unequalled in the Greek world.

2.2 Athens

Athens was an exceptional case due to the fact that the whole territory of Attica (ca. 2,500 km^2) had been formed into one political unit during the Dark Ages. Solon's legislation in 594 BC ensured social peace by establishing that the indigenous population should not be enslaved (which in turn created the demand for chattel slaves from outside), and by codifying large parts of Athenian law. The tyranny of the Peisitratids (561–510 BC) had further unifying effects. In 508/7 BC Cleisthenes laid the foundations for a political system based on the participation of the citizenry. A reorganization of the subdivisions of the citizenry made newly constituted local communities (demes) the backbone of the system. A council of 500, consisting of members delegated by every deme, took on the preparation of assembly meetings and a number of administrative functions. The council's importance grew, especially when the older council, the Areopagus, consisting of life members, lost political influence in 462/1 BC. During the fifth century, appointment by lot was introduced for councilors and the majority of (several hundreds of) magistrates, as well as daily allowances for them and the hundreds of laymen who served as jurors in courts that decided in criminal and civil cases. Every honest citizen (above the age of 30) was considered as being able to undertake public functions, and, due to the great number of positions that had to be filled each year, a great part, if not the majority, of the 30,000–40,000 citizens must have acquired this experience.

All important decisions, especially on foreign affairs, were taken in the assembly, which met regularly. Leadership in the assembly was assumed by generals (strategoi) whose office (a board of 10) constituted an exception, since they were elected (not appointed by lot) and re-election was permitted. But only a few generals acquired a reputation through military achievement and rhetorical ability such that the assembly was likely to follow their lead. The trend toward democracy (a term coined in the later fifth century BC) was not accompanied by disputes of an ideological nature. The central position of the assembly was the result of a dramatic increase in military and diplomatic activities, as tremendous successes in this field fostered the legitimacy of the system.

3. The Greek World during the Fifth and Fourth Centuries BC

At the Battle of Marathon (490 BC), Athens achieved a sensational victory over Persian troops. In 480 BC, Persia launched an attack to conquer Greece and was beaten off by an alliance of most Greek states, Sparta taking the lead in the land battles, Athens in the maritime operations (with a great victory in the Salamis naval battle). Due to the strength of its fleet, Athens became the leading power in the Aegean Sea and build up a collective military system from which Sparta kept away. To continue fighting Persia an alliance (the Delian League) was established, with a great number of *poleis* financially contributing to the maintenance of the Athenian fleet. Athens enjoyed a period of prosperity and became a cultural center that in the era of Pericles (the leading statesman since the 440s BC) attracted intellectuals, artisans, and craftsmen from all over the Greek world. Athens' political and cultural hegemony materalized in the great temple buildings on the Acropolis and in the great festivals including the theatre performances.

Athens' claim for leadership was based on its role in the Persian Wars but operations against Persia ceased after ca. 450 BC. Nevertheless, Athens did not allow any city to drop out of the alliance and showed an increasing tendency to interfere in the affairs of member states. Suspicion of Athenian ambitions to dominate all Greece arose in Sparta and its allies (especially Corinth) with the result that minor conflicts culminated in the 'Peloponnesian War' between Athens and Sparta and their respective allies. Both sides probably considered a final confrontation as inevitable and thought to fight a preventive war. The first period of warfare (431–421 BC) led to a confirmation of the *status quo ante*; the second one opened

with Athens' attack on Sicily (415–413 BC), a disaster for the Athenians, and ended finally in Sparta's total victory (404 BC), which was facilitated by Persian financial aid.

Sparta was not able to keep its hegemonic position for much longer. There were quarrels within the ruling group and, due to military losses and a concentration of landed property, the number of full citizens dwindled continually (down to 2,500 Spartiates by 370 BC). Athens partly regained its naval strength, although a new alliance, founded in 377 BC, lasted for only two decades. For a short time, 371–362 BC, Thebes maintained the position of a leading military power. The instability of the power system was increased by Persia's paying subsidies to varying allies, which led to a permanent reversal of coalitions. In the mid-fourth century BC, Macedonia, under King Philip II, entered the scene and tried to acquire a hegemonic position. Athens organized an anti-Macedonian alliance, but this was decisively beaten in 338 BC.

Athenian democracy had survived the defeat in the Peloponnesian War. The terror regime ('Thirty Tyrants') during the final phase of the war had definitively discredited any constitutional alternative. Democracy was restored in 403 BC. Fundamental criticism of political equality as articulated by Plato and Aristotle did not reflect even the opinion of the upper classes. Present scholarship is agreed that there was no decline in political participation. The growing tendency toward a separation of political and military leadership had certain negative effects on military efficiency, but the final defeat by Macedonia was due to the lack of sufficient resources. That Athens (and the other Greeks) should better have accepted a 'national' unity under Macedonian leadership (as was often said in nineteenth-century historiography) is an anachronistic idea, incompatible with the tradition of the autonomous city-state.

4. *The Hellenistic Age*

Macedonia did not formally abolish the autonomy of the *poleis*, but they were put under firm control and lost their capacity to pursue an independent foreign policy. Macedonia wanted to legitimize its leadership by embarking on retaliation against Persia. Philip's plan was realized by his successor Alexander ('the Great'). Heading an army of Macedonian and Greek troops, Alexander conquered Asia Minor, Syria, Egypt, Mesopotamia, and Iran with incredible speed (334–330 BC). Having declared the Panhellenic revenge war terminated, he dismissed the Greek contingents and started conquering the eastern parts of the Persian empire with Macedonian and Iranian troops. In 326 BC he reached the Indus Valley, but his intention to march to the 'edges of the world' failed as his exhausted troops refused. In his lifetime Alexander won a reputation for invincibility; his death in 323 BC, at the age of 33, made him a figure that was reflected upon by philosophers, historians, and rhetoricians. He became the prototype of a world conqueror later rulers would imitate, and a subject of popular romances which would receive adaptations in the major languages of the Middle Ages. Modern historians often cannot resist following their own imaginations with respect to Alexander's 'final plans.'

Alexander took over the provincial system of the Persian empire and considered himself a successor to the Persian Great King and the Pharaoh. His adoption of Persian court ceremonial and attempts to integrate Iranians into his elite units provoked alienation with his Macedonian troops. At the time of Alexander's death there was no successor. Control was taken over by several generals, who acted as governors in various parts of the empire. In a series of wars between them the unity of the empire was broken. Finally, around 280 BC, a new power structure consisting of Macedonia, Egypt under the Ptolemies, and Asia Minor, Syria, Mesopotamia, and parts of Iran under the Seleucids was established. Macedonian generals had succeeded in founding dynasties. In the Ptolemaic and Seleucid kingdoms leading positions in the army and bureaucracy were occupied by Macedonians and Greeks; Alexander's attempts to include native elites were not repeated. Greek-Macedonian and native populations lived under different legal orders. The system was kept together by the king, who was considered absolute ruler and overlord of the territory.

In spite of these limits of integration, there was a tendency toward assimilation of Greco-Macedonian and indigenous cultures, the spread of Greek as an international language, and the spread of the Greek life-style to cities and garrisons with Greek populations. Mercenaries, tradesmen, intellectuals, and artists enjoyed mobility throughout the Mediterranean and Near Eastern world. Alexandria in Egypt became a cultural center where the literary heritage of the fifth and fourth centuries BC was cultivated. These achievements of the 'Hellenistic age' (a nineteenth-century coinage) were still persisting when the Romans established their domination over the eastern parts of the Mediterranean world.

5. *Early Rome and the Middle Republic*

According to late Republican Roman tradition, the city of Rome was founded in 753 BC. Archaeological evidence suggests that settlements on the hills of the future city were established from the tenth to the eighth centuries BC. Formation of a city-state took place considerably later, and was due to strong Etruscan influences, although Rome was never dependant on an Etruscan city. The primordial kingdom, ever in need of cooperation with a landowner patriciate, was finally abolished around 500 BC. After that Rome was dominated by an aristocracy which,

however, changed its character. There were tensions between the patriciate and rising families, as well as peasant demands for land distributions and debt relief. The plebeians, i.e., all nonpatricians irrespective of their social status, combined in a separate organization with magistracy (tribunes of the people) and assembly to achieve access to political functions hitherto monopolized by the patriciate, and to secure the fulfillment of social demands. The 'Struggle of the Orders' is a somewhat dramatic term for a long process in which phases of conflict and reconciliation alternated. Piecemeal changes from the fifth to the early third centuries BC led to a political system with an equilibrium between magistrates, senate (a council of former magistrates sitting for life), and assemblies, which decided on war and peace, legislation, and the election of magistrates. Politics was determined by a nobility formed of the old patriciate and the plebeian elite who now had access to the magistracy. Office tenure for one year, collegiality in all magistracies, a hierarchy of magistracies to be occupied in successive order, and the senate's overall control ensured a certain equality within the ruling class. Ordinary citizens participated through the assemblies. Voting, however, took place in units structured according to wealth and place of residence, which implied a blatant weight in favor of the propertied classes; initiative for legislation was the monopoly of magistrates. Roman assemblies were far from being democratic in the Greek sense. But their very existence and their function as a forum for communicating with the people ensured consensus within the citizenry. The nobility presented itself as a ruling class not indulging in conspicuous consumption, but absorbed by their duties in public office.

Constitutional development and territorial expansion mutually enforced each other; the peasantry serving in the army put pressure on the nobility, who in turn would fulfil their demands by land distributions in newly acquired territories. During the fourth and early third centuries BC, Rome won control first over the neighboring region of Latium, then over mid- and south Italy. This tremendous success was not only due to the strength of a highly disciplined military but also the result of a prudent policy of integration. Whole communities were admitted to Roman citizenship (with or without the right to vote); others gained a special status by which their members could opt for Roman citizenship. All others were treated as allies enjoying autonomy, their obligation to military support being rewarded by a share in the profits of war. Thus Rome could rely on indirect domination based on the cooperation of local elites.

Roman involvement in Southern Italy led to confrontation with the Carthaginians who occupied parts of Sicily. As a result of the First Punic War (264–241 BC) Rome established domination over Sicily, Sardinia, and Corsica. The second war with Carthage (218–201 BC) opened with catastrophic Roman defeats against Hannibal, who had invaded Italy from Spain. But finally the Romans were able to make Hannibal retreat to North Africa, where he was decisively beaten. In the end, Rome extended its domination over Spain. During the second century BC, Rome established its hegemony in wider parts of the Mediterranean area. The Macedonian state was destroyed in 168 BC, Carthage in 146 BC. The Seleucid position in Asia Minor was undermined in favor of the rise of Pergamum, which in 133 BC would fall to Rome.

Beginning with Sicily, newly acquired overseas territories were made provinces under permanent administration by Roman magistrates and 'pro-magistrates' (whose authority was prolonged for that purpose after the regular one-year turn). Governors relied on the cooperation of local elites and, as a rule, did not change internal administration structures, especially the systems of tax collection. There were, however, always complaints about exploitation by governors who impudently enriched themselves.

Rome's overseas expansion did not follow a blueprint, and actual decisions were not taken primarily with respect to the acquisition of resources. But a tendency toward 'imperialism' was inherent in a system in which magistrates had just a short period to gain prestige and wealth, and soldiers were accustomed to participate in booty. The more conquest, the more chances to 'defend' Roman interests; Rome's determination to impose its will upon other states was compatible with its self-representation as fighting only 'just wars.'

6. *The Late Republic*

The establishment of a large empire had unforeseen repercussions at home. Part of the vast resources available because of the conquests was invested in Italian land. Aristocrats acquired great landed estates which were worked by slaves for the production of cash crops. Peasants were displaced and no longer met the property qualification for army service. This picture, going back to ancient narrative sources, represents a general trend, although it certainly needs qualification to take account of regional differences. The land reforms by Tiberius and Gaius Gracchus (133 BC and 123/2 BC, respectively) had only limited effects. Later the recruitment system was changed: volunteers without property qualification were enrolled; these soldiers showed special loyalty to their commanders, who in turn felt obliged to secure landed property for veterans. Sulla, who came to power (82 BC) after a series of civil wars (starting with the Italian allies' forcing their access to Roman citizenship) and the war with Mithridates of Pontus (who had attacked the Romans in Asia Minor and Greece), was the first to satisfy the soldiers' demands by large-scale confiscations in Italy. Sulla's attempt as *dictator* (tra-

ditionally only a short-time supreme commander) to strengthen the senate's authority was not really successful. It became necessary to entrust the great general Pompey with long-term command, but after his complete reorganization of Roman domination in Asia Minor and Syria (66–62 BC), Pompey could not arrange for the land allotments he had promised his soldiers. He engaged in a coalition with the ambitious Caesar, who used his provincial command in Gallia for a large-scale conquering campaign (58–51 BC). At last Pompey realigned with the senate to crush Caesar. Caesar won the ensuing 'civil war,' which was fought all over the Roman empire (49–45 BC). Being in sole power, Caesar was finally appointed dictator for life and the senate indulged in conferring extreme honors upon him.

Caesar's ostentatious disgust with aristocratic equality caused his murder by a group of senators (44 BC). His supposed 'final plans' have bedeviled generations of historians, but it seems doubtful whether he had had a clear-cut conception of a lasting reorganization of the political system. That a monarchical head of the empire was a historical necessity (as nineteenth-century scholarship put it in Hegelian terms) was an idea apparently not familiar to contemporaries, since military success over centuries had been achieved by an aristocracy. But the traditional republic could not be restored either, and after a further series of civil wars a new system emerged.

7. *The Early Empire*

The new order was established by Octavian, Caesar's personal heir, on whom the senate conferred the title 'Augustus' in 27 BC. Through cautious moves he constituted a monarchy in disguise, proclaimed as a 'restoration of the republic.' The emperor's formal authority consisted of a bundle of competencies derived from traditional magistracies, which allowed him to control all affairs. Continuance of magistracies and senate, and employment of senators as military commanders and governors ensured the loyalty of the senatorial elite, although the subsenatorial 'equestrian order' got a share in administration. The emperor played the part of the patron to the capital's population by grain and cash distributions as well as public games. The problem of veteran settlement was solved by the purchase of land in Italy and overseas colonization. Provincial governors still relied on the cooperation of local elites, who were rewarded with legal privileges and offered chances for ascendance into the equestrian and senatorial ranks.

Such a summary of the 'principate' inaugurated by Augustus should not result in ignoring internal tensions. Keeping a republican facade demanded the self-restraints of rulers, but the lack of constitutional controls and, for example, the tendency of Eastern provinces to confer god-like honors on them made emperors show their true faces as autocratic rulers again and again. Provincial government was improved, but charges of corruption and maladministration against governors did not cease (and led to a great uprising in case of the Jews in AD 66–70). The absence of a law of succession reflected the tension between meritocratic and dynastic elements within the emperorship. Designation of a successor was not necessarily decisive—at the crucial moment, the senate, the imperial elite troops (praetorians), even the capital's population might be influential, or a provincial army might promote a pretender.

All in all, during the first and second centuries AD the empire enjoyed stability and prosperity which was manifest in the sophistication of urban culture in all parts of the Roman world. Expansionist policy was given up in favor of territorial consolidation (although Britain was subjected to Roman rule throughout the first century). The majority of troops were stationed in fortified positions near the frontiers, especially the Rhine-Danube and Euphrates borders. During the third century AD, Rome came under increasing pressure by the Goths (who were invading the Danube area) and the new Sassanid dynasty in Persia. The situation was aggravated by instability on the throne: again and again army units proclaimed officers as emperors; most of them met violent deaths after a short time.

8. *The Later Empire*

After half a century of turmoil, Diocletian (AD 284–305) embarked on a comprehensive reform. It was based on devolving the imperial office on two senior and two junior emperors (as prospective successors), who would each have authority in a part of the empire but would govern jointly. The emperorship was symbolically enhanced by attributing a 'sacral' character to it and adopting oriental court ceremonial. However, regulated succession failed; from AD 305 onwards various pretenders fought each other, until Constantine and Licinius could consolidate their positions in the West and East respectively. Finally Constantine became sole ruler (AD 324).

The administrative reforms started by Diocletian were continued by Constantine. They included a reorganization of the army (now divided into field army and border troops) and of the provincial system (now including Italy), a separation of military and civil administration, and a new taxation system to meet the demands of the army and the enlarged governmental apparatus. These led to considerable consolidation although the intention to regulate more and more features of social life was partly defeated by corruption and maladministration, as well as the attempts of various social groups to escape the pressure put on them from above—local grandees sheltered their dependants from the state's demands and exploited

them at the same time. Citizenship (since AD 212 extended to all inhabitants of the Empire) lost its importance, as can be seen in the harsh penal system with distinctions according to the social status of citizens. Peasants, who had to take the burden of taxation, were reduced to a serf-like status; craftsmen were bound to their occupation and place of residence. These points signify tendencies; they should, however, not be understood as covering the multifariousness of social reality. There were considerable differences between the various regions of the empire, and discrepancies between the increasing legislation and its enforcement. The political and societal order of the post-Diocletian era had manifestly changed in comparison with the early empire, but there were also remarkable elements of continuity, for example with respect to higher education, local administration, and civil law. The traditional label of 'despotism' is not helpful.

A most important change happened with respect to the Christians. From the first century AD onwards Christianity had spread through all parts of the empire, and had taken on firm organization with the episcopal constitution. Christians who did not participate in the ruler cult were considered disloyal citizens. During the first two centuries AD, there were sporadic persecutions of Christians, mostly inspired by local communities. The Christians reacted, on the one hand, by praising martyrdom; on the other, by stressing the coincidence of Christ's coming and the Augustan reign of peace and (answering the charge of being a lower-class religion) by adopting 'pagan' literary culture. Since the mid-third century AD, rulers had considered the restoration of state cults necessary for the preservation of the empire. That led to systematic persecutions under the reigns of Decius (AD 250), Valerian (AD 257), and Diocletian (AD 303); indictments of clerics, prohibition of church meetings, confiscation of holy scripts and church property were aimed at destroying the church's very existence. As a whole the measures failed and were stopped in AD 311. After AD 312, Constantine pursued a policy not only of toleration but also of actively promoting the church by donations, granting privileges to clerics, conceding a public role to bishops, promoting Christians in public offices, and finally giving the new capital Constantinople, founded at the site of Byzantium (AD 324), a Christian outlook. Constantine's religiosity and the motives of his policy remain obscure. The strengthening of imperial authority by a theology that declared the emperor God's vicar on earth had to be paid for with involvement in inner-church conflicts, especially the Arian schism, which was not to be solved by the theological compromise found at the Council of Nicaea (AD 325) under Constantine's personal lead. Finally, Theodosius declared Christianity the state religion (AD 380) and pagans, heretics, and Jews became subject to persecution. Bishops played an important role as the heads of cities, and some, especially in the West, in imperial politics as well. The increasing interweaving of state and church, however, fostered ascetic monasticism.

The division of the empire into Western and Eastern parts after the death of Theodosius (AD 395) would last, although the fiction of unity was never given up. For a number of reasons the Eastern Empire did far better with the pressures from migrating Germanic tribes, especially the Goths. The weakness of the Western empire is symbolized by the Visigoths' sack of Rome (AD 410). The end of Western emperorship in AD 476 is traditionally taken as signifying the end of Antiquity. Whereas in the West, Germanic states were established, the East took up the Roman heritage (as symbolized by Justinian's codification of Roman Law, AD 534) and preserved its continuity through the Middle Ages.

9. *The Legacy of Antiquity*

In spite of manifold contacts with the oriental world, the political and cultural achievements of Greece and Rome were products of indigenous development. The notions of citizenship and individual rights, the ideas of republicanism and democracy, as well as universal emperorship, the continuity of Roman law and of the church (including the use of the Latin language), Christian preservation of 'pagan' literature and other traditions became formative for European culture through structural continuities and conscious renaissance. In this sense, it is still appropriate to treat Greco-Roman antiquity as a historical epoch of its own.

Anti-Semitism

The term 'Antisemitism' was first introduced into public discourse in Germany in the 1870s and thereafter quickly replaced all previous words denoting hostility to Jews, both in and out of the German *Kaiserreich*. Within months it was also applied to past cases of Jew-hating and to the historiography of anti-Jewish attitudes and policies, written by Jews and non-Jews alike. Scholarly attempts to restrict the meaning of Antisemitism either to the modern era or to that kind of anti-Jewish sentiment relying on racism, have usually failed. Thus, despite its limitations, the term continues to dominate the discussion of all anti-Jewish attitudes and measures in every period, in all cultures and in every geographical region.

1. The Term and its Early Applications

During the late eighteenth century, a group of mostly ancient Middle Eastern languages was first named 'Semitic' and soon afterwards the term 'Arian' was coined to denote another vaguely defined group of languages, later also known as Indo-Germanic. By the mid-nineteenth century, both terms began to be applied, as for instance by Ernst Renan, to peoples and to ethnic groups, too. The adjective 'Antisemitic' appeared during the 1860s, in at least two major German reference works, but it was only in Berlin, during the late 1870s, in the wake of a violent anti-Jewish campaign, that the term really entered public discourse. It was apparently the *Allgemeine Zeitung des Judentums*, in an article published on September 2, 1879, that first used the term in print. It reported plans to publish an Antisemitic weekly by Wilhelm Marr—by then one of the more outspoken anti-Jewish journalists in the German–Prussian capital. The circle around Marr may have indeed applied the term, though it was only somewhat later that he himself began to make use of it. By the end of the same month, the *Antisemiten-Liga* has been established, and despite its meager performance aroused some interests in liberal and Jewish circles. The debate that ensued, especially after the publication of Heinrich von Treitschke's article, *unsere Aussichten*, in the *Preussische Jahrbücher* of November 15, 1879, was known as the *Antisemitismusstreit*, and the petition against the legal and social position of Jews in Germany, circulating a year later—as the *Antisemiten-Petition*.

2. The Novelty of Modern Antisemitism

The term apparently served a needed function. It seemed to have indicated a new anti-Jewish attitude, unhinged from the old traditional Jew-hatred and directed against the modern Jewish community, now in possession of full civil rights and on the way—so it seemed to many—to full social integration. The new word made it possible to regard Jew-hating as a full-fledged ideology, presumably like Liberalism or Conservatism. Those who made it the focus of their overall social thought tried to explain it by both their own particular misfortunes and all evil in the world at large. By the late-nineteenth century, a full-blown conspiracy theory, identifying the Jews as an imminent danger to civilization and as enemies of all culture was added to this *Weltanschauung*; salvation finally meant freeing the world from this particular threat. Friedländer (1997) argues that such an encompassing kind of 'redemptive Antisemitism' was first elaborated by the members of Richard Wagner's circle of friends and admirers in Bayreuth, inspired by Houston Stewart Chamberlain's *Foundations of the Nineteenth Century*. An equally ambitious ideological system was more or less simultaneously advanced by Eugen Dühring's *Die Judenfrage als Rassen- Sitten- und Kulturfrage* (1881), while another version was formulated in France by Eduard Drumont in his widely read and much appreciated *La France Juive* (1886).

It has often been argued that the new term for what seemed only another version of age-old hostility to Jews did in fact signal the emergence of a new phenomenon. Its novelty was two-fold: first, it was based on racism instead of the old religious grounds. Second, it indicated the growth of a new political movement, whose purpose was to reverse the legal equality of Jews, sometimes even to rid Germany or France of them. To be sure, racial theories did reach a new level of presumed scientific precision at that time, and by the 1870s they were fairly well known in wide circles of the European educated public. Nevertheless, none of the Antisemites before World War I relied exclusively upon racial arguments. Jews continued to be attacked for their economic role as speculators, blamed for destroying the livelihood of small artisans and shopkeepers, and above all accused of destroying

the unique culture of the people amongst whom they dwelled. Moreover, the religious impulse behind the Antisemitism of these days should not be underestimated (Tal 1975). Even the overtly anti-Christian Antisemites displayed an eschatological fervor that was far from being wholly secular in tone or in character. Racism did not in fact replace previous Antisemitic views, but was crafted upon them.

The political organizations of that period, too, were not entirely new, nor were they of great importance at this stage. Toury (1968) has clearly shown the *political* function of Antisemitism in the revolution of 1848/1849 and in fact, even in Antiquity or in medieval Europe, many incidents of extreme Antisemitism were politically motivated and/or manipulated. Furthermore, the Antisemitic parties in Germany before Nazism, both those of the social-conservative persuasion and the more radical, oppositional ones (such as Theodor Fritsch's *Antisemitische deutsch-soziale Partei* or Otto Boeckel's *Antisemitische Volkspartei* later known as the *Deutsche Reformpartei*) had a very uncertain existence. Despite their fiery rhetoric they rarely managed to present a united front and even during their heyday, with 16 representatives in the *Reichstag*, they remained entirely ineffective. In France, too, public Antisemitism had a short blooming during the Dreyfus affair, but was of no real consequence as a parliamentary force. The strength of Antisemitism is better measured by the degree of its infiltration into the established parties, such as the *Deutsch-konservative Partei* since 1892, and the various associations and interest groups, such as the *Bund der Landwirte*, the *Deutschnationale Handlungsgehilfenverband*, and some of the students organizations (Jochmann 1976). The powerful *Pan-German League* too, added Antisemitism to its aggressive, expansionary nationalism, especially during the later years of World War I.

Despite the strength of the Antisemitic tradition, many historians insist upon the novelty of its 'post-emancipatory' stage (Rürup 1975). Arendt (1951) indicated the changing position of Jews within the emerging modern national state as the main prerequisite for Antisemitism in modern times. A strong historiographical trend has insisted upon the particular circumstances, socioeconomic or political, that brought about its rise. What may likewise be considered unique about this so-called 'Modern Antisemitism' was its link to a particular cluster of other, mainly cultural tenets and beliefs. Even the small, openly Antisemitic parties in Germany were never devoted to achieving anti-Jewish measures only. They all clung to monarchical and nationalist tenets and worked for a variety of social policies, usually in support of one of the pre-modern economic sectors. They urged control of what they deemed 'unworthy capitalist competition,' and propagated other explicitly anti-modern social and cultural views. By the end of the century, accepting Antisemitism became a code for the belief in all of these (Volkov 1990). In the liberal to mildly conservative atmosphere of pre-World War I Europe, supporting Antisemitism meant opposing the status quo, rejecting democratization, and allying oneself with nationalism and an imperialist foreign policy. In France, too, Antisemitism meant more than hostility to Jews. *Dreyfusards* were identified with the republic and its dominant values, while their opponents basically represented the antirepublican, catholic front.

3. *The Functions of Jew-hating*

3.1 *The Middle Ages*

With the possible exception of the ancient, pre-Christian world, anti-Jewish positions were always symbolic for more comprehensive views and associated with issues well beyond and outside the so-called 'Jewish question.' In early Christianity, the need to distinguish true believers from Jews, who rejected the messianic message of the new religion, was naturally very keenly felt. A complete disregard of Judaism was unthinkable at the time, since the new faith accepted the holiness of the Old Testament. By the twelfth century, Jews were considered an integral part of Christian society, fulfilling two essential functions within it, both in the present life of the church and in its sacred history. First, they were regarded as witnesses to the antiquity and truthfulness of the Bible, 'living letters of the law' (Cohen 1999). Second, their low status was seen as a proof of their anachronism, a consequence of their theological stubbornness.

Furthermore, the symbolic meaning of the Jew has had a dynamism of its own. By the time of the early Crusades, minor fluctuations turned into a major change, considered by some the most crucial break in the history of Antisemitism (Langmuir 1990). From that time onward, Jews became targets of direct attacks, both in theory, that is, within a new theological discourse, and, more significantly no doubt, in practice. A series of bloody assaults on their communities sought to achieve mass conversion, and, as this goal was repeatedly frustrated new accusations against them, concerning ritual murder and later also Host-desecration and well-poisoning, justified violent acts of revenge against them. In an atmosphere of radical struggle against the infidel—Moslems in the outside world and new heretics at home—the fight against Jews and Judaism received a new impetus. Stress was put on Jewish post-Biblical literature, especially on the Talmud, perceived now as an esoteric Jewish document, distorting the original message of the Old Testament and actively scheming against Christianity. This sometimes led to the burning of the Talmud, as in Paris, 1240, but actual, physical attacks

on Jews, carried out in numerous northern German and French towns at about the same time, are more often explained by socioeconomic rather than theological factors. As moneylenders and especially as pawnbrokers Jews were all too often hated by the peasantry and exploited—politically and economically—by landlords. In the aftermath of the Black Death, during the mid-fourteenth century, new massacres were clearly a part of an uncontrolled social upheaval. At the same time, the popular demonization of Jews continued unabated. They were seen as truly Satanic, infecting the healthy body of Christian society, arousing that dangerous mixture of hatred and fear that has since been typical of Antisemitism.

3.2 *The Early Modern Period*

The growing stress on rationalism in medieval thought, as shown by Funkenstein (1993), was no defense against Antisemitism. Neither were Humanism and the Protestant Reformation reliable bearers of toleration. Most humanists were either indifferent to Jews or fell under the influence of ancient anti-Jewish writers. While the growing interest in Hebrew and in ancient Hebrew texts led some to reconsider their negative attitudes towards Jews, others reaffirmed them. In contrast, the position of Lutheranism was more consistent. Luther himself had at first hoped to Christianize the Jews as part of reforming corrupt Catholicism, but he soon gave up that project and turned against them with unparalleled vehemence. Historians tend to see in his anti-Jewish writings the culmination of medieval hostility towards Jews rather than the opening of a new era (Oberman 1984). The demands to shake off the constraints of a previous faith legitimized previous doubts within Christianity and under the circumstances reformers could not afford to relax the boundaries that had for so long separated it from Judaism. Once again, they urgently needed to distinguish the true from the false faith, God from Satan. Jews continued to serve as a tool in building up their new identity.

At the same time, the Reformation and the ensuing religious wars deeply changed the nature of the prevailing political system in Europe. The independent secular state now became the seat of a single religion, in which—ideally at least—the crown ruled over a homogeneous society of subjects/believers. Exceptions could at best be tolerated, as under Calvinist governments, or at worst repressed and expelled—under Lutheranism and the Counter Reformation. To be sure, the needs of homogeneity were felt within the old Catholic world too, though exact motivations were locally varied, of course. England expelled its Jews in 1290. The kingdom of France ordered their exit first in 1306 and then again in 1394. Most outstanding were developments in the Iberian Peninsula after the *reconquista*, leading to expulsion and/or forced conversions in Spain and Portugal during the last decade of the fifteenth century. In the days of Moslem rule, Christian and Jews did occasionally suffer as adherents of minority religions, but under the ambitious government of the conquering Christian kings their position became practically unbearable. A thriving culture, relatively open to the 'other,' was replaced by a demand for uniformity and the merciless elimination of all unbelievers. The Inquisition, indeed, acted primarily against the 'New-Christians,' suspected of secretly upholding their old faith. But even true *conversos* were frowned upon in a Spain, obsessed with notions of blood and an early version of racism. In some reformed German states, too, rulers could not resist public pressure to expel Jews, as in Saxony (1536), and Bohemia (1541 and 1557), while Pope Paul IV ordered the establishment of the first Ghetto in Rome (1655) and tightened up all restrictions designed to prevent Jewish integration in Counter-Reformation Italian society. The worst physical attack against Jews in this period, however, took place in Eastern Europe. Jews were caught in the Cossacks' revolt of 1648/1649, made responsible for the brutal exploitation of the local peasantry, and fell victims to the fight over the nature of the Polish State. It was only during the next century that toleration began to be acknowledged as a necessary principle in a Europe torn by endless inner strife.

4. *Nationalism and the Fear of Modernity*

Even during the Age of Reason, rationality alone did not suffice for combating Antisemitism. While the English Hebraists of the late seventeenth century positively re-evaluated the contribution of Jewish writings, and a few of them even drew a defense of contemporary Jewry from their scholarly projects, the majority of the so-called Deists concluded that Judaism, past and present, was too particularistic and too unnatural to deserve their respect. Ettinger (1978) suggested, that although theirs was a negligible influence in eighteenth century England, they did effect some of the French *Philosophes*, especially Voltaire, who despised the old Jewish religion as much as the living Jews, with whom he apparently had unpleasant personal encounters. Nevertheless, the significance of the 'turn to rationalism' (Katz 1980) should not be underestimated. In its wake, that all too limited secularism of the Enlightenment, joined to a growing emphasis upon human equality, gradually made possible the acceptance of Jews as subjects/citizens in England, France, and the American colonies of the late-eighteenth century. In Germany, too, despite the twisted course of legal emancipation, Jews entered bourgeois society and were accepted within it to a degree never known before. Economic growth and the increasing influence of the bourgeoisie made for an uncongenial atmosphere to Antisemitism. Interest in

the actual life of Jews, their customs, and their habits, worked against xenophobic generalizations and the exploitation of old hatred for other purposes seemed outdated in the age of progress and liberalism.

Nevertheless, old-style, religiously motivated anti-Jewish positions had not entirely disappeared by then and Judaism continued to be seen as a legalistic, cold, and fundamentally inhuman religion. In addition, the process of making Jews stand for other negative aspects of contemporary European life received a new momentum. As early as 1781, in response to Christian Wilhelm Dohm's book on the *Bürgerliche Verbesserung der Juden*, Johann David Michaelis, an expert on ancient Judaism not previously known to hold Antisemitic views, insisted that Jews could not be equal members in a modern, nationally defined Germany. Precisely at the time when Jews were beginning to accept the option of turning their religion into yet another confession within a more tolerant and efficiently run state, their 'otherness' was being redefined so as to exclude them once again. Just as they were abandoning their separate group-identity in favor of joining the 'imagined' national communities, energetically formed everywhere around them, a new nationalism was making their integration all the more problematic, giving old-style Antisemitism yet another meaning.

As in the past, processes of identity formation and the drawing of new group boundaries required an apparent figure of the 'other' for their completion. Especially in Germany, Jews were made to play the role of the enemy from within. Early nationalism used open antisemitic slogans in trying to draw clear boundaries: Jews were to be excluded for all times from the emerging German nation. Throughout the first two-thirds of the nineteenth century, while on the one hand conservatives were only slightly modifying their traditional negative attitudes to Jews and while on the other hand many liberals were clamoring for their emancipation, nationalists, sometimes even of the liberal persuasion, sought to stress their status as outsiders. The fixed place of Jews in society, obvious in the prenational era was now becoming a major 'problem,' the so-called *Judenfrage*. During the revolution of 1848/1849, while the Frankfurt *Parlament* decided to grant full equality to Jews, opposition was rampant everywhere in the country. Peasants still considered Jews as allies of the oppressive local landlord and the tax-collecting, centralizing bureaucracy and in towns they were seen as representatives of a feared and hated new order. As early as the summer of 1819, while the 'Hep-Hep Riots' spread from Bavaria to the Rhine and then eastward and northward across Germany, Jews were identified as the forerunners of social and economic change. It was in this context too that they were attacked in the ensuing decades (Rohrbacher 1993). No less a thinker than Karl Marx, son of a converted Jew, accepted the symbolic role of Jews within the Capitalist system. In his *Zur Judenfrage* (1844) he envisioned their emancipation as liberation from their own nature, to be achieved only with the final collapse of the bourgeois world-order. By the late-nineteenth century, this was still the position of European Social Democracy, rejecting antisemitism, while objecting to any sign of 'Philosemitism' and negating every notion of a separate Jewish group-identity. At this time, both hostility to Jews and a defense of their emancipation were readily combined with more comprehensive world-views, used as symbols of their overall ethos.

5. *The 'Functionalist' vs. the 'Essentialist' Approach*

This 'functional' approach to the study of Antisemitism, however, has often been criticized, since it describes the dynamics of Antisemitism, not its sources. In applying it, one tends to stress the changing needs of the non-Jewish environment and neglect the search for a single explanation, based on Jewish uniqueness and history. In order to do that it is necessary to go back to a point in time, in which the forces of tradition may be, at least partially, neutralized and begin 'in the beginning.' According to Marcel Simon (1948), for instance, two aspects of Jewish life were the fundamental causes of ancient Antisemitism: their 'separatism' and their unique religion. The two, in fact, are inseparable. From the outset, Judaism made Jews different and adhering to it was the cause of their social isolation and the resentment they aroused among their neighbors. Beyond strict monotheism and the peculiarity of their God, three manifestations of Jewish life were the focus of ancient Judophobia (Schäfer 1997): the abstinence from pork, the upholding of the Sabbath, and the habit of circumcision. As early as the third century BC, one encounters accusations against Jews as misanthropic, cruel, and dangerous. The pagan counter-history to the story of Jewish exodus from Egypt describes them as lepers and unwanted foreigners. Apion of Alexandria has apparently reported stories of Jews worshipping a donkey-head and practicing human sacrifice. Popular outbursts against Jews are known as early as the destruction of their temple in Elephantine in 411 BC, and as late as the riots in Alexandria in 38 AD. While some historians argue that Jews were basically treated no worse than other barbarians, others convincingly show that they were treated, in fact, as 'more barbarian than others' (Yavetz 1997). After all, Jews were known to be an ancient, civilized people and their transgressions could not be as easily pardoned. They further aroused special resentment by their insistence on upholding their special way of life even in Greek and later in Roman exile. Indeed, Theodor Mommsen believed that Antisemitism was 'as old as the Diaspora' and historians who regard Antisemitism as no more than the age-old

'dislike of the unlike,' feel this was surely magnified by the fact of Jewish life among the nations. As in later periods, in Antiquity too, Jewish 'otherness' had been more or less tolerated in a culturally mixed pagan world. But it was 'the idea of a world-wide Greco–-Roman Civilization that made it possible for Antisemitism to appear (Schäfer 1997).

The controversy over the role of the Jews themselves in the history of Antisemitism has not been limited to the study of Antiquity. Medievalists, too, sometimes point out that Jews had some part in inciting hatred against them. It is generally accepted that their particular economic role was the cause of much resentment. Yuval (1993) also argues that close relationships existed between the hope for a 'revenging salvation,' often expressed by medieval Ashkenazic Jewry, and the Antisemitism of that time. He further links Jewish suicide in sanctification of God (*Kidush-ha'Shem*) with the practically synchronous emergence of the ritual murder accusations. While causal relationships are difficult to establish, such interpretations offer a more complex view of both Jewish life and Antisemitism during the Middle Ages.

Within a more modern context, too, the problem of Jewish 'responsibility,' if not out-right 'guilt,' has always accompanied the study of Antisemitism. Jews are known to have often taken the blame upon themselves. Orthodox made the unorthodox responsible for the evil that befell all Jews. Some historians regard Jewish capitalists as the main culprits; others blame Jewish socialists. Zionists considered Jewish life in the *Galuth* (exile) corrupt and reprehensible, and at the height of Jewish integration in German society, before World War I, Jews occasionally reproached themselves for being too successful, too culturally prominent, and too obtrusive. By then, the concept of Jewish self-hate also began to gain currency. In *fin de siecle* Vienna, days before he committed suicide, the young Otto Weininger published his *Geschlecht und Charakter* (1902), explaining that Antisemites were only fighting the feminine-Jewish side within themselves and that this fight had to be joined by every self-respecting Jew.

6. *National–Socialism*

Meantime, Antisemitism was gradually taking on an altogether different guise. In the wake of the 'Great War' most European countries were plunged into a prolonged crisis—economic, social, cultural, and political. Antisemitism indeed seems to thrive under such circumstances. While the new Europe was striving to regulate the treatment of minorities and the Weimar Republic repealed all remaining discriminations against Jews, popular Antisemites everywhere continued to blame them for causing and then profiting from military defeat, the hyperinflation, Bolshevism, and 'international' Capitalism. In *Mein Kampf*, recalling his early encounters with Jews and local Antisemites in prewar Vienna, Hitler finally called for action—in all matters, to be sure—but especially in respect of the 'Jewish Question.' Indeed, historians are still divided as to the exact role of Antisemitism in the Nazi project of exterminating European Jewry. Those known as 'intentionalists' see stressing Antisemitism as the only way of 'explaining the unexplainable' (Kulka 1985. The 'functionalists' introduce into their narrative other elements too, and see the 'Final Solution' as a cumulative response to more immediate problems, devoid of prior definition of aims or methods (e.g., Schleunes 1970). All agree, however, that Antisemitism was rampant among the Nazi 'true believers,' and was a necessary if not a sufficient precondition for the Holocaust. Recently, a middle-of-the-way position, shared by many, seem to have robbed the controversy of its pertinence. Instead, arguments about the relationships between pre-Nazi and Nazi Antisemitism have been renewed. Obviously, no history of the 'Final Solution' can be complete without joining the tradition of European Antisemitism to the unique exterminatory rage of the Nazis. Goldhagen (1996) presented a seamless continuity between the two, while most historians prefer a more differentiated approach. They insist on comparing Germans Antisemites to others, in and out of Europe, and on taking into account the century of essentially successful Jewish life in Germany prior to Nazism. It is also useful to follow Hilberg's (1992) distinction between perpetrators and bystanders. Perhaps the activists were spurred to action by racism, while passive participants, by no means only Germans, still relied upon older, more traditional forms of Antisemitism. In the end, all aspects of Jew-hating were necessary preconditions for the execution of the Nazis' murderous project, though none seems entirely sufficient for explaining it.

7. *Social Scientists Confront the Problem*

Facing the enormity of the problem, scholars outside the discipline of history also attempted to deal with it. As early as 1882, Leon Pinsker, in his path breaking *Autoemanzipation* (1881), diagnosed 'Judophobia' as a psychosis, an inherited pathological reaction of non-Jews to the ghost-like Jewish existence in the Diaspora. At the same time, Nahum Sokolov, another early Zionist, preferred to see in it a 'normal' phenomenon, to be explained in social-psychological terms. These two approaches characterize later efforts by social scientists. Especially in the USA, even before World War II, interest in racism, raised in conjunction with attitudes to blacks as well as to Jews, motivated social scientists to analyze what they then named 'prejudice.' Antisemitism was thus considered a particular instance of a more general phenomenon. Some psychoanalytical concepts, such as the Oedipal complex, seemed readily applicable. On the basis of

Freud's *Moses and Monotheism* (1939) one attempted to associate Jews with the distant punishing father of the Old Testament and Christians with the suffering punished son (Loewenstein 1951). Displaced aggression and anger, or the projection of guilt could also be applied here. Adorno and co-workers published *The Authoritarian Personality* in 1951. The force of their theory was the linkage they presented between a specific personal pathology and a particular form of political and social structure. Later on, however, emphasis shifted to the 'normalcy' of prejudice, adding the figure of the social conformist to that of the pathologically prejudiced, and stressing the prominence of social training and education in the fight against Antisemitism. In his *Towards a Definition of Antisemitism*, Langmuir (1990), summarizing existing theories in the field, suggests a division into 'realistic,' 'xenophobic,' and 'chimerical' Antisemitism. According to him, these represent both historical stages, from antiquity through the early Middle Ages until the irrationalism of the twelfth century, and classification of the different types of Antisemitism arranged by their distance from reality and the depth of anti-Jewish fantasies associated with them. Usually, it seems, all three kinds appear together and it is perhaps their special mix or relative importance that define the intensity of prejudice and the threat inherent in it.

8. *Antisemitism in the Post-Holocaust World*

In any event, in the post-Holocaust world, though Antisemitism has by no means disappeared, there is little evidence for the expansion of its 'chimerical,' virulent variety. But there are a few significant exceptions. These are the antisemitism in Soviet and post-Soviet Russia, as well as in some of the Eastern European countries; the case of the Middle Eastern Arab states, and the sporadic outbursts of anti-Jewish rhetoric and occasional violence characteristic of extreme right-wing parties and groups in the West. Thus, examples of the multiple manifestations of Antisemitism are available today too. Czarist Russia, to take the first case, was known for its repressive anti-Jewish policies during the nineteenth century (Wistrich 1991). While civil equality became the rule in the West, most Jews in Russia were restricted to the 'Pale of Settlement' and subjected to numerous humiliating decrees. The pogroms of 1881, partially condoned by the Czarist government, spread to more than 160 cities and villages and claimed thousands of lives. The later Kishiniev pogrom of 1903 aroused a great deal of indignation, especially outside of Russia, but this too could not stop further attacks upon the Jews. During the Civil War, following the 1917 Revolution, some 100,000 Jews were massacred by the Whites. The Revolution, indeed, put an end to all previous discriminations against Jews. Their religious and institutional life suffered of course from the atheist campaign against all religions, but no open Antisemitism was allowed in Soviet Russia until the late 1930s. After a short respite during the war, in which Jews often felt protected by the government, an official anti-Jewish campaign was pursued vigorously, reaching a peak during Stalin's last years and becoming particularly vicious after the 1967 Arab–Israeli war. Few expected a renewed wave of Antisemitism to characterize the collapse of the Communist regime. But under conditions of economic crisis and political chaos, mainly verbal attacks against Jews became common again. After all, exploiting the Jew as a scapegoat for all misfortunes is a well-known pattern and although it seems rather marginal in most parts of the world today, it has not completely faded away.

Under Islam, to take the second case, while Jews were never free of discrimination, they were only rarely subject to actual persecution (Lewis 1986). Like other non-Moslems, they enjoyed limited rights while their inferiority was formally established and considered a permanent fact of life. Ideological Antisemitism was imported into the Moslem Middle East. Its intensity there is a result of the actual political conflict with the State of Israel. In most countries involved in it, a distinction between Judaism and Zionism is usually preserved, but explaining defeat by reference to 'Jewish power' and some kind of 'Jewish conspiracy' has often proven irresistible. As in the previous Soviet Union, Antisemitism here too usually is directed from above, but unlike the Russian case, it is not based on traditional, popular enmity but on a real, ongoing struggle. It was, in fact, the combination of Soviet and Arab anti-Israeli position that produced the 3379 UN resolution of 1975, declaring that 'Zionism is a form of racism and racial discrimination.' Significantly, the resolution was supported by many developing countries, too, expressing what they saw as solidarity with the Arab world, while adopting Antisemitism as a code for their anti-Colonial, anti-Western attitude (Volkov 1990).

The third focus of Antisemitism in today's world is the right-wing organizations in Europe and in the USA. While America seemed at first an unlikely place for the growth of antisemitism, it has experienced a truly racist wave as early as the aftermath of World War I. Christian conservatives and revivalists of all sorts espoused Antisemitism, Ku-Klux-Klan activists incited against 'aliens,' and the *Protocols* were disseminated by such antisemitic advocates as Henry Ford (Wistrich 1991). Finally, the Immigration Law of 1924 legitimized the racist atmosphere, ever more noticeable during the 1930s. In the post-World War II years, Jews were sometimes associated with the danger of Communism, but soon the favorable economic circumstances of later years helped reduce tension and American Jews were able to improve their status considerably. In Western Europe too, openly neo-Nazi and neo-Fascist parties proved of little political

consequence and the small Jewish communities enjoyed relative security and prosperity. Lately, however, anti-immigration and xenophobic sentiments seem to have given rise to parties with a measure of wider mass appeal, propagating, though often only implicitly and always among other things, an Antisemitic message. Despite the fact that nowadays immigrants are only rarely Jews, and that in most countries they constitute only a very small minority, hostility towards them accompanies old fears of foreigners and the new panic in the face of rapid change. Antisemitism among Blacks in America, for instance, seemed for a while to be a real menace, while in Europe, the declining power of the nation–state, the new world of communication, and, above all, the specter of globalization produce sporadic manifestations of Antisemitism, too. Ultra radical, terrorist groups—all too often agents of Antisemitism—plague many countries. Side by side with the presumably intellectual brand of Holocaust denial, occasionally infiltrating even respectable university campuses, pseudo-Nazi groupings insist upon reviving Antisemitism in its crudest forms. A flood of Internet sites appeal to a new kinds of young audiences. Jews are once again symbolic for everything they hate and fear. Even in places such as Japan, where there is no Jewish minority to speak of, the presumed Jewish power and evil influence is a source of concern for some.

In most of the democratic countries, however, both right-wing parties and racist activists of the more militant type face a political system, determined to limit their activities. In countries where such countervailing forces are weak, outbursts of Antisemitism cannot always be controlled, but elsewhere, despite minor incidents—though sometimes numerous and occasionally violent—it does not present a real danger. Antisemitism continues to exist, and in view of past experience must be regarded as a serious potential threat, but clearly, the spreading of democratic education and the strengthening of democratic institutions have proven capable of curbing its propaganda and checking its power and influence.

Antisocial Behavior in Childhood and Adolescence

Antisocial behavior is a broad construct which encompasses not only delinquency and crime that imply conviction or a possible prosecution, but also disruptive behavior of children, such as aggression, below the age of criminal responsibility (Rutter et al. 1998). The age of criminal responsibility varies from 7 years of age in Ireland and Switzerland to 18 years of age in Belgium, Romania, and Peru. In the United States, several states do not have a specific age. Legal, clinical, and developmental definitions of antisocial behavior have different foci.

1. *Definitions of Antisocial and Aggressive Behavior*

Legal definitions of criminal offences committed by *young people* cover: (a) noncriminal but risky behavior (e.g., truancy) which is beyond the control of authorities; (b) status offences where the age at which an act was committed determines whether it is considered damaging (e.g., gambling); (c) crimes to protect the offender from being affected (e.g., possession of drugs); and (d) crimes with a victim (e.g., robbery) broadly defined (Rutter et al. 1998). The most common crimes among young people are thefts.

Only some forms of delinquency involve aggression which is a narrower construct than antisocial behavior. A meta-analysis of factor analytic studies of antisocial behavior (Frick et al. 1993) revealed four major categories of antisocial behavior defined by two dimensions (overt to covert behavior, and destructive to less destructive) as follows: (a) aggression, such as assault and cruelty (destructive and overt); (b) property violations, such as stealing and vandalism (destructive and covert); (c) oppositional behavior, such as angry and stubborn (nondestructive and overt); and (d) status violations, such as substance use and truancy (nondestructive and covert). Aggression and violence are related but not synonymous concepts. Violence usually refers to physical aggression in its extreme forms.

Clinical definitions of antisocial behavior are focussed on psychopathological patterns in individuals. Oppositional defiant disorder, which includes temper tantrums and irritable behavior, becomes clinically less problematic by age eight, but some children, more often boys than girls, are unable to outgrow these problems.

Conduct disorder is diagnosed on the basis of a persistent pattern of behavior which violates the rights of others or age-appropriate societal norms. To individuals who must be at least 18 years of age, a third diagnosis, antisocial personality disorder, can be applied. These psychopathological patterns may involve delinquent behavior, but the criteria of their diagnosis are broader in terms of psychological dysfunction.

Developmental approaches to antisocial behavior are focussed on its developmental antecedents, such as hyperactive and aggressive behavior in childhood, and maladjustment to school in early adolescence. The younger the children are, the more their 'antisocial' behavior extends beyond acts that break the law. Different delinquency-related acts may be indicators of the same underlying construct such as low self-control, or they may indicate developmental sequences across different but correlated constructs.

Development of antisocial behavior is studied using a longitudinal design which means repeated investigations of the same individuals over a longer period of time. The increasing number of longitudinal studies indicates a high continuity of behavior problems from childhood to adulthood. There is continuity between disobedience and defiance of adults, aggression towards peers, and hyperactivity at age three, and similar or more serious behavior problems in later childhood. Hyperactivity during the preschool years associated with aggressive behavior has the most robust links to later antisocial behavior.

Common definitions of *aggression* emphasize an intent to harm another person (Coie and Dodge 1998). References to the emotional component of aggression are not typically made in these definitions. *Anger*, the emotional component of aggression, and *hostility*, a negative attitude, motivate a person for aggressive acts, but aggressive behavior may also be displayed instrumentally. Hostile aggressive responding is characterized by intense autonomic arousal and strong responses to perceived threat. In contrast, instrumental aggression is characterized by little autonomic activation and an orientation toward what the ag-

gressor sees as a reward or expected outcome of behavior.

Each aggressive act has a mode of expression, direction, and motive. An aggressive act may be expressed physically, verbally, or non-verbally, and targeted, in each case, more directly or indirectly. It also varies in its harmfulness or intensity. The motive of the aggressive act may be defensive (reactive) or offensive (proactive). Among school children, proa ctive aggression is often displayed in bullying behavior, which means purposefully harmful actions repeatedly targeted at one and the same individual. From four percent to 12 percent of children—boys slightly more often than girls—can be designated as bullies and as many as victims depending on the method of identification, age of children, and culture. Both bullying others and being victimized tend to endure from one year to another, and they are related to relatively stable personality patterns. Besides Bullies and Victims, the participant roles include Assistants who are more or less passive followers of the bully, Reinforcers who provide Bullies with positive feedback, Defenders who take sides with the victim, and Outsiders who tend to withdraw from bullying situations (Salmivalli 1998).

Self-defense and defense of others are often culturally accepted, and many children limit their aggressive behavior to defensive aggression. Longitudinal findings show that 'defense-limited' aggression in early adolescence predicts more successful social adjustment in adulthood than 'multiple' aggression, which also includes proactive aggression. Only multiple aggression predicts criminal offences at a later age (Pulkkinen 1996). The distinction between hostile and instrumental aggression is not parallel to defense-limited and multiple aggression or to reactive and proactive aggression. Although proactive aggression often is instrumental, reactive (or defensive) aggression may be either instrumental or hostile.

2. *Development of Aggression and Antisocial Behavior*

2.1 *Development of Aggression*

Anger expression cannot be differentiated from other negative affects in newborns, but by four months of age angry facial displays—the eyebrows lower and draw together, the eyelids narrow and squint, and the cheeks elevated—are present and they are directed to the source of frustration (Stenberg and Campos 1990). The most frequent elicitors of aggression in infancy are physical discomfort and the need for attention. Peer-directed aggression, seen in responding to peer provocations with protest and aggressive retaliation, can be found at the end of the first year of life. At this age children become increasingly interested in their own possessions and control over their own activities.

During the second year of life, oppositional behavior and physical aggression increase. Most children learn to inhibit physical aggression during preschool age, but other children continue displaying it (Tremblay et al. 1999). Verbal aggression sharply increases between two and four years of age and then stabilizes. It is a time of fast language development which helps children to communicate their needs symbolically. Delays in language development are often related to aggressive behavior problems.

Between six to nine years of age, the rate of aggression declines, but at the same time its form and function change from the relatively instrumental nature of aggression in the preschool period to increasingly person-oriented and hostile (Coie and Dodge 1998). Children become aware of hostile intents of other people and they, particularly aggressive children, perceive threats and derogations to their ego and self-esteem which elicit aggression. Most longitudinal studies show a decrease in the ratings of aggression, that is, in the perceived frequency of aggressive acts as children enter adolescence. Nevertheless, serious acts of violence increase. Individual differences in aggressive behavior become increasingly pronounced.

2.2 *Individual Differences in Aggression and Antisocial Behavior*

Individual differences in anger expression emerge early in life. At the age of two years, consistency of anger responses across time is already significant. Individual differences in aggression remain rather stable during childhood and adolescence. Correlations vary slightly depending on the measures used, the length of interval, and the age of children, but they are generally between 0.40 and 0.70. The stability is comparable for males and females. Individual differences in responding to a conflict lie both in the frequency of aggressive behavior and in prosocial attempts to solve conflicts. The latter are facilitated by language development. Language may, however, provide children with verbal means of aggression. Additional factors, such as the development of self-regulation, perspective taking, empathy, and social skills, are needed for the explanation of individual differences in aggression (Coie and Dodge 1998).

Gender differences in aggression appear in preschool age, boys engaging in more forceful acts both physically and verbally. This sex difference widens in middle childhood and peaks at age 11 when gender differences in aggressive strategies emerge: girls display relational aggression (e.g., attempts to exclude peers from group participation) more than boys, and boys engage in fighting more than girls (Lagerspetz and Björkqvist 1994). Both fighting and relational aggression may aim at structuring one's social status in a peer group, but by different means.

Antisocial and other externalizing behavior is more common, and the offending career is longer among males than among females. There have been, however, changes in the ratio between male and female offenders during the 1980s and 90s in several western countries. Adolescent girls are increasingly involved in antisocial behavior. In the United Kingdom, the sex ratio was about 10:1 in the 1950s, and 4:1 in the 1990s. The peak age of offending among girls has remained at around age 14 or 15, but the peak age for male offenders has risen in thirty years from 14 to 18 (Rutter et al. 1998). The peak age of registered offences is related to police and prosecution policy, and varies by offense. For instance, peak age is later for violent crimes than for thefts.

2.3 Continuity in Antisocial Behavior

A multiproblem pattern is a stronger predictor of delinquency than a single problem behavior. For instance, aggression in childhood and adolescence predicts delinquency when associated with other problem behaviors, such as hyperactivity, lack of concentration, and low school motivation and achievement, and poor peer relations (Stattin and Magnusson 1995). Peer rejection in preadolescence, which indicates social incompetence rather than social isolation, predicts delinquency even independently of the level of aggression. Continuity from early behavioral problems to delinquency and other externalizing behavior is higher among males than among females, whereas girls' behavioral problems predict internalizing behavior (depression and anxiety) more often than boys' behavioral problems (Zoccolillo 1993).

Several studies show that a small group of chronic offenders accounts for half of the offences of the whole group. They tend to display the pattern of antisocial behavior called 'life-course-persistent.' It is characterized at an early age by lack of self-control, reflecting an inability to modulate impulsive expression, difficult temperament features, hyperactivity, attentional problems, emotional lability, behavioral impulsivity, aggressiveness, cognitive, language and motor deficits, reading difficulties, lower IQ, and deficits in neuropsychological functioning. Thirteen percent of the boys in the study by Moffitt et al. (1996) met criteria for early onset, but only half of them persisted into adolescence. Therefore, several assessments are needed for the identification of life-course-persistent offenders.

An adolescence-limited pattern of offending is more common than the life-course-persistent pattern. It reflects the increasing prevalence of delinquent activities during adolescence. Both overt (starting from bullying) and covert (starting from shoplifting) pathways toward serious juvenile offending have been discerned (Loeber et al. 1998). Compared to the life-course-persistent pattern, the adolescence-limited pattern is less strongly associated with difficult temperament, hyperactivity and other early behavioral problems, neuropsychological deficits, and poor peer relationships. Many problem behaviors are very common in adolescence. Self-reports show that half of males and from 20 percent to 35 percent of females have been involved in delinquency. Rutter et al. (1998) conclude that antisocial behavior 'operates on a continuum as a dimensional feature that most people show to a greater or lesser degree' (p. 11).

3. Determinants of Antisocial Behavior

With the increase of empirical findings, theories of crime which try to explain crime with a single set of causal factors have been increasingly criticized. The climate has changed also in regard to the possible role of individual characteristics as determinants of antisocial behavior. In the 1970s, theories emphasized social causes of crime, and paid little attention to individual factors. The situation is now different. Empirical studies have revealed that determinants of antisocial behavior are diverse ranging from genetic to cultural factors.

Studies on genetic factors in antisocial behavior have shown that the estimates for the genetic component of hyperactivity are about 60 to 70 percent. Antisocial behavior linked to hyperactivity, which is generally associated with poor social functioning, is strongly genetically influenced. In contrast, antisocial behavior which is not associated with hyperactivity is largely environmental in origin (Silberg et al. 1996). The genetic component for violent crime is low compared to the heritability of aggression (about 50 percent), but this difference may also be due to differences in prevalence of these behaviors, and its effects on statistical analyses.

There is no gene for antisocial behavior; it is multifactorially determined. Genetic effects increase a liability for antisocial behavior, but they operate probabilistically, which means that the effects increase the likelihood of antisocial behavior, if environmental and experiential factors affect in the same direction. This conclusion also concerns the XYY chromosomal anomaly.

The importance of experiential factors, particularly early family socialization, in the development of aggression has been shown in many studies (Coie and Dodge 1998). Aggressive individuals generally hold positive views about aggression and believe it is normative. Child-rearing strategies are related to subsequent aggression in the child, for instance, insecure and disorganized attachment with the caregiver, parental coldness and permissiveness, inconsistent parenting, and power-assertive discipline (Hinde et al. 1993). Low monitoring is particularly important to adolescent involvement with antisocial behavior. Parenting affects children's behavior in interaction with their temperament resulting in differ-

ences in self-control that are related to adult outcomes, such as criminality (Pulkkinen 1998).

An adverse immediate environment which increases a risk for antisocial behavior in interaction with genetic factors includes parental criminality, family discord, ineffective parenting such as poor supervision, coercive parenting and harsh physical discipline, abuse, neglect, and rejection, delinquent peer groups, unsupervised after school activities, and youth unemployment. These risk factors also increase the use of alcohol and drugs, which is often related to crime, and are very similar in different countries, although there are also some differences (Farrington and Loeber 1999).

There are also several sociocultural factors which may serve to raise the level of crime in the community, such as income differentials, antisocial behavior in neighborhood, the availability of guns, media violence, the quality of school and its norms, unemployment rate, and involvement in a drug market. Poverty is strongly related to aggression and possibly operates through disruption of parenting. Violent virtual reality is available for children of the present generation via electronic games playing. TV programs and video films are passive in nature, whereas electronic games involve the player's active participation and often violent winning strategies (Anderson and Ford 1986). Some minority ethnic groups are overrepresented in crime statistics, but causal factors are complex. Cultural traditions cause, however, vast differences in crime rates between different countries. In Asian countries, particularly in Japan, crime rates are lower than in western countries.

4. Conclusions

Official statistics in developed countries show that crime rates among young people have been rising since the 1970s. The results of recent longitudinal studies have increased our understanding of factors contributing to the incidence of antisocial behavior. A greater understanding of how causal mechanisms operate is, however, needed for the development of effective means of preventing crime. Since persistent antisocial behavior starts from conduct problems in early childhood, support for families and work with parents and teachers to improve their management skills are extremely important. An affectionate parent, nonpunitive discipline, and consistent supervision are protective factors against antisocial behavior. Parent management training is a neglected area in western educational systems. Socialization of children and youth might also be supported by, for instance, legislation against gun availability and sociopolitical improvements of family conditions.

Antitrust Policy

The term antitrust, which grew out of the US trust-busting policies of the late nineteenth century, developed over the twentieth century to connote a broad array of policies that affect competition. Whether applied through US, European, or other national competition laws, antitrust has come to represent an important competition policy instrument that underlies many countries' public policies toward business. As a set of instruments whose goal is to make markets operate more competitively, antitrust often comes into direct conflict with regulatory policies, including forms of price and output controls, anti-dumping laws, access limitations, and protectionist industrial policies.

Because its primary normative goal has been seen by most to be economic efficiency, it should not be surprising that antitrust analysis relies heavily on the economics of industrial organization. But, other social sciences also contribute significantly to our understanding of antitrust. Analyses of the development of antitrust policy are in part historical in nature, and positive studies of the evolution of antitrust law (including analyses of lobbying and bureaucracy) often rely heavily on rational choice models of the politics of antitrust enforcement.

The relevance of other disciplines notwithstanding, there is widespread agreement about many of the important antitrust tradeoffs. Indeed, courts in the US have widely adopted economic analysis as the theoretical foundation for evaluating antitrust concerns. Interestingly, however, antitrust statutes in the European Union also place heavy emphasis on the role of economics. Indeed, a hypothetical conversation with a lawyer or economist at a US competition authority (the Antitrust Division of the Department of Justice or the Federal Trade Commission) or the European Union (The Competition Directorate) would be indistinguishable at first sight.

While this article provides a view of antitrust primarily from the perspective of US policy, the review that follows illustrates a theme that has worldwide applicability. As our understanding of antitrust economics has grown throughout the past century, antitrust enforcement policies have also improved, albeit sometimes with a significant lag. In this survey the following are highlighted: (a) the early anti-big business period in the US, in which the structure of industry was paramount; (b) the period in which performance as well as structure was given significant weight, and there was a systematic attempt to balance the efficiency gains from concentration with the inefficiencies associated with possible anti-competitive behavior; (c) the most recent period, which includes the growth of high technology and network industries, in which behavior theories have been given particular emphasis.

1. *The Antitrust Laws of the US*

In the USA, as in most other countries, antitrust policies are codified in law and enforced by the judicial branch. Public cases may be brought under Federal law by the Antitrust Division of the Department of Justice, by the Federal Trade Commission, and/or by each of the 50-state attorneys-general. (The state attorneys-general may also bring cases under state law.) Further, there is a broad range of possibilities for private enforcement of the antitrust laws, which plays a particularly significant role in the USA.

1.1 *The Sherman Act*

Antitrust first became effective in the US near the end of the nineteenth century. Underlying the antitrust movement was the significant consolidation of industry that followed the Civil War. Following the war, large trusts emerged in industries such as railroads, petroleum, sugar, steel, and cotton. Concerns about the growth and abusive conduct of these combinations generated support for legislation that would restrict their power. The first antitrust law in the USA—the Sherman Act—was promulgated in 1890. Section 1 of the Act prohibits: 'Every contract, combination in the form of trust of otherwise, or conspiracy, in restraint of trade or commerce among the several States, or with foreign nations.'

Section 2 of the Sherman Act states that it is illegal for any person to '…monopolize, or attempt to monopolize, or combine or conspire with any other person or persons, to monopolize any part of the trade or commerce among the several States, or with foreign nations….' These two sections of the Act contain the

two central key principles of modern antitrust policy throughout the world—conduct that restrains trade and conduct that creates or maintains a monopoly—is deemed to be anticompetitive.

1.2 The Clayton Act

Early in the twentieth century it became apparent that the Sherman Act did not adequately address combinations, such as mergers, that were likely to create unacceptably high levels of market power. In 1914 Congress passed the Clayton Act, which identified specific types of conduct that were believed to threaten competition. The Clayton Act also made illegal conduct whose effect 'may be to substantially lessen competition or tend to create a monopoly in any line of commerce.' Section 7 of the Clayton Act is the principal statute for governing merger activity—in principle Sect. 7 asks whether the increased concentration will harm actual and/or potential competition.

Other sections of the Clayton Act address particular types of conduct. Section 2, which was amended and replaced by Sect. 1 of the Robinson-Patman Act in 1936, prohibits price discrimination between different purchasers of the same type and quality of a commodity, except when such price differences are cost-justified, or if the lower price is necessary to meet competition.

Section 3 of the Clayton Act specifically prohibits certain agreements in which a product is sold only under the condition that the purchaser will not deal in the goods of a competitor. This section has been used to challenge exclusive dealing arrangements (e.g., a distributor that is obligated to sell only the products of a particular manufacturer) and 'tied' sales (e.g., the sale of one product is conditioned on the buyer's purchase of another product from the same supplier). The Act does not prohibit all such arrangements—only those whose effect would be likely to substantially lessen competition in a particular line of commerce.

1.3 The Federal Trade Commission Act

The US is nearly unique among competition-law countries in having two enforcement agencies. In part to counter the power granted to the Executive branch under the Sherman Act, Congress created the Federal Trade Commission (FTC) in 1914. Section 5 of the Federal Trade Commission Act, which enables the FTC to challenge 'unfair' competition, can be applied to consumer protection as well as mergers. In addition, the FTC has the power to enforce the Clayton Act and the Robinson-Patman Act. While the agencies act independently of one another, the FTC and the DOJ's enforcement activities have generally been consistent with one another during most of enforcement history.

What then are the differences between the two enforcement agencies? A simple answer is that the FTC is responsible for consumer protection issues, whereas criminal violations of Sect. 1 of the Sherman Act (e.g., price fixing and market division) are the responsibility of the Antitrust Division. It is also important to note that most enforcement activities, when successful, lead to injunctive remedies, where the party that has violated the law is required to cease the harmful activity. Exceptions are the criminal fines that are assessed when Sect. 1 of the Sherman Act is criminally violated, and fines that are assessed in certain consumer protection cases. Damages are rarely assessed by the federal agencies, otherwise, although in principle there can be exceptions (e.g., when the US represents the class of government employees).

2. The Goals of Antitrust

Despite considerable economic change in the economy over the twentieth century, the federal antitrust laws have continued to have wide applicability in part because their language was quite vague and flexible. This has led, quite naturally, to extensive historical study of the legislative history and substantial debate about congressional intent, especially where the Sherman Act is concerned. Some scholars have argued that the Sherman Act was directed almost entirely towards the achievement of allocative efficiency (e.g., Bork 1966). Others have taken the view that Congress and the courts have expressed other values, ranging from a broad concern for fairness, to the protection of specific interest groups, or more simply to the welfare of consumers writ large (e.g., Schwartz 1979, Stigler 1985).

The debate concerning the goals of the antitrust laws continues today. The enforcement agencies, for example, evaluate mergers from both consumer welfare and total welfare (consumer plus business) points of view, in part because the courts are not clear as to which is the appropriate standard under the Clayton Act. While it seems clear that the Sherman Act was intended in part to protect consumers against the inefficiencies of monopolies and cartels, it is significant that at the time of the passage of the Act many economists were in opposition because they believed that large business entities would be more efficient. Whatever the goals of the Sherman Act, it is notable that a merger wave (1895–1905) soon followed the passage of the Act. It may be that outlawing various types of coordinated behavior (Sect. 1) may have encouraged legal coordination through merger.

3. Historical Developments

Because antitrust focuses on the protection of competitive markets, it was natural to suspect other nonstandard organizational forms as potentially anticompetitive. During the early part of the 1900s, most antitrust enforcement was public, and it was directed against cartels and trusts. Early successes included

convictions against the Standard Oil Company (*Standard Oil vs. US*) and the tobacco trust for monopolization in 1911.

It is important to note, however, that the Sherman Act does not prohibit all restraints of trade—only those restraints that are unreasonable. The distinction between reasonable and unreasonable restraints remains a subject of debate today. It is significant, however, that the distinction between *per se* analysis (in which a practice is deemed illegal on its face) and rule of reason (in which one trades off the procompetitive and anticompetitive aspects of a practice) was made during this early period, and it remains important today.

By its nature, a *per se* rule creates a rebuttal presumption of illegality once an appropriate set of facts is found. *Per se* rules have the advantage that they provide clear signals and involve minimal enforcement costs. Yet actual firm behavior in varying market contexts generates exceptions that call for in-depth analyses. It is not surprising, therefore, that the *per se* rule is the exception to the rule-of-reason norm.

An example of the application of rule of reason is price discrimination. Viewed as an exercise of monopoly power, the practice was seen as suspect. Indeed, the Robinson-Patman Act presumes that with barriers to entry, price discrimination marks a deviation from the competitive ideal that was presumed to have monopoly purpose and effect. Efficiency justifications for price discrimination and other 'restrictive practices'—promoting investment, better allocating scarce resources, and economizing on transaction costs—were overlooked during the early enforcement period. Confusion also arose between the goal of protecting competition and the practice of protecting competitors. At the beginning of the twenty-first century, however, efficiency arguments are clearly pertinent to the evaluation of Robinson-Patman claims.

There is no doubt that antitrust enforcement is difficult, even with the more sophisticated tools of industrial organization that are available today. The Sherman Act does not offer precise guidance to the courts in identifying illegal conduct. In both the Clayton Act and the Sherman Act, Congress has chosen not to enumerate the particular types of conduct that would violate the antitrust laws. Instead, Congress chose to state general principles, such as attempts to monopolize, and contracts or combinations that restrain trade, without elaborating on what actually qualifies for the illegal behavior. It was left to the courts to ascertain the intent of the antitrust statutes and to distinguish conduct that harms competition from conduct that does not.

In a significant early case, *Board of Trade of the City of Chicago vs. USA* (1918), the Supreme Court reiterated the reasonableness standard for evaluating restraints of' trade. The Court concluded that 'The true test of legality is whether the restraint imposed is such as merely regulates and perhaps thereby promotes competition or whether it is such as may suppress or even destroy competition.' In this and in subsequent cases, the court failed to provide a clear statement of when and how a rule of reason analysis should be applied.

Antitrust enforcement agencies and the courts continue to debate the mode of analysis that is most appropriate in particular market contexts and when particular practices are at issue. Both courts and agencies deem it appropriate to undertake some form of 'quick-look analysis,' one which goes beyond the application of a per se rule, but which falls short of a full rule of reason inquiry (see *California Dental Association vs. FTC* 1999, Melamed 1998). *Per se* rules are applied to certain horizontal restraints, involving two or more firms operating in the same line of business. Quick-look and rule of reason analyses are more prevalent when the restraints at issue are vertical (involving two or more related lines of business, e.g., a manufacturer and a supplier).

Quick-look and more complete rule-of-reason analyses have relied on a number of basic principles. First and foremost is the market power screen. Courts have appreciated that antitrust injury necessitates the exercise of market power. Antitrust analysis typically begins with the measurement of market share possessed by firms alleged to engage in anticompetitive conduct. As many scholars have noted (e.g., Stigler 1964), in the absence of collusion, the exercise of market power in unconcentrated markets is unlikely. Market concentration is often seen as a necessary but not sufficient condition for the exercise of' market power, since ease of entry, and demand and supply substitutability can limit the ability of firms to raise prices even in highly concentrated markets (e.g., Baumol et al. 1982). But, market concentration —market power screens are not essential; witness the Supreme Court's opinion in *FTC vs. Indiana Federal of Dentists* (1986).

Although courts have long recognized the importance of market power to conclusions about antitrust injury, the standards by which they adjudicate antitrust cases, and their willingness to apply sophisticated economic analysis, has varied significantly over time. Antitrust policy once treated any deviation from the competitive ideal as having anticompetitive purpose and effect. Vertical arrangements were particularly suspicious if the parties agreed to restraints that limited reliance on market prices. Over time, however, the critique of such arrangements diminished as economists began to appreciate the importance of efficiencies associated with a range of contractual practices.

3.1 The Structure-conduct Interventionist Period

During the 1950s and the 1960s the normative analysis of antitrust was dominated by the work of Joe Bain on

barriers to entry, industry structure, and oligopoly (Bain 1968). Bain's relatively interventionist philosophy was based on the view that scale economies were not important in many markets, that barriers to entry are often high and can be manipulated by dominant incumbent firms, and that supracompetitive monopolistic pricing is relatively prevalent. This tradition held, not surprisingly, that nonstandard and unfamiliar practices should be approached with skepticism. During this era, antitrust enforcers often concluded that restraints which limited the number of competitors in a market necessarily raised prices, and that the courts could protect anticompetitive conduct by appropriate rule making.

In this early structure-conduct era, industrial organization economists tended to see firms as shaped by their technology. Practices, such as joint ventures, that reshaped the boundaries of the firm (e.g., joint ventures) were often seen as suspect. Significant emphasis was placed on the presence or absence of barriers to entry, which provided the impetus for a very tight market power screen.

Because the government was often seen as benign, it was not surprising that antitrust looked critically at mergers and acquisitions. Moreover, absent a broader theory that encompassed a variety of business relationships among firms, it is not surprising that the Supreme Court often supported government arguments without seriously evaluating the tradeoffs involved (e.g., *USA vs. Von's Grocery Co.* 1966).

Economies of scale are illustrative. That they can create a barrier to entry was emphasized under Bain's point of view, whereas the clear benefits that scale economies provide were given little recognition. For example, the Supreme Court argued that 'possible economies cannot be used as a defense to illegality' (*Federal Trade Commission vs. Procter & Gamble Co.* 1967).

Government hostility during this period also applied to markets with differentiated products. In *USA vs. Arnold, Schwinn & Co.* (1907), for example, the government was critical of franchise restrictions that supported product differentiation because the restrictions were perceived to foster the purchase of inferior products at higher than competitive prices. The possibility that exclusive dealing was procompetitive was not given serious consideration during the 1950s and 1960s.

The failure of antitrust enforcers to appreciate the benefits of discriminatory contractual practices was also evident in the early enforcement of the Robinson-Patman Act. Through the 1960s, the Act was vigorously enforced. Legitimate reasons for discriminatory pricing were very narrow (e.g., economies of scale in production or distribution). Since the mid-1960s, however, there has been a significant shift. Fears that the Act might discourage procompetitive price discrimination have led to less aggressive enforcement by the FTC.

The 1960s and 1970s marked a period of substantial empirical analysis in antitrust, motivated by structural considerations. The literature on the correlation between profit rates and industry structure initially showed a weak positive correlation, suggesting that high concentration was likely to be the source of anticompetitive firm behavior. However, this interpretation was hotly disputed. If behavior that is described as a barrier to entry also served legitimate purposes, what can one conclude even if there is a positive correlation between profitability and concentration? The challenge to this line of empirical work is typified by the debate between Demsetz (1974) and Weiss (1974). Demsetz argued that concentration was a consequence of economies of scale and the growth of more efficient firms—in effect the early empirical work suffered from problems of simultaneity. If concentrated markets led to higher industry profits, these profits were the consequence and not the cause of the superior efficiency of large firms and they consequently are consistent with competitive behavior. Today, these early studies are viewed critically, as having omitted variables that account for research and development, advertising, and economies of scale. It is noteworthy that the observed positive correlation reflected both market power and efficiency, with the balance varying on a case-by-case basis.

3.2 *The Influence of the Chicago School*

All of the assumptions that underlie the tradition of the 1950s and 1960s came under increasing criticism during the 1970s, led in part by the influence of the Chicago School. While the views of its proponents (e.g., Posner 1979, Easterbrook 1984) are themselves both rich and varied, they have come to be typified as including the following: (a) A belief that the allocative efficiencies associated with economies of scale and scope are of paramount importance; (b) A belief that most markets are competitive, even if they contain a relatively few number of firms. Accordingly, even if price competition is reduced, other nonprice forms of competition will fill the gap; (c) A view that monopolies will not last forever. Accordingly, the high profits earned by dominant monopolistic firms will attract new entry that in most cases will replace the monopolist or at least erode its position of dominance; (d) A view that most barriers to entry, except perhaps those created by government, are not nearly as significant as once thought; (e) A belief that monopolistic firms have no incentive to facilitate or leverage their monopoly power in vertically related markets (the 'single monopoly rent' theory); (f) A view that most business organizations maximize profits; firms that do not will not survive over time; (g) A belief that even when markets generate anticompetitive outcomes, government intervention, which is itself less

than perfect, is appropriate only when it improves economic efficiency.

The period of the late 1960s and 1970s not only marked a significant influence by the Chicago School; it also saw an upgrading of the role of economists in the antitrust enforcement agencies. The increased role continued through the end of the twentieth century in the US, as it did in the European Union. For example, two economists play decision-making roles at the Department of Justice—one a Deputy for Economics and the other a Director in charge of Economic Enforcement.

Because of the influence of the Chicago School, nonstandard contractual practices that were once denounced as anticompetitive and without a valid purpose were often seen as serving legitimate economic purposes. Not surprisingly, for example, the *per se* rule limiting exclusive distribution arrangements in *Schwinn* was struck down by the US Supreme Court in *GTE Sylvania, Inc. vs. Continental TV, Inc.* (1977). Although the US DOJ–FTC Merger Guidelines does not explicitly spell out a tradeoff analysis of efficiencies and competitive effects, accounting for the economic benefits of a merger is now standard practice. Antitrust enforcement is alert to tradeoffs, and less ready to condemn conditions for which there is no obvious superior alternative.

3.3 The Post-Chicago School Analyses of Strategic Economic Behavior

In the 1970s and continuing through the 1990s new industrial organization tools, especially those using game-theoretic reasoning came into prominence. These tools allow economists to examine the ways in which established firms behave strategically in relation to their actual and potential rivals. The distinction between credible and noncredible threats, which was absent from the early entry barrier literature, has been important to an assessment of the ability of established firms to exclude competitors and to the implications of exclusionary conduct for economic welfare (e.g., Dixit 1979). These theories also illuminated a broader scope for predatory pricing and predatory behavior. Previously scholars such as Robert Bork (1978) had argued that predatory pricing imposes high costs on the alleged predator and is unlikely to be profitable in all but extraordinary situations. Developments in the analysis of strategic behavior provide a richer perspective on the scope for such conduct. Thus, nonprice competitive strategies that 'raise rivals' costs' (Krattenmaker and Salop 1986, Ordover et al. 1990) are now thought to be quite prevalent. Indeed, models of dynamic strategic behavior highlight the ability and opportunity for firms to engage in coordinated actions and for firms to profit from conduct that excludes equally efficient rivals (e.g., Kreps and Wilson 1982, Milgrom and Roberts 1982).

The implications of the various models of strategic behavior remain hotly debated. On the more skeptical side is Franklin Fisher, who stresses that while these new developments offer insights, they are insufficiently complete to provide firm conclusions or to allow us to measure what will happen in particular cases (Fisher 1989). A more optimistic view is given by Shapiro (1989) who believes that we can now analyze a much broader range of business competitive strategies than before. We also know much more about what to look for when we are studying areas such as investment in physical and intangible assets, the strategic control of information, network competition and standardization, and the competitive effects of mergers.

The analysis of strategic behavior has emphasized the potential for exercising market power, often to the detriment of consumers. At the same time, other analyses have stressed that there are gains to consumers from coordinated behavior among firms with market power. Thus, Coase (1937) argued that market forces were only one means to organize market activities, and that nonmarket organizations could provide a viable alternative. Further, Williamson (1985) developed the theory of nonmarket organization to show that contractual restraints can provide improved incentives for investments in human and physical assets that enhance the gains from trade. This transaction cost approach helps to provide a foundation for understanding the efficiency benefits of contractual restraints in vertical relationships.

Coupled with the game-theoretic analyses of firm behavior in imperfect markets has been the application of modern empirical methods for the analysis of firm practices. These newer methods allow for the more precise measurement of market power, and they indicate generally that market power is relatively common, even in markets without dominant firms (Baker and Rubinfeld 1999).

3.4 The Public Choice Approach

Today, a balanced normative approach to antitrust would involve reflections on the broad set of efficiencies associated with various organizational forms and contractual relations, as well as the possibilities for anticompetitive strategic behavior in markets with or without dominant firms. A positive (descriptive) approach focuses on the relationship between market structure and the politics of the interest groups that are affected by that structure.

The theory of public choice has been used as the basis for limiting competitor standing to bring antitrust suits. In support is the argument that competitors' interests deviate from the public interest because competitors view efficiencies associated with alleged exclusionary practices to be harmful, and therefore are not in a position to distinguish efficient from inefficient practices. On the other hand,

competitors are often the most knowledgeable advocates, and are likely to know more about the socially harmful effects of exclusionary practices long before consumers do. The debate over standing to sue has surfaced with respect to indirect purchaser suits (e.g., *Illinois Brick Co. vs. Illinois* 1977) and with respect to predatory pricing (*Brooke Group Ltd. vs. Brown & Williamson Corp.* 1993).

4. *High Technology and Dynamic Network Industries*

In the latter part of the twentieth century rapid changes in technology have altered the nature of competition in many markets in ways that would most likely have surprised the antitrust reformers of the late nineteenth century. The early debates centered on scale—did the benefits of economies of scale in production outweigh the associated increase in market power? In many dynamic high technology industries today, demand, rather than supply is often the source of substantial consumer benefits and significant market power. Economies of scale on the demand side arise in industries such as computers and telecommunications because of the presence of network effects, whereby each individual's demand for a product is positively related to the usage of the product (and complementary products) by other individuals. Network effects apply to communications networks (where consumers value a large network of users with whom to communicate, such as compatible telephone systems and compatible fax machines), and they apply to virtual networks or hardware–software networks (where there is not necessarily any communication between users).

In industries in which network effects are significant, a host of issues challenge our traditional views of antitrust. Because network industries are often characterized by large sunk costs and very low marginal costs, there is a substantial likelihood that a successful firm will come to dominate a market and to persist in that dominance for a significant period of time. Indeed, while there is no assurance that a single standard will arise in network industries, it is nevertheless often the case that users will gravitate toward using compatible products. This combination of economic factors makes it possible for firms to adopt price and nonprice policies that exclude competition and effectively raise prices significantly above what they would be were there more competition in the market (Rubinfeld 1998).

A host of hotly debated antitrust policy issues are raised by the increasing importance of dynamic network industries. Whatever view one holds, there is little doubt that the antitrust enforcement stakes are raised. On one hand, because the path of innovation today will significantly affect future product quality and price, the potential benefits of enforcement are huge. This perspective clearly motivated the Department of Justice and twenty states when they chose to sue Microsoft for a variety of antitrust violations in 1998 (*US vs. Microsoft* 1998). On the other hand, because the path of innovation is highly uncertain and technology is rapidly changing, barriers to entry that seem great today could disappear tomorrow, and the potential costs of enforcement are large as well. The threat of potential entry by innovative firms has been a significant part of Microsoft's defense in the Department of Justice case.

5. *Standard Setting*

In network industries competitive problems may arise in the competition to develop market standards. Dominant firms may have an incentive to adopt competitive strategies that support a single standard by preventing the products of rivals from achieving compatibility. Indeed, when the dominant firm's product becomes the standard for the industry, firms that are developing alternative standards may find it difficult to compete effectively (Farrell and Katz 1998). Alternatively, firms might collude to affect the outcome of the standard-setting (price-setting) process. Such collusion can be difficult to detect because firms often have pro-competitive reasons for cooperating in the race to develop new technology. Indeed, firms often possess assets and skills that can make collaboration in developing a market standard an efficient arrangement. An example is the pooling of technology related to video and audio streaming on the Internet. In its business review letter of the MPEG-II patent pooling agreement, the Antitrust Division of the Department of Justice spelled out a set of conditions under which the pooling of assets would be deemed to be pro-competitive. Where and how to draw the line between procompetitive sharing of assets of skills and other anticompetitive activities that will discourage competitors in the battle for the next generation standard remains a highly significant antitrust issue.

As a general rule, one should expect that sufficient competition will exist to develop a new product or market standard whenever more than a few independent entities exist that can compete to develop the product or standard. This rule of thumb is consistent with case law and conclusions in guidelines published by the US antitrust authorities. For example, the DOJ/FTC *Antitrust Guidelines for the Licensing of Intellectual Property* conclude that mergers or other arrangements among actual or potential competitors are unlikely to have an adverse effect on competition in research and development if more than four independent entities have the capability and incentive to engage in similar R&D activity (DOJ/FTC 1995). Similarly, the 1984 DOJ/FTC *Merger Guidelines*

(revised in 1992) conclude that mergers among potential competitors are unlikely to raise antitrust concerns if there are more than a few other potential entrants that are similarly situated.

5.1 Leveraging

Leveraging occurs when a firm uses its advantage from operating in one market to gain an advantage in selling into one or more other, generally related markets. Leveraging by dominant firms in network industries may take place for a variety of reasons that can be procompetitive or anticompetitive, depending on the circumstances. The challenge for antitrust policy is to distinguish between the two. On one hand, leveraging can be seen as a form of vertical integration, in which a firm may improve its distribution system, economize on information, and/or improve the quality of its products. Leveraging, however, can be anticompetitive if its serves as a mechanism by which a dominant firm is able to raise its rivals' costs of competing in the marketplace.

Leveraging can be accomplished by a variety of practices (e.g., tying, bundling, exclusive dealing), each of which may have anticompetitive or procompetitive aspects, or a combination of the two. For example, with tying, a firm conditions the purchase (or license) of one product—the tied product—on the purchase (or license) of another product—the tying product. A firm might choose a tying arrangement for procompetitive reasons, including cost savings and quality control. Suppose, for example, that a dominant firm offers to license its dominant technology only to those firms that agree to also license that firm's complementary product, and suppose that the complementary product builds on the firm's next generation technology. Such a tying arrangement could allow the dominant firm to create a new installed base of users of its next generation technology in a manner that would effectively foreclose the opportunities of competing firms to offer their products in the battle for the next generation technology (Farrell and Saloner 1986).

6. International Antitrust

The emergence of a global marketplace raises significant antitrust policy issues. On one hand, free trade and the opening of markets makes it less likely that mergers will significantly decrease competition, and indeed, creates greater opportunities for merging or cooperating firms to generate substantial efficiencies. On the other hand, international price-fixing agreements are more difficult for US or other domestic enforcement agencies to police, since success often requires some degree of cooperation with foreign governments or international organizations. In the 1990s we saw a significant increase in the prosecution of international price-fixing conspiracies. Indeed, in 1998, the Department of Justice collected over $1 billion in criminal fines, the bulk of which arose from the investigation of a conspiracy involving the vitamin industry.

The internationalization of antitrust raises a host of difficult jurisdictional and implementation problems for all antitrust enforcement countries. One can get a sense of the enormous difficulties involved by looking at the problems from the perspective of the US. The Sherman Act clearly applies to all conduct, which has a substantial effect within the US. However, crucial evidence or culpable individuals or firms may be located outside the US. As a result, it is imperative for US antitrust authorities to coordinate their activities with authorities abroad. This is accomplished in part through mutual assistance agreements, as, for example, in the agreement between the US and Australia under the International Enforcement Assistance Act. It is also accomplished through informal 'positive comity' arrangements, whereby if one country believes that its firms are being excluded from another's markets, it will conduct a preliminary analysis and then refer the matter to the foreign antitrust authority for further investigation, and, if appropriate, prosecution. (Such an agreement was reached with the EU in 1991.) Further, in 1998, the Organization for Economic Cooperation and Development formally recommended that its member countries cooperate in enforcing laws against international cartels. What role, if any, the World Trade Organization will play in encouraging cooperation or resolving antitrust disputes remains an open question today.

7. Conclusions

Antitrust policy has undergone incredible change over the twentieth century. As the views about the nature of markets and arrangements among firms held by economists and others have changed, so has antitrust. The early focus was on the possible anticompetitive effects of mergers and other horizontal arrangements among firms. The primary source of market power was the presence of scale economies in production. However, vertical arrangements receive significant critical treatment, and the sources of market power are seen as coming from the demand side as well as the supply side. Further, a wide arrange of contractual practices are now judged as creating substantial efficiencies, albeit with the risk that market power will be used for exclusionary purposes. Finally, significant changes in international competition, resulting from free trade and the communication and information revolution, have reinforced the importance of reshaping antitrust to meet the needs of the twenty-first century. Significant new antitrust challenges lie ahead. Whatever those challenges may be, we can

expect that industrial organization economics and antitrust policy will be sufficiently flexible and creatively to respond appropriately.

8. Statutes

Clayton Act, 38 Stat. 730 (1914), as amended, 15 USCA §§12-27 (1977).

Federal Trade Commission Act, 38 Stat. 717 (1914), as amended, 15 USCA §§41-58 (1977).

Robinson-Patman Act, 49 Stat. 1526 (1936), 15 USCA §13 (1977).

Sherman Act, 26 Stat. 209 (1890), as amended, 15 USCA §§1-7 (1977).

9. Cases

Board of Trade of the City of Chicago vs. USA, 246 US 231 (1918) (see Sect. 3).

Brooke Group Ltd. vs. Brown & Williamson Tobacco Corp., 509 US 209, 113 S. Ct. 2578 (1993) (see Sect 3.4).

California Dental Association vs. FTC, 119 S.Ct. 1604 (1999) (see Sect. 3).

Federal Trade Commission vs. Indiana Association of Dentists, 476 US 447 (1986) (see Sect. 3).

Federal Trade Commission vs. Procter & Gamble Co, Inc., 386 US 568, 574 (1967) (see Sect. 3.1).

GTE Sylvania, Inc. Continental TV, Inc., 433 US 36, 45 (1977) (see Sect. 3.2).

Illinois Brick Co. vs. Illinois, 431 US 720, 97 St. Ct. 2061 (1977) (see Sect. 3.4).

Standard Oil Co. vs. United States, 221 US 1 (1911) (see Sect. 3).

USA vs. Arnold, Schwinn & Co., 388 US 365 (1907) (see Sect. 3.1).

USA vs. Microsoft, Civil Action, 98-1232 (1998) (see Sect. 4).

USA vs. Von's Grocery Co., 384 US 270, 301 (1966) (see Sect. 3.1).

Anxiety and Anxiety Disorders

In addition to happiness, sadness, anger, and desire, anxiety is one of the five important normally and regularly occurring emotions which can be observed

throughout all human cultures and in several animal species (Ekman 1972). Anxiety *per se* is a complicated concept since several difficulties arise in defining this emotion and, in addition, it has to be differentiated from fear and stress (see below). Moreover, anxiety refers to a variety of other emotional experiences, for example, apprehensiveness, nervousness, tension, and agitation, which are partially directly related to anxiety, but occur also in other emotional states. Anxiety is defined by subjective, behavioral, and physiological characteristics. Anxiety involves the experience of dread and apprehensiveness and the physiological reactions of anxiety usually include trembling, sweating, elevated heart rate and blood pressure, and increases in muscle tone and skin conductance. Anxiety is defined as pathological when occurring inadequately or with much more pronounced severity and debilitating features. An additional defining criterion in standardized diagnostic manuals is the concomitant occurrence of anxiety and avoidance. Representatives for these diagnostic entities, in which anxiety is the leading symptom, are panic disorder and generalized anxiety disorder. Anxiety is experienced in phobic disorders when the subject is confronted with the feared stimulus, which results in its avoidance. One of the reasons for the declaratory confusion of the term *anxiety* is its psychological similarity to fear and its vegetative similarity to stress. Similar to anxiety, *fear* also includes the experience of dread, and fear seems to be largely included into the concept of anxiety. Moreover, anxiety and fear induce bodily reactions, which represent the so-called stress responses. Stress responses again can be divided into two large entities, the excitatory fight or flight response postulated by Cannon (1929) and the endocrine stress concept raised by Selye (1956). In contrast, the results of several studies indicate that the brain function during stress involves structures which mediate the perception of anxiety such as amygdala, hippocampus, and other limbic structures (see below).

1. *Differentiation of Anxiety*

Both anxiety and fear are regularly experienced within a range of normal emotional responses of everyday life. Specifically, fear is necessary to achieve personal growth and individual freedom during ontogeny.

1.1 *Anxiety*

Anxiety represents one of the five basic emotional states and can be defined by affective (basic emotional feelings), perceptive (realization of bodily or psychomotor sensations), and cognitive components. Besides these subjective components, behavioral and physiological characteristics can be used to define anxiety phenomenologically. In contrast to experiencing anxiety during everyday life, anxiety as psychopathologic disturbance or anxiety disorder includes specific diagnostic criteria, neurobiological dysfunctions, and a specific genetic background and leads to social and occupational disabilities.

1.2 *Fear*

Fear is the normal reaction to threatening stimuli and is common in everyday life. When fear is greater than warranted by the situation or starts to occur in inappropriate situations, a specific phobia arises which belongs to the diagnostic entity of anxiety disorders. One distinction between fear and anxiety is based upon the presence of commonly defined stimuli, a realistic relation between dangerousness and elicited fear, and the potential to adapt to the stimuli. Specific phobias are defined as persistent, irrational, exaggerated, and pathological dreads of a stimulus or situation combined with a compelling desire to avoid this feared challenge.

1.3 *Stress*

Stress is also regularly experienced by all organisms, and refers generally to physical or psychological stimuli or alterations that are capable of disrupting the homeostasis of one individual or animal. With regard to psychological aspects of stress, predictability, control, and coping skills are important determinants, which, however, are also threatened during anxiety or fear. Hence, anxiety and fear also represent important psychological stressors with their physiological sequelae being similar to stress reactions. The differentiation between stress and anxiety is difficult, since psychological and biological aspects of stress are linked to each other and are mutually interdependent.

2. *Anxiety Disorders*

As defined by means of the diagnostic and statistical manual of mental disorders (*DSM-IV*; American Psychiatric Association 1994), anxiety disorders comprise a heterogeneous group which share *anxiety* as a symptom. However, each of these disturbances has a different etiology and outcome and different physiological characteristics.

2.1 *Panic Disorder*

Panic disorder is characterized by recurrent paroxysmal anxiety which can even surmount the fear of death during an acute myocardial infarction. These attacks are regularly combined with bodily sensations such as tachycardia, suffocation, shaking, trembling,

sweating, abdominal distress, and dizziness. They typically have a sudden onset and are either unpredictable or occur before or during specific situations. If these attacks are affiliated to specific situations they can lead to avoidance of these specific events and an agoraphobia develops (see *Panic Disorder*).

2.2 Phobias

Phobias are usually differentiated into three specific subtypes: agoraphobia, as frequent sequels of panic disorder, social phobias, and simple phobias. Agoraphobia is the fear of being in situations from which escape is not immediately possible. The symptoms regularly include depersonalization, derealization, dizziness, and cardiac symptoms. Agoraphobia may occur without preceding a panic attack, but remain consolidated between attacks. Social phobias are characterized by the fear that someone may be exposed to a situation where this person is inappropriately scrutinized by others or where this person may behave inadequately. Exposure leads to prominent symptoms of anxiety including bodily alterations, and anticipatory anxiety leads to the avoidance of these situations. Simple phobias are characterized by a persistent fear of a defined object or situation such as fear of spiders or fear of height. The anticipatory anxiety is common and these stimuli are largely avoided, which can impair daily life routines.

2.3 Generalized Anxiety Disorders

This disorder is characterized by an unspecific, unrealistic, and excessive apprehension about a large variety of future events, which are difficult to control for the person. It has been classified as a chronic disorder lasting longer than six months. Specific physiological symptoms include motor tension, autonomic hyperreactivity, and sleep disturbances.

2.4 Post-traumatic Stress Disorders (PTSD)

In contrast to the above-mentioned disorders, PTSD does not present anxiety as the leading symptom. Typically this disturbance follows a psychologically and also physically distressing incident which is outside the realm of normal human experience and which is frequently life threatening. Incidents may be experienced alone or in groups and include natural or human-made emergencies. The disorder is characterized by re-experiencing the traumatic event in different ways: by recurrent intrusive thoughts, dreams, and flashbacks accompanied by intensive feeling or reliving the trauma in a dissociative state. Reminders of the incident can cause intense psychological distress. In addition, loss of interest, depressive mood, and feelings of detachment from family members or friends frequently occur. PTSD patients have a persistently increased level of arousal, concentration problems, sleep disturbances, and an increased sympathetic arousal, but surprisingly a decreased secretion of cortisol and related stress hormones (see *Post-traumatic Stress Disorder*).

2.5 Obsessive Compulsive Disorders

As mentioned for PTSD, this disorder also does not present anxiety as a leading symptom: essential features of this disorder are recurrent obsessions and compulsions that are strong and persistent enough to cause distress or that are disabling in daily life. Obsessions are defined as prominent and persistent thoughts about the same person, object, or action and compulsions are repetitive intentional behaviors that accompany these obsessive thoughts. All these behavioral manifestations are performed stereotypically and excessively. The actions are a function of a conflict between wanting to pursue and to resist this behavior. Whereas the patient realizes the irrationality, the compulsive behaviors typically provide a release of tension and fear (see *Obsessive–Compulsive Disorder*).

3. Sources of Anxiety in Humans

Anxiety has to be derived from complex origins and an interplay of genetic, biological, social, and psychological events and influences. Among the most important factors are the genetic or biological disposition, the developmental and environmental impact upon one individual, and acute stressors and experiences which challenge one person and lead to a variety of adaptational changes.

3.1 Genetic and Biological Disposition

Hints for a genetic background of anxiety disorders and indicators for their heritability have been considered as long as for mood disorders, despite the change of diagnostic criteria and labels for different anxiety disorders over the years. Among the anxiety disorders the genetics of panic disorder and generalized anxiety disorder have been most studied (Burrows et al. 1992). From a methodological point of view, family studies, twin studies, and linkage studies have to be differentiated. Regarding panic disorder it has been shown that relatives of patients have an increased risk of a similar disturbance. Among relatives a risk of up to 30 percent is reported, which is significantly different from a lifetime prevalence of about 2 percent in the general population. Also, twin studies support a heritable component since several

studies indicate that the concordance rates for panic disorder are higher in mono- than in dicygotic twins. Linkage studies have been attempted several times, but no single gene locus could be identified. Considering the great complexity of this disorder, it is to be expected that a single gene locus is unlikely to be responsible for the diagnostic entity *panic disorder*. However, association studies might lead to the detection of genes responsible for an enhanced vulnerability to anxiety disorders. Support for a genetic basis of anxiety stems also from preclinical studies. By selective breeding, different lines of rats can be established which differ markedly in their innate anxiety behavior. This might be also of importance in the initiation of alcohol consumption by these rats: animals with higher innate levels of anxiety show a greater preference for alcohol. It has been demonstrated by genetic knockout strategies in mice for specific receptors that deficiency of receptors, which are considered to be involved in anxiety and stress reactions, is correlated with a lower innate anxiety behavior. These receptors include, among others, the corticotropin-releasing factor (CRF) receptor (Steckler and Holsboer 1999; see *Endocrinology and Psychiatry*).

3.2 Social and Environmental Influences

Although the strong impact of child rearing or untoward events during childhood is evident, it is worth remembering that simple relationships cannot be constructed. Some child-rearing conditions such as family conflict situations have been correlated with anxiety during adolescence. Also other factors such as parental support, child rearing style, and personality traits have been linked to anxiety in adolescence (Spielberger and Sarason 1977). Especially spanking in childhood carries an association and increased lifetime prevalence of anxiety disorders as well as depression and alcohol abuse. Despite the great interest in this aspect of anxiety, the literature on the relationship between parent–child interactions and anxiety disorder is inconsistent. Besides these factors age also contributes to the expression of anxiety. Anxiety and anxiety disorders have a higher incidence in adolescence that cannot be reduced only to the use of different diagnostic tools, but seems to be related to other factors (*Psychiatry and Sociology*).

3.3 Life Events

In context with environmental and developmental influences, traumatic events, which are regularly out of the realm of normal human experience, are of special importance. A traumatic event can lead to increased anxiety after the event, but may have also long-term effects that emerge with future traumas. This has several implications: PTSD and increased arousal in response to the experience of a traumatic event have been related to adversities during childhood (e.g., childhood abuse). Childhood abuse, however, appears to increase an individual's risk to develop PTSD in response to extreme stressors in adulthood. Besides abuse, other adversities such as parental loss have also been related to the development of anxiety including PTSD (Friedman et al. 1995, Heim and Nemeroff 1999).

4. Neuronal Basis of Anxiety

Both the increasingly differentiated analysis of anatomical structures and biochemical and neurophysiological pathways have led to a more detailed concept about the neurobiology of anxiety and especially of panic attacks.

4.1 Neuroanatomical Structures

Whereas fear is one of best investigated emotions in terms of brain mechanisms, a direct comparison of animal models of fear is limited with respect to the spectrum of human anxiety disorders. It has been proposed that panic disorder involves the same pathways that support conditioned fear in animals. These findings support the theory that panic attacks arise from loci in the brain stem that control serotonergic and noradrenergic neurotransmission and respiratory control. Further, it was postulated that anticipatory anxiety arises from kindling of limbic areas and phobic avoidance from precortical activation. Sensory inputs for conditioned stimuli are mediated through the connection of the anterior thalamus to the lateral and then to the central nucleus of the amygdala. The latter coordinates physiological and behavioral responses related to anxiety. Efferents of this nucleus have several targets, for example, the parabrachial nucleus producing an increase in respiratory rate, the lateral nucleus of the hypothalamus activating the sympathetic system, the locus coeruleus resulting in an increase in noradrenaline release with its sequelae of increased blood pressure and heart rate and behavioral fear responses, and the nucleus paraventricularis of the hypothalamus causing an increase in corticosteroids. As outlined by LeDoux (1998), the overlap between effects of brain-stem activation by the central nucleus of the amygdala in animals with physiological effects in humans during panic attacks is striking. Besides these connections, mutual interactions between the amygdala and the thalamus, the prefrontal and the somatosensory cortex are obvious. An impairment of the cortical processing could lead to a misinterpretation of visceroafferent cognitions, leading to the activation of the above-mentioned systems. Because of these complex interactions with the autonomic and

endocrine regulation, panic attacks apparently result in equivocal physiological and behavioral sequelae (see below) (Gorman et al. 2000).

4.2 Transmitter Systems

Considering a large body of clinical and preclinical findings, the monoamine transmitters serotonin and noradrenaline and the neuropeptide corticotropin-releasing factor are most important in the regulation of the neuroanatomical structures involved in anxiety and fear. Regarding serotonergic neurotransmission, several findings support its involvement in mediating anxiety: serotonin neurons in the raphe nuclei have an inhibitory effect on noradrenergic neurons at the locus coeruleus. In addition, these neurons act at the periaquaeductal gray modifying the escape responses and are also thought to inhibit the hypothalamic release of CRF. From a clinical point of view, these findings are supported by the effects of serotonin reuptake inhibitors, that is, pharmaceuticals which inhibit the uptake of serotonin back into the presynaptic neuron and increase the amount of serotonin in the synapse to bind both to pre- and postsynaptic sites where more than 13 subtypes of serotonin receptors coupled to different membranous and intracellular effector systems have been identified (Kent et al. 1998). Overall, a long-term increase of serotonergic transmission by these compounds exerts antipanic and anxiolytic effects.

The other important neurotransmitter system involved in anxiety disorders is the noradrenergic system (Sullivan et al. 1999). Noradrenalin neurons largely originate in the locus coeruleus and some other nuclei in the medulla and pons. Projection sites include the prefrontal cortex, the amygdala, the hippocampus, the hypothalamus, the thalamus, and the nucleus tractus solitarius. Conversely, the locus coeruleus is innervated by the amygdala. Therefore, the locus coeruleus seems to integrate external sensory and visceral afferents influencing a wide range of neuroanatomical structures related to fear and stress. Clinically it has been proven that noradrenergic alpha-2 receptor antagonists such as yohimbine can be used to provoke panic attacks acting via an increase in synaptic availability of noradrenaline. In contrast, clonidine, an alpha-2 adrenergic agonist, exerts anxiolytic-like effects in experimentally induced panic attacks such as lactate infusions.

Both transmitter systems, the serotonergic and the noradrenergic, interact with the release of CRF, a 41 amino acid neuropeptide (Arborelius et al. 1999, Koob 1999). Neurons containing CRF and its receptors have been shown to be distributed throughout the brain and CRF has emerged as a neurotransmitter that plays a central role not only in stress regulation but also in anxiety and depression. CRF neurons are found in the amygdala, the hypothalamus, and the locus coeruleus. Their activity is regulated by adaptive responses. CRF neurons also project from the amygdala to the locus coeruleus. Hence CRF could act as a modulator of cognitive and physiological symptoms of anxiety. This factor initiates on the one hand a humoral cascade which enhances via the secretion of corticotropin the release of glucocorticoids, which in turn act at central gluco- and mineralocorticoid receptors. CRF is on the other hand involved in the modulation of anxiety and depression. Stress results in increased CRF concentrations in the locus coeruleus and CRF increases the firing rate noradrenergic neurons. In contrast, noradrenaline also potently stimulates the release of CRF. The involvement of CRF is interesting also with respect to respiratory alterations during panic attacks which have led to the 'suffocation false alarm theory' (Klein 1993), since CRF seems to be an important modulator of respiratory centers in the brain stem. Several studies support the contention that antagonists and inhibitors of the synthesis of CRF exert anxiolytic-like effects. A CRF-1 receptor-deficient mouse showed a significantly lowered anxiety behavior in comparison with controls. Antagonists of CRF receptors have also been examined in clinical trials for their anxiolytic and antidepressant potency.

Since serotonin reuptake inhibitors are involved in the inhibitory regulation of noradrenergic neurons of the locus coeruleus and since serotonin reuptake inhibitors are thought to reduce the hypothalamic release of CRF, these complex interactions suggest that noradrenergic, serotonergic, and CRF-regulated neurotransmission are linked together mediating the responses to anxiety, fear, and stress (see *Peptides and Psychiatry*).

5. Models of Anxiety

Anxiety is not merely one of the most important emotions throughout phylogeny and ontogeny, but is also provocapable by different means and can then be readily observed under experimental conditions. Both in humans and in animals a variety of investigations have been conducted which allow thorough insights into the pathophysiological conditions and the cognitive and neurobiological processes involved in these specific emotional states.

5.1 Animal Models

Animal studies in anxiety can be used both for investigating the physiological and anatomical substrates of anxiety and for studying pharmacological strategies for their potential anxiolytic or anxiogenic effects (Westenberg et al. 1996). Basically there are two types of animal behavioral models to detect anxiolytic-like effects. One is based upon conditioned behavior

and detects responses controlled by operant conditioning procedures. The other type of model involves unconditioned behavior which is mainly based upon naturally occurring behavior and is called ethologically based models. A different type are separation models, which mainly investigate the behavior of an offspring during separation from its mother and involves the investigation of developmental disturbances.

5.1.1 Conditioned emotional responses. The most important conditioned models comprise conflict models where behavior is suppressed by aversive stimulation. The release of the suppressed behavior without altering the levels of punished responding following pharmacological intervention is estimated as the anxiolytic-like effect. Using these models in rodents, for example, benzodiazepines are consistently effective, whereas for other compounds such as serotonin reuptake inhibitors anxiolytic-like effects are difficult to find. Other important models are the fear-potentiated startle response where the startle response of rats is augmented by fear conditioning. During the conditioning phase another stimulus is presented signaling the presence of, for example, a shock stimulus. During the startle response presentation of the stimulus enhances the startle amplitude. Also in this paradigm benzodiazepines exert anxiolytic effects. In addition to these models a variety of other conditioned responses and active and passive avoidance reactions can be determined.

5.1.2 Ethological models. In contrast to the conditioned responses, the ethological models are based upon naturally occurring behavior. The most important and frequently used models are the elevated plus-maze, the open-field, and the dark–light-box models. The elevated plus-maze uses the conflict between exploration and aversion to elevated open places. In this test, the anxiety is generated by placing the animal on an elevated open arm, where height and openness rather than light are responsible for anxiogenic effects. The device is shaped as a plus sign with two open arms and two arms enclosed by high walls. The time that rodents spend on the open arms and the number of entries are related to the anxiolytic effects. The open-field test investigates the distance traveled by rodents in a locomotor box within a given time interval. Usually, rodents avoid open areas and try to remain at the edge of the locomotor box. The overall distance traveled and the transitions of the central area of the box are related to the anxiolytic potency by a treatment. The dark–light box uses the number of transitions between a light and a dark, closed compartment as measure of anxiety, since rodents prefer the dark compartment. Peptide receptor ligands such as CRF (Arborelius et al. 1999) and cholecystokinin tetrapeptide (CCK-4) (Bradwejn and Vasar 1995) show anxiogenic effects in all three paradigms, whereas other substances such as atrial natriuretic peptide (ANP) (Wiedemann et al. 2000) and neuropeptide Y (Heilig and Widerlöv 1995) indicate anxiolytic-like effects.

5.2 Human Models

The interest in human models of anxiety has been catalyzed to a large extent by findings that panic attacks can be stimulated by a variety of different psychological, physiological, and pharmacological paradigms. Attempts to alter basic anxiety levels and especially those via induction of psychological stress have led to equivocal findings. This might indicate that within the above-mentioned neuroanatomical and physiological systems strong interfering factors exist, which modulate the responses to anxiety and stress.

5.2.1 State and trait anxiety. When investigating human anxiety, the distinction between state and trait anxiety is most important. State anxiety can be defined as a transitory emotional state consisting of feelings of apprehension, nervousness, and physiological sequelae such as an increased heart rate or respiration (Spielberger 1979). Whereas everyone can experience state anxiety occasionally, there are large differences among individuals in the frequency, duration, and severity. State anxiety can be determined by several rating instruments developed in the past. Trait anxiety represents a fairly stable characteristic related to personality. Experiencing more frequently state anxiety combined with a general view of the world as being threatening and dangerous is used as marker of trait anxiety. The initiation and maintenance of trait anxiety have been related to several factors as outlined above.

5.2.2 Challenge studies. The profound interest in state anxiety and especially panic attacks stems from a large variety of investigations provoking anxiety and panic attacks experimentally (Nutt and Lawson 1992). Panic attacks are unique in the spectrum of psychiatric disorders since their core psychopathology is temporally limited and can be provoked and investigated under laboratory conditions. Information provided by these studies has led to new cognitive and physiological theories about the basis of panic anxiety and anxiety diseases. Moreover, owing to the experimental character of these investigations, closer comparisons with experiments in animals can be drawn in contrast to other psychiatric animal models. Panic attacks can be elicited by various

Table 1
Experimentally induced panic attacks

Panicogen	Heart rate stimulation	Respiratory stimulation	HPA stimulation	NE stimulation

Caffeine	+	+	+	−
CCK-4	+	+	+	(+)
CRF	+	+	+	(+)

HPA, hypothalamo–pituitary–adrenocortical system; NE, noradrenergic system; CCK-4, cholecystokinin tetrapeptide; CRF, corticotropin-releasing factor.

means which are listed in Table 1. As indicated, the different paradigms can be differentiated into cognitive, metabotropic and direct receptor interactions. Especially naturally occurring, cognitive, and metabotropic panic attacks share many features. One of the most amazing findings is that, despite the dramatic anxiety felt, a uniform stress response either of the hypothalamo–pituitary–adrenocortical (HPA) or the sympathetic system is largely missing. These findings led to the hypothesis that in addition to a variety of stimulating agents, strong inhibitors also exist which physiologically antagonize the altered transmitter and modulator systems involved in panic anxiety. Considering the hypothesis that CRF is one important modulator of anxiety in humans and rodents, it is astonishing that no activation of the HPA system occurs in naturally occurring or metabotropic panic attacks. In contrast, compounds interfering with monoamine and peptide receptors stimulate the HPA activity and the noradrenaline system. Of the latter group, one of the most potent panicogens is CCK-4 (Bradwejn and Vasar 1995), which seems to exert its effect via CRF. Up to now only a few modulators have been identified, which are able to inhibit the exaggerated HPA system activity and, in addition, exert anxiolytic-like effects. One of these inhibitors might be ANP which is secreted in the atria of the heart and in various brain regions involved in anxiety. Hence it may be speculated that peptides such as ANP might help to explain the so far unknown mechanisms of terminating panic anxiety (Wiedemann et al. 2001). Despite a tremendously increased knowledge about the induction of anxiety, fear, and stress, the mechanisms of coping and terminating these emotional alterations need further investigations.

Anxiety and Fear, Neural Basis of

1. *Stress, Anxiety, and Fear*

The terms stress, anxiety, and fear are commonly used in the daily language, as well as psychological, psychiatric, and neuroscientific literature. Consequently, these terms have been defined from a variety of descriptive, phenomenological, psychodynamic, and biological standpoints. Behavioral, electrophysiological, pharmacological, and genetic methods increasingly facilitate research on the underlying cell biological mechanisms and neuronal circuitry of stress, anxiety, and fear.

Stress represents an integrated neuroendocrine response of humans and animals to stimuli perceived as novel or threatening. Although a variety of physical, psychological, and physiological stimuli may be perceived as stressful, at a biological level, the stress response is highly conserved, and consists of a set of emotional, cognitive, autonomic, and metabolic reactions that are elicited to enable rapid adaptation to the environment. One of the earliest chemical signals released after a stimulus is perceived as stressful is corticotropin-releasing factor (CRF), a hypothalamic peptide (Spiess et al. 1981) acting via the portal bloodstream at the pituitary thereby stimulating the secretion of the peptide corticotropin (ACTH). ACTH enters the bloodstream and elicits the release of glucocorticoid hormones from the adrenal gland. In addition to the activation of the hypothalamo-pituitary–adrenal (HPA) axis, the organism responds with a strong activation of the adrenergic system. Thus, a stress response can be reliably evaluated by measuring the blood levels of ACTH, glucocorticoids, and adrenaline at a very early stage. In addition, a stress response elicits numerous other molecular processes in the brain, which are not detectable in the systemic circulation, and valuable data about these processes have been generated from laboratory animals, in particular rats and mice. These processes consist of changes of protein phosphorylation, gene expression, and alteration of growth factor levels leading to plastic changes in the neuronal synapses. Upon re-exposure to the same or other stressful stimuli, the pattern of behavioral and molecular processes is altered. For example, in the limbic forebrain, the transcription factor FOS is not produced after exposure to a previously encountered stimulus independently from its aversive properties, and thus, in this context FOS may be regarded as a molecular marker for novelty (Radulovic et al. 1998a).

Rodents, as well as humans, respond to a stressful situation with alerting emotional responses such as anxiety or fear. An attempt to discriminate between fear and anxiety on a biological basis is undertaken below. For the presentation of several animal models of fear and anxiety (see Rodgers 1997, for review), it may be sufficient to point to the rather focused expression of fear when compared to the diffuse expression of anxiety.

2. *Animal Models: Anxiety and Fear*

2.1 *Animal Models of Anxiety*

In rodents, anxiety is measured by a number of paradigms that evaluate different sets of behaviors of rodents under defined environmental conditions. The most commonly applied tests measure the preference for dark over light environments (elevated plus-maze test, dark–light emergence task), the intensity of muscle contraction in response to sensory stimuli (startle), or contacts during social interactions. In the shock-probe-burying test, an animal encounters an electrified probe, and copes with it by burying or avoiding the probe. This test has been regarded as a model for fear as well as anxiety. Although the findings that lateral septal lesions affect burying whereas amygdala lesions affect probe avoidance may indicate that burying and probe avoidance reflect anxiety and fear, respectively, conclusive biological evidence is still lacking.

Most of the anxiety tests also measure additional behaviors, such as exploration, locomotion, and risk assessment that may or may not be directly linked to anxiety. As the interdependence of these behaviors and anxiety is difficult to evaluate, anxiety is optimally identified and quantified when the other behaviors are not affected (Weiss et al. 2000). With the exception of the startle assay, the rodent tests for anxiety evaluate acute anxiety responses and are optimally carried out once. Multiple exposures to the test are associated with strong interference of habituation, which adds learning components to anxious behavior.

2.2 Animal Models of Fear

With the exception of inborn fears such as fears of predators, evaluation of fear responses requires a two-step procedure. Classical fear conditioning occurs when the animal learns that an originally neutral stimulus (conditioned stimulus, CS) is predictive of danger. For training, the animal is placed in a novel environment (context) and at the end of an exploratory period a foot shock (unconditioned stimulus, US) is delivered. If a tone or light is presented as a CS before the shock, the animal learns to associate the CS with the US. The fear response is behaviorally evaluated after re-exposure to the used context, tone, or light by measuring the freezing behavior reflecting conditioned fear. Alternatively, conditioned light or tone may be presented when the animals are in a startle box, and in response to the CS exhibit fear-potentiated startle.

2.3 Potentiation of Anxiety

Animal models of potentiated anxiety apply the same tests that measure anxiety; however, before the anxiety test the animal experiences a stressful event that is unrelated to the stimuli of the test situation. Potentiated anxiety is commonly observed following exposure to uncontrollable stressors, such as immobilization, social defeat, ethanol withdrawal, or classical fear conditioning. Generalization, observed in response to stimuli other than the CS used for fear conditioning, may reflect potentiated anxiety. However, animals pre-exposed to a stressor they can control or escape from, as during active avoidance (when for example the animal's transition from one context to another stops the delivery of shock), do not develop potentiated anxiety.

Potentiated anxiety can also be induced pharmacologically by compounds that increase anxious behavior. For example, injection of the peptide CRF into the bed nucleus of the stria terminalis elicits a long-lasting facilitation of the startle response, whereas its injection into the lateral septum mimics stress-induced anxiety on the elevated plus-maze.

3. Similarities and Differences Between Fear and Anxiety

Anxiety and fear have been clearly distinguished in psychiatry. However, neurobiologists commonly treat these emotional responses as the same process, possibly on the basis of the close molecular, neuroanatomical, and functional relationship between fear and anxiety. This close relationship is demonstrated by the findings that: (a) both fear and anxiety elicit similar behavioral, somatic, motor, and visceral responses mediated by common pathways within discrete hypothalamic, midbrain, and brain stem nuclei; (b) acquisition of fear responses can be significantly prevented by anxiolytic drugs such as benzodiazepines and agonists of the serotonin receptor 5-HT1A; and (c) acquisition of conditioned fear responses is closely paralleled by increased anxiety which is maximal after memory consolidation (Radulovic et al. 1998b).

The differences between anxiety and fear are significant at the level of cognitive processing of the stimuli that elicit the emotional response, so that the stimulus recognition at the level of the cortical–limbic system significantly determines whether fear or anxiety is expressed.

3.1 Neuroanatomical Circuitry of Anxiety and Fear

As presented in Table 1, it is notable that lesions of distinct brain regions differentially affect anxiety, potentiated anxiety, and conditioned fear. These data suggest that the fear and anxiety systems are diffusely distributed throughout the limbic forebrain and that their expression recruits distinct sets of behaviors under different anxiety- or fear-provoking environmental conditions. A detailed analysis of anxiety and fear responses at the neuroanatomical level has been performed in a series of experiments using the model of startle response (Davis et al. 1997). These authors delineated the limbic structures differentiating fear-potentiated from light- or CRF-potentiated startle. These structures, however, do not affect anxious behavior on the elevated-plus maze, which is in turn highly susceptible to lesions of the lateral septum (Figure 1). Another differentiation can also be made with regard to the thalamic and cortical input providing these limbic structures with sensory information. For example, whereas the basolateral amygdala receives auditory and visual projections from the thalamus and perirhinal cortex, the major telencephalic input of the lateral septum is provided by the hippocampus, which is essential for processing of spatial and contextual stimuli and receives cortical fibers from the entorhinal cortex. Accordingly, either fimbria–fornix or lateral septal lesions can disrupt elevated plus-maze anxiety.

Taking into account the remarkable dissociation between anxiety and fear among the structures of the

Table 1
Dissociation of anxiety and fear by regional brain lesions of the rat

Test	Lesioned brain area	Effect	Reference
Elevated plus-maze test	Lateral septum	Increased time spent in the open arms	Treit et al. 1993
Shock-probe burying test	Lateral septum	Decreased burying	
	Amygdala	Increased contact with probe	
CRF-enhanced startle	Bed nucleus of the stria terminalis	Impaired	Davis et al. 1997
Light-enhanced startle	Amygdala	Impaired	
	Bed nucleus of the stria terminalis	Impaired	
Fear-potentiated startle	Amygdala	Impaired	
Contextual fear conditioning	Hippocampus	Impaired	Fendt and Fanselow 1999
	Basolateral amygdala	Impaired	
	Lateral septum	Enhanced	Vouimba et al. 1998

Figure 1
Brain regions and pathways mediating fear and anxiety. BLA, basolateral amygdala; BNST, bed nucleus of the stria terminalis; CeA, central amygdala; PAG, periaquaeductal gray matter; PnC, caudal pontine nucleus

limbic system, it remains unclear why anxiety develops along memory consolidation of conditioned fear. It is hypothesized that anxiety and fear potentiate each other by facilitation of the common pathways at the level of hypothalamus, midbrain, and brainstem.

3.2 Molecular Mechanisms of Anxiety and Fear

The balance between the activity of excitatory, glutamatergic, and inhibitory, GABA-ergic neurons is of utmost importance for the expression of anxiety (Clement and Chapouthier 1998). The blockade of NMDA or AMPA/kainate receptors prevents both anxiety and fear responses. In contrast, blockade of GABA receptors, in particular GABA-A receptors, increases anxiety whereas activation of the benzodiazepine site of the GABA-A receptor decreases anxiety. To date, the GABA-A receptor agonists, benzodiazepines, are widely employed in the treatment of anxiety disorders.

In general, the activation of glutamate receptors involved in anxiety is also essential for fear conditioning, whereas activation of GABA-A and sero-

tonergic 5-HT 1A receptors that prevent anxiety also prevent fear conditioning. These results are commonly observed not only after systemic drug application, but also after local injections into brain regions that differentially process anxiety and fear. Thus, generation of anxiety and conditioned fear appears to depend indistinguishably on excitatory and inhibitory amino acid transmission.

However, we have recently demonstrated that within a defined brain area, peptidergic action may differentially affect anxiety and learning measured as conditioned fear. Shortly after a stressful experience, the animal responds with general arousal and anxiety, whereas at a later time it responds with increased associative learning of specific aversive stimuli (Radulovic et al. 1999). Thus, the peptidergic action within the brain responds with a different regional time pattern after stress. Furthermore, without affecting anxiety, CRF enhances fear conditioning through hippocampal CRF receptor 1 whereas it impairs fear conditioning through lateral septal CRF receptor 2. Even within the CRF receptor 2 system, remarkable differences are observed. Thus, septal CRF receptor 2 mediates stress-induced anxiety (Radulovic et al. 1999), whereas non-septal CRF receptor 2 decreases baseline anxiety. Increased anxiety in male mice lacking CRF receptor 2 is accompanied in several brain areas by a significant reduction of phosphorylated CREB (cAMP responsive element binding protein), serving as a transcriptional activator. Thus, it appears on the basis of this observation that successful coping with a stressful stimulus is linked—at least in the mouse under investigation—to enhanced CREB phosphorylation (Kishimoto et al. 2000).

4. Perspective

Significant research efforts are targeted at the elucidation of the biological correlates of behavior with the objectives to fundamentally understand the basic principles of higher brain function and eventually emotional and cognitive disorders. In particular, anxiety disorders show increasing incidence. Free-floating anxiety or phobias occur in the absence of specific or appropriate association, and these and other clinical forms of anxiety represent chronic states in humans. The chronicity of these disorders largely impairs the delineation of the molecular mechanisms causally linked to anxiety from compensatory/secondary molecular changes. Therefore, animal experiments dealing with acute anxiety may provide unambivalent insight into the genetic, cellular, and biochemical mechanisms underlying the induction and termination of anxious behavior in the nervous system. Elucidation of these mechanisms could facilitate approaches to chronic anxiety states in humans. Interesting anxiolytic drug developments may result from the cell biological research on the transductional mechanisms assigning roles to CRF and CREB phosphorylation in coping with anxiety.

Anxiety Disorder in Children

Anxiety disorders relate to recurrent, excessive, and intense fears and anxiety relating to one or more situations resulting in disruption and interference to

1. Separation anxiety disorder (SAD)
   - excessive anxiety about separation from significant others or from home

2. Social phobia
   - excessive anxiety about social or performance situations in which the individual fears scrutiny or exposure to unfamiliar people, and in which the individual feels embarrassment may occur (APA 1994)

3. Agoraphobia
   - anxiety and/or avoidance of situations in which the individual feels that escape may be difficult or that help may not be available

4. Panic disorder
   - primarily defined by the occurrence of a panic attack, i.e., a short period of intense fear that is accompanied by a variety of physical or cognitive symptoms

5. Specific phobias
   - may be of animal, natural environment, blood-injection or situational type
   - defined as a marked and persistent fear of the object or situation

6. Generalized anxiety disorder (GAD)
   - excessive anxiety and worry about a number of things
   - accompanied by at least three physical symptoms

7. Obsessive compulsive disorder (OCD)
   - may experience obsessions (persistent ideas, thoughts, impulses or images, e.g., fear of contamination), compulsions (behaviors that are repeated in order to prevent or reduce anxiety, e.g., repetitive hand-washing) or both

8. Post-traumatic stress disorder (PTSD)
   - may occur after an individual experiences a traumatic event
   - includes persistent re-experiencing of the event and avoidance of stimuli related with the event
   - duration of at least one month

9. Acute stress disorder
   - may occur after an individual experiences a traumatic event
   - includes persistent re-experiencing of the event and avoidance of stimuli related with the event
   - duration must be less than one month

10. Anxiety due to a medical condition
    - occurs as a direct consequence of a general medical condition

11. Substance-induced anxiety disorder
    - panic attacks, obsessions, or compulsions as a consequence of substance intoxication or withdrawal.

Figure 1
Anxiety disorders that may present during childhood

daily living and personal competence. There are several different types of anxiety disorder that children may experience with each disorder being characterized by a pattern of presenting symptoms. While the *Diagnostic and Statistical Manual of Mental Disorders, 4th edition* (*DSM-IV*; American Psychiatric Association 1994) outlines only one anxiety disorder specific to children and adolescents, namely separation anxiety disorder, children may also experience several types of anxiety disorders that are also found in adulthood. Indeed, although there are a few developmental differences in the way that children manifest anxiety disorders compared to adults, to a large extent anxiety problems in childhood closely resemble those experienced by adults. Figure 1 lists the various anxiety disorders that may present during childhood and the primary features of these conditions.

Contrary to widely held public beliefs, childhood anxiety disorders are not simply a normal, transient part of childhood development. Rather, these problems are associated with a range of negative consequences relating to personal, social, and academic adjustment. Furthermore, such problems are likely to persist if left untreated, with many adults reporting that the onset of their difficulties commenced in childhood or adolescence.

1. Prevalence of Anxiety Disorders in Children

Anxiety disorders represent one of the most common and debilitating forms of psychopathology in children. Anxiety disorders have been variously estimated to affect between 8 and 17 percent of the child population at a given point in time depending upon the definition and assessment measures used to determine the presence of an anxiety disorder (e.g., Kashani and Orvaschel 1990). Clearly, anxiety disorders represent one of the most commonly presenting problems of childhood. Generally, anxiety problems have been found to be more common among girls than boys, although it is interesting to note that gender differences are not typically found for the prevalence of obsessive compulsive disorder (March et al. 1995). The age of the child also affects the frequency with which the problem is found. For example, separation anxiety disorder is more common among younger children and tends to decrease in prevalence in later childhood and adolescence, whereas social phobia tends to become more prevalent in later childhood and adolescence (Kashani and Orvaschel 1990, Last et al. 1992). The findings of epidemiological studies therefore rarely concur with respect to prevalence rates for specific child anxiety disorders, as the rates tend to vary depending on the age of the children involved in the study and the criteria used to determine the presence of a problem. Generally speaking, generalized anxiety disorder, social phobia, simple phobias, and separation anxiety present most frequently, with obsessive compulsive disorder and post-traumatic stress disorder being less common. The picture is also complicated by a high level of comorbidity, in that children who experience one anxiety disorder are highly likely to present with another anxiety problem. Indeed, more than 50 percent of children who manifest an anxiety disorder are also likely to meet diagnostic criteria for some other anxiety problem. Clinically anxious children are also more likely than other children to report other forms of psychopathology such as depression and attention deficit disorder.

2. Etiology

Empirical research in the area of childhood anxiety has identified a number of risk factors that, when present, increase the likelihood of the development of such problems. More recently, evidence is also emerging regarding protective factors that reduce the negative impact of risk factors.

2.1 Genetic Transmission

Anxious children are more likely to have anxious parents and anxious parents are more likely to have anxious children. These familial relationships could indicate either genetic or family environment influences. Evidence confirms that genetic factors do play a part in determining the development of childhood anxiety disorders, but clearly this explanation does not account for many cases of childhood anxiety. The research has found heritability estimates of around 40–50 percent (Thapar and McGuffin 1995), meaning that other factors play an important role, in addition to genetic determination. Although genetic factors are clearly involved in the development of anxiety for some children, it remains to be shown exactly what is inherited. What appears to be inherited is an increased propensity to develop anxiety related problems, rather than a specific anxiety disorder. This propensity may relate to some temperament pattern in the child that increases the risk of developing anxiety disorders.

2.2 Child Temperament

Temperament theorists believe that early child temperament is of etiological significance to the later development of childhood anxiety. 'Behavioral inhibition' is the term used to describe one particular pattern of childhood temperament that has been most frequently linked with childhood anxiety problems. It can be defined as a relatively stable temperament style characterized by initial timidity, shyness, and emotional restraint when exposed to unfamiliar people, places, or contexts. This temperament pattern is associated with elevated physiological indices of arousal and has been shown to have a strong genetic component. Most importantly, children exhibiting a temperament style of behavioral inhibition demonstrate an increased likelihood of developing child anxiety (see Kagan 1997 for a review of this area). Other temperament theorists argue for the existence of three stable factors: positive affectivity/surgency (PA/S), negative affectivity/neuroticism (NA/N), and effortful control (EC) (Lonigan and Phillips in press). According to this theory, high NA/N combined with low EC places children at risk for the development of anxiety problems, and there is some tentative evidence to support this proposition. However, as not all children exhibiting an early temperament style of behavioral inhibition, or high NA/N combined with low EC, go on to develop an anxiety disorder, the presence of moderating or mediating variables appears to be likely. In particular, attachment style and parenting characteristics (see Sects. 2.3 and 2.4) are likely to interact with early childhood temperament to determine the development of anxiety problems.

Although the literature regarding childhood temperament is interesting, it tells us little about the exact mechanism of action. It remains to be determined whether temperament impacts upon anxiety through greater susceptibility to conditioning processes, greater emotional and/or physiological arousability

to stressful events, or through cognitive processes. For example, it is feasible that 'at risk' temperaments have their impact though greater tendencies to detect and attend to threatening stimuli in the environment, or expectations regarding the occurrence of negative outcomes. It has been shown in several studies that anxious children are more likely than others to think about negative events and to expect negative outcomes from situations.

2.3 Parenting Characteristics

The strong family links found in childhood anxiety could also be explained to some degree by parental behavior and the family environments in which the children are brought up. Parenting behavior has been suggested to impact upon child anxiety in a number of ways. From a learning theory perspective, certain forms of parenting behavior may increase the probability that children learn to respond in an anxious manner and fail to acquire the skills needed to cope with the inevitable stressful events that occur during children's lives. Observational studies have demonstrated that parents of anxious children are more likely to model, prompt, and reinforce anxious behavior, such as avoidance and distress in stressful situations. Furthermore, parents of anxious children are more likely to draw their children's attention to the threatening aspects of situations and less likely to encourage 'brave' solutions (Rapee in press).

The parents of anxious children are also more likely to engage in behaviors that make it less likely that children will learn how to solve stressful problems themselves. Empirical enquiry has found that parents of anxious children demonstrate higher levels of overcontrolling and overprotective behaviors that disrupt coping skills development. As a group, they are also more likely to be critical of their child's coping attempts, thereby reducing children's confidence in their abilities to solve their own life problems (Dumas, La Freniere and Serketich 1995, Krohne and Hock 1991). These parenting styles may interact with childhood temperament in explaining why some behaviorally inhibited children develop anxiety problems and some do not. For example, parental overprotection and overcontrol appears to be influential in determining the stability of behavioral inhibition in children (Hirshfeld et al. 1997a, 1997b). Parental behavior has also been found to be important in determining the impact of traumatic life events upon childhood psychopathology. Following trauma, children are more likely to develop emotional and behavioral difficulties if their parents react in an overprotective manner after the event (e.g., McFarlane 1987).

It is also important to consider that children have an influence upon parents, and anxious child behavior may cause parents to behave in particular ways. In much of the literature to date, it is not clear whether the overprotective behaviors of parents are definitely a cause of childhood anxiety or whether they could be a consequence of living with an anxious child. Future research needs to clarify these relationships.

2.4 Attachment Style

Recognizing the reciprocal effects of parents and their children, researchers have started to examine the quality of the attachment relationship between children and their caregivers. For example, Warren et al. (1997) found that anxious-resistant attachment at 12 months predicted anxiety disorders in adolescence, even after the effects of maternal anxiety and infant temperament were removed. There is also some evidence that attachment style may interact with infant temperament in the prediction of early markers of anxiety problems (e.g., Fox and Calkins 1993, Nachmias et al. 1996). It appears likely that certain patterns of behavior characteristic of particular forms of early childhood temperament make it difficult for parents and children to form secure attachments. Although this research is in its early stages, it appears to be an area that warrants further investigation. The quality of the parent–child attachment relationship may represent one mechanism through which familial transmission could occur. It is well recognized that parental psychopathology, particularly depression, disrupts parenting skills and interferes in attachment relationships. It may be that high levels of parental anxiety also disrupt effective parenting and attachment relationships, thereby contributing to intergenerational transmission of anxiety.

2.5 Traumatic, Negative and Stressful Life Events

The effect of traumatic, negative, and stressful life events on the development of anxiety in children is another area of etiological investigation. Perhaps not surprisingly, higher rates of anxiety disorders are associated with a range of natural disasters and traumatic life events (Benjamin et al. 1990). However, as not all children experiencing traumatic, negative, or stressful life events go on to develop anxiety disorders, the moderating or mediating influence of parenting behavior has been suggested. Indeed, what emerges from the literature relating to the etiology of childhood anxiety is a complex picture of interacting determinants and multiple pathways through which such problems may develop.

2.6 Protective Factors

Protective factors refer to variables that increase resilience to psychological disorder by reducing the

impact of risk factors. Positive social support, particularly from a significant adult, is one such protective factor that has been suggested to provide a buffer against the development of anxiety problems, and indeed against the development of psychopathology in general. For example, a strong negative relationship has been found between child anxiety level and family social support (White et al. 1998). Child coping style is another protective factor suggested to play a role in child anxiety. Coping style is a generic term that relates to the way in which individuals attempt to cope with negative or aversive situations. There is some tentative evidence to suggest that children employing problem-focused strategies are less likely to experience psychopathology, whereas emotion-focused and avoidant coping styles are associated with higher levels of anxiety and depression (Compas et al. 1988).

3. *Assessment of Childhood Anxiety*

Research conducted on childhood anxiety is reliant upon methods of identifying and quantifying anxiety and different forms of anxiety disorder. Professionally, anxiety measures may also assist in the guidance of treatment. Various types of assessment measures are used, such as interviews, questionnaires, and direct observation. Methods also vary according to whether the informant is the child, a parent, teacher, or an independent observer. Several diagnostic interviews exist for the identification of childhood anxiety disorders, such as the Anxiety Disorders Interview Schedule for Children (Parent and Child Versions; Silverman and Albano 1996). Diagnostic interviews are extremely useful for obtaining a clinical diagnosis but are time consuming and require adequate interviewer training in order to obtain a reliable assessment. For large-scale screening purposes it may be necessary to use child and parent questionnaires for measures of childhood anxiety. Questionnaire data also provides valuable information to supplement the diagnostic interview. Various forms of questionnaires exist. Some focus on the more general aspects of the subjective, physiological, and behavioral aspects of anxiety, such as the State Trait Anxiety Inventory for Children (Spielberger 1973) or the Revised Manifest Anxiety Scale (Reynolds and Richmond 1978). There are also several fear survey schedules that examine children's fear of a wide range of trigger situations or outcomes. In the late 1990s researchers started to develop anxiety questionnaires for children and parents that examine the specific symptoms of anxiety associated with particular anxiety disorders, such as the Screen for Child Anxiety Related Emotional Disorders (SCARED; Birmaher et al. 1997) and the Spence Child Anxiety Scale (SCAS; Spence 1997). There is also an increasing number of instruments that focus in depth upon one specific anxiety disorder.

An important consideration in the assessment of child anxiety is the notoriously low reliability between child and parent sources. Given this difficulty, assessment information is generally obtained from a range of sources in order to obtain a fuller picture of the child's presenting problems.

4. *Treatment Strategies*

There is convincing evidence to demonstrate that childhood anxiety disorders can be treated effectively. Since the early 1990s, the majority of treatment outcome studies in this area have focused upon the evaluation of cognitive behavioral treatments (CBT). Most studies have examined the efficacy of a combination of treatment approaches, including the training of coping skills (e.g., positive self-talk and relaxation), graded exposure to a hierarchy of feared situations, and identification and challenging of irrational thoughts and beliefs relating to the feared events. The majority of programs have also included some form of modeling, prompting, and reinforcement of 'brave' and approach behavior to the feared situation. Generally, parents are also instructed to ignore and not to reinforce fearful and avoidance behavior.

Several studies have now demonstrated the effectiveness of this combined approach to the reduction of childhood anxiety disorders. The most frequently evaluated program has been the 'Coping Cat' approach (see Kendall 1994). Generally, the evidence suggests that around 60–70 percent of children are no longer regarded as experiencing clinically significant anxiety problems one year after participating in treatment. The challenge for researchers in the future will be to develop treatments that are effective with the 30 to 40 percent of children who either do not respond to treatment or relapse afterwards.

5. *Prevention*

Given the high financial cost of treatment and the personal cost in terms of emotional suffering and disruption to daily living for anxious children and their families, there is a strong case for developing methods to prevent the development of childhood anxiety disorders. In keeping with the recognition of the importance of prevention of mental health problems generally, there has been a recent increase in efforts to develop effective methods of preventing anxiety disorders in children. To date, most universal strategies that target entire populations have focused upon the enhancement of mental health generally, rather than focusing specifically upon the prevention of anxiety problems. However, several programs have been investigated that can be described as 'selective' preventive interventions. These aim to target sub-

groups or individuals who are assumed to have a high lifetime or imminent risk of developing a problem as the result of exposure to some biological, psychological, or social risk factor(s). Examples of selective prevention strategies include those aimed at children whose parents have been divorced, those who are making the transition to high school, and children undergoing painful medical and dental procedures. Researchers have started to examine the possibility of intervening with children who manifest early childhood temperaments of behavioral inhibition or disrupted attachment relationships, in order to determine whether it is possible to reduce the probability of the development of anxiety problems. However, these studies are in their early stages and there is no clear indication as to their efficacy.

Some tentative data does exist to suggest that 'indicated' prevention strategies offers promise in the prevention of childhood anxiety disorders. The Queensland Early Intervention and Prevention of Anxiety Project (Dadds et al. 1997) represents an 'indicated' prevention program that targeted high-risk children demonstrating minimal but detectable symptoms of anxiety. This intervention made use of a one-term program that taught anxiety management and coping skills to elementary school children and their parents. At two-year follow-up, significantly fewer children who participated in the preventive intervention met diagnostic criteria for an anxiety disorder compared to those who did not take part. Importantly, the study also demonstrated that children who showed mild, nonclinical symptoms were at particular risk of developing a full-blown clinical anxiety disorder over the following two-year period if they did not receive the intervention.

While prevention research and practice remains in its infancy, a number of issues concerning prevention research warrant discussion. First, methods of childhood anxiety prevention may be child, parent, or environmentally based, and should be derived from the plethora of information regarding etiological factors and effective treatment strategies. Second, preventative efforts must be aimed in accordance with the developmental level of the child, as different risk factors may impact upon a child at different developmental stages. Third, the importance of multilevel intervention must be recognized, as effective prevention must go beyond the acquisition of personal skills and must include environmental and community change.

Apartheid

An Afrikaans word meaning 'separateness,' apartheid was the name given to the legislative program enacted by the National Party that ruled South Africa from 1948 to 1994. Created to entrench domination by the white minority, apartheid represented a refinement of race-based policies implemented by successive colonial governments for three centuries. Apartheid was developed in the 1960s as Grand Apartheid, the never-realized vision of creating separate, independent states for different ethnic groups. Increasingly disruptive internal opposition to apartheid led, in 1960, to the banning of liberation movements that continued their campaigns to overthrow the apartheid state from exile and underground. The failure of apartheid's Total Strategy to stem opposition, the resurgence of popular protest in South Africa in the 1980s, and the ending of the Cold War led to the dismantling of legal apartheid and the nation's first democratic elections in 1994. Beyond its impact in Southern Africa, the struggle against apartheid fostered crucial developments in the evolution of international human rights, uniting the fractious United Nations Security Council to intervene, for the first time, in the domestic race relations of a sovereign state.

1. Apartheid's Antecedents

Formal apartheid originated in the legal and social structures that followed the settlement of southern Africa by Europeans in the mid-seventeenth century. After agents of the Dutch East India Company created the first permanent European settlement in modern-day Cape Town in 1652, they soon transformed their supply station into a base for European expansion. Over the next 250 years, the settlers consolidated their control of land and livestock, conquering the indigenous Khoisan and Bantu peoples through war and disease. The British colonial authorities who administered the Cape Colony from 1806 perpetuated the Dutch policies of segregation and discriminatory legal standards. While the British abolished slavery and granted putative equality of political rights to the Khoisan in the Cape Colony in 1828, they denied meaningful political representation to the indigenous population who came increasingly under colonial control.

The discovery of vast diamond and gold deposits in the interior of South Africa in the late 1800s spurred colonial settlement and British interest in areas that had been declared independent republics by Afrikaans-speaking settlers of Dutch, French, and German descent. It would take the devastating South African War (Anglo–Boer War) of 1899–1902, during which a British force of 200 000 troops stamped its authority on the independent republics, to settle the territorial claims of the Boer, British, and local people. While the 1902 peace treaty entrenched the property rights of white settlers, the Union of South Africa, established in 1910, reasserted the race-based policies of the formerly independent colonies, denying the franchise to non-whites in all but the Cape Colony. The 1913 Natives Land Act delineated reserves for indigenous people, eventually barring them from owning land in 87% of the country, and forcing thousands into the labor market by banning share-cropping on white land.

During the 1930s, political leaders became increasingly successful in stimulating the nationalist ambitions of the Afrikaans-speaking population. Heavily influenced by the strict, Calvinist, Dutch Reform Church, the Afrikaners largely constituted a white underclass of small farmers and workers. The Reunited National Party's promise to overturn British domination, campaign against the South African government's military alliance with Great Britain, and an economic and social platform that focused on preserving white privilege and segregation earned them a surprise victory in the 1948 general election. Some ideologues within the National Party (NP), many influenced by Nazi ideology, sought complete separation between whites and all other people. Complete separation, however, would have removed the source of abundant cheap labor on which white wealth relied, undermining the National Party's plans

for uplifting Afrikaners economically. Apartheid evolved over the next half-century as an attempt to resolve the dilemma of how the outnumbered whites could exploit black labor while maintaining political control and racial separation.

2. *Evolution of Apartheid Policy and Protest*

Upon assumption of power in 1948, the NP quickly passed a series of laws aimed at reversing and preventing even the smallest steps toward integration. The Prohibition of Mixed Marriages Act and Immorality Act of 1949 banned miscegenation, while the Group Areas Act of 1950 extended the powers created by previous land acts to segregate urban residential and commercial areas. The Population Registration Act of 1950 underpinned apartheid legislation by recording the racial category of all South Africans from birth. The NP also ensured their continued legislative success by removing the descendents of Khoisan and mixed-race citizens from the voters roll in the Western Cape in 1956. Emphasizing the Afrikaners' independence, the NP led South Africa out of the British Commonwealth in 1961. On the economic front, successive NP governments channeled state resources into Afrikaner empowerment schemes and set aside jobs in the burgeoning bureaucracy for their supporters. The *Broederbond*, a shadowy network of Afrikaner intellectuals, politicians, clergymen, and other powerful figures, took control of most of the important positions in the public sector.

2.1 *Grand Apartheid*

After the initial flurry of apartheid legislation failed to halt the influx of Africans into cities, the government sought to implement Grand Apartheid. Advocates of this extreme form of separation envisioned transforming the least productive 13% of the country's land into homelands—independent nation states in which blacks would undertake 'separate development.' Black South Africans would be granted citizenship in one of the homelands, each representing a supposed tribal group. Stripped of their South African citizenship, they would only be allowed to enter white South African areas to work. Despite the rhetoric that described the homelands as part of a constellation of independent states in Southern Africa, the South African government would maintain political control through largesse and the right to appoint political representatives.

Four homelands eventually did opt for 'independence' between 1976 and 1980, but the concept of separate development neither mollified internal dissent nor acquired international legitimacy. With consolidation plans for the homelands scuttled by white farmers unwilling to part with fertile land, in reality the homelands became a patchwork of overgrazed lands that could not sustain the populations imposed on them. The homelands policy, and the enforcement of other segregation legislation, eventually led to the forced removal of 2 million people.

2.2 *Opposition to Apartheid*

The imposition of formal apartheid from 1948 reinvigorated internal resistance to the government and domestic and international support for what was increasingly seen as part of the broader anticolonial struggle sweeping Africa. A coalition led by the African National Congress (ANC) waged a campaign of civil disobedience in 1952 and proposed a dramatic alternative to apartheid in the 1955 Freedom Charter. When the state responded with arrests and repression, banning liberation movements in 1960, the ANC and other groups organized armed resistance from exile and underground. Brutal and effective police action, and the economic boom that followed the increase in commodity prices in the 1960s and the sharp rise in the price of gold in the early 1970s, allowed the state to crush internal opposition. At the same time, by portraying the liberation struggle as linked to a global communist conspiracy that might threaten access to South Africa's strategically important minerals and sea lanes, the apartheid state was able to win important, if wary, political support and security assistance from the West and neighboring countries under colonial domination or heavy Western influence.

In the mid-1970s, rising repression encountered a resurgence of activism, especially among young proponents of the black consciousness philosophy. Challenged by a wave of worker action in 1973, the state provoked international outrage with the 1976 killing of student protestors in Soweto and an ensuing clampdown. With the overthrow of colonial governments in Mozambique in 1975 and Zimbabwe in 1980, the South African government also faced a renewed threat from external guerilla armies who could use neighboring countries as rear bases. These international developments, coupled with growing worldwide isolation of the apartheid government, forced a further evolution of apartheid policy.

2.3 *Total Strategy*

Known as the Total Strategy, this new policy attempted to preserve white control in South Africa by making cosmetic changes in apartheid policies, co-opting other racial minority groups, and winning political co-operation from neighboring countries, while increasing the repressive might of the state. The

government implemented a tricameral parliamentary system that created token parliamentary houses for Indian and mixed-race representation in 1984, repealed the Mixed Marriages Act in 1985, and abolished the hated pass laws in 1986. Building on the outward policy of the 1970s, the government also signed a non-aggression pact with Mozambique in 1984. At the same time, the Total Strategy channeled more resources into covert operations to undermine neighboring black governments and unleashed the armed forces to engage in cross-border raids and political repression.

Like earlier apartheid policies, the Total Strategy failed to stem opposition or win international favor. Instead of deflating protest, the tricameral parliament proposals galvanized internal opposition under the banner of the United Democratic Front, an umbrella of hundreds of diverse opposition groups. The structure of grass-roots leadership, with subterranean ties to the banned ANC, coordinated national protests with techniques that confounded the apartheid state. From 1984, an increasingly devastating spiral of unrest, repression, and international condemnation took hold.

2.4 International Intervention

Personified in the campaign to release Nelson Mandela, the rising tide of international protest against apartheid became the first major international movement that asserted the prerogative of all people and international organizations to protest against human rights violations in a sovereign state. By imposing mandatory sanctions in 1979, the United Nations Security Council for the first time overrode traditional international legal norms that held problems of national integration to be an exclusively domestic matter. Spurred by a grass-roots campaign, the US Congress imposed sanctions against South Africa in 1986, overturning a presidential veto. These actions, coupled with the decisions by private banks to deny access to new capital in the face of rising political uncertainty in the mid-1980s, weakened the apartheid government's resolve, though to what extent their impact was material, not just symbolic, remains disputed.

3. Apartheid's Negotiated Demise

The winding down of the Cold War in the late 1980s undercut both the opposition's financial support base and the ability of the South African government to defend its repressive actions as an anti-communist crusade. The resulting stalemate between an increasingly powerful, but militarily diminished, opposition movement and the highly militarized, but isolated, state ended with the unbanning of opposition parties in 1990 and the initiation of political negotiations. The cornerstones of apartheid legislation, the Population Registration Act and Group Areas Act, were repealed the following year. In April 1994, after a series of complex negotiations, virtually the entire South African adult population voted in a peaceful election, choosing the ANC to become the ruling party.

Apartheid's demise, by political rather than military means at the end of history's most violent century, confounded many experts who believed that the divisions were too deep and the economy too weak to support a compromise. Yet South Africans, with very little help from outsiders, brought to an end one of humanity's longest-running dramas; the struggle against colonialism, segregation, and other forms of institutionalized racism in Africa. Even after the abolition of legal apartheid, the huge economic and social disparities that it created will persist for generations in South Africa. Post-apartheid South Africa represents one of the world's most prominent attempts to meet what the British philosopher, Sir Isaiah Berlin, termed the greatest challenge facing humanity: building the political frameworks to manage cultural diversity. Few nations have had to deal with as profound cultural, racial, and religious differences, compounded by a history of race-based political oppression and economic deprivation. If South Africans can continue to govern themselves peacefully, their example could potentially have a greater political impact on the global spread of democratic values in the twenty-first century than the fight against apartheid had on the spread of human rights in the twentieth century.

Apathy

Apathy stems from the ancient Greek *apathies*, which means 'lack of feeling.' Apathy plays an important role in theories of democracy that stress citizens' involvement in public affairs (see *Democratic Theory*; also see *Democracy*). Ancient Athenians' praise for attentive citizens and condemnation of apathetic ones established a tradition in democratic theory. Apathy saps public spiritedness, which is why it is thought to be one indicator of waning 'social capital' in modern societies (see *Social Capital*). Apathy also inhibits citizens' 'cognitive mobilization,' which is an important political resource (Inglehart 1997). Small wonder that apathy among citizens of democratic countries worries politicians, pundits, and professors.

Apathy means political indifference; its opposite is political interest. Apathy/interest entails the expression of 'curiosity' about public affairs (Gabriel and van Deth 1995). Apathy/interest is an attitude, not an absence of activity. Apathy does not mean 'nonvoting,' for example, for people do not vote for many reasons (see *Voting: Turnout*), most having nothing to do with lack of interest in public affairs. Before passage of the 1965 Voting Rights Act in the US, for example, African-Americans living in the South were prevented from voting by several means, including intimidation and violence (see *Race Relations in the United States, Politics of*). It would be wrong to equate southern blacks' absence from the voting booth as indicating apathy.

Although apathy was once equated with alleged 'pathologies' such as alienation, hostility, isolation, and suspicion (Campbell 1962), that is no longer true. Psychological involvement in public affairs is one of the most important political dispositions a person has. Citizens who pay attention to public affairs are different political actors than those who are indifferent (Almond and Verba 1963, Bennett 1986, Converse 1972, Gabriel and van Deth 1995, Inglehart 1997, van Deth 1990, Verba et al. 1995).

How should apathy/interest be measured? Prior to the advent of scientific public opinion surveys in the 1930s (see *Polling*), generalizing about mass publics was risky, although it could be done well (Lippmann 1925). Even after public opinion polling emerged, estimates of mass publics' apathy/interest were not problem free. Although some researchers think it is possible to use a single item to measure apathy/interest, it is best to use multiple items to tap this attitude. It is preferable to avoid combining measures of 'subjective political interest'—the topic of this article—with indicators of political behavior, such as talking about politics with family and friends.

In their study of political attitudes in five western democracies, Almond and Verba (1963; see also *Civic Culture*) developed a multi-item indicator of subjective political interest. They combined a measure of general political interest with another, tapping attention to election campaigns to form 'the civic cognition.' Following Almond and Verba, Bennett (1986) constructs 'the Political Apathy Index,' which is a combination of general political interest and attentiveness to election campaigns. Since both items have had the same wording since 1968, and had virtually the same location on the University of Michigan's biennial National Election Studies since 1978, the Political Apathy Index provides an excellent vehicle for exploring Americans' interest in public affairs over more than 20 years. Multiple item measures of Europeans' political interest do not exist over a very long period (Gabriel and van Deth 1995, van Deth 1990).

What do researchers know about democratic citizens' interest in public affairs? Except for short-term emergencies or catastrophes, most people are not very interested in public affairs (Bennett 1986). Most Americans normally express only a 'lukewarm' interest in public affairs. Nevertheless, Americans are more politically interested than most West Europeans, probably because educational attainment is higher in the US (Powell 1986). There is little evidence of growing political interest in most European nations in recent years (Gabriel and van Deth 1995).

Several factors affect psychological involvement in public affairs. Education strongly shapes interest in the US and elsewhere (Bennett 1986, Converse 1972, Gabriel and van Deth 1995, Nie et al. 1996, van Deth 1990). Formal schooling imparts the intellectual skills and motivation needed to pay heed to public affairs, and exposure to higher education often ensconces people in social niches that encourage and reward political attentiveness.

Location in a social structure affects apathy/interest. It is easier to pay attention to public affairs if one's occupation and lifestyle place the individual at or near the center of a society. Some professions

encourage political interest. Members of the legal profession, for example, tend to be very attentive to government and public affairs. Those living on the periphery of society—by virtue of their job, race, religion, or ethnicity—are less inclined to be politically interested.

Age also affects political attentiveness. Young people tend to be less politically attentive than their elders, mostly because they are distracted by the 'start-up phenomenon,' which involves completing school, getting started in a job or career, searching for a life-mate, and even being socially mobile. Political interest requires the capacity to concentrate on issues and events outside one's immediate concern, and most young people tend to focus on personal matters. In this view, the passage of time and the assumption of mature adult roles produced a steady increase in political interest over the life cycle, an increase that would be partly reversed as people reached extreme old age.

Some evidence questions the life-cycle explanation for the relation between youth and apathy. American men who came of age during World War II were especially politicized, and they remained atypically interested in politics over the next four decades (Bennett 1986). Similar evidence occurs among Early Baby Boomers in the US, whose male members were exposed to the Vietnam-era draft, and Late Baby Boomers, who were born too late for the draft (Bennett and Bennett 1990). On the other hand, younger citizens of West Germany expressed more political interest than older persons in 1994, perhaps because the latter were still haunted by the Nazi past (Bennett et al. 1996). (When looking at the relation between most social factors and a disposition such as apathy, one should take note of a nation's history, culture, and institutions.)

Another contradiction to the life-cycle thesis is the emergence in the US of 'Generation X,' or persons born between 1965 and 1978, who have been particularly apathetic (see *Generations: Political*). Young Americans today (Bennett 1997), and to some degree young Europeans (Gabriel and van Deth 1995), are less politically attentive than youth were a generation ago, and American young people show little inclination to become more politically interested as time goes by.

Certain political dispositions also affect apathy/interest. People who believe they have a moral obligation to be politically active are more likely to be attentive than those who lack a sense of 'civic duty' (Bennett 1986). In addition, strong adherents of a political party are more politically attentive than independents and 'apoliticals' (see *Party Identification*). Therefore, Generation Xers' tendency to avoid attachment to a political party has worrisome consequences for their political attentiveness. Other political attitudes, such as the belief that one is a competent citizen and that political activity is worthwhile, or political efficacy (see *Efficacy: Political*), are tied to political interest, but scholars cannot tell which causes which.

What difference does it make if citizens are politically indifferent? Apathy violates the assumption that a healthy democracy requires attentive citizens. There are demonstrable consequences of apathy that trouble many (e.g., DeLuca 1995), but not everyone (Berelson et al. 1954). Not only is psychological involvement in public affairs a powerful goad to political participation (see *Participation: Political*), interest also affects exposure to the mass media and political information (Bennett 1986). Finally, although the relationship is complicated, interest also affects political sophistication (Converse 1972). If one is interested in the grassroots foundations of democracy, there are ample grounds for concern with apathy/interest.

Scholars stand on the threshold of several discoveries about apathy/interest. It now appears that apathy/interest has at least two related components: an 'ego involvement' dimension and a 'general subjective interest' dimension. If true, the disposition is more complex than researchers previously assumed. The future may also witness the passing of the well-documented fact that women have been less politically attentive than men (Bennett and Bennett 1989, Inglehart 1981). As older women who were raised to believe that 'politics is a man's business' pass from the electorate, and especially if new birth cohorts do not subscribe to traditional norms, the next century may see an end of gender differences in political interest.

Additional research will also improve people's understanding of apathy's causes and consequences. Previous scholarship was limited by both the way in which apathy/interest was conceptualized and measured and by the research tools used to study the disposition's causes and effects. As new means to measure the phenomenon emerge, and as more sophisticated data analysis procedures are utilized, future scholarship will sharpen and refine what is known about apathy/interest in the US and elsewhere. It will help greatly, for example, to understand better the complex relationships between apathy/interest and other political dispositions such as party identification, efficacy, and sense of civic duty. The nexus between apathy/interest and exposure to the mass media also needs to be better understood. Critics allege that the American news media's style of political coverage saps people's interest in public affairs. Researchers need to see if this is true in other polities, as well as in the US. New, more sophisticated comparative studies can shed useful light on the association between a nation's political culture and its citizens' attention to public affairs (see *Political Culture*).

Finally, Western nations are experiencing a renewal of civic education. Scholars do not understand very well how to motivate more young people to become politically attentive, but the will to accomplish that goal seems to be emerging. The struggle to educate the

young to the norms of citizenship will call for blending theoretical and applied research (see *Socialization: Political*). As ancient Greek democrats appreciated, encouraging political interest among democratic citizens is a worthy enterprise.

Aphasia

1. *Definition*

The term 'aphasia' refers to disorders of language following diseases of the brain. As is discussed in other articles in this encyclopedia language is a distinctly human symbol system that relates a number of different types of forms (words, words formed from other words, sentences, discourse, etc.) to various aspects of meaning (objects, properties of objects, actions, events, causes of events, temporal order of events, etc.). The forms of language and their associated meanings are activated in the processes of speaking, understanding speech, reading, and writing. The processes whereby these forms are activated are largely unconscious, obligatory once initiated, fast, and usually quite accurate. Disturbances of the forms of the language code and their connections to their associated meanings, and of the processes that activate these representations in these ordinary tasks of language use, constitute aphasic disturbances. By convention, the term 'aphasia' does not refer to disturbances that affect the functions to which language processing is put. Lying (even transparent, ineffectual lying) is not considered a form of aphasia, nor is the garrulousness of old age or the incoherence of schizophrenia.

Language consists of a complicated system of representations, and its processing is equally complicated, as described in other entries in this encyclopedia. Just the representation of the minimal linguistically relevant elements of sound—phonemes—and the processing involved in recognizing and producing these units constitute a highly complex domain of functioning. When all the levels of language and their interactions are considered, language processing is seen to be enormously complex. Aphasic disturbances would therefore be expected to be equally complex. Researchers are slowly describing the very considerable range of these disorders.

2. *History of the Field: The Classic Aphasic Syndromes, and Alternative Views*

However, the first modern scientific descriptions of aphasia were quite modest with respect to the descriptions of language processing that they contained. These descriptions were made by neurologists in the second half of the nineteenth century. Though modest with respect to the sophistication of the descriptions of language, these studies laid important foundations for the scope of work on aphasia and for the neural basis for language processing, which has always been a closely associated topic. The first of these late nineteenth century descriptions was that by Broca (1861), who described a patient, Leborgne, with a severe speech output disturbance. Leborgne's speech

Table 1
Classical aphasic syndromes

Syndrome	Clinical manifestations	Postulated deficit	Classical lesion location
Broca's aphasia	Major disturbance in speech production with sparse, halting speech, often misarticulated, frequently missing function words and bound morphemes	Disturbances in the speech planning and production mechanisms	Posterior aspects of the 3rd frontal convolution (Broca's area)
Wernicke's aphasia	Major disturbance in auditory comprehension; fluent speech with disturbances of the sounds and structures of words (phonemic, morphological, and semantic paraphasias)	Disturbances of the permanent representations of the sound structures of words	Posterior half of the first temporal gyrus and possibly adjacent cortex (Wernicke's area)
Pure motor speech disorder	Disturbance of articulation Apraxia of speech, dysarthria, anarthria, aphemia	Disturbance of articulatory mechanisms	Outflow tracts from motor cortex
Pure word deafness	Disturbance of spoken word comprehension	Failure to access spoken words	Input tracts from auditory system to Wernicke's area
Transcortical motor aphasia	Disturbance of spontaneous speech similar to Broca's aphasia with relatively preserved repetition	Disconnection between conceptual representations of words and sentences and the motor speech production system	White matter tracts deep to Broca's area connecting it to parietal lobe
Transcortical sensory aphasia	Disturbance in single word comprehension with relatively intact repetition	Disturbance in activation of word meanings despite normal recognition of auditorily presented words	White matter tracts connecting parietal lobe to temporal lobe or portions of inferior parietal lobe
Conduction aphasia	Disturbance of repetition and spontaneous speech (phonemic paraphasias)	Disconnection between the sound patterns of words and the speech production mechanism	Lesion in the arcuate fasciculus and/or corticocortical connections between Wernicke's and Broca's areas
Anomic aphasia	Disturbance in the production of single words, most marked for common nouns with variable comprehension problems	Disturbances of concepts and/or the sound patterns of words	Inferior parietal lobe or connections between parietal lobe and temporal lobe; can follow many lesions
Global aphasia	Major disturbance in all language functions	Disruption of all language processing components	Large portion of the perisylvian association cortex
Isolation of the language zone	Disturbance of both spontaneous speech (similar to Broca's aphasia) and comprehension, with some preservation of repetition	Disconnection between concepts and both representations of word sounds and the speech production mechanism	Cortex just outside the perisylvian association cortex

was limited to the monosyllable 'tan.' Broca described Leborgne's ability to understand spoken language and to express himself through gestures and facial expressions, as well as his understanding of non-verbal communication, as being normal. Broca claimed that Leborgne had lost 'the faculty of articulate speech.' Leborgne's brain contained a lesion whose center was in the posterior portion of the inferior frontal convolution of the left hemisphere, an area of advanced cortex just adjacent to the motor cortex. Broca related the most severe part of the lesion to the expressive language impairment. This area became known as 'Broca's area.' Broca argued that it was the neural site of the mechanism involved in speech production.

In a second very influential paper, Wernicke (1874) described a patient with a speech disturbance that was very different from that seen in Leborgne. Wernicke's patient was fluent; however, her speech contained words with sound errors, other errors of word forms, and words that were semantically inappropriate. Also unlike Leborgne, Wernicke's patient did not understand spoken language. Wernicke related the two impairments—the one of speech production and the one of comprehension—by arguing that the patient had sustained damage to 'the storehouse of auditory word forms.' The lesion in Wernicke's case was unknown, but a lesion in a similar case was the area of the brain next to the primary auditory receptive area, which came to be known as Wernicke's area.

These pioneering descriptions of aphasic patients set the tone for much subsequent work. First, they focused the field on impairments of the usual modalities of language—producing and producing speech and later on, reading and writing. This seems like an obvious area for aphasiology to be concerned with, but not all researchers of the period agreed with this focus. In another famous paper, the influential British neurologist John Hughlings Jackson (1878) described a patient, a carpenter, who was mute but who mustered up the capacity to say 'Master's' in response to his son's question about where his tools were. Jackson's poignant comments convey his emphasis on the conditions that provoke speech, rather than on the form of the speech itself:

> 'The father had left work; would never return to it; was away from home; his son was on a visit, and the question was directly put to the patient. Anyone who saw the abject poverty the poor man's family lived in would admit that these tools were of immense value to them. Hence we have to consider as regards this and other occasional utterances the strength of the accompanying emotional state' (Jackson 1878, p. 181)

Jackson sought a description of language use as a function of motivational and intellectual states, and tried to describe aphasic disturbances of language in relationship to the factors that drive language production and make for depth of comprehension. Broca, Wernicke, and the researchers who followed, focused aphasiology on patients' everyday language use under what was thought to be normal emotional and motivational circumstances.

These and related subsequent papers tended to describe language impairments in terms of the entirety of language-related tasks—speaking, comprehending, etc.—with only passing regard for the details of the language forms that were impaired within a task. A patient's deficit was typically described in terms of whether such an entire function was normal or not, and in terms of whether one such function was more impaired than another was. Here, for instance, is the description of Broca's aphasia by two twentieth-century neurologists whose work follows in this tradition:

> 'The language output of Broca's aphasia can be described as nonfluent … Comprehension of spoken language is much better than speech but varies, being completely normal in some cases and moderately disturbed in others. (Benson and Geschwind 1971, p. 7).'

The one level of language that descriptions did tend to concentrate on was the level of words. For instance, many patients with language disturbances that are classified as Wernicke's aphasia make many errors in word formation, substituting one type of word ending for another, but Wernicke's description of the impairment in his patient dealt only with the storehouse for individual words, not the locus of the word formation process. Put in other words, though the early work on aphasia emphasized the usual tasks of language use, this work, and research that followed in this tradition, did not describe these impairments systematically in either linguistic or psycholinguistic terms.

This approach to aphasia led to the recognition of some 10 aphasic 'syndromes.' These are listed, along with their proposed neural bases, in Table 1.

3. *Psycholinguistic Approaches to Aphasia*

As noted in Sect. 2, these classical syndromes do not give a complete account of the range and specificity of aphasic impairments. More recent descriptions of aphasia add many details to the linguistic and psycholinguistic descriptions of these disorders. It is impossible to review all these impairments in the space of a short article, but a few examples will illustrate these results. For instance, at the first step of speech processing—converting the sound waveform into linguistically relevant units of sound—researchers have described specific disturbances affecting the ability to recognize subsets of phonemes, such as vowels, consonants, stop consonants, fricatives, nasals, etc. (Saffran et al. 1976). In the area of word production, patients have been described with selective impairments of the ability to produce the words for items in particular semantic categories, such as fruits and vegetables, but sparing animals and man-made

tools (Hart et al. 1985), selective impairments affecting the ability to produce nouns and verbs (Damasio and Tranel 1993), and other highly restricted deficits. In the area of reading, patients have been found to have impairments of the ability to sound out novel written stimuli using letter-sound correspondences but retained abilities to read familiar words, and vice versa (Marshall et al. 1980, Patterson et al. 1985).

Linguistic theory provides a basis for exploring the nature of aphasic disorders, by providing evidence for different types of linguistic representations. Models of the psychological processes involved in activating linguistic representations suggest other possible loci of impairment. Many researchers have worked backwards from clinically observed phenomena, developing or modifying theories of language structure and processing on the basis of the disorders seen in aphasic patients. For instance, Shallice and Warrington (1977) challenged the then-popular view that verbal short-term memory fed verbal long-term memory by documenting a patient with a severely reduced verbal short-term memory capacity whose performance on tests of verbal long-term memory was normal. Ullman and his colleagues (Ullman et al. 1997a, 1997b) have argued that the impairments seen in patients with Alzheimer's and Huntington's Disease provide support for a view of language that distinguishes between regular, rule-based, word formation processes, and irregularly formed complex words that are listed in a mental dictionary. (For a discussion of this distinction and its broader implications for language and the mind, see Pinker 1999.) Characterizing aphasic disorders is an interactive, interdisciplinary, bootstrapping process that is presently in active evolution.

The psycholinguistic approach to aphasia is based upon a model of language structure and processing. Experts disagree about these models. The greatest disagreements center on the issue of the extent to which linguistic representations are highly abstract structures that are produced and computed in comprehension tasks by rules (Chomsky 1995), as opposed to far less abstract representations that are processed largely by highly developed pattern associations (Rumelhart and McClelland 1986). If language is seen in the former perspective, many aphasic impairments are considered to be the result of damage to specific representations and/or processing operations. If language is seen in the second perspective, aphasic disturbances are largely conceptualized as resulting from reductions in the power of the associative system, due to loss of units, increases in noise, etc. Empirical study suggests that both specific impairments and loss of processing power are sources of aphasic disturbances. This can be illustrated in one area—disorders affecting syntactic processing in sentence comprehension.

Disorders of syntactically based comprehension affect the ability to extract the relationships between the meanings of words in a sentence that are determined by the syntactic structure of a sentence. For instance, in the sentence 'The dog that scratched the cat killed the mouse,' there is a sequence of words—the cat killed the mouse—which, in isolation, would mean that the cat killed the mouse. However, this is not what the sentence means, because of its syntactic structure. 'The cat' is the object of the verb 'scratched;' 'the dog' is the subject of the verb 'killed' and is the agent of that verb. Caplan and his colleagues have explored the nature of these disturbances (Caplan et al. 1985, 1996). They found that, in many hundred of aphasic patients, mean group performance deteriorated on sentences that were more syntactically complex and that more impaired groups of patients increasingly performed more poorly on sentences that were harder for the group overall. These patterns suggest that the availability of a processing resource that is used in syntactic comprehension is reduced to varying degrees in different patients. A second finding in their studies has been that individual patients can have selective impairments of syntactic comprehension, just as is the case in the other areas of language processing previously mentioned. Published cases have had difficulty constructing hierarchical syntactic structures, disturbances affecting reflexives or pronouns but not both, and other more subtle impairments of syntactic processing (Caplan and Hildebrandt 1988).

Overall, these studies suggest that a patient's aphasic impairment can be described in terms of a reduction in the processing resources needed for this function and disruption to specific operations. An unresolved question is whether the entire pattern of performance seen in these disorders can be attributed to just one of these types of impairments, as the two types of models previously outlined maintain. This may be possible, but the challenges in explaining all these aspects of these (and other) aphasic disorders within a model that either does not incorporate the idea of a processing resource limitation or one that does not recognize specific operations are considerable.

4. *Functional Consequences of Aphasic Impairments*

The focus of this article has thus far been on aphasic disturbances as impairments of the largely unconscious processes that activate the elements of language in the usual tasks of language use. The functional consequences of these disorders deserve a brief comment. Functional communication involving the language code occurs when people use language to accomplish specific goals—to inform others, to ask for information, to get things done, etc. There is no simple, one-to-one relationship between impairments of elements of the language code or of psycholinguistic processors, on the one hand, and abnormalities in performing language-related tasks and accomplishing the goals of language use, on the other. Patients adapt

to their language impairments in many ways, and some of these adaptations are remarkably effective at maintaining at least some aspects of functional communication. Conversely, patients with intact language processing mechanisms may fail to communicate effectively. Nevertheless, most patients who have disturbances of elements of the language code or psycholinguistic processors experience limitations in their functional communicative abilities. In general, as the intentions and motivations of the language user become more complex, functional communication is more and more affected by disturbances of the language code and its processors. Thus, though 'high-level' language-impaired patients may be able to function well in many settings, their language impairments can cause substantial functional limitations. The language code is a remarkably powerful code with respect to the semantic meanings it can encode and convey, and psycholinguistic processors are astonishingly fast and accurate. Without this code and the ability to use it quickly and accurately, one's functional communicative powers are limited, no matter how elaborate one's intentions and motives. This is the situation in which many patients who have disorders affecting the language code and the processors dedicated to its use find themselves.

5. *Concluding Comments*

This essay should not end on this negative note. Rather, it is important to appreciate that many aphasic patients make excellent recoveries, for a variety of reasons. The natural history of many aphasic impairments is for considerable improvement, especially those due to smaller or subcortical lesions. Though still in their infancy, modern approaches to rehabilitation for aphasia are developing a sounder scientific basis. Technological advances allow for more professionally guided home training using computers, improved augmentative communication devices, and other useful support mechanisms. Support groups for patients and their families and friends are increasing in number; these help patients adjust to the changes in their lives and remain socially active. Though aphasia deprives a person of an important function to a greater or lesser degree, reactions to aphasia are as important as the aphasia itself in determining functional outcome and many aphasic patients function in vital ways after their loss. Lecours et al. (1983) cite a patient described by the Soviet psychologist A. R. Luria, who continued to compose music after a stroke that left him very aphasic; some critics thought his work improved after his illness. Time, rehabilitation, support, and a positive attitude can allow many aphasic patients to be productive and happy.

Appeals: Legal

An *appeal* is a proceeding in a higher court of law initiated by a party contending that a decision of a subordinate court is erroneous. Appeal is to be distinguished from other proceedings sometimes initiated in high courts for purposes other than the

correction of error by a subordinate court. It is also to be distinguished from review proceedings conducted without regard for any previous disposition by the subordinate court, as where a case is subjected to *trial de novo* in the higher court. The latter form of proceeding is, for example, standard practice at the first level of review in Germany (Meador et al. 1994, pp. 893–979). It is not unknown in the USA, where its use is most common when a higher court is reviewing a small claims court where professional lawyers seldom represent the parties and where the judge is sometimes nonprofessional. Appeal is also to be distinguished from the *discretionary review* that may be observed in the Supreme Court of the United States and most other highest courts of states or of large nations. A court performing discretionary review may select the issues or rulings that it chooses to review; its primary purpose in making its selection is to explain the correct resolution of issues that are likely to recur in the lower courts or are otherwise important to persons other than those who are parties. In the USA and in many other countries, most appeals are taken to intermediate courts that are subject to discretionary review in courts of last resort. This article is an account only of the principles governing such appeals, primarily in the intermediate courts of the USA. Some variations in other systems will be noted, but those variations are so numerous that they defy synthesis.

1. Not Universal

The appeal is not a universal feature of legal systems. Some tribal courts, for example, bring to bear in the first instance most of the wisdom and authority of the community (see, e.g., Gluckman 1955). There is then no body of higher persons to whom an appeal might appropriately be addressed. Also, there are autocratic systems, generally those having strong religious roots, in which an individual chief, priest, or judge is accorded the power of decision without possibility of review. Islamic law is noted as an example; the *kadi* administers an elaborate code of conduct contained in holy writ that no mere lawyer can presume to interpret, and the *kadi's* decision is not subject to review (Shapiro 1980).

The appeal as it is known in Western legal systems appears to have been devised by the early Byzantine Empire and rested on the idea that all power was a delegation from the emperor (Pound 1941). It was reinvented in the twelfth century as a method of centralizing power and was used for that purpose by French monarchs as early as the thirteenth century. For similar reasons, the appeal was used intensively in socialist legal systems patterned on the Soviet model (Damaska 1986, pp. 48–52). Its use in the USA reflects the different reality that trial courts there enjoy a measure of political autonomy and are supported by the politically important institution of the local jury, so that the appeal is needed to correct for the tendency of American law to be diffuse.

Typically, in those systems using an appeal, the review is conducted by a larger bench of judges than the court whose judgment is under review. In the USA, there is almost without exception a single judge presiding over a trial court from whose decisions an appeal may be taken to a three-judge court. Judges sitting on an appellate court are generally designated as persons of higher rank, and are likely to receive marginally higher salaries than judges sitting on the trial courts they review.

Even in the USA, the right of appeal in a civil case is generally a matter of legislative grace. Until 1888, there was no appeal from a criminal conviction in a federal court, even if the convicted person was subject to capital punishment (Frankfurter and Landis 1928). However, the constitutions of some states have long guaranteed the right of appeal in criminal cases. It is still the law in all American jurisdictions that a state may not appeal a judgment of acquittal in a criminal case because a second trial would place the defendant in double jeopardy of conviction. Where there is no right to appeal, trial judges were seen to accumulate excessive discretionary power over the individuals engaged in disputes brought before them and on occasion to engage in seemingly lawless behavior. The Congress of the United States and state legislatures have in this century been attentive to the importance of constraining that discretionary power and have provided for appellate review in civil cases and in criminal cases not resulting in judgments of acquittal.

2. Principles of Restraint

The development of the appeal in American courts has resulted in the formulation of principles of restraint that are also in use in various forms in other legal systems. The institution described here is analogous to the *writ of error* familiar to ancient practice of English common law courts as an instrument for bringing a local one-judge decision to the attention of the larger court sitting in Westminster, but departs from that usage in important respects. Contemporary American practice took its present form in the federal and in the courts of the states over the course of the nineteenth century. Six principles of restraint emerged.

2.1 Reversible Error: The Adversary Tradition

The first of these is the concept of *error*, a principle rooted in the Anglo-American adversary tradition placing primary responsibility for the conduct of litigation on the parties and their counsel. Because the burden is on the parties to present the evidence and inform the court of their claims or defenses, it is

not generally error for a court to fail to identify a fact not proven or to fail to enforce a legal principle not invoked. The political function of this principle is to reduce the role of the court: disappointed parties often share responsibility for their own defeats. The administrative purpose of the principle is to encourage thorough preparation and presentation of the case by counsel and to protect the court from being trapped by deceitful or negligent counsel. It follows from this principle of reversible error that an appellant, to be successful on appeal, must generally point to a ruling made by the lower court to which the appellant made timely *objection* (Tigar and Tigar 1999). In times past, it was often required not only that there be an objection to the erroneous ruling, but that an appellant have taken *exception* to the adverse ruling, thus putting the trial judge on notice that the ruling may be challenged on appeal. The requirement of an exception has been eliminated from the practice of federal and most state courts.

Even in American courts, the requirement of a timely objection is sometimes disregarded for erroneous rulings so egregious that the judgment under review deeply offended the appellate court's sense of propriety. Such errors are denoted as *plain errors*. Rarely is the plain error doctrine invoked because it allows counsel to proceed in a no-lose situation, knowing that if the error is not corrected by the trial judge there will be a successful appeal affording a non-objecting party with a fresh start. On the other hand, appellate courts may be reluctant to punish a party having a clearly meritorious claim or defense for no reason other than a lapse on the part of counsel.

2.2 Harmless Error

A second and more universal requirement is that no error however egregious is an occasion for reversal unless it was consequential. The familiar expression is that a *harmless error* is not reversible. Thus, an appellant who should and would have lost on other grounds cannot secure relief from an adverse judgment even if that party can identify blatant errors of fact or of law that were committed by the court below and to which timely objection was made.

2.3 Standing to Appeal

A third requirement is *standing* to appeal. This principle is related to that just stated. Generally, only a party who has participated in the proceeding is bound by the decision below. Hence, one who was not a party is not directly harmed by a judgment even though he or she may strongly disapprove of the outcome and assert that a grave injustice has been done. The requirement of standing may be extended to bar appeal by nonparties who are only remotely affected by a judgment. Thus an investor or employee lacks standing to appeal a judgment rendered against a corporation in which he or she owns shares or by which he or she is employed. The decision to appeal a judgment rendered against a corporation resides with the corporate directors acting on the advice of the officers, and to no one else.

2.4 Ripeness for Review

A fourth common requirement is that of ripeness for review. In general, an appeal is premature until a *final decision* has been reached in the court below. This is a principle of economy. An error of the lower court may turn out to be harmless; the higher court cannot know until a final decision has been reached. Moreover, there would be serious diseconomies in allowing every litigant adversely affected by a provisional ruling of a trial court to take an appeal at once. Not only would this afford parties a means of imposing needless financial costs on adversaries, but it would force the trial court or perhaps even the appellate court to decide in each instance whether the lower court proceedings should be stayed pending the outcome of the appeal. If a stay is granted, the appellant has been empowered to delay the proceeding; and the delay itself may often result in injustice. If a stay is denied, there is the risk that further proceedings will be set aside as a result of the interlocutory decision of the higher court.

There are in most jurisdictions numerous exceptions to the ripeness requirement. For example, in the federal practice, an *interlocutory appeal* may be taken from the grant or denial of a preliminary injunction for the reason that an error in such a ruling can have grave consequences for the party adversely affected (Steinman 1998, pp. 1388–476). Immediate appeal may also be allowed with respect to other rulings involving substantial procedural rights that are very likely to affect the outcome of a case. With respect to important issues of judicial administration, it may be said that an otherwise unripe appeal should be entertained in order to sustain the supervisory power of the appellate court, i.e., to prevent lawless behavior by a trial judge. An appellate court in the USA will also generally possess the power to issue an *extraordinary writ* such as a writ of *mandamus* (a tool of Roman origins) to forestall an abuse of discretion by a subordinate court. In addition, a lower court may be permitted to certify to a higher court a question of law to which the lower court has no answer and which is central to a lengthy trial. And in New York state courts, a ripeness requirement is itself an exception to the more general rule that a party aggrieved by a ruling of the trial division can seek prompt review in the appellate division of the same court.

2.5 The Record on Appeal

A fifth concept shared by all American and most other jurisdictions is that of the *record on appeal*. That is an

official account of the proceedings below, or at least that part of the official account that the lawyers deem pertinent to the issues raised on appeal and therefore worth the cost of reproduction. The record is generally produced by the clerk of the court below and will contain documents filed with the court and a transcript of any oral proceedings prepared by a professional court reporter. In general, an appellate court will not consider information that is not contained in the record (Marvell 1978, pp. 160–66). There is an exception to this principle generally known as the *judicial notice* doctrine. A court may without proof take notice of common knowledge not contained in the record, or knowledge that is readily available to all, such as the coincidence of days of the week with days of the month. In a civil case, the appellant must generally advance the cost of preparing such a record, but a state may be required to bear the cost in a criminal case if the convicted person is indigent.

2.6 *Deferential Review of Factual Determinations*

Finally, there is a principle of deference to trial courts. Among the aims of this principle are to dignify the proceedings below and to discourage appeals challenging the guesswork inevitably done in the trial court to resolve issues on which there is conflicting evidence. The principle is expressed in an elusive distinction between *law and fact*. It is generally agreed that trial courts are entitled to no deference in their rulings on questions of law. Such rulings may be embodied in the *instructions* on the law given to a jury, or if there is no jury demanded, in the *conclusions of law* stated by the court to explain its disposition. An erroneous statement in either of those utterances of the trial judge is a sufficient ground for reversal. On the other hand, trial courts having dealt directly with the evidence submitted by the adversaries are extended the benefit of some doubt with respect to the determinations of fact. The appellate court hears no witnesses and sees only a transcript of the testimony. If the trial court judgment rests on a *jury verdict*, the factual determination in a civil case can be reversed on appeal only if the appellate court finds that there is no *substantial evidence* in the record to support it. In the absence of a jury, a trial judge's decision on evidence will in a civil case be expressed in the judge's *finding of facts*; such findings may be reversed in American courts only if the reviewing court finds '*clear error*.' It is generally assumed that the latter is a lower standard and that fact finding by a judge is more closely scrutinized on appeal than is fact finding by a jury.

The distinction between fact and law is subtle and even sometimes circular; a much oversimplified summary is that issues of fact are those involving specific past events about which there is doubt, whose resolution has little or no bearing on future cases. Issues of law are typically those involving an interpretation of legal texts, but it is often said that whether there is evidence sufficient to support a jury verdict is itself a question of law. All this really means is that sufficiency of the evidence is a question in the first instance for the trial judge but that the ruling on the issue will be reviewed without deference. It is therefore not wrong to say that an issue of fact is simply one that the courts leave for decision by a trier of fact while an issue of law is any issue that the appellate court chooses to decide on its own.

A homely example may assist understanding of this professional jargon. A farmer seeks compensation from the railroad adjoining his farm for a cow hit and killed by the train. The controlling law is that the railroad has a duty to fence livestock out of its right-of-way. But it allows the farmer to keep a gate in the fence. If the cow went through a hole in the fence, the railroad is responsible; if she went through the gate, it is not. If the accident happened at a spot equidistant to the gate and a hole in the fence, convention would say that there was substantial evidence from which a trial court might infer that the railroad's negligence probably caused the misfortune. If, however, the accident occurred near the gate and a long distance from the hole in the fence, it would be unreasonable to infer that the cow probably came through the hole and not the gate. Convention would then say that there is no substantial evidence to support a jury verdict for the farmer; that such a decision by a judge sitting without a jury would be clear error; and that *as a matter of law* the railroad has no liability. How close to the gate and how far from the hole the accident must be in order for the case to present an issue of fact for a jury to decide is itself a question of law.

This distinction is not made in some other legal systems. It is unknown to Japanese practice modeled on the French. It is generally less useful in systems placing heavy reliance on written submissions of evidence. In such systems, the appellate court has access to the same information as the trial court, and hence there is less reason for deference to the judicial officer who saw and heard the adversary presentation of the parties.

2.7 *Abuse of Discretion*

Notwithstanding these settled principles of restraint, an appellate court is also empowered to correct actions of a trial judge that it deems to be an abuse of discretion. This principle is most frequently invoked to challenge and correct procedural rulings that are seen to be idiosyncratic or manifestly unjust (Friendly 1982).

3. *Appellate Procedure*

In addition to these principles of appellate jurisdiction, American courts share a traditional procedure that is replicated in many legal systems. Until about 1960,

this process was universal in the USA and included (1) the submission of written *briefs* prepared by counsel on both sides that present their legal arguments and provide citations to pertinent legal texts and authorities; (2) an *oral argument* at which counsel might engage the appellate judges in dialogue and answer questions they might pose; (3) a conference of the judges responsible for the appellate decision, and (4) a published *opinion of the court* explaining the legal principles underlying the disposition on appeal. These procedural amenities have since been foreshortened in most American appellate courts, especially since the number of criminal appeals has increased precipitously in recent decades, many raising no serious issue worthy of the effort to conduct oral argument, confer, and write an opinion. It has also become common, especially in federal appellate courts, for much of the responsibility to be delegated to law clerks serving as members of the judges' staffs. In recent years, it has been argued that the right of appeal should be abolished in federal practice in recognition of the reality that many appeals are never seriously studied by the judges commissioned as members of the court (e.g., Parker and Chapman 1997). Others have resisted this trend (Arnold 1995). It has even been contended that the erosion of appellate procedure has diminished the *raison d'etre* of the federal appellate courts (Carrington 2000). This is an aspect of judicial administration that is likely to be profoundly affected by electronic communications (Carrington 1998).

4. *The Opinion of the Court*

English appellate courts have since ancient times favored oral opinions delivered separately by each appellate judge in immediate response to the oral argument (Meador et al. 1994, pp. 751–892). This method has the virtue of accelerating the decision, but it is less instructive to lower courts and citizens expected to obey the utterances of the court. The American concept of the opinion of the court is an invention of John Marshall as Chief Justice of the Supreme Court of the United States. Before his time, American appellate judges like their English forebears rendered their decisions orally from the bench after oral argument and without conferring among themselves. The opinion of the court is most useful for courts of last resort having the duty of explaining legal texts not only to subordinate judges and other officials, but also to citizens expected to obey the law and conform their behavior to its requirements. Out of the practice of publishing opinions of the court comes the understanding that American courts 'make law.' In many other legal systems, such opinions of the court are not prepared and published, or if prepared are presented in such summary and didactic form that they shed little illumination on the meaning of the legal texts cited. In countries adhering to that practice it is seldom said that courts make law.

Appeasement: Political

Appeasement is a policy of settling international disputes by admitting and satisfying grievances through rational negotiation and compromise, thereby avoiding war. Because of British and French concessions to Hitler at Munich in 1938, appeasement has

acquired an invidious, immoral connotation. In the classic balance-of-power system, however, appeasement was an honorable policy reflecting the principle that the international system needed some means of peaceful adjustment to accommodate changing national power and aspirations. As a small insular power with a far-flung empire, the British successfully pursued appeasement throughout the nineteenth century. Even the conventional wisdom about the 'lessons of Munich' has been questioned by revisionist historical scholarship. Scholars and policy analysts now view appeasement as a useful strategy for maintaining international stability under certain conditions.

1. *Definition*

As late as 1944, Webster's dictionary defined appease as 'to pacify (often by satisfying), to quiet, soothe, allay.' The 1956 edition of Webster's dictionary adds another clause: 'to pacify, conciliate by political, economic, or other considerations; now usually signifying a sacrifice of moral principle in order to avert aggression' (Herz 1964).

Appeasement, however, may have little to do with moral principles but instead reflect national interests. In the classical era of diplomacy, appeasement was a method of adjusting the balance of power to preserve an equilibrium between the relative power of states and the distribution of benefits. A declining state might accommodate a rising power with colonies or spheres of influence to dissuade it from engaging in a costly bloody war to overturn the international system. The British followed such a policy in the nineteenth century as their industrial, military, and economic strength declined relative to the United States and Germany.

Appeasement was also used to satisfy a revisionist state's legitimate grievances so that it would not go to war. Diplomatic theorists believed that it was futile and self-defeating to try to prevent all change because the revisionist state would eventually try to achieve its objectives by force unless some effort was made at negotiation and conciliation.

2. *British Tradition of Appeasement*

Historians Paul Schroeder and Paul Kennedy have shown that Munich was not a departure from the traditional British policy of maintaining a balance of power, but a continuation of a tradition of appeasement that was a prudent response to entangling obligations and commitments. For the British in the nineteenth century, appeasement referred to the attempt to stabilize Europe and preserve peace by satisfying a revisionist powers' justified grievances.

The British tradition of appeasement was a response to ideological, strategic, economic, and domestic political considerations. The British adhered to internationalist principles favoring arbitration and negotiation of differences between states, disarmament, and abhorrence of war except in self-defense. By the middle of the nineteenth century, Britain's Royal Navy could not defend the far-flung global empire, and British commitments outreached its military capabilities. The British suffered from strategic overextension. With her military forces stretched thinly over the world, Britain had an incentive to establish priorities among global interests, settle disputes peacefully where possible, and to reduce the number of its enemies. The center of a global economy, Britain imported raw materials and foodstuffs, and exported manufactured goods and coal. Britain provided insurance and overseas investment. The British economy would have been severely disrupted by war, as imports would have exceeded exports and Britain's income from 'invisible' services would have been cut off. Peace for Britain was a vital national interest. As the franchise expanded after 1867, British governments increasingly had to take into consideration public opinion. The British public disliked wars, especially expensive ones, preferring expenditures on social programs and economic reforms.

The British often used appeasement, and it was a successful policy for them, particularly toward the United States. The United States was a rising power. By the 1820s the United States had a larger population than Britain; by the 1850s it had a larger gross national product (GNP); and in the 1890s, the United States was expanding its navy. Yet, Britain and the United States did not fight a hegemonic war for world power. Much of the credit for avoiding war should be given to Britain for its numerous concessions to the United States.

The British had commercial and strategic reasons for appeasing the United States. Britain bought American cotton and wheat. The British were also aware of the vulnerability of Canada; in any war with Britain, the United States would invade Canada. The British did not have ground troops in Canada. Finally, Britain was already involved in quarrels with France, Russia, and Germany, and needed to reduce the number of its enemies.

In the 1842 Webster–Ashburton Treaty, Britain handed over most of northern Maine and the head of Lake Superior to the United States. The 1846 Oregon Treaty extended the border of Canada to the Pacific coast along the 49th parallel, giving the United States most of what is now called Washington State and Oregon. The Oregon territory, which included what is now Washington, Oregon, Idaho, parts of Montana and Wyoming, and half of British Columbia, had been held jointly by Great Britain and the United States. President James Polk had campaigned on the slogan 54–40 or fight, meaning that the United States should have the entire Oregon territory. After being elected, Polk announced that the United States was with-

drawing from the treaty sharing Oregon with Britain, and that the USA would put forts and settlers in the territory. Using deterrence, the British promptly sent thirty warships to Canada. Polk backed down, and submitted a compromise to Congress at the 49th parallel. Canadians viewed these treaties as sellouts to the United States, but Britain did not believe that the territory was worth fighting for, and if there was a fight, Britain might lose.

In 1895, Britain accepted US arbitration in a territorial dispute between Venezuela and British Guiana that almost led to war between the United States and Britain. Britain claimed part of Venezuela for British Guiana. In 1895, the USA demanded that it be allowed to arbitrate the dispute under the Monroe Doctrine. After four months, the British sent a note declining arbitration and the legitimacy of the Monroe Doctrine. President Grover Cleveland was enraged by the condescending tone of the note and by denial of the American right to settle the dispute. In December 1895, in a belligerent speech to Congress, President Cleveland threatened to go to war. The British were beginning to fear Germany, and they had no desire to get into a war with the United States. In 1896, the British accepted the US proposal that the dispute be arbitrated, and the crisis was over. Afterwards, American–British relations improved dramatically. The USA and Britain were never again close to war.

In 1902, Britain gave up its right under the Clayton–Bulwar treaty to have a share in any canal constructed in Panama. At the turn of the century, Britain withdrew most of her navy from the Western Hemisphere. Through appeasement, Britain satisfied American demands and altered American attitudes toward Great Britain, which led to a transformation of their relationship. The United States did not increase its demands as a result of British concessions, and America fought with Britain in World War I.

3. *Munich*

British and French attempts in the 1930s to buy off aggressors at the expense of weaker states have made a permanent stain on the policy of appeasement. The same strategic, economic, and domestic political conditions that encouraged the British to pursue appeasement in the nineteenth century, though, were even more pressing in the interwar period. The worldwide depression caused a contraction in Britain's invisible earnings as well as its overseas exports. By 1935, when the need for rearmament was apparent, defense expenditures were limited by the need to avoid jeopardizing Britain's economic recovery and financial position. In 1937, the Chiefs of Staff warned that British defenses were not powerful enough to safeguard British trade, territory, and vital interests against Germany, Italy, and Japan. Diplomacy must be used to reduce the number of potential enemies and to gain the support of allies. The British public had horrific memories of World War I (Kennedy 1983). Britain could not go to war without the support of the Dominions and before completing its rearmament program. In short, the British policy of appeasement was overdetermined by the popular fear of another devastating war, military unpreparedness, concern about the British economy and the Empire, and isolationism in the Dominions and the United States (Schroeder 1976).

A widely drawn lesson of Munich is that appeasement merely increases the appetite of aggressors, avoiding war now in return for a worse war later. The Munich agreement signed by Italy, France, Britain, and Germany on September 29, 1938 ceded to Hitler the Sudetenland of Czechoslovakia. On March 15, 1939, the Germans invaded Prague and annexed the rest of Czechoslovakia, provoking an outcry among British public opinion, and permanently discrediting the policy of appeasement.

Recent scholarship, though, brings into question some aspects of the conventional wisdom concerning 'the lessons of Munich.' British Prime Minister Neville Chamberlain suspected and mistrusted Hitler, but did not believe that the fate of the Sudetenland Germans was a cause justifying war, given the apparent reasonableness of the demand for self-determination. British appeasement did not whet Hitler's appetite for territory, because he had already formulated his foreign policy aims. In 1939, Hitler decided to attack Poland and was willing to risk war with Britain to do so. Hitler could not have been deterred from his plans by British threats to go to war; he *wanted* war (Richardson 1988).

4. *Uses and Limitations of Appeasement*

Rather than using 'appeasement' as a term of opprobrium, we need to identify the conditions under which it is a viable strategy for avoiding war, and those under which it will increase the likelihood of war. Appeasement of a revisionist state's grievances may be necessary if the status quo power has other competing geopolitical interests and domestic public opinion does not favor armed resistance to any changes in the international system. Yet, almost no systematic work has been done to compare successful and unsuccessful uses of appeasement.

Preliminary analysis, though, suggests that in order for appeasement to work, the revisionist power's demands should be limited. Ideally, the revisionist power's claims should have inherent limits—bring members of their ethnic group into their territorial boundaries, more defensible frontiers, or historic claims to some land. For example, the United States was expanding throughout the continent, but did not have any aspirations for overseas colonies or for world

domination. Because American aims were limited, British concessions were not likely to provoke additional demands. If concessions are made gradually, then the status quo power can assess the other state's intentions and provide incentives for good behavior.

Appeasement is usefully combined with deterrence toward any additional changes to a settlement. This means that the appeasing state should retain the option of using force—by developing adequate military capabilities to defend a settlement. Concessions made from a position of strength are more likely to be viewed by the opponent as an attempt to conciliate rather than as evidence of weakness. In the nineteenth century, Britain was more powerful than the United States. Neither deterrence nor appeasement is likely to be useful by itself.

Appetite Regulation

As it is commonly used, the concept of appetite is identified with the sensation of hunger or the subjective 'urge to eat.' Accordingly, much research on appetite regulation is devoted to specifying the processes or mechanisms that are involved with meal initiation, termination, frequency, duration, and food selection. Although most of this work attempts to describe physiological (e.g., neural, hormonal, metabolic) control mechanisms, the role of psychological factors such as learning about foods and the consequences of eating have also received much recent attention. The purpose of this article is to summarize briefly what is known about the physiological and psychological bases of appetite regulation.

1. Physiological Controls of Appetite

1.1 Central Control Mechanisms

Early studies showed that electrical stimulation of the lateral hypothalamus (LH) evokes robust eating, whereas destruction of this area produces a dramatic suppression of intake. In contrast, respective stimulation and lesion of the ventromedial hypothalamus (VMH) has the opposite effects on food intake. Based on such findings, the LH and VMH were conceptualized as forebrain hunger and satiety centers, respectively. More recently, emphasis on hypothalamic control of intake has been reduced based on evidence that brainstem areas also have a significant role in appetite regulation. Decerebration is a procedure that can be used to surgically disconnect the hypothalamus and other forebrain structures from neural input originating at sites in and below the level of the brainstem. Although decerebrate rats do not search for or initiate contact with food, when liquid food is infused directly into the mouth, these rats consume discrete meals. In addition, the taste reactivity (appetitive orofacial responses) of these rats also appears to be sensitive to food deprivation and other manipulations that influence the intake of intact animals. As noted by Berthoud (2000), these and other findings suggest that hypothalamic and brain stem nuclei are important components of a larger neural system for appetite control. This system also includes brain regions that are involved with the rewarding aftereffects of eating (e.g., prefrontal cortex, nucleus accumbens), that mediate learning about internal signals (e.g., hippocampus), and that are potential processing sites for peripheral signals related to energy balance (e.g., central nucleus of the amygdala).

1.2 Peripheral Controls and Signals

Appetite regulation by the brain undoubtedly depends on signals received from the periphery. The stimulus to eat, at first claimed to originate in the stomach, is now proposed to be a consequence of departures from homeostatic levels of glucose, lipids, or amino acids. Debate continues about whether changes in the availability of each of these metabolic fuels give rise to separate feedback signals or whether this information is integrated to produce a single, common, stimulus to eat. Receptors for such metabolic signals have been found in the liver (see Langhans 2000). The liver is centrally located with respect to metabolic traffic and is capable of detecting even slight changes in circulat-

ing metabolic fuels, including those that are denied access to the brain by the blood–brain barrier. Infusing metabolic antagonists directly into the liver promotes food intake and induces electrophysiological changes in vagal afferent pathways that project from the liver to brainstem loci known to be involved with feeding.

The termination of meals also seems to depend on the detection of specific peripheral signals. For example, when nutrients are first absorbed in the gut, the rate at which food is emptied from the stomach slows resulting in stomach distension as eating continues. Vagal afferent fibers carry signals produced by stomach distension to the brain. Food intake also produces short-term hormonal changes that appear to be involved with meal termination. Early findings that systemic injection of the gut peptide cholecystokinin (CCK) reduces meal size in a variety of species, including humans, led to the suggestion that CCK might play a role in normal meal termination (see Smith 1998). Findings that CCK is released by the presence of preabsorptive nutrients in the small intestine, and that blocking the effects of endogenous CCK release by administration of CCK receptor antagonists increases meal size support this hypothesis. Furthermore, the presence of CCK increases vagal afferent activity, an effect that is also blocked by CCK antagonists. Thus, CCK release may lead to meal termination as part of a mechanism that informs the brain when food has been detected in the gut.

Neuropeptides may also play an important role in the long-term control of appetite. Recent evidence indicates that the brain receives information about the status of bodily fat stores via neuropeptide signaling systems. One such signal may be provided by leptin, a circulating neuropeptide that is the product of the adipose tissue-specific *ob* gene. Secretion of leptin is correlated with body fat mass. Furthermore, extreme fasting decreases, whereas overfeeding increases, leptin concentrations in the blood. In addition, genetic mutations that produce defects in either leptin production or in its hypothalamic receptor lead to the development of obesity in several rodent models. Thus, leptin may be part of a signaling system that enables information about body fat mass to be communicated to the brain. The brain may use the information provided by the leptin signaling system to defend a 'set-point' or homeostatic level of body fat. Many other neuropeptides have been shown to alter food intake. For example, neuropeptide Y (NPY), and several opioid peptides are known to increase food intake. Along with CCK, serotonin, estradiol, and glucagon are prominent on the list of peptides that suppress feeding. In addition, the central melanocortin system has endogenous agonists and antagonists that are known to suppress and promote intake, respectively. Furthermore, some neuropeptides may influence the selection of specific macronutrients. For example, NPY and serotonin have been reported to selectively alter carbohydrate intake, whereas as galanin and enterostatin modulate selectively the intake of fat. This suggests that neuropeptides may influence not only energy balance but also the types of foods that are selected.

2. *Psychological Controls of Appetite*

2.1 *Social/Cultural Factors*

The traditions and standards of one's social group or culture to which we belong are important determinants of meal initiation, termination, and food selection. For example, the relative tendency to eat chilli peppers, sushi, and cheeseburgers is influenced by which type of food is most common or available in one's culture. Furthermore, even though a young child may at first reject, for example, very spicy or piquant foods, preference for such foods often develops after repeated exposure. Because one's culture determines, in large part, the types of food to which one is exposed (e.g., spicy foods, fatty foods, highly caloric foods), including what foods are considered acceptable at all (e.g., insects, dog meat, pork), it follows that food preferences and, to some extent, level of caloric intake are subject to strong cultural influences.

2.2 *Learned Controls of Eating*

One way to develop a preference for a particular food is to associate that food with a stimulus that is already preferred. Conversely, a preferred food will be liked less to the extent that it is associated with an aversive or unpleasant stimulus. A form of learning that produces changes in food preferences is flavor–flavor learning. For example, animals will come to prefer flavor A relative to flavor B (two hedonically neutral flavors) to the extent that flavor A has been combined previously with the sweet taste of saccharin. This outcome is obtained when both flavors are presented without saccharin during testing. Because saccharin contains no calories, increased preference for flavor A must have been based on its association with saccharin's sweet taste rather than its caloric consequences. Conversely, presenting a neutral flavor in solution with quinine (a bitter substance that is normally rejected by rats) reduces the preference shown by rats for that flavor when it is presented without quinine.

The flavor of food can also be associated with the postingestive consequences of intake. Conditioned taste aversion, which is demonstrated when animals avoid eating a normally acceptable food that has been associated previously with intragastric malaise, provides a robust example of this type of learning. Conversely, food preferences result when flavors are associated with the caloric or nutritive postingestive aftereffects of eating. This flavor–nutrient learning has

been demonstrated with rats in studies where the consumption of one noncaloric, flavored cue solution (CS+) is paired with the infusion of carbohydrate or fat solutions directly into the stomach, whereas intake of a different noncaloric solution (CS–) is paired with gastric infusion of water (see Sclafani 1997). After several of these training trials, strong preferences develop for the flavor that was followed by intragastric infusion of nutrients. Thus, the fact that conditioned food preferences are observed even when the nutritive consequences of intake completely bypass the oral cavity confirms that flavor–nutrient and flavor–flavor learning can occur independently.

Learning also contributes to meal initiation. Conditioned meal initiation occurs when environmental cues that are associated with eating when animals are hungry acquire the capacity to initiate large meals when the animals are tested when food sated. For example, repeatedly consuming meals at the dining room table when hungry may endow that place with the ability to initiate meals even when hunger is absent. The phenomenon of conditioned meal initiation has been demonstrated for both human and nonhuman animals, with punctate cues (e.g., discrete tones or lights) as well as contextual stimuli. Thus, the initiation of feeding appears under the control of learning mechanisms.

Experience with the sensory aspects of food can also contribute to meal termination independent of any reduction of physiological need produced by that experience. For example, hungry rats will eat a substantial meal of Food A before they voluntarily stop feeding. If the rats are offered the same food again a short time later they refrain from eating. However, if they are offered a new food, Food B, they ingest a second meal that can be calorically equal to or greater than the first. This is not simply a consequence of a difference in palatability between the original and novel foods. A large second meal is consumed even when the order of the foods eaten is reversed. Thus, rats do not become satiated for calories *per se* but become 'satiated' for specific tastes, textures, odors, or other sensory properties of food. This type of specific satiety has also been found in studies of human eating.

2.3 Appetite and Incentive Value

Animals are said to be attracted to pleasant or rewarding stimuli. Incentive motivational accounts propose that increased hunger promotes eating and appetitive behavior by enhancing the reward value of food (e.g., its taste or positive postingestive aftereffects). In addition, the attractiveness of environmental stimuli that are associated with the presentation of food are also enhanced by hunger. Enhancing the attractiveness or value of a stimulus improves its ability to compete with other environmental cues for behavioral control. Thus, modulation of the value of the orosensory and postingestive consequences of food and of stimuli associated with food may be an important psychological basis for appetite regulation.

Applied Geography

Applied geography emphasizes the social relevance of geographic research, which focuses on human-environment interactions, area study, and spatial-location problems. In general, the spatial distributions and patterns of physical and human landscapes are examined, as well as the processes that create them. Applied geography takes place within and outside of university settings and often bridges the gap between academic and nonuniversity perspectives.

Wellar (1998a) has referred to the difference between purely academic research and applied research as client-driven vs. curiosity-driven research. Whether university or nonuniversity based, geography becomes applied when the researcher undertakes a problem for

a client. While academic geographers' research is driven by their curiosity to understand patterns and processes, applied geographers perform research for a client with a 'real-world' problem. This results in a very different approach than an academic endeavor. The client can be a retailer in a capitalist economy, a group that receives unequal treatment from a capitalist or some other society and, therefore, would benefit from the empowerment that applied research findings may provide, or any other person or agency seeking or needing relief from a solution to a geographic problem.

The 'applied' approach provides a user-orientation and an effectuation plan quite different from those of curiosity-driven academic research. The research results are also presented in different formats and used differently. Applied research results may be input into the design of a new product, may result in a strategy for delivering a new product, or may be a set of recommendations that inform decisions. Academic research pursued for curiosity, typically results in the production of a book, monograph, or research article in a journal publication for the purpose of informing colleagues of findings, especially in terms of the contribution to existing theory. Applied geographers in vs. out of the university often differ in their views of what applied geography is. Despite these differences, applied geography is united by emphasis on useful knowledge.

University-based applied geography is narrower in scope than nonuniversity applied geography. The university presumes a theoretical and an empirical basis for applied research. Nonuniversity-based applied geography occurs within business and government cultures that often results in highly specialized roles for individuals applying geographic knowledge and skills in the solution of problems. The differences between the two workplaces shape research perspectives, define broader nonresearch obligations, and result in different perspectives. For example, in the university context the researcher controls and participates in all aspects of research, leading most academics to define 'applied' as the research performed by the researcher for a client. Most academics also emphasize research over effectuation planning.

By contrast, in a nonuniversity setting an applied geographer has a job description that indicates specific tasks and places the employee in a reporting hierarchy. Individual responsibilities are tied to a 'client relationship' that is inherent to a production environment. The employment specializations of nonacademic geographers range from planner-technician to analyst, from a research scientist to director of operations, and from project director to executive (Frazier 1994). In the nonacademic world every cog in the wheel is crucial. In short, the very nature of the nonacademic world requires multiple stages in the creation of a product. An applied geographer may be performing research or implementing the research of others, doing none herself, but contributing greatly to the process. Being directly involved in all parts of the applied research process is not a prerequisite to doing applied geography outside academia.

What holds applied geography together is the value context placed on knowledge. The applied geography approach seeks useful knowledge that helps solve a specific problem for a specific client. Pacione (1999) describes examples of practical recommendations for policy that address the issue of ethical standards in applying science. Specifically, he used British and American examples that illustrate applied geographers taking anti-establishment, unpopular positions to effectuate research findings that would change existing urban policies.

The goals of applied geographic research differ from those of basic research but the boundary between the two can be fuzzy. The value of 'useful knowledge' helps clarify the differences between the two approaches.

1. *Applied Geography: An Historical Context*

1.1 *Early Leaders by Example*

A dialectic between academic (pure) and nonacademic (applied) geography is reflected in the work of many famous geographers in the early twentieth century. Perhaps the most frequently cited case of geography in action is the work of L. Dudley Stamp in the Land Utilization Survey of Great Britain. Stamp called for geography not only to use its methods and concepts to interpret the world, but also to help forward the solution of some of the great world problems (as quoted in Frazier 1981, p. 3). Stamp's work in the 'Survey' put geographic methods and concepts into action and provided a touchstone for their utility. The 'Survey' methods and findings were replicated by others and informed geographic theory and approach for decades, providing not only planning inputs but research topics in academic geography.

In the US, several geographers of national reputation converted their academic interest in human-environmental topics into government employment. Among them were Harlan Barrows, who between 1933 and 1941 worked on a variety of water resource projects, including the design of comprehensive development schemes on a regional basis (Colby and White 1961). Even earlier, Carl O. Sauer, an architect of academic cultural-historical geography, played a leadership role in the Michigan Land Economic Survey. The frequently employed theme of 'human as agent' was applied in this land assessment and classification effort. Sauer applied well-established academic geographic concepts and methods in an applied research mode. He dealt directly with specific forms of 'destructive exploitation' and their specific impacts on the land. Further, his scheme included a model of potential future uses, including modifications

that would realize better results. Sauer's efforts were utilized in land management planning as well as being published in the academic literature (Sauer 1919); they informed future action and future academic research. In Sauer's case he followed up on applied research by being involved in the implementation stages as an activist.

Perhaps the most internationally respected expert on natural hazards is Gilbert F. White. He is another example of an academic geographer that has served the nonacademic community for half a century. White's early concern for victims of flooding and other natural hazards led to applied work for the administration of Franklin D. Roosevelt and new policy. White established academic and nonacademic followings and his leadership resulted in the creation of The Center for Natural Hazards Studies at the University of Colorado, Boulder. White and his colleagues have used geographic concepts and methods to understand different types of natural hazards and find ways to mitigate their impacts on people. Stressing physical and human variability, White has focused on improving the plight of human kind (White 1974).

While this is not a comprehensive review of applied geography, we would be remiss to exclude the founder of business geography in the nonacademic world. In the 1930s William Applebaum accepted a position with The Kroger Company. His introduction of very basic geographic concepts and methods for analyzing market regions was highly successful and created a career path for others to follow. Initially, applied geographers focused on measurement techniques, market delimitation and competitor analyses. However, Applebaum maintained a close relationship with a small group of academic geographers and hired new geography graduates. Slowly, applied business geographers expanded their roles to include location analyses, site selection, and the application of models. As a result of this dialectic relationship between Applebaum and, later, others from the business world with academics, a new subspecialty, business/marketing geography, emerged in the US and new concepts and methods were exchanged between the two environments. In Europe, Ross L. Davies is an example of an academically based applied geographer who has spent a career conducting research that guides understanding of retail structure and behavior and that has informed business decisions.

1.2 Institutionalizing Applied Geography: Two American Examples

Geography has been incorporated into government and business at various levels and in various ways. At one level, geography is inherent in business decisions and has resulted in many firms hiring geographers as location and/or site analysts. Some have risen to managers and executives. At another level, however, agencies formalize geography through their missions and/or internal organizational structure. Two American examples suffice.

1.2.1 The American Geographical Society: useful knowledge and geography in action. When writing the history of the American Geographical Society, J. K. Wright noted its earliest public purposes: '... The advancement of geographical science and the promotion of business interest of a "great maritime and commercial city" were the Society's two leading purposes' (Wright 1952, p. 69). These were most often expressed in the society's early years through published research reports, including those resulting from Society-backed field expeditions. An early example, which also reflects another Society purpose, supporting religious causes, was the appointment of the 'Committee on Syrian Exploration,' which was championed by a rabbi and, according to the Committee, would 'lead to important discoveries and human development by reclaiming the desert, creating self-sufficiency and linking the region to world trade' (Wright 1952, pp. 39–40). This was in keeping with the Society's purposes and exemplifies its efforts to put geography into action that would promote human welfare.

In attempting to institutionalize applied geography in society, the AGS sought to provide important data useful to government and business decision making. This is obvious in a number of the Society's efforts. In its early years statistics had been hailed as knowledge capable of eliminating 'the fogs of human ignorance and suffering' (Wright 1952, p. 47). The Society attempted to influence census taking and even proposed a new federal tax system as its 'most ambitious attempt to influence government policy' (Wright 1952, p. 50). The intended applied thrust of the AGS is perhaps best stated in its inaugural issue of the *Geographical Review*: 'It is the essence of the modern ideal that knowledge is of value only when transformed into action that tends to realize the aspirations of humanity. It is precisely this view that the Society has always taken' (*Geographical Review*, 1916, pp. 1–20, as quoted by Wright 1952, p. 195).

Other national and international roles by the Society and its members are well documented. Among the most prominent are Society activities associated with the Congressional Act that established the International Meridian Conference in Washington, DC and the leadership role of Society Director, Isaiah Bowman, in 'The Inquiry' after World War I. This enterprise was headquartered at The Society. At the Paris Peace Conference that followed, Bowman served in an executive capacity at the request of President Wilson.

1.2.2 Applied geography in government: The US Bureau of Census Geography Division. Perhaps no federal agency anywhere has been more influenced by

the geographic perspective than the US Bureau of the Census. For more than a century, the value of geographic knowledge has been applied in the acquisition and reporting of data for the establishment and monitoring of national and state programs in Commerce, Agriculture, Housing and Urban Development, Health and Human Resources, Indian Affairs, Transportation, Energy, Defense and CIA, and others. Applied geographers have played important roles throughout the federal government in such activities. However, the Geography Division of the US Census has long been charged with very specific duties, including the delineation of meaningful statistical areas, the creation and/or implementation of methods for the capture, organization, and reporting of useful geographic knowledge for problem solving. Torrieri and Radcliffe (in press) noted the early work of Census Chief Geographer, Henry Gannett, who by 1890 led the development of area definitions and mapping techniques, and was largely responsible for a variety of population reports, including the 'Report of the Nation' (Torrieri and Radcliffe in press).

Over the next century Geography's role expanded and by 1978 Chief Geographer, Jacob Silver, provided a summation of responsibilities that included the development of national geographic reference files and digital mapping techniques (Silver 1978). By the close of the twentieth century the Geography Division supports the most widely used digital base file in the world (TIGER) and is planning new census techniques, area definitions and portrayal methods for census data in the twenty-first century.

1.3 Themes in Applied Geography

Most subdisciplines of geography contain examples of applied geography. Examples include a concern for environmental processes and patterns that influence human development and well-being, such as the physical processes of erosion, sedimentation, and desertification. Human–environmental relationships take on many forms but prominent among them are natural hazards behaviors and environmental degradation of all types. The applied regional approach, or area study, involves any effort to create or analyze geographic zones for the benefit of human welfare. We already reported the leadership role of census geography, but others include the creation of planning regions by applied geographers to plan, administer, and monitor urban and environmental areas. Location principles are applied to a wide range of analyses but are probably best known in applications for site selection in business and government and for retail market analyses, including the internationally known Huff model.

Recently, Torrieri and Radcliffe identified seven general classes into which they believe most applied geography falls: (a) market/location analysis; (b) medical geography; (c) settlement classification and statistical geographic areas; (d) land use, environmental issues and policy; (e) transportation planning and routing; (f) geography of crime; and (g) developmental tools and techniques for aiding geographic analysis (Torrieri and Radcliffe in press). They admit that these classes are not exhaustive. It is unlikely that any nomenclature will satisfy all applied geographers. However, such classifications are useful in understanding the wide range of applied geography that occurs internationally.

One contemporary example illustrates geography at work in the transportation and routing area. Barry Wellar, who worked for the Provincial government of Ontario before becoming a professor at the University of Ottawa, has led a research team under contract with the government to develop a 'Walking Security Index.' This index will be used to assist Canadian officials and citizens in assessing the safety of signalized intersections for pedestrians (Wellar 1998b). After developing the necessary indices and examples for the government, Wellar and his colleagues have presented their results in public meetings and through the media. The final report contained 17 intersection recommendations based on the research and interactions with the three clients, government officials, staff professionals and citizens. It also contains implementation issues and strategies.

1.4 Future of Applied Geography

Several trends indicate a bright future for applied geography. As noted above, applied geography was institutionalized both inside and outside academia in important ways. One trend is its increasingly formal treatment as part of academia, where it is considered a valid approach challenged in the philosophical debates of the discipline (Pacione 1999). Further, the British journal, *Applied Geography*, created a lasting publication forum for those interested in particular aspects of this approach. Finally, in America, the annual 'Applied Geography Conferences' can be considered an institution that has brought thousands of applied geographers together from business, government, and the university.

The second trend in Geography is the recent improvements in geographic education at all levels. Professional European Geography was founded in the nineteenth century at least in large part due to educational concerns. At the close of the twentieth century, concerns for geographical ignorance spawned a revolution in geographic education. In America, the generosity of the National Geographic Society and the labor of educators of the National Council for Geographic Education have contributed significantly to improving the quality of geographic teaching through geographic alliances in all 50 states. If applied geographers can be viewed as the 'outputs' of geographic education, then children are the 'inputs' that are shaped and mentored at all levels of the edu-

cational process. This trend of improved geographic education to rid the world of geographical ignorance has contributed positively to a third trend, that of greater public awareness of the importance of geography and its value, not only in better appreciating and understanding our local and global environments, but in contributing to the solution of significant global (e.g., global warming), national (e.g., poverty and inequality), and local (e.g., environmental health) problems.

Another trend that has contributed to our ability to recognize and solve geographic problems and to institutionalizing geography in the public and private sectors is the creation of geographic-based automated technology. Geography is now inseparably linked to information systems via GIS (geographic information systems). Many employers seek technical and analytical employees who can use this technology in problem solving. Among the other digital technologies often linked to GIS and, therefore, extended to applied geography, are remote sensing and global positioning systems (GPS). Both technologies frequently find their academic homes in geography departments and are requirements for undergraduate and graduate degrees. In short, technical skills are now often associated with applied geography and its practitioners because they acquire, portray, and analyze useful geographic knowledge for problem solving.

Finally, and perhaps most important, there is no shortage of pressing global, regional and local problems that require an applied geography approach. Many have been mentioned here. As long as there are geographers willing to contribute to the solution of problems that are inherently geographic or have geographic dimensions, there will be applied geography. Where geography is put into action, applied geography occurs.

Apportionment: Political

Most contemporary students of democratic theory take for granted that the basis of political representation will be geographic. There are two key components of any geographic system of representation: apportionment and districting. While the two terms are often used synonymously, formally, *apportionment* refers to the determination of the number of representatives to be allocated to pre-existing political or geographic units, while *districting* refers to how lines are drawn on a map within those units to demarcate the geographic boundaries of individual constituencies. *Malapportionment* refers to differences in the ratio of number of voters/electors to number of representatives across different constituencies. *Gerrymandering* refers to the drawing of districting lines for purposes of political (e.g., partisan or ideological or ethnic) advantage/disadvantage.

Use of geographical districting leaves open many key questions: How many and how large are the districts to be? Will seats be allocated to whole political units, such as provinces or towns, or will district lines be permitted to cut across existing political sub-unit boundaries? Will district lines be required to satisfy standards of compactness or contiguity? To what

extent will apportionment and districting lines be based (entirely or almost entirely) on total population? Or on population of (eligible) voters?

The USA has been a leader in defining standards of apportionment and districting to implement the principle of popular sovereignty. The US House of Representatives was intended by its founders to be the representative chamber of a bicameral legislature and its apportionment rules were set up to require a purely population-based allocation of House districts to the states, with changes in seat allocations made after each decennial census. Indeed, the various apportionment methods that have been used for the House over the past several centuries are mathematically identical to proportional representation methods such as N'Hondt and Ste. Laguë (Balinski and Young 1982; also see *Electoral Systems*). In Baker vs. Carr, 369 US 186 (1962), the US Supreme Court held that failure to redraw district lines when new census data was available was unconstitutional and that courts could fashion appropriate remedies. In subsequent landmark districting decisions, such as Reynolds vs. Sims 377 US 533 (1964), the US Supreme Court went much further, proclaiming '*one person*, *one vote*' as the only appropriate standard for both districting and apportionment.

While one person, one vote notions of representation have had a profound influence throughout the world, by and large, the USA remains extreme among nations in its insistence on strict adherence to one person, one vote standards. For state legislative and local redistricting plans, where the one person, one vote standard is derived primarily from the equal protection clause of the Fourteenth Amendment, Supreme Court cases in the USA have established a 10 percent total deviation as prima facie evidence of constitutionality. (*Total deviation* is the sum of the absolute values of the differences between actual district size and ideal district size of the largest district and the smallest districts, normalized by dividing through by ideal district size.) For congressional districting, where standards are based directly on the supposed meaning of language in Article I of the Constitution, the Supreme Court has held that districts must be as close to zero deviation as is practicable. For example, in Karcher vs. Daggett, 462 US 725 (1983) a congressional plan with a total deviation of only 0.698 percent was invalidated. In reaction to this ruling, in some 1990s congressional plans, districts were drawn that were equal in population to within a handful of persons. In contrast, in other countries, especially those using plurality elections, no such strict population requirements exist. Many countries require (or even only just suggest) that differences should be no greater than plus or minus 25 percent or plus or minus 50 percent of ideal (Butler and Cain 1992).

However, the notion that near perfect equality of political representation has been achieved in the USA is misleading. The grossly malapportioned US Senate tends to be omitted from international comparisons despite the fact that it is a co-equal chamber. The US House requires that each state have at least one representative—a rule that usually gives representation to several small states who would not otherwise be entitled to seats. Also, since states are the units, 'rounding rules' create variation in average House district population across states. For example, based on 1990 census figures, the largest House district in the 1990s apportionment was 1.7 times the size of the smallest House district, and the House had a total deviation of 61 percent (based on absolute deviations from the ideal size of 572,465 of 231,289 (Montana, too many) plus 118,465 (Wyoming, too few)). The discrepancies have been even greater in earlier apportion ments. Moreover, even districts that are equal in population need not be equal in terms of (eligible) voters. Perhaps most importantly, unless we somehow regard voters as completely interchangeable units, neither population nor voter equality across constituencies, however perfect, guarantees equality of effective representation of the disparate groups and interests within a society.

The degree and geographic locus of malapportionment and differential turnout across groups interact with how a group's voting strength is distributed across districts to affect the translation of a group's voting strength into actual electoral impact (Grofman *et al.* 1997). Indeed, malapportionment is sometimes referred to as a form of '*silent gerrymander*,' since malapportionment can easily translate into the political disadvantage of groups whose influence has been diminished because their members are disproportionally concentrated in constituencies whose voters have been underrepresented relative to their numbers. Even without conscious gerrymandering, the way in which districting lines are drawn will necessarily have an impact on the representation of different parties or groups (Dixon 1968).

The term gerrymandering comes from word play on the last name of Elbridge Gerry, Governor of Massachusetts. In 1812, Gerry signed into law a districting plan for the Massachusetts Senate, allegedly designed to maximize the electoral successes of Republican-Democrat candidates and minimize the electoral successes of Federalist candidates, which included some rather strangely shaped districts. In a map in the Boston Gazette of March 26 1812, the strangest of these districts was shown as a salamander, given tongue and teeth (Fig. 1). Perhaps the most pernicious aspect of this figure is that it has led to a potentially misleading association of gerrymanders with oddly shaped districts. The defining aspect of a gerrymander is the political consequences it entails, not its shape. Political disadvantage can come about even when districts look like squares or hexagons (Grofman 1990). In fact, however, the 1812 Senate plan did achieve partisan advantage for the Republican–Democrats; in the next election they won

Figure 1

29 of 40 seats even though they received less than half of the votes (Hardy 1990).

Gerrymanders can be classified as partisan, bipartisan (often called 'incumbent gerrymanders'), racial, and personal, depending on who can be expected to be harmed or helped. In the USA, for example, the debate about gerrymandering has been fought largely over racial rather than partisan issues, e.g., over the extent to which plans should seek to place members of historically disadvantaged groups such as African-Americans into districts where they comprise the majority of the population even if doing so meant drawing districts that were irregular in appearance or cut across municipal and other political unit boundaries (Grofman 1998).

There are two basic techniques of gerrymandering: (a) 'packing' members of the group that is to be disfavored into districts that are won by very large majorities, thus 'wasting' many of that group's votes; and (b) 'cracking' the voting strength of members of the group by dispersing the group's population across a number of districts in such a fashion that the group's preferred candidates will command a majority of the votes in as few districts as possible. In addition, if elections are held under plurality, a group's voting strength may be submerged in multimember districts that use bloc voting—a technique sometimes called 'stacking.' The terms 'affirmative action gerrymander,' and 'benign gerrymander' have been used to denote districting done to advantage members of a historically disadvantaged group. However, it is important to distinguish between plans that are drawn with an aim to create a level playing field by avoiding unnecessary fragmenting of minority population concentrations, but that otherwise generally take into account the usual districting criteria such as respect for natural geographic boundaries and historical communities of interest, and plans that seek to specially privilege particular groups by totally disregarding features other than race in drawing lines.

Because the way in which lines are drawn can be expected to matter, an important issue has to do with who draws the lines. In most democracies, especially those electing under plurality, non-partisan boundary commissions are responsible for drawing district lines (Butler and Cain 1992). In the USA, the preponderant pattern is for a legislature to be responsible for its own redistricting, and for each state legislature to be responsible for the drawing of congressional district lines for its state. However, in most US legislatures, no plan can be passed without gubernatorial agreement. Because of divided party rule and other factors, states may be unable to reach agreement on plans, thus throwing decision-making into the courts. One way in which districting practices in the USA are distinct from those in other countries is the extent to which courts play a critical role as arbiter. In recent decades, all but a handful of states have had a legislative or congressional plan challenged in court, and many plans have been rejected—in the 1960s and 1970s mostly for reasons having to do with population inequalities across districts, in the 1980s and 1990s for reasons having to do with racial representation (Grofman 1998). Indeed, throughout these decades, courts themselves were responsible for drawing some of the legislative or congressional districting plans that were actually used. Another peculiarity of US districting practices is the role of the US Department of Justice under Section 2 and Section 5 of the Voting Rights Act of 1965 as amended in 1982 (Grofman 1998).

From a comparative perspective, we may say that, generally speaking, gerrymandering is more important in plurality elections than in elections under proportional or semi-proportional rules. In particular, when there are more than two candidates or political parties competing, districting can have a dramatic impact on outcomes in plurality elections Taylor et al. 1986). *Ceteris paribus*, for elections under proportional or semi-proportional methods, the larger the average *district magnitude* (the number of representatives to be elected from the constituency), the less the probable impact of districting choices on outcomes; in contrast, for elections under plurality voting, the greater the average *district magnitude* (the number of representatives to be elected from the constituency), the greater is the expected impact on outcomes, since *plurality bloc voting* (the extreme case of which is an *at-large election*) can result in the virtual submergence of the views of those in the minority. However, even under proportional representation, expected outcomes can still be manipulated by districting choices, especially choices as to district magnitude (Mair 1986).

Apprenticeship and School Learning

Apprenticeship models provide a view of school learning processes that is quite different from traditional models. In particular, apprenticeship learning is less prone to the inert knowledge phenomenon. In this article, the main characteristics of apprenticeship learning and its theoretical background are described, and pros and cons of apprenticeship learning vs. traditional school learning are discussed.

1. Apprenticeship Models as Solutions for Problems with School Learning

Qualification and integration-enculturation are amongst the most important functions of schools for society as well as for individuals. School learning therefore should teach students facts and skills that are necessary for later life. However, evidence exists that school learning is often far removed from application situations out of school; critics have argued that it frequently leads to knowledge that is inert (Bransford et al. 1991) and thus cannot be used for solving real-world problems. A plausible reform idea is to make school learning resemble learning out of school. Resnick (1987) identified four principles in which learning in school and out differ:

(a) Individual cognition in school vs. shared cognition outside. Learning in school focuses on individual performance, students have to work in isolation; in contrast, learning out of school usually focuses on shared knowledge and cooperative problem solving.

(b) Pure mentation in school vs. tool manipulation outside. School learning focuses on abstract mental activities that have to be done without the use of any external support like one's own notes or Internet research systems; in contrast, learning out of school heavily relies on individuals' competence to use adequate tools in an adequate way.

(c) Symbol manipulation in school vs. contextualized reasoning outside school. With its focus on symbol-based reasoning, school learning often lacks close connections to events and objects in the daily world that are characteristic for learning out of school.

(d) Generalized learning in school vs. situation-specific competencies outside. School learning aims at the acquisition of general, widely usable principles, whereas learning out of school focuses on solving problems that actually arise at places and contexts the individual is situated in.

The analysis of discrepancies between learning in school and out includes criticisms of present school instruction concerning both the qualification function of school and its integration-enculturation function. Similar arguments were brought forward by the German *Reformpädagogik* (educational reform) at the beginning of the twentieth century. Alternative instructional models developed in these years are closely related to the proposals nowadays made by situated learning theorists. One common principle is that students participate in more advanced individuals' activities and thus increasingly become part of the community of practice. In such apprenticeship models of learning, besides knowledge students have to acquire the ways of thinking in communities of practice.

Since the early 1990s, a number of situated learning models have been developed in order to decrease the discrepancy between learning in and out of school and to avoid the acquisition of inert knowledge (Gruber et al. 2000). In each, students learn within complex contexts like apprentices by solving authentic problems in a community of practice. The approaches are based on the idea that knowledge is socially shared so that plain teaching of 'objective' knowledge does not suffice because each working situation includes de-

mands for adaptive problem solving (Derry and Lesgold 1996). The view that knowledge in principle is situated in the environment within which it was acquired is the perspective of situated learning.

2. Theoretical Background: 'Reformpädagogik,' Situated Learning

Many aspects of the mentioned situated learning approaches resemble concepts of the *Reformpädagogik*. When the agents of this German educational movement expressed their ideas a century ago, they were well aware of developments in the Deweyan Chicago school (e.g., the project plan; Kilpatrick 1922), and vice versa. *Reformpädagogik* criticized the 'book school' in a similar way school learning nowadays is criticized. The central counter-idea then was the 'work school,' most prominently proposed by Kerschensteiner (1854–1932). Kerschensteiner broadly reorganized the elementary and vocational school system; the German dual system in vocational learning emerged from his work. Kerschensteiner (1912) emphasized the importance of manual work which should be closely tied to mental work; among his school reforms was the introduction of kitchen and garden instruction in schools. Based on authentic activities, students learned chemistry, physics, physiology, and mathematics. Instructional questions usually were not posed by the teacher, but rather by the students when working on problems. Such self-regulated activity reduced the discrepancy between school and everyday life: work school no longer was an *Ersatzwelt* (artificial world) in which ersatz activities had to be carried out. Since the problems posed were of relevance to the students' life outside school, besides skills and knowledge, learners acquired socially conscious attitudes and a sense of responsibility as members of society.

Later, Kerschensteiner became extremely concerned about the question of whether school prepared for later professional life. He thus initiated the German vocational training system, the dual system, which is a form of training tied to the workplace with supplementary teaching in the compulsory, part-time vocational school. In this system, not only manual work is stressed: the notion of work can also be denoted to cognitive learning processes or, in Gaudig's term, 'free mental work.'

Many of the *Reformpädagogik* ideas were theoretically reconsidered in the situated learning movement under cognitive psychological and constructivist perspectives. Five major instructional principles can be identified:

Learning by solving authentic problems. In problem-oriented learning, an authentic, rather complex problem marks the starting point. Its function is not only motivating students, but also, by embedding the learning process in meaningful contexts, knowledge acquisition through application instead of abstract teaching. Knowledge is conditionalized to application conditions from the beginning.

Multiple perspectives. Domains are analyzed from multiple perspectives and multiple contexts in order to foster multiple conditionalization. Preventing the emergence of dysfunctional oversimplifications and fostering active abstraction processes are the main instructional functions, thus supporting flexible use of knowledge and skills.

Articulation and reflection. Externalizing mental processes enables students to compare their own strategies with those of experts and other students. Articulation facilitates reflection and thus fosters the decontextualization of acquired knowledge.

Cooperative format. Cooperative learning facilitates the comparison with experts and peer learners. In addition, competencies for cooperation are useful in later professional life.

Learning as enculturation. A particular function of learning is to become enculturated into communities of practice. To achieve this, students have to acquire a sense of authentic practice. They have to acquire functional belief systems, ethical norms, and the tricks of the trade.

These principles of situated learning have been realized in several instructional models, most convincingly in the model of cognitive apprenticeship.

3. Microanalytic Use of Apprenticeship in School Learning: The Model of 'Cognitive Apprenticeship'

The apprenticeship metaphor for designing situated learning arrangements has its origin in skilled trade domains, e.g., tailoring or midwifery. Collins et al. (1989) adapted the concept for cognitive domains. In 'cognitive apprenticeship' as in trade apprenticeship, students are introduced into an expert culture by authentic activities and social interactions. Important is the sharing of problem-solving experiences between students and mentors (experts, teachers, or advanced students), thus negotiating their understandings and actions through dialogue. Since in cognitive domains mental activities prevail, the explication of cognitive processes is extremely important in order to publicly expose knowledge and thinking processes involved in the cooperative problem solving (Derry and Lesgold 1996).

The core of cognitive apprenticeship is a particular instructional sequence. Learning takes place in sequenced learning environments of increasing complexity and diversity. In the early stages of learning, mentors provide overall direction and encouragement; as students improve, mentors gradually withdraw support, encouraging students to work and think more independently. At all phases of apprenticeship, the mentor is assigned an important role as a model and as a coach providing scaffolding. However, the

student has to increasingly take over an active role, as the mentor gradually fades out. Articulation and reflection are promoted by the mentor in order to persist on externalization of cognitive processes.

This instructional sequence supports students in increasingly working on their own (exploration) and taking over the role initially held by the mentor. Lave and Wenger (1991) similarly described the development of competence in nonexplicit learning contexts as development from legitimate peripheral participation to full participation. Learning is thus not confined to the acquisition of knowledge or skills, but is a social process of enculturation by becoming a full participant in a community of practice that can cope with the problems typical for the domain in a flexible manner. Considering learners as apprentices ascribes them a novel role: From the beginning, they are active participants in authentic practices instead of passive recipients (Gruber et al. 1995).

Empirical evidence exists that cognitive apprenticeship learning supports the acquisition of applicable knowledge in a variety of domains (e.g., programming, medicine). However, successful learning is not guaranteed. High demands are made on learners, so that careful instructional support is necessary (Stark et al. 1999).

4. *Macroanalytic Use of Apprenticeship in School Learning: Communities of Practice—Implementation of Apprenticeship in School Systems*

Cognitive apprenticeship stresses that learning performance, like all authentic cognitive activity, is socially constituted. Learning environments inevitably are part of a complex social system, and the structure and meaning of learning processes are substantially influenced by that system. It is unlikely that an adequate understanding of learning processes can be developed without taking the social context into consideration in which learning processes are situated. Conceiving learning as becoming enculturated into communities of practice thus concerns not only the individual processes during learning, but also the implementation of learning environments in large social contexts, frequently denoted as the prevailing 'learning culture.' Taking the apprenticeship idea seriously, such macroanalytic concepts of learning are inseparably connected with microanalytic analyses of learning processes. In a study of insurance claims processors at work, Wenger (1990) showed that there are large discrepancies between the official agenda of insurance management and what was actually learned and practiced at workplaces. Wenger concluded that knowledge and expertise cannot be understood separately from the social environment in which they are observed. A consequence for instruction is that learning has to be bound to application situations and has to be integrated into a large system with adequate learning culture.

The principle of the dual system of vocational training in Germany tries to fulfill this requirement. It includes simultaneous qualification at two learning locations: vocational school and enterprise. Thus school learning and professional practice are closely tied. Winkelmann (1996) compared the experience of apprenticeship graduates to that of graduates from universities, full-time vocational schools, and secondary schools when entering the job. He showed that apprentices experienced fewer unemployment spells in the transition to their first full-time employment than did nonapprentices. One reason is the interaction of different social components in the training process.

Efforts to implement the dual system in other countries (Harthoff and Kane 1997, Heikkinen and Sultana 1997) showed that many organizational preconditions are required, such as flexibility of enterprises in the adoption of the system, an elaborated widespread school system, adequate teacher education, etc. The dual system cannot serve as a panacea if the learning culture within a society is not prepared. Additionally, modern developments in workplaces—globalization of enterprises, new principles of working organization, etc.—yield difficulties for the dual system. New approaches in educational research are being developed as a response to emerging imbalances between the learning locations school and enterprise. For example, 'discipline and location-crossed training' aims to implement new ways of cooperation between learning locations.

5. *Outlook: What Remains of 'Traditional' School Learning?*

The view that knowledge is essentially situated has major educational implications. Learning is regarded as a process of enculturation in order to take part in a particular community of practice, to get acquainted with the culture of the community, the jargon used, the beliefs held, the problems raised, and the solving methods used. This entails the notion of apprenticeship to learning.

Traditional school learning is accused of producing inert knowledge as students fail to transfer their knowledge to tasks embedded in contexts other than school settings. Lave (1988) argued that traditionally school is treated as if it were a neutral place, with no social and cultural features of its own, in which competencies are acquired that easily can be transferred later to any other situation.

As mentioned above, there is evidence for the inert knowledge phenomenon. However, this evidence does not necessarily require the importance of traditional school learning to be denied. Even if there exist resources other than teaching through which apprentices acquire competences, apprenticeship is not the

only effective means of learning. The academic context of school learning proves useful for a variety of learning situations. It is very likely that an interaction exists between learning purposes and preferable learning contexts. Educational psychology has to decide carefully which kind of learning context is appropriate for which kind of learning, and should use the results of respective analyses for the design of school learning as well as for the design of teacher education.

Thus, the notion that 'traditional' school learning should be entirely abolished cannot be maintained. However, it is worth analyzing under what conditions apprenticeship models are an attractive alternative to traditional school learning. For which kinds of competence and knowledge, in terms of their complexity (elementary, intermediate, sophisticated) and nature (declarative, procedural, strategic), is apprenticeship deemed necessary? By what means can students obtain maximal benefits? These questions must be addressed in future research in order to determine the role apprenticeship can and should play in future so that an adequate balance between traditional school learning and situated learning is found.

Apprenticeship: Anthropological Aspects

Anthropological treatments of apprenticeship have until relatively recently been sporadic and piecemeal. Lately, however, there has been a surge of interest in the topic, and since the mid-1980s it has received much more sustained attention. Three themes emerge from the literature as predominant anthropological approaches to apprenticeship: first, as a form of social organisation occurring in a variety of social and cultural contexts; second, as an anthropological method of field research; third, as a domain for the analysis of social, cognitive, and bodily processes of learning. These aspects will be dealt with in turn below, but first some remarks to indicate how the concept has been formulated in the West.

The subject of apprenticeship comes with a good deal of conceptual baggage derived from European and North American history. An institution known in ancient Greece and Rome, as well as from the early history of the Middle East, apprenticeship in Europe in the Middle Ages was regulated by craft guilds; specifically in Britain under sixteenth-century Elizabethan statutes which were later repealed in the early nineteenth century. As a nineteenth-century institution, it has received a particularly bad press in Britain and the United States, where it was used as means of poor relief for pauper children who were bound and

indentured into trades so as to relieve local communities of the burdens placed on them by the poor. The lives of such children have been described as 'at best a monotonous toil,' 'at worst a hell of human cruelty.'

Anthropological perspectives on apprenticeship and the use of child labor in non-Western cultures are confronted today by a not dissimilar problem: what relationship should be drawn between the condemnation of the use of child labor and of the frequently accompanying economic poverty, on the one hand, and the recognition, on the other hand, that in some cultural contexts children are not excluded practically or ideologically from relations of production (see Nieuwenhuys 1996). The dilemma over how to approach this problem is informed in part by the history of the institution in the West, and by our knowledge of the abuses to which it has been put in the past. In order for apprenticeship to be viewed as a cross-cultural concept, therefore, it has to be disentangled from our own conceptual baggage. This is not a simple or easy task.

Apprenticeship is a key institution, then, in the West's history of craft production, of capitalist industrialized manufacture, and of the transition between the two. Whilst Adam Smith regarded it as an archaic institution whose abolition should be welcomed, Marx saw it as a form of organisation that protected a skilled workforce from the logic of machine manufacture and from the subsequent deskilling of labour (Marx 1887/1947).

Apprenticeship, viewed in the context of craft production or of industrial manufacture is a mode of organization for acquiring trade skills and for the supply of able practitioners in a trade. It also involves a relationship between a novice, who is usually a minor, and a master (usually not the novice's parent) who teaches a trade and who is recompensed for the instruction given in the form of the novice's products. Furthermore, the master stands *in loco parentis* to the novice, for they are responsible for the minor's moral development and general conduct, as well as for furnishing their board and lodgings.

1. *Apprenticeship as a Form of Social Organization*

Coy's edited collection on the topic (Coy 1989) was one of the first works by a group of anthropologists to treat apprenticeship explicitly as a social institution in comparative cross-cultural perspective. His definition of it echoes that given in the preceeding paragraph, but he suggests also that it is 'rite of passage' involving 'specialized' and 'implicit' knowledge; he emphasises too observation and participation as a mode of learning about a craft, about social relations, and about the social self and forms of cultural identity (1989 pp. 11–12) (see *Craft Production, Anthropology of*). Ethnographic examples in the volume range from north to south America, from Africa to the Far East. One of the major conclusions of the volume is that apprenticeship as a mode of social organization 'displays more similarity cross-culturally and historically than any of us realised' (Coy 1989 p. 15).

Goody (1989) goes on to theorise about these commonalities, arguing that apprenticeship is a characteristic of social systems undergoing increasing differentiation in a division of labor that has breached the limits of domestic, kin-based production; systems that are undergoing structural changes by virtue of entry 'into the market.' Whilst there is debate about the factors that determine the similarity of forms that apprenticeship takes across the world, some anthropologists have highlighted as well the unique features it takes in particular contexts (see Singleton in Coy 1989, Kondo 1990).

Coy's volume sets a contemporary benchmark for developments in the study of apprenticeship: first, it provided a set of comparable ethnographic descriptions of apprenticeship systems in a range of cultures; second, it examined in depth the idea of apprenticeship as an anthropological field method. More recent work on the topic has moved debates along in a number of directions. For example: Is apprenticeship a means of imparting knowledge or of restricting it? (cf. Singleton in Coy 1989 on 'stealing the master's secrets') What are the relationships of dominance operating within, and indeed outwith, apprenticeship systems? (Herzfeld 1995). Is there an objective body of knowledge that is passed on to novices or is knowledge negotiated and situational? (Lave and Wenger 1991, Keller and Keller 1996).

The first two questions introduce the issue of power into the organization of apprenticeship, viewed as a means of the transmission of knowledge and skills to future generations. Training apprentices produces potential future competition in the form of skilled practitioners who might one day, once they are economically independent, take trade away from their former master. These issues must be seen also within the purview of the wider political economy in which the reproduction of a trade does or does not take place.

The third question about the form that knowledge takes relates to whether specialists possess a body of knowledge that exists in the conventional terms in which we often think about it. Even if knowledge does not exist in the form of books, databases and so on, but in the form of oral traditions, does the achieving of knowledgeable practice rest on the acquisition of the latter? In many cases of apprenticeship, very little seems to be passed verbally from master to novice. So in which case what is being passed on? The development of knowledgeable practice might then be viewed in the framework of interaction and negotiation between two parties, and might too be connected with bodily praxis: a topic dealt with in Sect. 3.

The significance of the master–apprentice relationship is another topic of debate, especially whether it should be seen as a central characteristic of apprenticeship. Whether apprenticeship is a formal or an informal arrangement, many studies emphasise the relation between teacher and pupil as crucial to the processes and the experience of learning (e.g., Stoller and Oikes 1987 and Singleton in Coy 1989). Cooper (1989) describes the constant criticism by his master of his own practice as an apprentice woodcarver, and it seems that the theme of discomfort between master and pupil is one which recurs in many other studies, too (e.g., Marchand 2002). However, following Lave and Wenger's suggestions (1991) about a 'decentred' approach that focuses on 'communities of practice' rather than single dyadic relations, some analyses have now shifted emphasis away from the master–apprentice dyad to focus on whole communities of actors (e.g., Palsson 1994). The question raised here concerns how much apprentices actually learn directly from a master and how much is simply absorbed through participation with a group of skilled practitioners. There seems to be a degree of variation in the emphasis placed on master–novice relations depending on the kind of specialism being learned.

2. *Apprenticeship as an Anthropological Field Method*

The second aspect of apprenticeship is as a method of anthropological field research (see *Fieldwork in Social and Cultural Anthropology*). An increasing number of field researchers have apprenticed themselves to practitioners of a variety of crafts, trades, and other specialisms in order to acquire particular social and practical skills, and to gain a deeper insight to cultural practice and processes; in short, to learn about cultural learning (see e.g., Coy 1989, Keller and Keller 1996, Marchand 2002, Stoller and Oikes 1987). The intense interaction entailed by such participation provides a point of entry into a community and a way of learning through practice. Types of knowledge, secrets, and specific skills are also accessed, and these might otherwise remain hidden to investigations by other methods. Tedlock (1992) describes how she and her husband used the method of apprenticeship successfully to learn the art of Mayan divination.

Apprenticeship as a field method is not without its critics, who point out the methodological dangers of compromising 'objectivity' and succumbing to partiality. Few anthropologists, however, rely totally on this method and often use other techniques to investigate wider, macrosocial processes beyond the workshop. Cooper discusses the 'fiction' of apprenticeship: the requirement for fieldworker and fellow practitioners to enter into a pretence and to know when the pretence ends. A kind of 'enforced schizophrenia prevails' (Cooper 1989, p. 138). The 'enforced schizophrenia' inherent in the method allows for a continual methodological movement in and out of roles, and indeed sets up a distance from as well as an engagement with the subjective and experiential aspects of being apprenticed. Apprenticeship has of course much in common with traditional participant-observation, in which the fieldworker is as much a kind of 'cultural apprentice' as he or she is a detached observer (see for e.g., Coy 1989, Goody 1989, Keller and Keller 1996, Palsson 1994 on this comparison). 'Apprentice participation' is, thus, an extension of traditional anthropological methods of participation and observation, and is pertinent to the investigation of particular kinds of activities that may be closed, specialized or in some way inaccessible.

3. *Apprenticeship and Forms of Learning*

The third aspect of apprenticeship is the way it has been linked to the anthropology of education (see Pelissier 1991), and to the analysis of cultural theories of learning (see *Education: Anthropological Aspects*). Lave and Wenger (1991) have reworked this area to propose a shift away from the study of apprenticeship *per se* to the more general idea of 'situated learning' and 'legitimate peripheral participation,' in which the learning process is embedded in 'communities of practice.' The analysis of cognitive activity is firmly placed back in the domain of everyday life. Their work reviews a range of learning contexts from Yucatec midwifery to the US navy, and it raises questions about the relationship between participation and knowledge.

This relationship can be seen as problematic in that much of the knowledge learnt in such contexts is not verbalized and indeed is nonpropositional in nature. What is learnt is gained through mimesis, practice, and repetition of tasks performed routinely by skilled practitioners. Bodily knowledge, bodily techniques, and aesthetics now become the focus of study (see *Body: Anthropological Aspects*). Examples of this type of approach are Marchand's study of Yemeni master builders (Marchand 2002), and especially Wacquant's examination (1998) of his own apprenticeship as a boxer among prize-fighters in Chicago. Novices learn through their bodies as well as their minds, and the bodily discipline of a trade creates moral and aesthetic sensibilities. Moreover, these learning processes are not just about practical skills or producing objects, but are also concerned with the creation of cultural identities and selves. As Kondo points out with regard to Japanese artisans, work involves self-realization, a 'polishing of self through hardship'; for 'a mature artisan is a man who, in crafting fine objects, crafts a finer self' (Kondo 1990, p. 241). These studies suggest, therefore, that the rigid Cartesian distinction between mind and body, thought and action needs to be critically re-examined.

The concept of apprenticeship is a matrix connecting a set of keystone issues within the contemporary frame of social and cultural anthropology. When employed in cross-cultural comparison, it demands explanations for its apparent commonalities across a wide range of social settings as well as for its cultural particularities specific to place or time. The practitioners of apprentice field methods have raised questions about the delicate balance between subjective participation and distanced observation that lie at the heart of empirical fieldwork procedures: indeed, it suggests a way of bridging this distinction. As a domain of enquiry, apprenticeship highlights cultural conceptions of knowledge and the processes of learning, of embodiment and bodily praxis, of self and identity formation. It highlights too the need to examine the connections between knowledge and power in dynamic interactive contexts embracing both individual practitioners situated in different social roles and communities of skilled actors whose practices create wider webs of relations. These concerns about knowledge and power extend, moreover, beyond the parochial boundaries of the workshop or place of learning to the broad social world in which apprenticeship takes place.

R. M. Dilley

Apraxia

The concept of apraxia was elaborated by Hugo Liepmann (Liepmann 1908) in the early twentieth century. Liepmann noted that patients with left sided brain damage (LBD) committed errors when performing motor actions with either hand. This obvious deviation from the rule that each hemisphere controls the motor action of only the contralateral hand led him to conclude upon a general dominance of the left hemisphere for the control of motor actions. At that time it had already been established that the left hemisphere is dominant for comprehension and production of speech, and indeed most of Liepmann's apraxic patients were also aphasic, but he found some apraxic patients without aphasia and argued convincingly that faulty motor actions could not be referred to being a sequel of language impairment.

The nature of left hemisphere motor dominance and its relationship to language gave rise to various conflicting interpretations and remains an unsettled question after 100 years of reasearch. Any valid interpretation must take account of the fact that apraxia following LBD does not affect all kinds of motor actions. There is a striking discrepancy between fast and accurate performance of some motor action and hesitant and grossly erroneous performance of other actions which do not pose higher demands on the coordination of muscular innervations. Three kinds of actions are traditionally investigated for a clinical diagnosis of apraxia, because they yield clear manifestations of apraxic errors: imitation of gestures, demonstration of meaningful gestures, and use of tools and objects. This article will examine each of them on its own and then return to their implications for understanding hemisphere specialization of action control.

1. Imitation of Gestures

Faulty imitation of gestures has been said to prove that apraxia is a disorder of motor control and not a sequel of language disturbance or general asymbolia, that is, inability to comprehend and produce any signs or significations. The conclusion is strongest for faulty imitation of meaningless gestures. As these gestures have neither a verbal label nor a conventional signification, their imitation should be immune against disturbances of language or symbolic thought. More specifically it has been proposed that errors in

Figure 1
Imitation of hand postures by a patient with visuo-imitative apraxia. Left: model, right: imitation (reprinted from *Neuropsychologia*, **35**, Goldenberg G and Hagmann S 1997, The meaning of meaningless gestures: A study of visuo-imitative apraxia, pp. 333–341 Copyright 1997, with permission from Elsevier Science)

imitation testify disturbance of an executional or 'ideo-motor' stage of motor control succeeding to a conceptual or 'ideational' stage in which a plan of the intended action is formed (Barbieri and De Renzi 1988, Roy and Hall 1992). This proposal rests on the assumptions that the demonstration of the gesture for imitation leaves motor execution as the only possible source of errors. Defective imitation thus appears as evidence endorsing motor theories of hemisphere dominance which assume that there is a left hemisphere motor dominance which preceded and laid the ground for its language dominance (Liepmann 1908, Kimura and Archibald 1974). There are, however, several lines of evidence against this seducingly limpid interpretation of faulty imitation in apraxia.

The idea that imitation disorders arise at an executional stage of motor control predicts that patients who commit errors on imitation of meaningless gestures should encounter similar difficulties when performing meaningful gestures in response to a command specifying the meaning that is to be expressed by the gesture. There is no reason to assume that the motor implementation of gestures varies depending on whether the shape of the intended gesture is given by direct demonstration or by its meaning. This prediction is falsified by the observation of patients with 'visuo-imitative apraxia' who commit errors on imitation of meaningless gestures but not when demonstrating meaningful gestures. They may even achieve a correct imitation of meaningful gestures by first understanding their meaning and then reproducing them from long-term memory (Goldenberg and Hagmann 1997).

Kinematic studies of imitation show deviations from the normal profile of ballistic movements in patients with left brain damage and apraxia, but no correlation between the severity of these abnormalities and spatial errors of the finally achieved position (Hermsdörfer et al. 1996). There are even single patients who arrive at wrong final positions by kinematically perfect movements. This has led to the proposal that hesitancy, searching, and blocking of normal joint coordination are a reaction to ignorance of the exact shape of the intended gesture. This reaction may be absent in single apraxic patients who do not even note that they have not been able to build

up a correct representation of the demonstrated gesture and hence reach an incorrect target position with normal movements.

Further evidence that difficulties with imitation of meaningless gestures arise at a conceptual level preceding motor execution comes from the observation that patients who commit errors when imitating meaningless gestures commit errors also when asked to replicate these gestures on a mannikin or to match photographs of meaningless gestures demonstrated by different persons and seen under different angles of view (Goldenberg 1999).

The interpretation of left hemisphere dominance for imitation is further complicated by findings of defective imitation by patients with right brain damage (RBD). Whereas imitation of hand positions like those shown in Fig. 1 is affected exclusively by LBD, imitation of finger configurations, like those used for finger spelling in sign language, is affected by RBD even more than by LBD (Goldenberg 1999). RBD patients may also have difficulties when imitating sequences of gestures rather than single postures (Kolb and Milner 1981). Apparently, a left hemisphere contribution is necessary but not always sufficient for imitation.

The inconsistencies of a motor interpretation of LBD patients' difficulties with imitation motivated the revival and elaboration of an idea which had been put forward by Morlaas in 1928, held some popularity until the 1960s, but was then abandoned in favor of a return to Liepmann's original ideas (compare the articles on apraxia in the 1969 and 1985 edition of the *Handbook of Clinical Neurology* (De Ajuriaguerra and Tissot 1969, Geschwind and Damasio 1985). It was proposed that the left hemisphere contributes to imitation by coding meaningless gestures with reference to a classification of body parts (Goldenberg and Hagmann 1997, Goldenberg 1999). This classification reduces the multiple visual features of the demonstrated gesture to simple relationships between a limited number of body parts and accommodates novel and meaningless gestures to combinations of familiar elements. Furthermore, translating the gesture's visual appearance into relationships between body parts produces an equivalence between demonstration and imitation which is independent of the different modalities and perspectives of perceiving one's own and other persons' bodies. Absence of body part coding renders imitation an error prone to 'trial and error' matching between multiple visual details of perceived gestures, motor actions, and feedback about the own body's configuration (Goldenberg 1999).

Additional right brain involvement for some types of gestures can be referred to as demands on visuospatial analysis which may be lower for hand postures than for finger configurations. Hand postures are determined by relationships of the whole hand to perceptually salient body parts with very different shapes like the lips, the cheeks, or the ears. It is likely that demands on visuospatial analysis increase when, for example, finger postures require a distinction between extensions of index, middle, or ring finger.

2. *Meaningful Gestures*

Meaningful gestures serve communication. Their dependence on simultaneous verbal communication varies from gestures which emphasize or modulate the meaning of simultaneous oral speech to sign languages which are independent of, and can completely substitute for, oral language (McNeill 1992). The meaningful gestures which are usually examined for a diagnosis of apraxia lie in the middle of this continuum: they carry a meaning of their own and can be understood without accompanying speech, but their range of expressions is very limited, and there are no syntactic rules for combining them to a full language. Such gestures may either have a conventionally agreed, more or less arbitrary, meaning like 'somebody is nuts,' 'military salute,' or 'okay,' or they may indicate objects by miming their use. Usually, diagnosis and research on apraxia concentrate on miming of object use, because aphasic patients may not understand the verbal label of gestures with conventional meaning, whereas comprehension of the object name can be facilitated by showing either the object or a picture of it.

Examination of meaningful gestures requires that they are demonstrated outside their appropriate behavioral context. The instruction is 'show me how you *would* show to somebody that they are nuts' or 'show me how you *would* use a hammer.' This is significantly different from the instructions given for imitation: 'Do as I do' or, for actual object use, 'use this object.' To follow such instructions requires symbolic thought or, respectively, an 'abstract attitude.' Miming the use of an object without tactual contact poses additional demands on imagination and inventiveness. The motor actions of actual object use are partly determined by mechanical constraints and properties of the used objects. The patients must compensate for the absence of this information by conjuring up a mental image of actual object use and extracting from this image the shape and motion path of the hand holding the object. Indeed, it has been observed that provision of an object whose tactual properties resemble those of the pretended object (e.g., a stick for a hammer) may induce a significant improvement of miming. Of course, miming object use would be impossible without any knowledge about how the actual object is to be handled. This knowledge—the nature of which will be the subject of the following section—is needed in addition to the ability to demonstrate it without touching the object.

Defective demonstration of meaningful gestures is exclusively linked to LBD (Barbieri and De Renzi 1988, Goldenberg and Hagmann 1998). Although

some deviations from normal performance have been documented in RBD patients by applying sophisticated measurement of all spatial and temporal details of gestures, these deviations never approach the gross errors or total failure which apraxic patients with LBD encounter when asked to demonstrate meaningful gestures. Many LBD patients who cannot mime object use can demonstrate the use of the same objects when allowed to take them in their hands (De Renzi et al. 1982, Goldenberg and Hagmann 1998), whereas the possibility of a reverse dissociation of impaired actual object use with intact miming is questionable. By contrast, there are patients who cannot demonstrate meaningful gestures but can imitate meaningless gestures (Barbieri and De Renzi 1988) and—as already discussed—patients who can demonstrate meaningful gestures but cannot imitate. Such a double dissociation suggests that demonstration of meaningful gestures and imitation involve nonoverlapping components of left hemisphere competence.

The multifaceted nature of meaningful gestures makes it difficult to draw any firm conclusions as to which aspect of them is exclusively bound to the left hemisphere. Possibly, the left hemisphere contribution is essential for the elaboration of comprehensive communicative signs and and for the ability to demonstrate them in the absence of their habitual behavioral context.

3. *Tool and Object Use*

The inability to use real tools and objects is the least frequent but most dramatic manifestation of apraxia. For example, patients may try to cut bread with the reverse edge of the knife or even with a spoon, may press the head of the hammer upon the nail rather than hitting, or may try to press toothpaste out of a firmly closed tube. There is general agreement that such errors arise at a conceptual level of motor control. 'Agnosia of utilization' (Morlaas 1928) renders patients unable to recognize how objects should be used.

Knowledge about how to use tools and objects can have several sources: it may be specified by 'instructions of use' stored in semantic memory and retrieved as one of multiple semantic features when the object has been identified. Such instructions can exist only for familiar objects and are likely to specify their prototypical use, like inserting nails for a hammer and extruding nails for pincers. One can, however, use pincers for hammering. Possible nonprototypical uses of familiar objects as well as possible uses of unfamiliar objects could be detected by a direct matching between structural properties of objects and the affordances posed by actions (Vaina and Jaulent 1991), that is, by a direct inference of function from structure.

When the task transgresses the use of single tools and objects to require the coordination of multiple actions with several objects, like, for example, preparing a meal or fixing household repairs, additional cognitive resources are invoked. The task must be parsed into its component actions and their adequate sequence must be determined considering hierarchical relations between goals and subgoals. During the course of actions the running of the sequence must be checked, updated, and possibly revised. It is likely that these demands pose loads on memory and on general reasoning abilities.

There is evidence that the first two of these sources, retrieval of instructions of use from semantic memory and inference of function from structure, are exclusively bound to left hemisphere function. Patients with LBD make errors when requested to match objects according to similiarities of function rather than to perceptual similarities (Vignolo 1990). As already noted, retrieval of knowledge about object use is a component of pantomiming object use which is deficient exclusively in LBD patients, and although real object use is usually less affected than miming, the severities of their disturbances are correlated (Goldenberg and Hagmann 1998). It thus seems very likely that LBD patients have difficulties with retrieval of instructions of use from semantic memory.

Evidence for an inability to directly infer function from structure comes from experiments in which patients are requested either to find alternative uses of familiar objects for accomplishing a given task (e.g., selecting a coin for screwing when there is no screwdriver), or to find out the possible applications of unfamiliar tools (Heilman et al. 1997, Goldenberg and Hagmann 1998). With both types of tests only patients with LBD encounter difficulties.

The role of the left hemisphere is much less clear for the additional cognitive components that come into play when the task affords a chain of actions with several tools and objects. Whereas disturbances of simple object use (e.g., hammering a nail, opening a bottle) are found exclusively in patients with LBD, complex actions sequences (e.g., preparing a lunch, wrapping a gift) also pose difficulties for patients with RBD or with diffuse brain damage (Schwartz et al. 1999).

4. *Conclusions*

Apraxia was crucial to Liepmann's proposal that the left hemisphere is dominant for the control of motor actions. This proposal was attractive because it promised to explain many, if not all, clinical symptoms of left brain damage within the framework of one coherent theory of hemisphere specialization. One hundred years of research have falsified the hypothesis by demonstrating that apraxia embraces a collection of heterogeneous symptoms and cognitive deficits which can be brought forward by examining motor actions but cannot plausibly be reduced to insufficient

motor control. These symptoms are, however, worthy of being studied in their own right. They refer to central domains of human competence. Learning novel skills through imitation, the use of symbols to denote absent objects and events, and creation and use of tools, have all been proposed as being unique to man and crucial for the development of human culture. Abandoning motor dominance as their common denominator leaves open the question why decisive components of these aptitudes are bound to left hemisphere function. Apraxia continues to promise a key to understanding hemisphere specialization and its importance for the development of specifically human aptitudes.

Archaeology and Cultural/National Memory

Individual humans can remember occurrences of their own lifetimes as well as of a collective past, whether near or far removed in time from the moment of remembering. While the former is restricted to events and processes at which the particular person was physically present as a conscious human being, the latter includes accounts of occurrences happening both before and during an individual's life. Although records of personal memories may be an important source for some areas of archaeological research (e.g., twentieth-century archaeology, San rock art), most archaeologists are dealing with collective memories.

This article discusses several models of how collective memory functions. An overview will be given of the different implications for both the archaeological study of ancient sites and objects, and archaeology as an academic discipline in the context of a given society or nation of the present.

1. Archaeology and Theoretical Approaches to Memory

For the longest time in intellectual history, human memory has been seen as a huge archive in every human being from which, at any point in time, specific items can be retrieved in the process of remembering. This was, for example, the view of Saint Augustine (*Confessions*, X.viii(12)). In this perspective, individuals may create mnemonics in order not to forget on particular occasions (Yates 1966) and they are able, in principle, to remember past events accurately. Collective memories may work accordingly. More recently, however, it has been argued that the issues involved in remembering and forgetting are not that simple.

1.1 Memory as a Social Construction

Remembering, and indeed forgetting, are strongly influenced by circumstances of the time in which they take place. Moreover, memory can fail completely or

'make up' stories or events that allegedly took place in the past. Maurice Halbwachs argued that some key factors affecting memory derive from the social arena which people always inhabit when they remember. Halbwachs introduced the concept of '*mémoire collective*' (collective memory), and emphasized how strongly social processes influence not only people's personal memories of their own lifetimes, but also a community's shared memories of the past. Collective memories are crucial for the identity of groups such as families, believers of a religion, or social classes (Halbwachs 1992). Although memories vary between individuals and no two persons share identical 'collective' memories, anyone who has ever lived for some time in a foreign country knows what it means not to share the same collective memories as colleagues and friends. Collective memories can be evoked at particular sites (see below), and they have, in turn, the potential to shape such sites. As an example of the latter, Halbwachs discussed the Medieval 'creation' of the Holy Land by the superimposition of an imaginary landscape on Palestine (Halbwachs 1971).

The collective memory of archaeology provides a topical example. Although little research has been done on that topic, it is clear that some historical figures such as J. J. Winckelmann, C. J. Thomsen, General A. Pitt-Rivers, and H. Schliemann are considered widely to be the 'fathers' of the discipline. Similarly, sites such as the Valley of the Kings, Troia (Troy), Teotihuacan, and Stonehenge, are remembered collectively as key sites of archaeology and are now major tourist sites. While the significance of any of these persons and sites is not disputed here, it is clear that they function *de facto* as parts of the collective memories of archaeology and its successes. The way they are remembered tells us as much, if not more, about specific people and their identities in the present as about the history of archaeology.

Going beyond Halbwachs's argument, social scientists have argued recently that memory of the past is not only influenced but also constituted by social contexts of the present (Middleton and Edwards 1990, Fentress and Wickham 1992). Such reasoning questions the separation of past and present in a fundamental way. It becomes pointless to discuss whether or not a particular remembered event or process corresponds to what 'actually' happened: all that matters are the specific conditions under which such memory is constructed, and its full personal and social implications at a given point in time and space. The distinction between personal and collective memory is thus not necessarily a sharp one. Both reflect, first and foremost, the conditions of the present in which they originate. Individual persons learn collective memories through socialization, but they retain the freedom to break out of it and offer alternative views of the past which may themselves later inform the collective memory. It may eventually become impossible to tell which memory is indeed an accurate remembrance of an occurrence at which a person was present, and which is merely a remembrance of an earlier remembrance that was created by a story read in a book or watched on television.

1.2 'Les lieux des mémoire'

Pierre Nora edited a monumental work of seven volumes about the loci memoriae of France, entitled *Les lieux des mémoire* (Nora 1984–92). A '*lieu de mémoire*' (site of memory) is any significant entity, whether material or nonmaterial in nature, which by dint of human will or the work of time has become a symbolic element of the memorial heritage of any community (see *History and Memory*). Nora deals specifically with sites where modern France constructs its national identity by constructing its past. Crucially, these sites of memory do not only include places, e.g., museums, cathedrals, cemeteries, and memorials; but also concepts and practices, e.g., generations, mottos, commemorative ceremonies; and objects, e.g., inherited property, monuments, classic texts, and symbols. Archaeological sites of memory discussed in individual contributions include Palaeolithic cave-paintings, megaliths and the Gauls.

According to Nora, all sites of memory are artificial and deliberately fabricated. Their purpose is to stop time and the work of forgetting, and what they all share is 'a will to remember.' Such sites of memory are not common in all cultures, but a phenomenon of our time: they replace a 'real' and 'true' living memory which was with us for millennia but has now ceased to exist. Nora thus argues that a constructed history replaces true memory.

1.3 Cultural Memory

Jan Assmann employed the term '*kulturelles Gedächtnis*' (cultural memory) in a study of the past in ancient Egypt (Assmann 1992). Cultural memory can be defined as the cultural expressions of a collective memory, including written texts, symbols, monuments, memorials, etc. It is distinct from the 'communicative memory' of individuals' lifetimes, which is expressed by means of direct communication (see *Oral History*). Cultural and collective memories are 'retrospective.' Correspondingly, the hopes and expectations of people for what will be remembered in the future can be termed 'prospective memory.' Such hopes find their expression not only in the design and 'content' of a site of memory, but also in its monumentality and the durability of the materials employed. If prospective memory is the desired memory when building a site of memory, retrospective memory is how this site is in fact later remembered.

According to Assmann, cultural memory embraces both '*Erinnerungskultur*' (memory culture) and '*Ver-*

gangenheitsbezug' (reference to the past). Memory culture is the way a society ensures cultural continuity by preserving, with the help of cultural mnemonics, its collective knowledge from one generation to the next, rendering it possible for later generations to reconstruct their cultural identity and maintain their traditions. Memory culture relies on later references to (mnemonics of) the past. Such references reassure the members of a society of a shared past and collective identity, and supply them with an awareness of their unity and singularity in time and space. Cultural mnemonics, such as preserved ancient monuments or artifacts, trigger recollections of past times, although these can be fabrications rather than accurate representations of the past. Arguably, this second aspect of cultural memory has the wider implications. The fact that collective memories of the past occur without being able to ensure cultural continuity, suggests that the past can be given specific meanings for reasons other than accurate reconstruction. In effect, as interpretations of the past have changed over time, ancient sites and artifacts have been interpreted quite differently during their long 'life-histories (Holtorf 2000).'

For archaeologists, both actual continuities and various archaistic reinventions or other symbolic references to a rediscovered or recreated past are interesting phenomena to study. Because both already occur widely in antiquity, Nora is arguably misguided in limiting the existence of sites of memory to the modern era. There is evidence for deliberate attempts to stop time and make contemporaries remember by 'artificial' means, from the ancient Near East (e.g., Assmann 1992, Jonker 1995) as well as from prehistoric Europe (Holtorf 2000).

2. *The Relationship between Archaeology and Collective Memories*

2.1 *Archaeology vs. Memory*

It has often been assumed that the academic study of the past is superior epistemologically to popular notions of the past, as they are reflected in folklore, myths or in other expressions of collective memory. Maurice Halbwachs contrasted memory and history as two oppositional ways of dealing with the past. Whereas historians aim at writing a single objective and impartial universal history, collective memories are numerous, limited in their validity to members of a particular community, subject to manifold social influences, and restricted to the very recent past in scope.

Likewise, Pierre Nora argued that memory and history are two very different phenomena, but his preference was the opposite to that of Halbwachs. Nora distinguished true memory, borne by living societies maintaining their traditions, from artificial history, which is always problematic and incomplete, and represents something that no longer exists. For Nora, history holds nothing desirable. In each case, the term 'history' might be replaced with 'archaeology.'

2.2 *Archaeology as Memory*

Recently the split between history/archaeology and memory was challenged fundamentally, and a more fluid transition proposed instead (e.g., by Burke 1989). In this view, history and archaeology are seen as special cases of social and cultural memory. Doing archaeology simply means (a) to recognize, and treat, certain things as 'evidence' for the past; and (b) to describe and analyze it in a way that is valuable according to the standards of archaeologists. These practices are not categorically different from how people engage with the past in their everyday lives. History and archaeology, like all forms of memory, give particular meanings to ancient sites and artifacts. Some of these 'academic' meanings eventually influence collective memories of the past in the present. But many never leave the sphere of academia, and are short-lived there too. What is interesting, therefore, in studying collective memories of the past, is not only how accurately they might fit (some) part of a past reality, but also why particular memories are created and adopted (or not) in particular contexts, and what falls into oblivion.

2.3 *Archaeology and Nationalist Agendas*

The history of archaeology provides a fitting example of the great importance of the past for collective identities. Archaeology originated as an academic discipline in the nineteenth century—the great age of the European nation states. This is no coincidence: archaeology has from its beginnings been directly bound up with politics (see *Archaeology, Politics of*). By establishing the origins of their respective national people in the distant past, the young nations reassured their citizens of a shared past, and thus a shared identity and legitimacy in the present. A case in point are the defences of Masada in Palestine, which fell to the Romans after several years of Jewish resistance in 73 AD, but not until the last defenders had committed collective suicide. They were not rediscovered as a prime object of Jewish collective memory until the 1920s coinciding with the rise of Zionism (Schwartz et al. 1986). At times of fundamental social change, people turn to their 'origins' and seek reassurance either in a 'better' past, or in historical traditions and collective identities which legitimate a political movement or new social order. Not surprisingly, much of early archaeological research focused on 'culture-historical' approaches, and invested much effort in the ethnic interpretation of material evidence (see *Ethnic Identity/Ethnicity and Archaeology*). This connection between archaeology and the modern nation is still

visible at the beginning of the twenty-first century in many 'national museums' of archaeology, national academic journals with titles such as *Germania* and *Gallia*, and in the key role of the national pasts in both teaching curricula and popular culture. During the last decade of the twentieth century, and with the emergence of new nation states in many parts of Eastern Europe and the former Soviet Union, similar processes were repeated (Kohl and Fawcett 1995, Diaz-Andreu and Champion 1996).

In some cases, collective memories support nationalist ideologies effectively, while contradicting results gained from archaeological research. Some archaeologists too may lend their authority to support such ideologies. At first this appears to raise a dilemma for those archaeologists who are prepared to accept the equal legitimacy and value of collective memories of different groups, whether academic or not: either they have to accept all constructions of the past as legitimate alternatives to their own accounts, or they would contradict themselves by dismissing some as false. A realistic solution is to allow many alternative collective memories in principle, but be prepared to fight some of them on political or other grounds, and publicize widely any dangerous consequences or implications.

Such issues have recently come to the fore in several regions of the world. They demonstrate that archaeology and collective/national memory are deeply intertwined and ultimately interdependent. Instead of arguments about theoretical principles, future archaeologists will be challenged increasingly to find pragmatic guidelines as to how to behave and act in politically highly charged situations.

Archaeology and Philosophy of Science

Archaeologists have long been concerned with questions about the scientific status of their discipline, periodically engaging in debate about goals and standards of practice that raises issues central to the philosophy of science. In the 1960s and 1970s, with the advent of the New Archaeology in North America, the philosophical content of these debates became explicit. The New Archaeologists advocated a scientific program of research modeled on logical positivist theories of science, and their critics have since drawn on a range of post-positivist philosophies of science for alternative guidelines and ideals. Philosophers of science have been direct participants in some of these debates. There is now growing interest, among both philosophers and archaeologists, in a range of philosophical questions that extend well beyond debate about whether archeology does (or should) conform to models of practice derived from the natural sciences: the naturalist commitments (in philosophical terms) that initially motivated archaeologists to turn to the philosophy of science.

1. Interactions

The influence of naturalist ideals are evident at many junctures in internal archaeological debate. In the early twentieth century, when archaeology was taking shape as a museum and university-based profession, advocates of a 'new archaeology' defined the difference between archaeological and antiquarian practice in

terms of a commitment to anthropological goals and scientific methods. They insisted that the value of archaeological material lies, not in its intrinsic or artistic merits, but in its capacity to serve as evidence in a program of systematically testing 'multiple working hypotheses' about the cultural past; in this they invoked an influential account of scientific method that appeared in *Science* (Chamberlin 1890).

1.1 Critiques of 'Narrow Empiricism'

When these themes reemerged in the 1930s and 1940s it was in opposition to forms of archaeological practice that were described, in explicitly philosophical terms, as 'narrowly empiricist.' Internal critics objected that the discipline had become mired in empirical detail. Although anthropological goals were widely endorsed, rarely were they directly addressed. The process of recovering and systematizing archaeological data had become an end in itself; it was assumed that interpretive or explanatory theorizing must be deferred until an exhaustive archaeological data base had been secured and systematized. These forms of practice were impugned as 'narrowly empiricist' because they were said to presuppose, in a particularly stringent form, the central presuppositions of an empiricist theory of knowledge: that empirical or sensory experience is the source and ground of all legitimate knowledge and, more specifically, that it constitutes a foundation for knowledge that is independent of the theoretical or interpretive claims it may be used to support or refute.

One prominent anthropological critic, Kluckhohn, published a critique of such practice in *Philosophy of Science* (1939) in which he challenged the assumption, based on these principles, that anthropological goals can be realized only inductively, that is, by first collecting archaeological data and then gradually building up a body of interpretive or explanatory theory. Kluckhohn and aligned archaeological critics argued that the contents of the archaeological record have no significance except in light of a theoretical framework; and if interpretive or explanatory questions about the cultural past are to be answered, empirical investigation must be theoretically informed and problem-oriented. These critics drew on a number of philosophical sources including Whitehead, philosophers of history such as Teggart and Mandelbaum, and pragmatists such as Dewey. A decade later these questions about epistemic foundations emerged again in the context of debate over the status of typological constructs: are typological categories discovered in or derived from empirical data, or are they interpretive constructs, and, if they are constructs, are they irreducibly subjective? Those who took the former position appealed to the 'liberal positivism' of such philosophers of science as Bergman, Brodbeck, Feigl, and Hempel.

It was primarily to Hempel that the New Archaeologists turned in the 1960s and 1970s when they argued the case for a self-consciously scientific research program predicated on the principles of logical positivism (Watson et al., 1971). What they drew from Hempelian positivism were models of scientific explanation and confirmation which they saw as an antidote to 'traditional' (empiricist and inductivist) practice. Hempel's models are representative of what has since been described as 'received view' philosophy of science, the product of 50 years of careful reconstruction of the logic of scientific reasoning that presupposes the central tenets of the empiricist tradition. On his covering-law (C-L) model, explanation is accomplished when a particular event or property can be shown to fit (by deductive subsumption) the patterns of conjunction or succession captured by law-like generalizations. Explanation and prediction are thus symmetrical: the laws support deductive inferences from established regularities to instances which show that they can be, or could have been expected. This symmetry is central to Hempel's hypothetico-deductive (H-D) account of confirmation in which hypotheses about prospective law-like regularities are tested by determining what empirical implications follow if they are true and then systematically searching for evidence that fits or violates these expectations.

The New Archaeologists were confident that, if they made it their central objective to develop and test law-governed explanatory hypotheses, following the guidelines suggested by these deductive models, they could transcend the limitations of 'narrow empiricism' without indulging in inductive speculation. On an H-D model of confirmation, interpretive and explanatory hypotheses become the departure point for empirical inquiry, rather than its deferred goal; and if laws connect antecedent cultural processes to archaeological outcomes, explanatory inference is secured. What the New Archaeologists did not appreciate is that Hempelian positivism presupposes the central tenets of empiricism; logical positivism is an empiricist theory of science. On such an account, empirical evidence is not only the final court of appeal for adjudicating theoretical claims, but the exhaustive source of their content. If claims about unobservables such as the cultural past are to have cognitive significance, they must be reducible to, or derivable from, the observations they subsume.

1.2 Post-positivism

The positivism of the New Archaeology drew immediate critical attention, both from fellow archaeologists and from philosophers of science. Many objected that the 'received view' philosophy of science had met its demise by the time archaeologists invoked it as a model for their practice. Post-positivist philosophers and historians of science, most famously Kuhn, had

decisively challenged its foundationalist assumptions, arguing that theory and evidence are interdependent (evidence is theory-laden). Moreover and the enthusiasm for 'theory demolition' and deductive certainty had been called into question by critics who showed that the most interesting theoretical claims overreach all available evidence (theory is underdetermined by evidence). But beyond this critical consensus, responses to the demise of positivism diverged sharply.

Many philosophical commentators were sympathetic to the scientific (naturalist) ideals of the New Archaeology but, together with internal archaeological critics, they made the case for alternative models of science that better fitted the conditions of practice and ambitions of archaeology. Those proposed by Salmon (1982), and the Popperian models advocated by Bell (1994), fall within the ambit of a liberal empiricism even if they are not positivist in conception, while others represent a more fundamental reconception of scientific practice: the scientific realism endorsed by Gibbon (1989) and the coherentism elaborated by Kelley and Hanen (1988). More radical departures are to be seen in post-processual critiques of New Archaeology. The advocates of broadly interpretivist, humanistic approaches (e.g., contributors to Tilley 1993) reject the naturalist assumption that archaeology is best conceived as a scientific enterprise. They draw inspiration from a range of philosophical traditions outside analytic philosophy of science (e.g., critical theory, phenomenology, and philosophical hermeneutics).

2. *Issues*

While debate over naturalist ideals has most often been the catalyst for interaction between archaeologists and philosophers of science, several more narrowly defined philosophical issues have become a recurrent focus of attention.

2.1 *Explanation*

The explanatory goals of archaeology are a perennial concern. Critics of the Hempelian C-L model argue for a range of alternatives, chiefly accounts which recognize forms of explanation that do not depend on laws. Systems models of explanation were initially popular among archaeological critics. Salmon proposed a causally enriched statistical-relevance (S-R) model on which explanation is accomplished, not by invoking a covering-law but by enumerating the factors that can be shown (statistically) to make a difference to the occurrence of the events or conditions that require explanation (Salmon 1982, Chap. 3, 5, 6, pp. 84–139). Gibbon elaborates the causalist elements of Salmon's model in a realist account. According to this approach, explanation is a matter of building models of the antecedent causal processes and conditions that were responsible for the surviving archaeological record (1989, Chap. 7, pp. 142–72).

This makes sense of the central role, in archaeological explanations, of claims about unobservables, both material and intentional, a feature of scientific explanation with which logical positivists have always had difficulty (Hempel 1965, pp. 177–87). By contrast, Kelley and Hanen advocate an anti-realist, pragmatist position. They consider that explanatory power is a key consideration in evaluating competing hypotheses but not the central aim of scientific inquiry. Explanations are answers to 'why-questions' that deploy whatever scientifically credible information will satisfy a specific inquirer (1988, Chap. 5, pp. 165–224).

2.2 *Theory and Evidence*

A second focus of jointly philosophical and archaeological interest is a family of questions about the nature of archaeological evidence and its use in formulating and evaluating claims about the cultural past. In early programmatic statements, the New Archaeologists repudiated any dependence on inductive forms of inference in favor of an H-D testing methodology. They quickly realized, however, that archaeological data stand as test evidence only under interpretation and, in most cases, this requires the use of background or collateral knowledge ('middle range theory') in reconstructive inferences that rarely realize deductive security. By the late 1970s many had turned their attention to development of the necessary linking principles and, since the mid-1980s, one of the most pressing philosophical problems at the interface between philosophy and archaeology has been to explain how evidence can be theory-laden without risking vicious, self-justifying circularity when used to test interpretive theory. One strategy of response, developed by Kosso (1992) and Wylie (2000) is to identify conditions of epistemic independence between test hypotheses and linking principles which ensure that the 'middle range theory' used to interpret archaeological data does not necessarily ensure a favorable outcome for a particular test hypothesis.

At a broader level of analysis, a number of alternatives to the H-D model confirmation have been proposed. Salmon advocates a modified Bayesianism model which captures the complex reasoning by which archaeologists weigh the significance of evidence for a particular hypothesis against its prior probability of being true (1982, Chap. 3, pp. 31–57). Many of these considerations figure in Kelley and Hanen's account of archaeological practice as a comparative process of inference to the best explanation, but they also emphasize several other epistemic virtues such as explanatory power and consistency with established 'core beliefs.' Popper's falsificationist account of theory testing has been advocated by Bell (1994) who

argues that archaeologists should proceed, not by building support for bold conjectures confirmationally, but by searching for the evidence that is most likely to refute them.

3. Metaarchaeology

Although archaeologists have long drawn on the philosophy of science to articulate their programmatic goals and guidelines, philosophers took little systematic interest in archaeology before the 1970s. There are, however, some notable exceptions. One is Collingwood, a philosopher of science and of history who was also an active archaeologist and historian of Roman Britain in the inter-war period (Collingwood 1978, [1939]). He made frequent and subtle use of archaeological examples to develop models of historical inquiry that do not fit neatly on either side of the conventional naturalist–anti-naturalist divide. His influence is evident in the work of Clarke, a British contemporary of the New Archaeologists who was a staunch naturalist but insisted that archaeologists should not assume that any existing models of scientific practice will serve them well as a guide to more systematic empirical practice (1973). At the same time, Collingwood's philosophy of history has been an important inspiration for interpretivist critics of the New Archaeology.

Since the 1970s sustained interaction has developed between archaeologists and philosophers of science. In the process, attention has shifted away from questions about whether archaeological practice does, or should, fit existing models of scientific practice. Increasingly the focus is on distinctive problems of archaeological practice, or on the use of archaeological examples as a basis for reframing and extending philosophical models developed in other contexts. The result has been the formation of a vigorous field of 'metaarchaeological' inquiry (Embree 1992) at the intersection between philosophy and archaeology.

Archaeology and the History of Languages

Possible correlations between the histories of the major language families and major traditions within the archaeological record have exercised the minds of scholars since Gustav Kossinna, and Gordon Childe attempted early in the twentieth century to trace the archaeological record of the Indo-European languages. But long before the rise of archaeology as a research discipline, some of the major language families had already come into historical perspective through comparative linguistic research. This perspective is often claimed to have emerged when Sir William Jones in 1786 suggested that Greek, Sanskrit, Latin, Gothic, Celtic, and Old Persian were 'sprung from some common source.' (Jones 1993).

In the twenty-first century, language history and the archaeological record can be studied in combination to recover history at two major (but clearly overlapping) levels:

(a) at the level of the individual language, *ethnolinguistic group*, or historical community; and,

(b) at the level of the *language family* or major subgroup.

It is also possible to seek linguistic correlations for some archaeological complexes, particularly those which are sharply bounded and defined by consistent stylistic features, although this tends to become more difficult as the complex in question extends further back into prehistory and becomes more diffusely defined. Such correlations, for obvious reasons, also benefit from the assistance of written and translatable texts.

In general, it is a very difficult task to trace the identity into deep levels of prehistory of a specific ethnolinguistic or historical population (e.g. Celts, Greeks, Etruscans), unless one is dealing with a very isolated region or an island where one can assume there has been no substantial population replacement

during the period in question. A good example of the latter would be certain Pacific islands, for example Easter Island or New Zealand, both fairly isolated since their first human settlements by Polynesians (Kirch and Green 1987). However, this entry is not primarily concerned with such society- or culture-specific correlations amongst language, history, and archaeology, but focuses instead on the study of languages as members of genetically constituted and evolving families, combined with the study of large-scale archaeological traditions as they spread, evolve, and interact through time and space.

Historical reconstruction at this level tends to be organized such that language families (e.g. Indo-European, Austronesian) are foregrounded as the major foci of enquiry, rather than archaeological complexes. This is because language families are usually more sharply defined and reveal much clearer patterns of genetic inheritance than do archaeological complexes. In such situations, archaeology tends to be used to support or refute historical linguistic questions (for instance, where was the Indo-European homeland located, what lifestyle did its inhabitants enjoy, and when?). However, some archaeological complexes of particularly wide distribution, internal homogeneity, and short time span (e.g., the Linearbandkeramik (LBK) early Neolithic of Central Europe, the Lapita cultural complex of the western Pacific) are also sometimes foregrounded as requiring a paleolinguistic identity. For instance, does the LBK correlate with Indo-European dispersal into Central Europe; does Lapita correlate with Austronesian dispersal through Melanesia into Polynesia?

In order to understand how the data of historical linguistics and archaeology might be compared against each other in order to improve understanding of the human past, it is first necessary to state clearly the abilities and limitations of the two disciplines.

1. *Language as a Source of Information on Human Prehistory*

The branch of linguistics which is of most interest to prehistoric archaeologists is that known as comparative historical linguistics, in which the structures and vocabularies of present-day or historically recorded languages are compared in order to identify families, and subgroups within these families. The methodology of comparative linguistic reconstruction is precise. Like the methodology of cladistics, as applied in biology, its main goal is to identify shared innovations which can identify language subgroups. Such subgroups comprise languages which have shared a common ancestry, apart from other languages with which they are more distantly related. Languages which comprise a subgroup share descent from a common 'protolanguage,' this being in many cases a chain of related dialects. The protolanguages of subgroups within a family can sometimes be organized into a family tree of successive linguistic differentiations (not always sharp splits, unlike real tree branches), and for some families it is possible to postulate a relative chronological order of subgroup formation. For instance, many linguists believe that the separation between the Anatolian languages (including Hittite) and the rest of Indo-European represents the first identifiable differentiation in the history of that family. Likewise the separation between the Formosan (Taiwan) languages and the rest of Austronesian (Malayo-Polynesian) represents the first identifiable differentiation within Austronesian.

The vocabularies of reconstructed protolanguages (e.g., Proto-Indo-European, Proto-Austronesian) can sometimes provide remarkable details on the locations and lifestyles of ancient ancestral communities, with many hundreds of ancestral terms and their associated meanings reconstructible in some instances. There is also a linguistic technique known as glottochronology which attempts to date protolanguages by comparing recorded languages in terms of shared cognate (commonly inherited) vocabulary, applying a rate of change calculated from the histories of Latin and the Romance languages. But the rate of change varies with sociolinguistic situation, often a complete unknown in prehistoric situations. Glottochronology can be used only for recent millennia and for those languages which have not undergone intense borrowing from languages in other unrelated families. It is not a guaranteed route to chronological accuracy.

The other major source of linguistic variation, apart from modification through descent, is that termed by linguists 'borrowing' or 'contact-induced change.' This operates between different languages, and often between languages in completely unrelated families. Borrowing, if identified at the protolanguage level, can be as much an indicator of the homeland of a language family or subgroup as can genetic structure. It can also reflect important contact events in language history. (See *Phylogeny and Systematics*.)

2. *Archaeology as a Source of Information on Human Prehistory*

Archaeology is concerned mainly with the recovery and interpretation of the material remains of the human past, and the environmental contexts in which those remains were originally deposited. Such remains can be dated, and grouped into regional complexes of related components. Such complexes can then be compared with other complexes, and the natures of the boundaries between such complexes can be studied carefully. Some are sharply bounded, hence possible candidates for correlation with an ethnolinguistic group, others are simply nodes of relative homogeneity in a kaleidoscope of ever-shifting patterning. Archae-

ology alone cannot pinpoint ethnicity, unless of course it operates in an environment associated with literacy and the availability of written records (and even then ambiguity can plague interpretation, as in the modern debate in the UK archaeological literature about the definition and archaeological history of the Celts). Any correlations between the archaeological and linguistic records will always require care—prehistoric artifacts cannot talk!

3. *How Can Language Family History and Archaeological Prehistory be Correlated?*

Because languages change constantly through time, and because relationships between languages become ever fainter as we go back in time, it is assumed by most linguists that language family histories apply only to the past 8,000 to 10,000 years. At a greater timescale we enter the arena of 'macrofamilies' such as Nostratic and Amerind, concepts which cause rather vituperous debate amongst linguists because of their very ambiguity and elusiveness. Most of the examples discussed below relate to historical trends which have occurred since the beginnings of agriculture and which do not extend back as far as the macrofamily level.

Correlation of the archaeological and linguistic records is not always a simple matter because the two classes of data are conceptually quite discrete. However, correlations can be made when language family distributions correspond with the distributions of delineated archaeological complexes, particularly when the material culture and environmental vocabulary reconstructed at the protolanguage level for a given family correspond with material culture and its environmental correlates as derived from the archaeological record. Many reconstructed protolanguages, for instance, have vocabularies which cover crucial categories such as agriculture, domestic animals, pottery, and metallurgy, these all being identifiable in the archaeological record.

The concept of the language family is more sturdy than that of the archaeological culture. This is important, because linguists have come to a remarkable level of agreement on the classification of the world's language families. Apart from a small number of Creoles, mostly a result of European colonization and population translocation, the vast majority of the world's language families are clearly bounded in a classificatory sense and not beset with huge numbers of 'mixed' languages. As an example, the Indian subcontinent has been a region of interaction between the speakers of Indo-European and Dravidian languages for at least three millennia. Languages within these two families have borrowed extensively from each other, to the extent that the subcontinent is often referred to by linguists as a 'linguistic area' (a zone of widespread areal diffusion). Nevertheless, the subcontinent is not covered by languages which are half Indo-European, half Dravidian, chaotically mixed. This means that language families are coherent entities, capable of maintaining coherence and independence through long periods of time. As such, they are believed to carry traceable records of history and to be associated, in their origins, with homeland regions and processes of population dispersal. Where different language families meet, we can infer that different populations have met as well. Although some populations have changed their languages in the past, it is unlikely that language shift, as opposed to an actual dispersal of ancestral speakers of a protolanguage, can be the main mode of dispersal of a major language family. All of this means that the origins and dispersals of the protolanguages from which language families are created should correlate with major population movements, frequently on a scale which should be visible in the archaeological record.

4. *Some Examples of Language Family Origin and Dispersal Histories with Claimed Archaeological Correlations*

Some of the major language families of the Old World are shown in Fig. 1 (the American families are much more mosaic-like in distribution and cannot be mapped so easily). Also shown in Fig. 2 are regions where agriculture developed independently. Many archaeologists and linguists today recognize that many language families could owe their initial creations to population dispersal as a result of population growth following on from the development of agriculture. If this is so, then the homelands of these families can be expected to overlap with the regions of early agriculture, as indeed seems to be the case for the Middle East, China, and Mesoamerica. However, it is important to remember that many language families are associated totally with hunting and gathering populations, and presumably always have been, so their histories obviously will not involve this factor. Such hunter-gatherer families include Khoisan in southern Africa, the Australian languages (probably several families), Athabaskan and Eskimo-Aleut, and the languages of western North America and southern South America. Other families, such as Uralic, Algonkian, and Uto-Aztecan, have both agricultural and hunter-gatherer populations. In some of these cases it is possible that former agricultural peoples have actually become hunters and gatherers in difficult environments (e.g., the Great Basin Uto-Aztecans).

It is also apparent that some languages and subgroups (but not whole language families) have been recorded as spreading over large distances in historical times, under conditions of statehood, religious evangelism, and colonialism. Thai, the Chinese languages, Arabic, and of course English and Spanish all come to

Figure 1
The major language families of the Old World

Figure 2
Regions of the world where agriculture is believed to have developed independently

mind here. In the twenty-first century, it is also apparent that lingua francas and national languages can spread rapidly as a result of educational policy, literacy, mass media, and sociolinguistic status; but it is more difficult to imagine such processes of language adoption as being of great significance amongst the small-scale societies of preurban prehistory. Nevertheless, many prehistorians have suggested that language replacement processes of this type, whereby people adopt a language deemed to be of high social status and abandon their original language, have been instrumental in the spread of some families. One such family is Indo-European, for which some linguists and archaeologists have long agreed on a homeland in the steppes north of the Black Sea, followed by a spread into Europe by Late Neolithic and Bronze Age pastoral peoples with domesticated horses and wheeled transport. According to the archaeologist Marija Gimbutas, these people undertook their migrations into Europe between 4500 and 2500 BC, dominating and absorbing the older Neolithic societies in the process.

This view of Bronze Age conquest and language replacement for Indo-European dispersal has been challenged by the archaeologist Colin Renfrew (1987, 1996), who opts instead for an association of early Indo-European with early Neolithic farming dispersal into Europe from Turkey. Nowadays, the idea that many of the major agriculturalist language families spread as a result of the early development of agriculture is taking firmer hold. Farmers typically have larger populations than hunter-gatherers, and if farmers are not enclosed by other farming populations i.e., if they live in a region surrounded essentially by low-density hunter-gatherers, then expansion is a likely outcome, exactly as in the European frontiers in Australia and western North America. So, while the agricultural dispersal hypothesis is no more 'provable' than any other hypotheses to explain language family origins, it does at least have the strong supporting factor of a historically proven mechanism which can allow and encourage population expansion to occur. Such expansion need not mean extinction of all hunter-gatherers. In many ethnographic situations, hunter-gatherers have survived in the interstices of agricultural or pastoralist landscapes, perhaps for millennia.

Put simply, the farming dispersal hypothesis would see the protolanguages for Indo-European, Semitic, Turkic, Sumerian, Elamite, and possibly Dravidian located in the wheat, barley, cattle, and caprine zone in the Middle East, with dispersals occurring mainly in the period between 6500 and 3000 BC. During this time mixed farming became widely established and the archaeological record tells us unambiguously that population was increasing in an overall sense quite rapidly (despite periodic environmental setbacks and short-term population retractions). Sino-Tibetan, Austroasiatic, Austronesian, Tai, and Hmong-Mien would all have begun their dispersal from the region of rice and millet cultivation in China, focused in the middle and lower Yellow and Yangzi valleys, between 5000 and 2000 BC (with Austronesians eventually colonizing the greater part of the Pacific). Niger-Congo (including Bantu) resulted from the development of agriculture in West Africa and the Sahel zone, mainly after 3000 BC, and perhaps following earlier pastoralist dispersals in northeastern Africa by Afroasiatic (Berber, Chadic, Cushitic) and Nilo-Saharan speakers. In the Americas, the Mayan, Otomanguean, Mixe-Zoque, Uto-Aztecan, and Chibchan language families probably spread as a result of agricultural developments in Greater Mesoamerica after 3500 BC. In South America the picture is a little more diffuse, but some of the major Andean and Amazonian families might have spread as a result of the establishment of maize and manioc agriculture after about 2500 BC—examples here would include Quechua and Aymara, and lowland Amazonian families such as Arawak, Carib, and Tupi.

Archaeologically, these suggested language radiations associated with early agricultural societies should be reflected in the distributions of some very widespread archaeological complexes. In particular, it has been noted in many regions that the archaeological complexes of early agricultural phases are much more widespread and homogeneous in content than the highly regionalized complexes of later periods. This appears to be the case in early Neolithic Europe, East Asia, and the Pacific, and amongst the Early Formative cultures of the Americas.

5. *Language Contact and Cultural Contact*

Language and archaeology correlations can be sought not only for the origins and dispersal histories of language families, but can also reflect the contacts which take place from time to time between languages in different families and subgroups. For instance, the Austronesian speakers of New Guinea have been in intense contact for upwards of 2,000 years with the speakers of Papuan languages in several unrelated families. This has led to a great deal of contact-induced change and even language shift, and it is therefore not surprising to discover that distributions of material culture often cross-cut language boundaries. The archaeological record, however, suggests that quite strong differences in material culture would have distinguished Papuan and Austronesian societies 3,000 years ago, at the time of the Lapita archaeological spread through much of the western Pacific. The Lapita spread was probably associated with the initial Austronesian colonization of many of the western Pacific Islands, but it is significant that it appears to have avoided the island of New Guinea itself, where Austronesian speakers even today are found only in a

few pockets of coastal distribution (Kirch and Green 2001).

Indeed, the linguist Robert Dixon (1997) has suggested that the overall history of the major language families can be separated into short periods of widespread dispersal, when the families are actually founded, interspersed with long periods like that described for New Guinea when populations of quite different linguistic and cultural origin interact, whether peacefully or belligerently. This hypothesis resembles the theory of punctuated equilibrium as applied to the biological evolution of species.

A final point to note is that, whereas archaeology and language history can often come together to throw independent light to support a plausible historical reconstruction, we often find that genetic data are not in full agreement. It is not the intention to discuss human genetics here, but it is perfectly obvious that not all of the speakers of some of the major language families are of tightly defined and geographically restricted genetic origin. For instance, the speakers of Austronesian languages range from Southeast Asians to Melanesians and Polynesians. The speakers of Indo-European languages range from northern Europeans to northern Indians. It is possible, but rather unlikely, that these differences represent no more than natural selection operating since the initial population dispersal which founded the language family in question. But it is far more likely that these differences reflect population mixing not always paralleled by an equivalent amount of language mixing. In other words, language families can have a life of their own, as can nodes of biological variation. Many population dispersals must have incorporated large numbers of the existing inhabitants of the newly settled regions, with consequent genetic effects stamped on later generations. This does not mean that there are no correlations between variations in language and biology in the human species, but we must be aware that any correlations will not always be clear-cut and obvious. They must be teased apart with care.

This field of archaeolinguistic research is not one in which we can expect absolute proofs for suggested correlations, particularly when dealing with prehistoric societies, but firm hypotheses are worthy of the research effort. The goals of archaeolinguistic research are laudable ones since they help us to interpret and understand so many fundamental developments and transitions in human prehistory.

Archaeology, Politics of

The results of archaeological research have long been used by individuals, groups, and nations for political purposes such as nationalism, colonialism, tourism, and the development of group identities, but archaeologists have generally not seen themselves conducting work which is political in nature. The traditional view of archaeology has been that of a group of scholars working systematically and scientifically to discover and excavate information (usually in the form of objects and monuments) about past societies around the world. What people did with that information once it was published and described was seen as being distinct from what archaeologists did; archaeologists saw themselves as objective in their interpretations and descriptions. This view of archaeology began to change in the 1980s, but became dramatically different by the 1990s, with the development of new attitudes both within and outside archaeology. In the United States, the passage of the Native American Graves Protection and Repatriation Act (NAGPRA) in 1990 was a particularly important milestone.

1. Archaeology and Politics: A Brief Historical View

In discussing nationalism as one political force that has affected archaeology, Trigger (1995) outlines the history of archaeology from this perspective, and the changing views he summarizes represent one example of how politics can affect archaeology.

Trigger notes (1995, p. 266) that throughout antiquity, royal families and ethnic groups strengthened their positions by linking themselves to particular figures or events of the past. During the Renaissance, scholarship was often used more broadly to support political changes by providing precedents from antiquity.

There were several shifts in the way archaeology was used during the Enlightenment. Trigger (1995, p. 267) notes that revolutionary leaders in France supported Napoleon's 1798 invasion of Egypt because they saw ancient Egypt as a source of wisdom. A more scientific archaeology replaced the object-focused archaeology of the previous periods, and the attention of archaeologists shifted to cultural evolution, and to archaeology as a means of documenting the progress of human development. As colonialism expanded, however, the application of theories of cultural evolution, as a benefit to everyone, began to change. Europeans could benefit from cultural progress, but indigenous peoples were viewed as less developed and less capable of development. This racist view helped support the expansion of colonialism, and the then limited archaeological record was used to support this perspective (Trigger 1995, p. 268).

In the 1860s, nationalism took a more prominent role in shaping archaeological research, although its influence depended upon the impact of colonialism, class struggles, and ethnic nationalism (Trigger 1995, p. 269). Archaeology responded by shifting its focus to reconstructing the history of specific peoples or, more formally, the development of culture historical archaeology. Archaeological cultures were identified and defined as early representations of historically known groups. This allowed groups to add to their own history, and glorify themselves in relation to others. In the United States, where there was no bond to the indigenous people being studied, culture history also became popular, primarily because it could account for geographic variation and change that could not be explained by cultural evolution (Trigger 1995, p. 269).

The early twentieth century practice of tying interpretations of past groups to specific indigenous peoples and tribes became less common as archaeology became more complex, and as archaeologists realized that it was difficult to associate an ancient group with a particular modern tribe. Because of intervening years of movement (often dramatic because of forced movements of tribes by the US government) and change, the match was inexact and difficult to support with the kind of scientific certainty that archaeologists would like. Further, archaeologists had begun to ask other kinds of questions beyond whether or not a particular archaeological culture was associated with a particular living one. As the discipline moved in new directions, linking past cultures to modern ones became less and less common. Archaeologists now understand that race, language, and culture are independent variables that can change for different reasons and in many different ways.

During the 1980s and 1990s, another shift in archaeology can be subsumed under the heading of postmodernism. For this discussion, the most important aspect of this development is the rise of a self-reflective archaeology which questions the perspective and political nature of everything that an archaeologist produces, and stresses the importance of cultural relativism, which in its most extreme form, suggests that all archaeological interpretations are subjective, and that any one interpretation is as valid as any other. A major focus of this approach has been to give voice to indigenous groups and their interpretations, as well as to the views of the general public. A recent statement (Shack 1994, p. 115) provides an example:

> Archaeology and history share common features of malleability, continually recreating the past, a principal function of which past is to socially construct the present. … The impulse to preserve the past is part of the impulse to preserve the self, an impulse that is given 'legitimacy' when grounded in objects from the past.

Shack concludes with the observation that constructions and representations will be misconstrued until

indigenous voices are heard unfiltered and in the first person.

2. Changing Attitudes and Times

During the last two decades, with the increasing demand by indigenous groups to be heard and given a say over their past, present, and future, archaeology increasingly found itself in an awkward position. Groups that have been disenfranchised and ignored have moved to empower themselves and develop political strength and attention. Archaeologists, who often see themselves as champions of such groups and as people whose work focuses on the histories of these groups, are cast as enemies. It is often difficult, unfortunately, for disenfranchised groups to get people's attention on issues such as education, food, and healthcare, but it is easier to draw the attention of the media and the public by focusing on human bones. Archaeologists, a not particularly powerful political group, are portrayed as grave robbers and people who ignore the beliefs and desires of indigenous peoples. When combined with the cavalier treatment of native sensibilities and concerns that archaeologists and physical anthropologists exhibited in the late nineteenth and early twentieth centuries, the discipline appears in a bad light. This framing of the problem gets immediate public attention. Bones represent powerful cultural symbols, especially in the United States, and this approach by indigenous peoples is understandable, if uncomfortable for archaeologists and physical anthropologists.

2.1 Who Pays for Archaeological Research?

Although archaeologists have often been uncomfortable with the idea that their work is used for political purposes, because archaeology is important for political and cultural reasons, it is seen as important for the State to fund. As this funding has increased, however, there has been a growing awareness that archaeologists have a direct obligation to the public and to the people being studied. These obligations can perhaps best be represented by two of the principles of archaeological ethics crafted by the Society for American Archaeology (Lynott and Wylie 1995): the principle of accountability, and the principle of public education and outreach. The principle of accountability notes that archaeologists must acknowledge public accountability and must 'make every reasonable effort, in good faith, to consult actively with affected group(s), with the goal of establishing a working relationship that can be beneficial to the discipline and to all parties involved' (Watkins et al. 1995, p. 33). In public outreach and education, archaeologists are told to engage the public in stewardship for the archaeological record, to explain how archaeology is used in understanding human behavior, and also to explain interpretations of the past. There is also a recognition that a variety of different kinds of audiences exist for these efforts (Herscher and McManamon 1995, p. 43).

2.2 Power and Control

Developments and changes in archaeology and in the larger society have resulted in a real shift in power and control. The question now posed is who owns or controls the past, and the shifts in archaeology are similar to those found in other disciplines. Changes in medicine provide a useful analogy.

2.3 An Analogy with Medicine

For generations, physicians used authoritative knowledge in healing patients; they knew best, and our job as patients was to follow directions. Patients were often not even told the details of their condition. Many, however, grew up in communities which had their own medicines and ways of treating illness. The success of such approaches was uniformly rejected by physicians as representative of 'old wives tales' or as being anecdotal in nature. Science held the correct and proven ways to treat illness. Over time, people began to questions physicians more, demanding more say in their treatment and care, and wanting empowerment. In addition, many returned to their traditional approaches to medicine, in part because they worked or worked as well as 'scientific' remedies, and they were often cheaper and easier to use. Eventually, physicians began to accept some of these treatments, indicating that they were not harmful and might have some placebo effect. As more evidence supported the value of traditional approaches, and as patients gained more say in their own care, the views of the medical establishment shifted to the point that alternative medicine is now taught at many medical schools. A number of traditional approaches are covered by insurance, and foundations and federal agencies are funding research in alternative medicine. The trajectory in archaeology is similar, with an equal proportion of professionals who see such changes as wrong and dangerous, those who see them as long overdue, and those who see them as necessary but problematic.

3. Repatriation as an Example

The call for the repatriation or return of Native American human remains, funerary objects, and sacred objects in the United States represents the best

example of change in the political nature of archaeology and the resulting changes in the way that archaeology is conducted.

3.1 The History of Repatriation in the United States

As in medicine, archaeology for many years presented authoritative knowledge about the past. While Native American tribes who lived throughout the US were seen as distant descendants of the people who lived there prior to the 1600s, their perspectives were either ignored or used only as analogy. An important exception was the use of the culture-historical approach, in which the history of modern tribes was traced backward in time to link to earlier groups. Nonetheless, the data used by archaeologists in creating culture histories was generally authoritative knowledge provided by ethnographers, not information directly from tribes.

For many members of native communities, the past, and especially human remains and sacred objects, represent symbols of political and spiritual power, and that power does not diminish over time. The importance attributed to time differs across tribes and cultures, and the distinctions archaeologists see between historic (written records) and prehistoric (prior to written records) are not understood by many who make no distinction between the present and the past. Similarly, the distinctions we make between the written and oral record vary in their relevance to traditional groups: many see the two as equally valid. How can such dramatic differences be reconciled?

Price (1991) outlines a history of repatriation law and policies, and provides a summary of federal laws and policies and of state laws. He notes that for many years tribes focused on their diversity and differences, but legal procedures such as the Indian Claims Commission, established in 1946, educated Indians to the effects and advantages of legal representation (Price 1991, p. 10). Later, an event that many believe began a national Indian movement, the American Indian Chicago Conference, was organized in 1961 by anthropologist Sol Tax (Price 1991, p. 10). The conference brought together over 90 tribes and bands for the first time. Subsequent advances in technology and communication made sharing of knowledge between tribes much faster and easier, including increased communication internationally. New laws were the eventual result.

The federal laws which provide the clearest recognition of aboriginal rights and interests in human remains and sacred objects are the National Museum of the American Indian Act of 1989 (which applies only to the Smithsonian Insitution) and the Native American Graves Protection and Repatriation Act (NAGPRA) of 1990 (which excludes the Smithsonian). More recent revision of the Museum of the American Indian Act has made the two laws more comparable in scope, but the Smithsonian has a separate review panel. Both panels are composed of representatives of native communities and scientific organizations, with native representatives holding the majority.

Some archaeologists viewed NAGPRA as designed to empty museums of all of their collections, but ignored the second part of the law which may have more far-reaching implications. Under NAGPRA, Native American cultural items and remains discovered or excavated on federal or tribal lands are under the control of Native American groups, listed in a priority order. Many states have followed suit, writing or revising laws to mirror this procedure. Ultimately, there may be very few places that archaeologists can excavate without the direct involvement of native groups.

4. The Future of Archaeological Research in a Political World

The museums of the US have not been emptied by the introduction of NAGPRA, but this does not mean that the law has not had a permanent effect on the conduct of archaeology. Archaeologists have been forced to change, and to acknowledge that 'The past belongs to everyone' (Lowenthal 1981, p. 236). Sharing control of the past is not easy, and archaeologists have had to learn to change their approaches and their methods of communication in order to level the playing field (see Leone and Preucel 1992, Goldstein 1992 for examples). Equally significantly, archaeologists have had to expand the lines of evidence they use to develop interpretations of the past, and the potential of oral traditions is one of the most exciting and difficult areas to incorporate. The shifts in archaeology do not mean that any view is as valid as any other view, but rather that archaeologists must realize that their work will be used for political purposes, they must take a more active role in directly involving Native American communities in their work, they must acknowledge and address the many publics interested in the past, they must continually expand the lines of evidence they employ, and they must remember that a static view of the past does not allow anyone to learn.

Archaeometry

1. Archaeometry

'Archaeometry' is a specialized discipline within archaeology in which various scientific methods of chemical and physical analysis are applied to archaeologically derived materials. Archaeometry therefore centers on research whose aim is to explain and test archaeological questions about ancient things or phenomena related to human cultural activities. The research measures or quantifies parameters using analytical techniques borrowed from earth science, chemical, biological, and other scientific disciplines. The field of archaeometry includes, for example, determining the ages of sites and artifacts, sourcing objects to the original localities of raw materials, identifying the components and processes involved in converting earth materials into metals and ceramics, and determining patterns of dietary exploitation. Many analytical techniques have been applied in these investigations and some common ones are briefly described below to illustrate the diversity of archaeometric techniques.

1.1 Age Determinations

Probably the first example of the use of archaeometrical methods was the realization that the annual growth rings of trees could be used to determine the age of construction of prehistoric pit houses in the southwest of the USA using cores taken from wooden beams (Douglass 1936). The tree rings were also shown to indicate variations in climate within the time span of the life of the tree (Judd 1954). This method of tree-ring dating, or dendrochronology, is still widely used to date habitation sites in the Americas and in Europe.

The dating of carbon-bearing substances associated with archaeological deposits has revolutionized the determination of absolute ages in archaeology. Radiocarbon dating (Libby et al. 1949) has been used to place time markers on important periods of human activities and climatic change, and to date the extinctions of animals, for example the woolly mammoth and sabre-toothed tiger (Ho et al. 1969). Refinements to the method and development of the accelerator mass spectrometer (AMS) have allowed for the dating of microgram quantities of carbon (Nelson et al. 1977). For example, a famous case involves the AMS radiocarbon dating of the Shroud of Turin (Damon et al. 1989). While many people believe the shroud was wrapped around Christ's body, fragments of its linen fibers were dated independently by three radiocarbon laboratories to the late thirteenth century.

Archaeologists have also been able to date individual seed grains, beeswax resins (Nelson et al. 1995), charcoal scrapings from Paleolithic cave paintings (Valladas et al. 1992), and buried Australian rock art (Watchman 1993). Pigment painted on rock in South Africa was the first application of the AMS radiocarbon technique for dating rock art (Van der Merwe et al. 1987). Innovative methods have since been developed for extracting carbon from paintings. Oxidation of carbon compounds associated with pigments or rock surface mineral deposits using either an oxygen plasma (Russ et al. 1990), laser energy (Watchman et al. 1993), or permanganate chemistry (Gillespie 1997) can be used to prepare samples prior to AMS radiocarbon dating. Rock art in Texas has been dated to between 4,100 to 3,200 years ago (Russ et al. 1990). Rock paintings in northern Australia have been dated using carbon in rock surface encrusted 'canvasses' and mineral coatings (Watchman 1993) and in plant fibers used as paint binders (Watchman and Cole 1993).

Analytical methods employing light (luminescence) are also being used to date sediments in occupation shelters and in pottery. The basis of the luminescence methods is that natural radiation provides energy to the electronic structure of some crystals, particularly quartz and feldspar minerals (Aitken 1985). Grains that are heated (thermoluminescence) or illuminated by green light (optical luminescence) emit small amounts of light that reflect the level of radiation and

length of time since they were incorporated in a sediment or pot. In a controversial case the floor sediments containing stone artifacts at Jinmium in northern Australia were dated at 116,000 years old using thermoluminescence (TL) and quartz grains (Fullagar et al. 1997). The age of those sediments were disputed by proponents of an optical stimulated luminescence method (OSL) who found that the maximum age of the deposits was only 10,000 years (Roberts et al. 1998). Arguments about the reliability of the age determinations for the sediments are concerned essentially with bulk-samples versus single-grain analyses, incomplete bleaching by sunlight of the luminescence centers in quartz grains generated by *in situ* disintegration of rock fragments compared with well-bleached sand grains. These controversial situations and measurements highlight the complex nature of many archaeometric techniques, and indicate the potential problematical results obtained from applications where the experimental conditions are not well known.

2. *Identifying the Sources of Artifacts*

Determining the characteristics of raw materials obtained from quarries and recognizing the same attributes in archaeological objects allows an archaeologist to describe trading routes and interactions between groups of people. The simplest archaeological technique is to look at earth materials using a microscope. Such petrological analyses can be used, for example, to identify the rock types selected for production of prehistoric polished edge-ground axes. The texture and assemblage of minerals in stone tools can be compared with similar features in rocks at known quarry sites. This method was used to indicate complex prehistoric trading patterns in southeastern Australia. Hard, fine-grained hornfels from the Mt. William quarry was traded across hundreds of kilometers (McBryde 1984). Similarly, Neolithic communication networks and boundaries were defined in England based on the petrological analysis of edge-ground hand axes (Cummins 1980).

Subatomic particles can also be used to provide geochemical information about rocks and minerals to substantiate petrological and stylistic information about artifacts. For example, in the proton induced X-ray emission (PIXE) analysis of artifacts, high-energy protons are used to induce X-ray excitations from a range of elements. The measurement of multiple trace element abundances in artifacts, waste materials, and known sources can differentiate between quarries and can allocate artifacts to individual deposits. An example of this archaeometric method is the characterization of obsidian artifacts and sources for the investigation of the production, trade, and patterns of consumption of that natural resource in Melanesia. The systematic analysis of obsidian deposits and excavated flakes on New Britain have demonstrated that two exposures and possibly a third site supplied most of the obsidian for use as stone tools for more than 11,000 years (Summerhayes et al. 1993). Another analytical technique employing subatomic particles is neutron activation. Energetic neutrons, like the protons in PIXE, allow the measurement of elemental abundances in artifacts. Neutron activation analysis (NAA) has been used to source Late Neolithic and Early Bronze Age obsidian in Macedonia (Kilikoglou et al. 1996). Sources more than 300 kilometers north and south of the archaeological site at Mandalo were shown to have provided raw obsidian for use as artifacts.

Neutron activation analysis has also been used to characterize steatite (soapstone) sources in eastern North America (Truncer et al. 1998). Relatively small quantities of rock can be analyzed using the NAA method to produce gamma rays from many elements, which are measured over four weeks. A wide range of trace and major elements, as well as rare earth elements can be measured after a single long irradiation in a flux of neutrons from a reactor. Statistical analysis of the large numbers of analytical measurements eases the burden of discriminating between quarry materials, and permits the identification or 'fingerprinting' of elements that are characteristic of each quarry.

The chemical and mineralogical characteristics of Australia ochers have been determined to discriminate between various sources and to confirm ethnographic accounts of long-distance trade. PIXE analyses have been used to characterize ocher sources in central Australia, with implications for defining trading networks and, delineating boundaries between Aboriginal populations (Smith et al. 1998). X-ray fluorescence has also provided major and trace element analyses, and Rietveld X-ray diffraction has identified the principal mineral phases for each known ocher source in southern Australia (Jercher et al. 1998). Ochers smeared on bones and objects have been traced to potential sources within geologically defined areas. The high degree of natural variability in ocher compositions makes such sourcing studies extremely challenging, so much so that it may be easier to exclude certain locations rather than identify specific sources.

Chemical analyses of other materials can also be used by the archaeometrist to provide useful information for the archaeologist. For instance, the minor ingredients in glass, especially the presence of lead, can be used to indicate the likely sources of glass production and the existence of trading networks. The ecclesiastical glass found at Koroinen, Finland illustrates how the tools of archaeometry provide insights into medieval manufacturing and trading processes (Kuisma-Kursula and Raisanen 1999). Using X-rays generated from focused electrons in a scanning microscope and a beam of protons directed onto small glass fragments, the average chemical composition of the Finnish glasses were found to be remarkably

similar to northwestern European glasses. The abundances of minor elements, particularly lead, sodium, and calcium, in medieval Finnish glasses are inconsistent with likely Russian sources, but match German and southern European glasses. The indication is that glass-making was not practiced in Finland at that time, but that supplies of colored glass for Finnish monasteries depended on trade links with Western and Central Europe.

3. *Metallurgy*

Unlike other geochemical sourcing studies that rely on finding significant archaeological variations in the intrinsic trace element compositions between different sources, the study of metal processing is far more challenging for an archaeometrist. Concentrations of trace elements vary between the ores and the processed metal, and complications arise because of the introduction of fluxes and refractory components. Lead isotope analyses, on the other hand, provide an alternative means for sourcing alloyed or leaded artifacts because the relative proportions of isotopes from ores to artifacts are not measurably affected by chemical and pyrometallurgical processes (Srinivasan 1999). For example, thermal ionization mass spectrometry produces lead isotope ratios ($Pb^{208/207}$ and $Pb^{207/206}$) which were used to discriminate between known deposits of Indian lead ores and artifacts made from them. Matching artifacts to specific ore deposits using the isotopic ratios resolved contentious chronological issues based on art-historical criteria. Western Indian lead ores rather than local sources were found to have been used for brass in northern India during the premedieval period, and also in lead and brass in southern India during the medieval period. Recycling of materials was also observed in Indian coins where lead isotope analyses of later bronzes fitted the trends established for earlier groupings.

4. *Ceramics*

Geochemical studies of pottery and porcelain have focused mainly on grouping complete objects or sherds into products that were either made locally or imported (see Ceramics in Archaeology). This has been done to establish or confirm suspected cultural links and trading associations between groups of people. Basic analyses of pottery sherds usually include determining the mineralogical compositions of the clay and temper to find out what specific materials were used and where a pot was made. This is done using petrographic and scanning electron microscopy. More detailed geochemical analyses may include the use of inductively coupled plasma emission spectroscopy, NAA, PIXE, or gamma-ray emissions. An example of one of these techniques is the confirmation of the extent of local production of fineware between the seventh and second centuries BC at a village on the Calabrian coast, Italy (Mirti et al. 1995). Often, distinctive patterns of elemental abundances are not readily evident in the large amount of geochemical data that is collected. Multivariate statistics are needed to separate disparate groups of pots, as in the case of Roman Samian pottery (Argyropoulos 1995).

5. *Paleodiets*

Adaptation by people to changing environments and the transition in prehistoric societies from hunting and gathering to agricultural subsistence are topical themes in archaeology. These changes can be better understood through the measurements of stable carbon ($*^{13}C$) and nitrogen ($*^{15}N$) isotopes obtained from skeletal materials, and edible plants and animals (DeNiro and Epstein 1978, 1981). Stable carbon isotopes were first used to study the introduction of maize into northeastern North America (Vogel and Van der Merwe 1977). Their use is based on the observation that different groups of plants differ markedly in their isotopic compositions, and that therefore animals that live mainly on particular plants will have bones of matching composition. For example, studies of the paleodiets of people occupying southern Ontario, Canada (Katzenberg et al. 1995) and coastal New England, USA (Little and Schoeninger 1995) have shown reliance on animal proteins rather than on maize or legumes during the Late Woodland period.

These examples of the applications of various analytical techniques reveal how archaeometry plays an important role in archaeology. Archaeometric methods are not used in isolation, but complement a range of other archaeological observations that build a more complete picture of the past. Archaeometry therefore provides a variety of tools that allow archaeologists to understand better human relics of the past.

Architectural Psychology

1. *Definition*

Architectural psychology may be defined as that field within the discipline of applied psychology which deals directly with the response of people to designed environments. In this way, architectural psychology is differentiated from environmental psychology (see *Environmental Psychology: Overview*). The latter may be found under the appropriate headings in this encyclopedia. Generally, the primary focus of architectural psychology has been on cognitive and affective responses to conditions which are, at least partly, under the control of building designers. Responses to attributes of enclosure (shapes, colors, sounds, temperature, lighting, degree of complexity, and so on),

control of interaction with others, and ability to find one's way around buildings (both with signposting and without) are three broad categories which have enticed many researchers. Responses of specific groups to buildings commonly used by them—children and schools, university students and dormitories, the sick and hospitals, workers and offices—have often established areas of study.

2. History

The identification of a subfield within psychology to be called environmental psychology, and its own subfield, architectural psychology, dates from the last half of the twentieth century only. The latter subfield seems to have been inspired by interests among architects, and by the potential for practical application of psychological theorizing, at a period when applied psychology was flourishing.

The first architectural psychology program was established in the USA in the early 1960s at the University of Utah. It was funded as a focus for investigation of the relationship between psychiatric disorder and physical environments. In the UK, recognition of a 'new' approach to architectural issues was given in 1965 by the 'journeyman's' architectural journal, *The Architects' Journal*, in an article by a psychologist, B. W. P. Wells. Wells had been involved in an interdisciplinary study of a workplace—an office building (Manning 1965). Two members of that research team were involved in the establishment of the Building Performance Research Unit at the University of Strathclyde in Glasgow in 1967, and members of that unit organized the first British architectural psychology conference in 1969. Examination of the proceedings shows that participants shared a common orientation to person–environment interaction: an orientation which assumed a close causal relationship between the physical environment and individual behavior.

Also in 1969, the first conference of the Environmental Design Research Association (EDRA) was held in Raleigh, North Carolina. Assumptions of the value of empirical (and preferably experimental) psychological methods are evident in the reports. The results of findings would result in 'better' architectural decision making. This was the hope. There was also a hope that the interaction between many physical, social, and psychological variables would be increasingly understood. To quote one widely used textbook in the discipline whose authors were pioneers in the field (Ittelson et al. 1974, p. 9):

> We are dealing with a theory of environment that removes the individual from the physical isolation in which he is usually studied. This in itself is a significant advance in our understanding of human behavior.

Perhaps unfortunately, this humanistic and/or ecological orientation has not been evident in all, or even the majority, of the published work in the area. Analysis of the content of the early editions of the first specialized journal in the field (of environmental psychology) *Environment and Behavior*, from 1969, indicates that the majority of published articles presuppose the possibility of manipulation of people, in one way or another. The underlying assumption seems to be that human behavior in relation to the environment is capable of being understood in terms of a discrete number of variables (then-developing methods of statistical manipulation of multivariate data, such as factor analysis, had an influence on research design, too). If the assumption were true, then control of behavior by manipulation of these variables becomes a possibility. With control comes power; a valued commodity within professions, and something which could have market value (however ethically dubious its use value).

In the early 1970s, the first reports appeared from Australia and Scandinavia. David Canter (a student of Wells' and subsequently influential in the field) ran a course in architectural psychology in Sydney, Australia in 1971. A conference was organized in Lund, Sweden in 1973, and there the influential reported work on color and measurement techniques derived from a cognitive orientation. Generally, the subdiscipline developed later in continental Europe, though by the late 1970s, *psicologia ambientale* was a recognized subfield in Italy, for example. The International Association for the Study of People and their Physical Surroundings (IAPS), with significant European membership, was founded in 1981.

Some ideas that were not seen by their authors as 'environmental' were influential in shaping the subdiscipline. George Kelly is one example. His personal construct theory of the 1950s focuses on the individual's understanding of his or her world, but was adapted to architectural psychology by several researchers. Roger Barker's behavior-setting theory was not well developed in respect of physical environmental components (a deficiency recognized by Barker), but the theory has powerful explanatory potential for understanding physical environments. In methodology, too, the interviewing techniques developed by Carl Rogers have highlighted the importance of listening skills, and have been used to focus attention on users' interpretations of their life world, for example. These three investigators share a humanistic orientation. Their central concern is not prediction, but understanding. Researchers using this approach use methods which are almost always qualitative, impossible to reduce to general hypotheses about the relation between people and their physical world (indeed, the very act of distinguishing the two is an error, seen from the standpoint of some). Prediction is not understood to be the major objective. The majority of published research, however, is not of this kind, but falls within the rubric of cognitive psychology, with its empirical/experimental biases.

3. Specific Areas of Significance in Architectural Psychology

As indicated above, a number of specific fields of psychological study have been seen to have potential value for architects. The most obvious are:

(a) Perception/cognition;
(b) Color;
(c) Proxemics (the study of people spacing, and including studies of crowding and privacy);
(d) Wayfinding;
(e) Affect (the relation of emotion and/or mood to variations in physical environment).

These fields are not autonomous. Color is widely believed to influence emotional response (and there is some experimental support for this view). Perception is involved in establishing whether one feels crowded. Some studies attempt to consider the complexity of environments in social terms as well as physical. The variations in the literature are significant. Nonetheless, the five fields listed provide a simple taxonomy which includes a very large number of reported studies and texts.

3.1 Perception/Cognition

The variety of approaches to perception reflects differing ideas of what is important. No approach is specific to architectural psychology. Kaplan and Kaplan (1981) focus on functioning in the world. They ask the question: 'What does the process of perception/cognition help us to do?' The answer given is that what is important in real life is functioning—and with minimum stress, if possible. People search to make the world familiar, so that they may move smoothly and confidently through it. Experience is organized, so that we learn what constitutes salient information. Thus, the way the world seems is directly related to the way we process received environmental information.

By an understanding of these processes, designers might be enabled more confidently to solve problems with people in mind.

3.2 Color

Few subjects have so great a potential for claiming the interest of both designers and architectural psychologists as does the topic of subjective responses to various colors. There has been a long history of attempts to 'prove' (show scientifically) certain beliefs about the effect of color on people, generally with little success, or with little relation to everyday environments.

Taking an experiential perspective, it might be claimed that people do know about color in their everyday lives, that it is part of their lived experience. Given this way of thinking about color, it might be expected that there would be some phenomenological accounts of color that might lead to greater understanding, if not to prediction, of emotional response to colored environments. Yet these are not easy to find.

It is 'common knowledge' that perception of red is 'arousing' and of green is 'calming' or 'soothing.' It seems that 'common knowledge' is not necessarily correct. Working with strict experimental controls and with a strong physiological bias, Mikellides (1990) found that it is not hue that directly influences responses but chromatic strength. Pale colors are less arousing, whatever the hue.

When actual interiors are considered, the limitations of experimental studies become obvious, however. 'Real' interiors inevitably display a range of colors, in which a single dominant color is extremely rare. Psychologists are still a long way from being able to say very much of value to designers about color perception or response to colored interiors. Thus, several commonly cited texts in the field of architectural psychology make no reference to color in their index.

3.3 Proxemics

The study of social spacing in humans (proxemics) was an early focus of study. Studies of crowding, for example, illustrated that the phenomenon was not simply a function of the density of occupancy. It is now recognized that there are aspects of crowding which were often ignored in early research—situational, affective, and behavioral—and that even knowledge of the response of others in similar situations can modify behavior.

Generally, the extent to which individuals feel in control in relation to their spatial environment has much to do with their satisfaction, but studies of privacy have illustrated its complexity in terms of interacting cultural, personal, and physical conditions, and no simple hypotheses cover all cases, except perhaps the following: The critical characteristic of human behavior in relation to the physical environment is control—the ability to maximize freedom of choice. Clearly, this is not very helpful to designers, or even to, say, office managers, who are almost certainly going to want to limit the freedom of subordinate workers, for example.

Recognizing the application problem, Robert Sommer, who completed the original research, observing the way that students occupied seats at library tables—a kind of territorial behavior—wrote (in Lang et al. 1974, pp. 205–6):

> When I did this research originally, I believed it would be of use to architects. Since architects were concerned with designing spaces and this research was concerned with space, there must be something useful in it for architects. Looking back I think this assumption was, if not unwarranted, at least overoptimistic.

Nonetheless, Sommer still believes that architectural psychology offers architects the means to avoid making false assumptions about the ways in which their decisions will influence behavior.

Irwin Altman deserves special mention in this context. His 1975 book on the material was broadly influential, as was a 1977 edition of the *Journal of Social Issues* (33, 3) devoted entirely to privacy theory and research (and to which Altman contributed).

3.4 Wayfinding

The task of finding one's way to a desired destination in complex environments has interested researchers because it has clearly defined preferred behavioral outcomes and a relatively limited number of physical variables which affect the outcome. These variables are mainly maps and signs of various kinds, but 'building legibility' is rather more complex, and concerns the organizing principles people use to make sense of the buildings which they occupy. Factors such as spatial landmarks and spatial distinctiveness and cognitive mapping (or the way in which individuals order, store, and retrieve their cognitions) have been central to numerous studies.

In solving wayfinding design problems, information-processing theories of perception/cognition can be applied. As hinted at in Sect. 3.1 above, it seems that there are no features of the environment which are essential to cognition. An adequate sample of characteristic features is enough. Taken together these allow for recognition. The environment is diverse, complex, and uncertain. Situations do not repeat exactly. Despite this, adequate theory can lead to the making of choices within the physical environment which reduce ambiguity and make for greater legibility within large buildings.

3.5 Affective Response to Environments

For some time, in the 1970s especially, there were high hopes held by some psychologists that physical environments could be 'measured' using various polar verbal scales (semantic differentiation scales). J. A. Russell was a prominent researcher in this area, and developed the view that responses based on two key dimensions—arousal and pleasure—accounted for most of the variability in human responses. For Russell, the two are independent bipolar variables (orthogonal if graphically represented). Other researchers in the area (without apparent interest in architectural psychology) lend support to the idea that affective response to building environments could be 'measured' by measurement of internal arousal states. Further, there seems some support for the idea that self-report methods (say the adjectival scales) correlate pretty well with physiological measures. Despite this, in recent times, there have been very few reported attempts to investigate responses to interior spaces using such techniques. Perhaps, because mood is not usually related to a particular stimulus in field situations, and the range of responses within a given setting is likely to be large, there has been a loss of confidence that any variation is attributable to the physical environment.

4. Phenomenological Approaches

Although much of the theoretical work and methods adopted in research designs derive from a cognitive orientation, mention must be made of the contribution of phenomenological approaches. Many explicitly qualitative studies have been reported by people whose first interest is not psychology, but David Seamon (1982) has explained how a humanistic psychology which emphasizes intersubjectively shared understanding has contributed to understanding of place. This is especially the case when considering responses to the concept 'home,' for example.

5. Postoccupancy Evaluation

One area where architectural psychology has changed the behavior of architects, to a degree, is in the evaluation of buildings after completion and a period of use. The argument in favor of undertaking post-occupancy evaluation (POE) studies goes as follows. It is assumed that all building designers have intentions in respect of their designs in relation to human behavior (which, of course, for the psychologist includes a wide gamut, including thinking). There is little evidence that designers ever follow up on these assumed behavioral responses to check whether their intentions are reflected in actual outcomes. POE is intended as a method of rectifying that perceived lack of feedback. Without feedback, each new design is a set of untested behavioral speculations. If there is to be cumulative knowledge in design, there have to be some supportable hypotheses about the relation between designed environments and behavioral outcomes.

All of the above assumes there is a direct relationship between physical environments and behavior which is causal. No determinism is implied here. The best way to understand the relationships involved is to consider the idea of 'affordance': does the physical environment help or hinder people in achieving their preferred behavioral outcomes (whether action, cognition, or affect)?

In research, a variety of methods have been adopted. However, in many instances, in the practice of architecture, feedback is limited to forced choice pencil-and-paper responses and the findings have more to do with meeting requirements of quality assurance procedures of bureaucracies than they have with ensuring a closer fit between agreed design criteria and building outcomes.

6. Future Directions

A recent textbook on environmental psychology (Bonnes and Secciaroli 1995) suggests, by its content, that the impetus for new research in the subdiscipline has lessened in recent years. While the book covers much more than just architectural psychology, it is of interest that, of close to 600 citations, fewer than 20 percent are dated 1985 or later, while a third of all of the citations date from the 1970s. This hardly suggests a growing and expanding subdiscipline.

The potential for failure in the dialog between the social and behavioral science and architecture was summarized by Jameson (1970). A breakdown in communication was evident in 1970, as it still is. In the late 1960s and 1970s, it would seem that schools of architecture had high hopes for the potential of architectural psychology. Courses in architectural psychology were incorporated in the curriculums of many schools, either as core material or as significant option streams. Nearly all have disappeared. While the work of some psychologists might have led to greater understanding of, and empathy for, users of buildings, such understanding seems to have done little to inform the practices of architects (although there may be greater concern for users in some practices). Without the impetus of potential applications for research findings, it is not clear what directions architectural psychology will take.

Architecture

Architecture is a complex area of social life to which the social sciences have paid relatively scant attention. The term refers to an art with a long history and a theoretical tradition and also to its products, which are one constituent of the built environment. This article examines how the architects' claim to be the foremost producers of architecture has been grounded historically in their relations with power, and considers the main shifts in Western societies' conceptions of architecture. It concludes with the implications of architecture for the social sciences.

1. Architecture and Building

For the philosopher Suzanne Langer, architecture 'is a total environment made visible.' Architecture creates its own specific illusion, not the ingredients and fragments of a culture, but a total image of it. Langer calls it the image of 'an ethnic domain,' implicitly stressing its sacred, collective origins and its public nature. She follows in this the dictum of Le Corbusier, one of the twentieth century's greatest architects, that 'Architecture is the masterly, correct and magnificent play of masses brought together in light.' But for a philosopher like Roger Scruton, architecture is an art of everyday life, the application of a sense of what is culturally appropriate. Any person with a sense of 'visual decorum' can pursue architecture, and the visual order it creates. If these acceptations may seem incompatible, it is because 'architects' architecture,' solely recognized as art by patrons and intellectuals, stands in opposition to 'mere' building and the untutored search for what looks right.

Architecture *is* building. It serves as shelter and as the stage of social life, but it rises above utility and transforms it. In ancient civilizations, the *telos* of architecture, its function and its traditional forms,

were sacred and transcendent, part of the ritual and theological knowledge monopolized by the priesthood. In Greece and Rome architects were secular, and their access to elite positions depended on mastery of both *telos* and *techne*, the organizing form and the technology of construction. Historians of architecture have noted that Roman buildings endow with meaning and dignity forms such as the barrel vault and the arch, and materials such as concrete that had only had utilitarian purposes. Roman civilization expands and diversifies the register of architectural types, while its domestic architecture marks the emergence of the architect as interpreter of the patron's private needs. But not until the Italian Renaissance do we find a new social definition of design and construction, harbinger of the modern architect's role.

The kind of building that we call architecture is defined in its essence by the relationship of *telos* and *techne*, conception and execution, symbolic intentions and materialization, but also by the fact of patronage. Before the Renaissance, special groups of builders or exceptional individuals had appeared as mediators of the elites' desire to express their piety or their hope for immortality in beautiful buildings. In Greek cities, the pursuit of beauty and excellence in building had already given rise to theorizing addressed by architects to other builders, artists, and intellectuals. We may call these mediators 'architects,' insofar as they inserted their practice between the *telos* and the *techne* of construction, but they *had* to be in control of technology. The complexity and the large scale of a project obtained for them a better chance to claim a measure of authorship from their patrons and enter their name in the historical record.

By 1400, the historical repertory already contained three potential strategies of collective social upgrading for the 'architects': one pre-eminently based on the development and mastery of technology, of which large-scale projects were the base; another dependent on the service of the state and official religion; and finally, an 'intellectual' strategy aimed directly at the symbolic and aesthetic dimensions of buildings. These three ways overlap, each historical situation offering or closing some alternatives. In the Italian Renaissance architects strove to appropriate the *telos* of architecture by intellectual and almost *purely stylistic* means; architecture would henceforth be distinguished from mere building by scale and a new set of stylistic conventions. In this crucial phase, Western architecture severed its intimate relationship with the technology of construction; *design* was instituted as the new discipline's foundation, while monumental projects remained the architects' *voie royale* for making their mark upon the city. The relationship of architects' architecture to the city's anonymous fabric was marked by latent conflict, both visual and social. It was transformed by change in the nature of cities, and no change was more revolutionary than urbanization in the industrial age.

2. *The Social Construction of Architecture in Western History*

The development of Gothic buildings provided remarkable constructional means to the fifteenth century, and a labor force with a tradition of technical competence that has not been equaled since. Renaissance architects could therefore concentrate on designing buildings, only needing to know what was technically possible in order to command the construction crews.

2.1 *Architecture and Power*

In the emblematic case of Florence after the Black Death, a revived economy gave the merchant elites capital, and the desire to spend it in celebration of themselves and their city. They looked for design talent in the ranks of decorative artists much rather than among the building trades (of the major architects only Sangallo the Younger and, later, Palladio came from the trades). Their keen interest in building sustained the designers' social ascension, as also did every city's need for civil engineering projects and complex fortifications. Architecture emerged thus in early modern Europe as a special medium for the needs of power and the expression of status.

Regular collaboration with their patrons gave architects, among other artists, a social position inaccessible to mere craftsmen. The distance they established between themselves and their technical base was never to be closed in the subsequent evolution of their role, but patronage continued to fetter their autonomy. Individual patrons and building committees not only supervised their considerable investments, but they involved themselves frequently in design, claiming authorship of the building (and they still do today!). At this social and ideological turning point, architects used the possibilities offered by the new forms of patronage to separate form from function in the *telos* of building, claiming conception, which translates function into form, for their own. The organization of construction proper was therefore left open to *other* delegates of the patrons, or other mediators. Architects turned to humanist intellectuals to explain the new style and its significance, while natural scientists began to study the nature of materials, and physical builders concentrated on the machinery of building. The rivalry with engineers, characteristic of the industrial age, was thus prefigured at birth for the specialized occupation of architecture.

Renaissance architects used the theory produced on behalf of their art to advance and legitimize their position. By the late sixteenth century, with the first academies, they began once again to write about practice for other architects. Theoretical foundations and treatises meant that architecture had to be studied, and that the title of architect could thus be denied to

the uneducated. In seventeenth century France, where the monarchy had been developing the administration of buildings for three centuries, the occupation of architect-urbanist entered an academic and official phase. As Louis XIV's phenomenal building programs were emulated by other monarchs, so was the Royal Academy of Architecture established in 1671. It integrated the Renaissance conception of the architect-artist with an *ancien regime* version of the civil servant's role, introducing a premodern notion of corporate professional power. The elite academicians were the expert judges of the beautiful, and monumental royal projects their preserve. The engineer also had made his appearance and asserted domain upon utility, his presence increasingly blocking any attempt by architects to recapture the control of *techne*.

Academic teaching diffused the conception of architects as specialists in stylistic codes, carrying it into the industrial age, where challenges against the architects' role in the system of construction multiplied. Architects defended themselves in a state of stylistic disunity, brought about by the exhaustion of the classic orders. Where an academy existed, officially charged with defending taste and elaborating doctrine as in France, they still enjoyed considerable advantages over other building designers. The French Academy, dissolved in 1793, reappeared in 1819 as the celebrated Ecole des Beaux-Arts. The classic coherence that it managed to preserve made the Ecole into a professional model, closely emulated in the United States practically until World War II.

Thus, at the beginning of the industrial age, architects retain in principle the control of aesthetics through the discourse that defines good 'architecture.' Among their patrons, state and church commissions remain important, although new monumental types have appeared often at the behest of business: universities, post offices, railroad stations, hospitals, but also stores, hotels, and the American 'tall office buildings.' Architects' architecture, propagated on paper by its own institutions, depends for realization on finding and pleasing patrons or clients. It works, as it always has, in the service of power and social status, which is now pursued by culturally divided and heterogeneous elites. As a learned discipline, architecture faces the challenges of industrial capitalism and professionalization in its own ranks with a traditional identity ill-suited to its very modern ambitions.

2.2 Architecture and the City

By the seventeenth century, the military engineer had become a separate role, but architects retained control over the monumental design of cities and over the complex, dynamic form of individual buildings. Neither the relentless axiality of monumental plans, nor the palatial style of life and conspicuous consumption of the age of the baroque could defeat, however, the cities' unruly growth. The anonymous urban fabric had always been a reminder that architects cannot monopolize architecture for, in a sense, the more beautiful and coherent a city is, the better it sets out the architects' designs, and the more it denies the uniqueness of their function.

Since the sixteenth century, capital cities held in a straight jacket by their walls had known overcrowding and rising land values, but urban disorder could still be contained physically. In the seventeenth and eighteenth centuries, the regimented holistic environments built for the state contrasted with mansions built for new classes of patrons—a physical counterpart of the stratification produced among architects by private and public patronage. But architects had nothing to say, except in planned utopias, about the need for housing of working populations. Before industrial capitalism, three major ways of addressing the city's problems had emerged: the gridiron plan of real estate speculators; improved lines of circulation and transportation (the basic approach of engineers, which Lewis Mumford called the 'bull-dozing habit of mind' and Baron Haussmann applied unforgivingly in Paris); and utopian schemes, proposed mainly by architects. The latter juggled uneasily with total monumental conceptions, with the integration of nature into the city, or with escape and reconstruction.

The industrial revolution's utilitarian buildings put old and new materials—iron, glass, concrete—to bold new uses, while the unplanned growth of the modern metropolis seemed to confirm architects' architecture as a superfluity of the rich and powerful. Yet new needs and new technologies meant that it could become directly relevant to larger sectors of society than ever before in history. Architects had to redefine their role in the politics of construction to confront the task. As in the crucial phase of the Renaissance, they used doctrine, which they controlled, to secure their social foothold.

3. Doctrinal Shifts in Architecture

A specialized occupation, which produces discourse about its activity and objectives, will use it to legitimize, confirm, and also transform its conditions of practice. The audience for whom discourse is intended will inflect and influence its content and manner.

Thus, in the Renaissance, intellectuals educated potential patrons in the *stil novo*, providing explanations, and exhortations to spend money. From the treatises, a more autonomous discourse also emerged. Leon-Battista Alberti integrated the rediscovery of the classic Orders with a theory of harmonic proportions, pronouncing architecture the spatial materialization of mathematical truth. The rationalism of an emancipated minority of intellectuals echoed the buoyant sense of power of the new patron class, contributing to the divinization of art and conferring charisma upon

architecture. The ideology and the new architects' masterpieces made architects into artists who henceforth competed with their patrons, not in the political economy of construction, but in a symbolic dialectic of charisma. Intellectual work and publics allowed architects to appropriate the pure *telos* of architecture, but the environment was changed only by the decisions to build which belonged to the patrons.

Five centuries later, the modernist *avant gardes* also launched a powerful symbolic and ideological movement. Renaissance architects had advanced their own collective social status and that of their discipline relying on their own shared origins and locality, as well as on the worldview of the elite whom they served. Modernist architects worked in different nations and in different circumstances, but they too led a transnational movement with a coherent doctrine. These minorities within architecture shared a long-standing discontent with what architecture had become; their opposition to academicism, which ignored the problems and the possibilities of the modern era, unified them. Four key factors describe modernism's conditions of birth: the existence of artistic *avant gardes* in the European capitals; the devastating experience of World War I and the massive need for housing it exacerbated; the response to socialism and the revolutionary movements of the brief interwar period; and the demonstration of enormous productivity provided by large-scale industry during the war effort. At all the levels of their aesthetic and ideological battle, the modernists sought an integration of architecture within the mainstream of industrial production. As Reyner Banham has shown, the aesthetics were derived from an *image* of machine-made objects, with the ideological premise that art would conquer mass production by fusing with it.

In the first part of the twentieth century, architectural modernism represented as total a departure from the immediate past as the Renaissance was from the Gothic. In both cases, ideology and aesthetic theory were the guiding principles, just as in both cases the movement leaders attempted a social redefinition of the architect's role. Modernism, however, depended closely on new technologies and new materials for the realization of its radically antihistorical aesthetics. Claiming to speak for the largest number and to the largest public, modernists presented their ideas as a world architecture for the masses. Their doctrine called for the abandonment of regionalism, nationality, traditionalism, and local particularities, for the ahistorical domain of function, never a guiding principle of design but an image wedded to that of the machine. Abolishing the worn-out *signifiers* of the past, and leaving only pure, efficient Form, the modernists attempted to bridge the opposition between buildings where people work and buildings where they live. Freed from load-bearing walls by the new technology, they could design continuous spaces and 'dematerialized' glass walls that went beyond the antinomy between inside and outside inscribed in heavy ornamented facades.

Modernism did not redefine the position of architects in the political economy of construction. Driven to America by Nazism and war, the German modernists, in particular, conquered for a time an almost hegemonic academic base. After World War II, the steel and glass aesthetic identified with Ludwig Mies van der Rohe fused with the large architectural office (an American late nineteenth century invention) to furnish the corporate reconstruction of the world with its towering glass boxes. The next doctrinal shift, starting in the 1960s, attacked once again architects' architecture for having become a mere instrument of profit and power.

The revisionist attacks gathered under the label of *postmodernism* had different origins and a different thrust in America and in Europe. European architects, dependent on public funds for their most important commissions, never abandoned the idea that architects have an important social role to play (Champy 1998). Yet on both sides of the Atlantic, the attack started within the specialized *discourse* of architecture, in which architects reserve for themselves the authority to participate. The passage from the specialized discourse (situated mainly in universities, museums, journals, and intellectual circles, and interesting primarily for architects and cognoscenti) to the streets required as always that new, defiant buildings be realized. In the United States, postmodernism was marked by a manner rather than a coherent conception of architectural design; the manner admitted ornament and thrived on eclectic allusions, ranging from reinvented history to regional vocabularies and populist gestures toward a mostly commercial 'vernacular.' The movement attacked the modernist aesthetic concretely embodied in its archetypal buildings. The modernism of skyscrapers and 'growth machines' was indicted in the name of another architecture, which thrived on small projects, relatively modest housing, new kinds of clients, and new kinds of needs, both frequently subsidized by the War on Poverty. The battle for the control of architecture's discourse marked the arrival of a new generation, but also the affirmation of a different kind of practice (Larson 1993).

During the 1970s, however, the professional elites, buffeted with a crisis of construction that reached depression levels, gradually conferred legitimacy upon almost any definition of what constituted good architecture. In the ensuing confusion, a brand of revisionism that rejected both the social mission of architecture and the historicist vocabulary asserted once again the supremacy of design and form as the primary competence and concern of architects. The ideological restoration of the architect-as-artist role opened the 1980s, a decade of ferocious real estate speculation and chronic overbuilding, which coincided with the Reagan era and incorporated all the forms of

postmodern revisionism into the establishment's architecture. The era saw the preponderance of architecture as provider of eclectic *images*, prime assets in the ever-faster cycles of upscale consumption, and the never-ending search for product differentiation. Architecture became more glamorous than ever at the service of postindustrial and global capitalism, but it was neither more secure nor autonomous vis-à-vis clients and competitors than before. At the end of the twentieth century, some leading architects and critics saw as deeply problematic the relations between scenography and construction, between image and reality in architecture, agonizing once more about the role of architecture and architects in the now global economy.

4. Concluding Remarks

Architecture has interested the social sciences as a profession, whose weakness is in part explained by its base in aesthetics. It has not succeeded in establishing jurisdiction against either professional competitors or lay resistance, and it is marked by apparently unsurmountable lines of internal stratification, based on the form and the volume of practice. Typical of architecture is the deep cleavage that distinguishes the elite designers who control discourse from everyone else. Logically, architecture has also been studied as a form of production of culture closely interdependent with the economy and inserted into a very complex division of labor (Blau 1984, Gutman 1988, Larson 1993, Moulin 1973).

The architects' expertise is challenged by cultural plurality, permissible and encouraged in the arts as it is not in the sciences, or even in the law. In the global economy, both practitioners and theorists, seeing architecture subjected to the realities of 'transnational' construction and real estate promotion, have become aware of endangered cultures, always a concern of lay people (Saunders 1996). The behavioral sciences may have been closer than sociological research to the interests of architects, although the former have tended to privilege individual reactions to very general characteristics of the built environment. Recently, social scientists have approached the problem of *reception* of architecture (Larson 1997) and included it in the development of a sociology of place (Gieryn 2000). The emphasis is on the scripts, conventional and otherwise, that may be inscribed in the architectural object, and read, or followed, by the users. The importance given to meaning and agency seeks to bridge the gap between architecture and building, and between lay people and their culture, returning thus to the point where this account began, and to the contradictions inscribed in architects' architecture.

Archival Methods

'[N]o documents, no history' declare Charles-Victor Langlois and Charles Seignobos (1898, p. 2) at the end of the nineteenth century as they begin their guide to historical research. They continue: 'To hunt for and to gather the documents is therefore a part, logically the first part, and one of the most important parts, of the historian's craft' (1898, p. 2). They thus state a methodological principle as well as a defining marker for a social science discipline. A standard for progress: if more recent historians are in any way superior to those of the past it is because they have 'the means to be better informed' (1898, p. 3); these means are the modern public archive, with its large and effectively catalogued collection, and the careful training of fledgling historians in the critical use of documents. A century later, historians were still far more likely than other social scientists to exchange tales of archival discomforts and delights, and to guide their graduate students in crafting essays built around properly referenced primary sources. But new information technologies were somewhat blurring the distinction between archival and published sources, between primary and secondary sources, and between the

methods of history and the methods of other social sciences.

1. Archives as Research Sites

Archives are the records of an organization's activities. The term is used both for the place those records are housed and for the body of records themselves. These records may have been produced by that organization or gathered by it. Such organizations include businesses, religious bodies, and government agencies, and we may stretch the notion to include the records of individual persons. Since the records were produced for the purposes of that person or organization, they tend to be organized for those purposes and not those of researchers. This means that archives are often difficult and sometimes impossible to use effectively without detailed knowledge of the organization in question. Researchers could hardly make much of the documents in some governmental archive without understanding the agencies that produced or collected the documents.

Archives tend, therefore, to be organized idiosyncratically. One archive may well differ from another not only in its classificatory categories, but also in the extensiveness of inventories, catalogues, and other aids to research. There may be no list of individual documents, but just indications of more or less broad categories. The records of some country's regional or local governments may not be organized in a uniform manner. As a result of such challenges to a user's ingenuity and patience, a researcher may derive considerable pleasure from the sense of mastering an archive. By contrast a researcher can get very far in most libraries the world over by expecting to find an alphabetical catalogue of authors and titles.

2. The Modern Public Archive

The linking of the modern practice of historical research and the modern public archive is generally dated from the French Revolution, but archives of some form are considerably older. Since states have often needed records of laws, tax assessments, and interstate treaties, state archives existed in antiquity. *Arkheia* is the Greek for an authority's records. It is even probable that the invention of writing was spurred by state need for documentation. So archives were part of the technology of state power, but they could also play an important role in the power claims of other social actors. In the European middle ages, lords and ecclesiastical institutions maintained records spelling out their privileges (etymologically: private laws). The possession of documents attesting to immunities from royal claims or the antiquity of claims over others (for seigneurial dues, for example) was an important instrumentality of such privilege.

Early modern European states had their document collections, too, but these were often semiprivate, with individual agencies and even individual officials having their own archives. Steps towards centrally organized collections were part of the history of European statemaking; early centralizers included the Spanish archives of Charles V in 1545, the English State Paper Office in 1578, and the Archivium Secretum Vaticanum in 1611 (Favier 1958, p. 24). But these were not publicly accessible, secrecy being as significant an attribute of the monarch's documentary collection as of the lord's.

The French Revolution launched the modern public archive. In France's villages, peasant attacks on the documentary collections of lords and monasteries testified to their continuing significance. Although the new revolutionary authorities promoted some archival destruction, the overwhelming thrust of their efforts ran in a very different direction. The separate collections of royal agencies, old regime corporate institutions, and local powerholders were made public in two senses:

(a) They were brought under state management and thereby opened up to systematic classification, not only in the National Archives housed in Paris, but in the uniformly organized departmental archives as well. This development greatly facilitated measures for preservation, as well as cataloguing. A modern profession of archivists formed around these tasks.

(b) They were made accessible to the public. With exceptions for state secrets (a far more limited notion than before the Revolution) and the privacy of individual citizens whose identities might figure in state records, documents were to be made available for the scrutiny, and research, of French citizens. Archival documents were redefined from being primarily instruments of power, often private power, to aspects of the national cultural heritage.

In establishing France as the center of a reconstructed Europe, Napoleon had vast archival holdings transferred from Spain, Vienna, and much of Italy to Paris. In the wake of the French defeat, the recovery of documents from France further strengthened the notion that a respectable modern state needed its own respectable modern archives; as the nineteenth century went on this increasingly meant that, like France's, other archives were going to be open to a far broader public than in the past.

3. Professional History

The historical profession that emerged in the nineteenth century combined a distinctive sense of evidence, a distinctive form of professional apprenticeship, and a distinctively organized intellectual product. This was being developed in many places but the model for the new professional history was provided

in the writings and seminars of German historian Leopold von Ranke, beginning in the late 1820s (Novick 1988, Smith 1998).

(a) Historical claims were supposed to be grounded in the best possible primary sources, generally those located in searching relevant archives. Historical knowledge would be disciplined, a notion that acquired important additional baggage as the German *wissenschaft* was transmuted into the English *science* as a description of the kind of learning produced by historical research.

(b) Apprenticeship included practice in making something of primary sources in graduate seminars. To the extent the seminar was seen as a sort of 'laboratory' (Novick 1988, p. 33), the sense of history as a sort of science was augmented. Mastery would be further demonstrated by the completion of an original work dependent for its primary sources on unpublished, generally archival, materials. The budding historian would acquire not only the cognitive skills but also the character needed for archival labors. Historians needed to be 'calm, reserved, circumspect; in the midst of the torrent of contemporary life which swirls about him, he is never in a rush.' Those 'always in a hurry to get to the end of something…may manage to find honorable employment in other careers' (Langlois and Seignobos 1898, p. 103).

(c) Professionally respectable intellectual products consisted of books and articles whose factual claims were, in principle, verifiable from the primary documents to which the text would explicitly refer. The footnote to sources was a vital part of the prose of professional history (Grafton 1997). Denoting the structure of reference—footnotes plus bibliography—as the scholarly 'apparatus' fostered rhetorical associations with science.

Important and diverse consequences followed from its characteristic methods for such a professionalized history:

(a) *National specialization*. Historical specialties tended to be organized thematically around national histories because the archives were organized by states. Beyond linguistic familiarity, practitioners who had invested their energies in mastering one archive or set of archives found it advantageous to continue future work that would reap the benefit of those investments.

(b) *Building national identities*. Partly as a consequence of this technology of history, and partly because states were supportive of such work, the writing of history itself became an important component of the very forging of national identities in the nineteenth and twentieth centuries.

(c) *Focus on elites*. Since what was in these state archives was, by definition, documents that had been of interest to state managers, professionalized history had a tendency to privilege the doings of states and other human practices of interest to administrators while paying lesser attention to other ways of exploring human experience.

(d) *Focus on Western history*. Since the standards of professional history could best be attained where there were rich archival collections, cared for by skilled practitioners of preservation and cataloguing, those parts of the world relatively well endowed in those regards were attractive to researchers who hoped to achieve professional advance. Such conditions meant governments: (i) with rich documentary collections; (ii) with the resources to support the preservation and cataloguing of these collections; and (iii) for which the French revolutionary model of a public national archive as an essential component of a modern national identity had some resonance. Nowhere were these conditions better met than in France itself. Part of what has made France such an important center of innovation in professional history in the twentieth century has been its marvelously organized archives. Countries (i) lacking extensive documentation, (ii) having documents but lacking the resources or the interest in preserving them or organizing them coherently, or (iii) with strong traditions of archival secrecy were all, in their different ways, more difficult terrain for professional historians.

(e) *Marginalization*.The inverse of the previous points: social activities, social strata, and entire continents that have either been of little interest to states' producers of documents, or that have not developed such extensive and usable documentary collections, have tended to be marginal areas for professional history. Historians interested in such subject matters have had to be methodologically innovative and have sometimes faced an enormous challenge for professional recognition.

(f) *Eschewing explicit methodological discussion*. A professional socialization oriented to the careful scrutiny of the provenance of particular documents and the opportunities for knowledge and the motivations for falsification on the part of that document's author encouraged historians to delight in the particular. This was reinforced by the particularities of archives, knowledge of whose quirks was not readily transferable to other archives. Historians understood their own methods in large part as the location of useful texts in idiosyncratically organized archives in conjunction with the careful criticism of documentary sources. Such skills were acquired by experience and the patient application of a few readily assimilable critical rules of thumb. The capstone of training involved immersion in some idiosyncratic archive. Thus Langlois and Seignobos: '[t]o learn to distinguish in this enormous confused literature of printed inventories (to confine ourselves to such), that which merits confidence from that which does not, in a word to be able to make use of them, is a complete apprenticeship' (1898, p. 12). Historians have therefore directed far less of their intellectual efforts at methodological discussion and have therefore also had fewer methods courses as part of graduate training than the other social sciences. In 1971, one study of

graduate education commented that 'methodology is the orphan of the history curriculum' (Landes and Tilly 1971, p. 82); there is no reason to think that three decades later things had significantly changed.

(g) *Eschewing explicit theory construction*. Dependence on the fortunes of document survival, as Murray Murphey observes (1973, p. 148), is a major reason historians have been less prone than other social scientists to pursue a model of inquiry in which abstract hypotheses are formulated, then tested against available evidence. The unpredictabilities of archival research suggest instead the development of hypotheses in tandem with the exploration of data. One often finds wholly unexpected documents sitting on a shelf somewhere. Theory building as an explicit and valued agenda is therefore less characteristic of people in departments of history than it is of those in sociology or political science and very much less than in economics. Nor does a broad knowledge of history's big themes without a deep reserve of pertinent facts earn much esteem from professional peers. By way of contrast, graduate students in top US economics programs do not regard a deep knowledge of the economy as nearly as important to their professional futures as they do skill in mathematics (Klamer and Colander 1990). One could not imagine graduate students in first-rate departments of history similarly downplaying the significance of a rich and concrete knowledge of some specific time and place in favor of mastering methodological or theoretical tools.

4. *Working with Documents*

The notion of 'archival methods' comprehends two rather different sorts of activity. First, there are the methods of collection, preservation, and cataloguing on which documentary research in archives depends (Schellenberg 1956, Brooks 1969). Second, there is the work of historians (or others) with those documents. Essential to nineteenth century notions of historical method was the 'criticism of sources.' Classic works of method, like that of Langlois and Seignobos (1898) provided a broad taxonomy of ways in which one document might be superior to another. For example, historians became skilled at considering:

(a) possible errors of transcription in the reproduction of or quotation from ancient texts

(b) whether a document's author was in a position to reliably know that which was claimed

(c) what motivations that author might have for slanting a story this way and that

(d) how to select from among multiple documents the most credible account.

According to Langlois and Seignobos (1898, p. 131), historians need to cultivate an attitude they call 'methodical distrust': an author's 'every claim' must be suspected of being 'mendacious or mistaken' (p. 132). (There follows a taxonomy of possible guises assumed by documentary deceit and error as a guide for avoiding the snares and pitfalls that might lead a researcher too easily to accept some statement as historical truth.)

More recent reflection has pondered the forms of distortion that might exist in whole collections of documents, and recognizes with Murray Murphey (1973, p. 146) that the survival of documents has often depended on fires, floods and 'the concern of loving daughters.' If there is still much to be said for the formulation of Langlois and Seignobos that there is no history without documents, we may consider how it is that documents come to be available to the historian's scrutiny. We should consider (Shapiro et al. 1987):

(a) *Recording*: what social processes bring documents into existence? This includes taking into consideration what sorts of things are or are not of interest to states, economic enterprises, religious bodies, and other recorders of words. An increase in counted murders may indicate a greater interest of states in whether or not people are killing each other, for example. No doubt in many times and places social struggles in and near centers of government generate far more paper than those far away.

(b) *Preservation*: what social processes destroy or preserve documents? We must consider not only the destructiveness of war and fire which often are random destroyers of texts and the wishes of loving (or hostile) relatives for preservation (or elimination) but also the existence of organized agencies for preserving or eliminating the records of the past. The existence of well-trained and dedicated archival professionals is more probable in some countries than others, more (we may speculate) in large urban centers, more in relation to some subject matters (but which?) than others. (The study of the professional cultures of archivists would seem an important agenda for a self-critical history.)

When economists, sociologists, or political scientists turn to archival sources to construct statistical series about social processes that extend over time and space they are likely to encounter several problems. Some of these problems may be amenable to amelioration by statistical manipulation but others demand the kinds of analysis of sources that are characteristic of historians—and still others call for both in conjunction.

(a) *Missing data*. Random document loss from moisture, fire, and the gnawing criticism of the mice; deliberate destruction of troublesome records by those who might be embarrassed by some datum or data; and errors in filing by clerks all generate considerable missing cases in many potentially valuable data series. Statistical judgments about the appropriateness of completing the series by extrapolation and interpolation from surviving data may be complemented by the institutional knowledge that sometimes permits a researcher to find an alternative source for the same data.

(b) *Changing definition*. Much data of interest to states is subject to changing definition and therefore many series of great interest to social scientists cannot be used intelligently without a study of those definitions. Crime, ethnicity, conflict, and poverty, for example, are all subject to considerable redefinition, both formally and informally. To make use of any long data series on crime, one would have to have acquired considerable knowledge of the changing interests of states in accurate data collection for different kinds of offenses. One would also have to know something of the changing mores that redefine actions as criminal or not (and which kind of crime they are). In addition, the boundaries of such administrative subdivisions as counties and municipalities often change, and a study of changing administrative geography is often an essential step on the way to some form of statistical correction.

5. *Challenges to Professional Traditions*

The last quarter or so of the twentieth century saw challenges to such notions of research methods from several converging sources. Since what was easy to examine with prevailing methodologies were those facets of human experience that had left traces in the documentary collection of states, the subject matters of professional history gave great weight to adults, men of weapon-bearing and income-earning age, dominant ethnicities, state politics, and dominant powers on the world scene. Those curious about other realms of human experience, including members of some of the under-represented groups and places, were led to develop new methodologies.

To some extent these involved innovative use of state archives, as in the mobilization of records of births and deaths to develop the new historical demography, a vital window on the past lives of ordinary people. To some extent these involved the use of new kinds of sources, as in the discovery of the value of visual materials for clues to the history of childhood or aging. To some extent these involved extensive interaction with other social science disciplines, as in important interchanges with anthropology in the hope for getting a handle on people whose activities have left less easily pursued traces in the written records of states or in the importation of quantitative methods from economics, sociology, and political science (Rabb and Rotberg 1982, Revel and Hunt 1995).

Fueled by these trends, and fueling them, professional historians became inclined to doubt the clarity and coherence of the entire project of a scientific history. This further eroded the rationale for a methodologically distinctive enterprise, thus opening the way for even further cross-disciplinary fertilization. But it also opened the way for a radical skepticism about any form of historical knowledge or inquiry whatsoever. In the last quarter of the twentieth century, increased sensitivity to the ways in which the subject matter and methods of past historical research had been intertwined with social power was leading some to abandon the notion of any coherent historical truth altogether (Appleby et al. 1994).

6. *Challenge and Opportunity of Electronic Information Technology*

The new information technology becoming increasingly widely available at the end of the twentieth century seemed likely to reshape the ways in which archives would be used and perhaps to reshape what an archive was.

(a) *Cataloguing* could now be enhanced radically. Particular items could be cross-classified in innumerable ways since electronic data files are not subject to the same sorts of space limits as a catalogue's page or a card file, making it easier for researchers to find all that is relevant. User-manipulated databases meant that users could sort through files according to the categories important to them, relieving them, to at least some limited extent, of the challenging burden of mastering the intricacies of the classificatory systems of particular archives. Since electronic information could be transmitted around the world at high speed through the Internet, researchers were becoming less dependent on visits to distant archives to have some notion of their contents.

(b) *Reproduction* of documents was immeasurably enhanced. Age-old errors of transcription, inherent in hand copying of archival materials, were alleviated by the development of microfilming technologies, and further reduced by photocopying. Both microfilming and photocopying technologies enhanced the labors of researchers from afar. But they also meant that archives and research libraries could duplicate their own scarce holdings and distribute them either to individual scholars or other research institutions. The potential of high-quality electronic scanners as input devices to computers was only at the very beginning of use in archival work at the beginning of the twenty-first century, but no one could doubt that the potential impact on research activities was going to be enormous. Not only could a visiting scholar store large collections of source materials, but such materials could also be readily transmitted to far-off scholars. If, as seems likely, there come to be improvements in the quality of software for optical character recognition, an electronic archive including scanned documents opens up the possibility of high-speed searches according to multiple criteria, further freeing researchers from the idiosyncrasies of particular catalogues.

(c) *Publishing*. New modes of electronic publishing, barely launched at the beginning of the twenty-first century, looked likely to be similarly revolutionary, and with similarly important implications for

redefinition of professional scholarly standards (Darnton 1999). A conventionally published book, for example, might omit its apparatus of learned footnotes and bibliography, but make them available to other interested scholars on a disk or an Internet site. One might speculate that this would lead to new forms of scholarly precision and richness (as scholars supplemented a basic text with footnoted references to sources, critiques of learned predecessors, methodological commentaries on sources or predecessors, annotated rather than bare-bones bibliographies, and even scanned copies of vital original documents). At the beginning of the twenty-first century, for example, it was technologically feasible for the learned footnote at the bottom of the printed page to be replaced by the electronic note in some online text in the form of a hyperlink to a scanned copy of the referenced text itself. Such super-references would actually send the primary sources to the reader's screen or printer, rather than tell the reader in which place in which archive the source could be consulted (if that reader had the time and the good fortune to win a fellowship and to have a dean kind enough to grant leave). The capacity of historians to check each other's research against the primary sources would be greatly facilitated. Graduate students with no research funds to travel to document collections could nonetheless hone their critical faculties by studying the sources of prominent works without mastering archival idiosyncrasies.

7. *The Future of Archival Methods*

The new technologies, moreover, were opening up what could be called *the electronic archive* (Shapiro and Markoff 1998). Databases, possibly accompanied by programs to facilitate use, once created, could be readily distributed, and even augmented by new scholars.

Possible consequences for the future culture of historical research might include:

(a) Blurring the distinction between research on primary and secondary materials as researchers grew comfortable with electronic archives built of many components that might range from scanned primary sources, quantitative data extracted from such sources, quantified data created from such sources by a researcher, and new variables or indexes added by a community of users.

(b) Blurring the distinction between archival and published primary sources as information became available in electronic form, regardless of whether it was extracted from a book or found in an archival dossier.

(c) Increasing attention to issues of representativeness of large bodies of data (and diminished concern for the traditional criticism of sources?).

(d) More research using primary sources by social scientists with the appropriate technical skill who were not employed by departments of history.

(e) Increasing use of archival materials by scholars, whether professional historians or not, who are not primarily specialists in the national history of the country from which the data are derived as it becomes easy for someone on the other side of the planet to use an electronic archive without having to master the particularities of traditional repositories of documents.

(f) Increasing accessibility of materials vital to historical problems that cross national frontiers, as teams of scholars assemble relevant electronic archives.

In such ways the boundaries between history and the other social sciences may become less sharp than they have been since the emergence of the social science disciplines.

Archives and Historical Databases

This article discusses the history of archives from antiquity to the present day. It makes clear that archives follow a legal tradition that reaches back to the beginnings of occidental civilization. The use of archives for research is a relatively recent development that basically began with the French archives law of 1794. A broad organization of archives, both public and private, has developed since that period and now encompasses all the countries in the world. The scope of this material (i.e., charters, records, registers, maps, plans, audiovisual media, electronic documents, private collections, and archives) and its appraisal pose serious problems for archivists today. Those problems include all questions dealing with preservation and information technologies.

1. *Terminology and History of Archives*

The term 'archive' comes from *arché*, the Greek word for beginning. In Herodotus' *History*, *Archeion* is the town hall or government office. The word was not used to refer to preservation of the written word in ancient Greece, but was used in that manner by Josephus and later by Eusebius during the Hellenistic period. Roman jurists later adapted the Greek *Archeion*, using it in the Latin *Archium* and later *Archivum*. By the end of the fourth century, *Archivum* refers to the place where public records are preserved (*locus quo acta publica asservantur*). The archival tradition, therefore, is not based on the concept of preservation for research, but it was preservation for public administration purposes. Elements of this idea that archives only preserve public documents can still be found in present-day British and Dutch archives. It follows that the English language makes a difference between records that possess legal character and papers that possess no such qualities. The official character of such archival material, as well as the fact that its preservation is a responsibility of the state, both explain the understanding of public faith and the concept of unbroken custody in the Anglo-Saxon world.

Research done by Johannes Papritz, Ernst Posner, and others indicates that clay tablets from 3000 BC found in the Near East were preserved to facilitate commercial and public administration. Strictly speaking, these tablets are registries, but were not intended for permanent preservation as an archive. Literature that uses the term 'clay tablet archives,' often referring to the royal palaces of Minoan civilization on Crete and the Palace of Nestor at Pylos (Peloponnese), is therefore misleading. While clay tablets are exceptionally durable, even fire-resistant, other material used to write on, such as leather, wooden tablets, or papyrus, proved to be less durable. Finds of such materials are therefore quite fragmentary. In Athens, laws and decrees of councils and assemblies, documents concerning acts of state, and copies of state-commissioned plays were stored at the town hall and, after the fourth century, at the Temple of Kybele. In Rome, senate resolutions were kept in the Temple of Saturn until 78 BC, and after that time senate minutes, state payment demands, census records, and so forth were placed in the 'Tabularium.'

Some remains of this ancient tradition can be found in the registers of the Middle Ages, that is, in the secure documentation of resolutions and records through continuous notation on archival tablets, which were later replaced by papyrus rolls. In 538 AD, emperor Justinian ordered all cities to preserve the *commentarii* and *gesta municipalia*, to facilitate jurisdiction, in a separate location, the *Archeion* or *Archivum*. Nevertheless, political upheavals in late antiquity and the beginning of the medieval period led to breaks in archival traditions. Roman registers can still be found in the cities of northern Italy and Gallia Cisalpina. Notary registers as compiled by Johannes Scriba of Genoa came into use in the middle of the twelfth century. The Papal Curia reintroduced register-keeping in the eleventh century (on parchment since 1088, though only records from 1198 survived due to a fire in the Lateran). The papal example may have had influence on the creation of a royal archives in Aix-la-Chapelle under Charlemagne. The lack of a permanent residence among his heirs prevented the development of an archival organization. The influence of Persian–Arabian legal practice under Norman rule in Sicily could still be felt in France and England in the twelfth century.

Unlike the archives of antiquity, those developed in the medieval period did not serve the public interest in the first place, but rather helped to secure legal positions of individual institutions and groups, i.e., church and monastic repositories, municipal archives, and archives of the nobility. The refinement of paper in the fourteenth century led to a reorganization of office and chancellery management. Registers, minutes, bills, and so forth became an administrative memory. Older archives were rearranged and concentrated in the fifteenth and sixteenth centuries: the Spanish court archives at Simancas (1548) is one notable example.

2. *Modern Archives since the French Revolution*

The French Revolution was an important turning point in the advancement of the archives. It was the revolution that introduced the developments we associate with archives today. The concentration of archival materials in central locations, the organization of an archives administration, the civil administration's jurisdiction over registries, public access,

and historical research are all characteristics of this new world of archives.

The National Archives in Paris, established in 1789–90, was initially intended only for the preservation of records produced by the national assembly. Records from *ancien régime* administration boards were not incorporated until 1793. The law passed on June 25, 1794 declared the National Archives to be a *Centre Commun*, giving citizens the right of access to the documents preserved. Two years later, the departmental archives were created and put under the jurisdiction of the National Archives. Much literature refers to 1794 as the 'constitution' of modern archives. Napoleon's 'Universal Archive' of 1810–11, which integrated important artifacts from the conquered German empire, Austria, Italy, Spain, and the Vatican, lasted only briefly. What made the National Archives revolutionary was the fact that the arrangement of the archives followed the librarians' principle of pertinence. In 1839, initial calls were made, however, to introduce in the departmental archives the principle of provenance, which was codified in a circular on April 24, 1841. This concept of *respect de fonds* stipulates that all records created by one institution remain together. The paleographer Natalis de Wailly said of it, '*La methode est fondée sur la nature des choses*.' The same principles were introduced on a municipal level in 1857.

In 1861, the principle of provenance was realized in Denmark's ministerial archives. In Germany, it was Prussia that prescribed the principle of provenance with the regulation of July 1, 1881: 'Every government board will, once it generates records, receive its own repository.' The regulation initially applied only to the Prussian Secret State Archives. Not until 1896 were the provincial archives advised to follow suit. Primary credit for the international success of the principle of provenance in the following decades must be given to the Dutch: in the Netherlands the principle of provenance was introduced in 1897. The archivists Samuel Muller, Johan Adriaan Feith, and Robert Fruin described the principle of provenance in their handbook of archives, achieving worldwide recognition for Dutch archival theory. Translations into German (1905), Italian (1908), French (1910), and English (1920) followed. The conclusion of this discussion, which dominated the late nineteenth and early twentieth centuries, came at an international conference in Brussels in 1910. Archivists claimed the principle of provenance as fundamental for their profession. The principle of provenance had been accepted by Denmark in 1903, and by Sweden and the USA in 1909. Vienna's Haus-, Hof- und Staatsarchiv accepted it in 1914. In 1920 Hilary Jenkinson achieved implementation in England, where the law had controlled archives since 1838. A decree by Lenin issued on June 1, 1918, dealing with the reorganizations of archives, gave Russian archives the chance to respect the principle of provenance whenever possible. An international conference in Stockholm in 1993 proved that the principle of provenance continues to play a role in international archival theory and discussion.

3. *Records as Historical Sources: Appraisal and Use*

Historical research and the development of critical methods, as exemplified by the German editions of the *Monumenta Germaniae Historica* since 1826, promoted archival description of older documents. Inventories have been published in England, France, and Belgium since the third decade of the nineteenth century. Editions of charters and records from Prussian archives have appeared since 1878.

While historians in Germany still discussed Karl Lamprecht and his cultural and sociohistorical theory from 1893 to 1898, archivists were already discussing topics that were very modern at the time, such as whether or not to preserve judicial records, which contained material on the administration of justice as well as the moral, financial, and economic circumstances of different classes of society. There were demands for the preservation of records relating to the labor movement and social questions, for census records and, from 1904 onward, there were tendencies to preserve archives from private firms. It is no coincidence that during the first decade of the twentieth century in Germany the first private business archives were established. These were quite different from Europe's preindustrial trade and merchant registries that survived from the late Middle Ages (e.g., the Datini archives in Prato).

The disintegration of states and society as well as the massive amount of documentation in the twentieth century has led to an international discussion on archival appraisal and preservation. All efforts to come up with a generally applicable model of appraisal have led to dead ends. Obviously, every model of appraisal is in a certain way subjective in that historians' initial questions are formed by their generation: 'Every political system considers different documents worthy of preservation' (Papritz 1983). A free society cannot dictate binding rules for appraisal. The result of this insight was a closer look at Theodore R. Schellenberg's (1903–70) theories. Schellenberg, former administrative head of the US National Archives, first published *Modern Archives. Principles and Techniques* (Schellenberg 1964) in 1956. In the Anglo-American world at least, Schellenberg's ideas changed appraisal theory fundamentally. Schellenberg called for the appraisal of an entire institution's records. Besides the information in the documents about people, places, and events that were documented (the 'content' of records), the principle of evidence is focused on. Evidence in public records involves the archivist finding out how the originating government bodies functioned and what competence they had. For

appraising purposes it is indispensable that the archivist knows how the records in question were produced. The decision of whether or not to preserve records is then made on both formal and content-based criteria.

Papers issued by the Paris-based International Council of Archivists (ICA) indicate that networks of archives exist worldwide, even in developing nations. Because of its rich cultural tradition, China has the greatest number of archivists. Most countries have laws regulating users' access to archives. Conditions on access vary greatly. The Vatican only allows access to documents originating before 1922, while Scandinavians enjoy freedom of information rights that include access to current registries. In the Anglo-Saxon countries and in Germany there is a limitation on access of 30 years. Records on individuals and private data are regulated separately.

4. *Current Problems: Preservation and Information Technology*

Archives deal with two major problems today: the conservation/preservation of archival material, and the effects of information technology. The material that is to be preserved does not age well, compared to medieval parchment. It requires the employment of complicated preservation techniques, among them restoration, microfilm, and digitization.

As far as information technology is concerned, archives are presented with two major challenges: they must develop models for appraising and taking over of electronic media, and they wish to provide universal access for researchers as well as for an interested public. The NARA (National Archives and Record Administration) in Washington, DC are the most experienced in this field. As of May 1999, some 100,000 files comprising more than 500 gigabytes had been taken over and stored there. Some 10,000 new files are expected to be added every year. Data that is transferred must first be copied onto separate tapes or cassettes. This procedure then has to be repeated every 10 years (concept of migration). A provisional list of the data available can be found on the Internet. Since data loss can occur in the copying process, Jeff Rothenberg has come up with a concept for emulating software that allows archivists to make copies using the original or related programs. The concept is currently undergoing tests as part of a project in the Netherlands. The goal of the project is the long-term preservation of digitized data in their original, authentic form (concept of emulation). In Germany, the German federal archives, the *Bundesarchiv*, is the most experienced in the appraisal and storage of digitized data. The *Bundesarchiv* is involved in a pilot project sponsored by the federal administration office called DOMEA (Document Management and Electronic Archiving in IT Supported Operations), which is developing methods of saving, appraising, and preserving electronic files permanently.

For research purposes, the new possibilities which allow the searching of archives both nationally and internationally via the Internet are especially interesting. In Germany, most archives are accessible via the Internet. The state of North-Rhine Westphalia alone has made some 450 guides to state, municipal, church, and business archives accessible for Internet users. Marburg Archive School has presented the prototype of an online search aid especially suited to German descriptive methods, but also with an interface to an international standard of Internet presentation of search aids.

A major undertaking being discussed internationally is called EAD (Encoded Archival Description). In the USA the Berkeley Art Museum, California State University, and the Library of Congress were instrumental in developing EAD, and have been joined by the Public Record Office in London. EAD has found an ever growing following in the Anglo-Saxon world since the mid-1990s. It has meanwhile been made compatible with the international ISAD standard issued by ICA. Actually implementing these standards on a large scale requires a retroconversion of handwritten and typewritten search aids to a digital format. In Britain, home to some 2000 archives, the National Council on Archives introduced an archival network in 1998, which, after retroconversion of existing search aids, will provide a virtual guide to the archives and an incentive to make increased use of the archives over the Internet. The San Francisco-based Research Library Group (RLG) knows no national boundaries. Founded in 1974, the group comprises some 160 member universities, libraries, archives, museums, and scientific organizations. Databases of libraries and digitized finding aids of archives are made accessible by RLG.

In the 1990s, technological progress has changed archives in a way experts never thought possible. Following the digitization of archival guides, and the retroconversion of existing search aids and the organization of this metadata into databases, the digitization of entire fonds seems at least possible. Most progress has been made in digitizing collections of individual items like photographs and posters from various institutions such as museums, libraries, and archives. The digitization of files, that is, documents with several pages, has not yet begun. Information technology has made archives still more accessible and interesting for the public and has blurred the lines between archives, libraries, and documentary institutions.

Archiving: Ethical Aspects

1. Archiving Social and Behavioral Research By-products

Archiving refers to the process of appraising, cataloging, organizing, and preserving documentary material—of any type and in any medium—for open use by specific (e.g., scholarly) or general audiences. The social and behavioral sciences produce intellectual by-products at various stages of the research process that, if preserved and organized, could further basic and applied research, aid policy making, and facilitate the development and replication of effective social intervention programs. A variety of institutions preserve such materials. They include government archives, academic data archives and libraries, and specialized organizations in both the public and private sectors. Professional organizations of social science archivists and librarians have been formed to further the field.

The National Archives and Records Administration (NARA) is the US federal agency that preserves and ensures access to those official records which have been determined by the Archivist of the United States to have sufficient historical or other value to warrant their continued preservation by the Federal Government, and which have been accepted by the Archivist for deposit in his custody (44 U.S.C. 2901). Information about NARA's electronic records holdings (most of which are data files) can be obtained from the Internet site http://www.nara.gov/nara/electronic.

The Inter-university Consortium for Political and Social Research (ICPSR) is the largest academic-based social science data archive. Founded in 1962 at the University of Michigan, ICPSR is a membership-based organization which provides access to a large archive of computer-based research and instructional data in political science, sociology, demography, economics, history, education, gerontology, and criminal justice. More information about ICPSR and its holdings is available from http://www.icpsr.umich.edu.

Sociometrics Corporation was established in 1983. The company's primary mission is the development and dissemination of social science research-based resources for a variety of audiences, including researchers, students, policymakers, practitioners, and community-based organizations. Sociometrics has pioneered in the establishment and operation of topically-focused data, instrument, publication, and (since the mid-1990s) program archives (http://www.socio.com): (a) *Data Archives*: collections of original machine-readable data from over 300 exemplary studies, many of them longitudinal, on the American family, teen sexuality and pregnancy, social gerontology, disability, AIDS and STDs, maternal drug abuse, and geographic indicators; (b) *Instrument Archives*: the questionnaires, interview protocols, and other research instruments that were used to collect the data in the data archives; (c) *Bibliographic Archives*: collections of abstracts of research papers, books, and other publications dealing with topics covered by the data archives; and (d) *Program Archives*: collections of program and evaluation materials from several dozen intervention programs that have proven effective in preventing risky behaviors such as unprotected sex and drug use. These topically-focused archives synthesize research in the field in one

place; facilitate further research with the best existing data and accompanying instruments; promote data-based policymaking; and help service providers and practitioners use the insights gained from research.

Two professional organizations of social science data archivists and librarians are the Association of Population Libraries and Information Centers (APLIC) and the International Association for Social Science Information Service & Technology (IASSIST). APLIC's membership, consisting of both individuals and organizations, represents some of the oldest population and family planning agencies and institutions in the US. IASSIST is an international organization dedicated to the issues and concerns of social science data librarians, data archivists, data producers, and data users. This unique professional association assists members in their support of social science research. The APLIC and IASSIST membership lists provide pointers to the various social science data collections housed all over the world. (http://www.med.jhu.edu/ccp/aplic/APLIC.html; http://datalib.library.ualberta.ca/iassist/index.html).

2. *Ethical Aspects in Archiving*

The development of collections such as those contained in the above archives involves a series of decisions with ethical considerations and implications.

2.1 *Protecting the Integrity of the Selection Process*

Given the limited nature of resources allocable to archiving, how should the contents of the collection be selected? Some archives sidestep this challenge by merely cataloging and warehousing archival material (e.g., data sets) donated to them by the field. While this procedure undoubtedly results in the lowest per-capita archiving cost, the quality of the resultant archival collection is uncertain at best. A better procedure is to set objective technical and substantive standards for inclusion in the archival collection and then actively recruit material meeting or surpassing such standards. The previously described data and program archives at Sociometrics have worked with Scientist Expert Panels in establishing criteria for inclusion in the various collections. For the data archives the selection criteria are scientific merit, substantive utility, and program and policy relevance of the data sets comprising the collection. For the program archives the selection criterion is documented effectiveness in preventing the social problem or disease (e.g., drug use, teen pregnancy, sexually transmitted disease, HIV/AIDS) or in changing these problems' risky-behavior antecedents (e.g., delaying age at first intercourse, increasing the use of contraception and/or an STD-prophylactic at first and every act of sexual intercourse, abstaining from or reducing the frequency of drug use). Having established these objective inclusion criteria, archive staff then work with their respective Scientist Expert Panels to identify and prioritize available data sets and intervention programs for inclusion in the collections. The end result is an archival collection with integrity and credibility.

2.2 *Protecting Respondents' Confidentiality*

Data archives often contain responses to sensitive questions, some of which, for example, ask respondents to admit to illegal, immoral, or 'private' behavior such as abortion, premarital or extramarital sexual activity, mental illness, alcohol abuse, and drug use. How can researchers' need to know (the incidence, prevalence, antecedents, and consequences of these social problems) be balanced against respondents' rights to privacy? This ethical consideration is most often addressed by stripping all archival material of information that could be used to identify individual subjects, for example, name, address, social security number, exact date of birth (often only month and year of birth are included in a public use database). A problem arises when data holders want to strip the data set of key variables such as those measuring the sensitive behaviors listed above, prior to placing a data set in a public use archive. This desire is motivated by the fear that such information could be linked to particular respondents by malicious, hardworking sleuths, even without the help of individual identifiers such as name, address, and so forth. Such censorship restricts the range of uses to which the data set can be put by future researchers, and archives typically make an active attempt to find alternate solutions. For example, users could be asked to sign a confidentiality agreement prior to being allowed access to the data, pledging to use the data for legitimate research purposes only.

2.3 *Censoring Potentially Controversial or Offensive Material in the Collection*

Intervention program archives occasionally encounter an analogous censorship-related challenge. For example, several of the effective programs selected for archiving by the Scientist Expert Panel for the Program Archive on Sexuality, Health and Adolescence (PASHA) contain sexually explicit material that could be viewed as offensive and inappropriate by some individuals and communities. However, because these prevention programs are targeted at high-risk, already sexually active youth, the material could also be seen as appropriate, even necessary, to drive home relevant points. In addition, these programs, like other PASHA programs, meet the collection's inclusion criterion of demonstrated effectiveness in changing sexual risk-related behavior in at least one subgroup of teens. The

decision was made to include the material without alteration or censorship, but to publicize and disseminate the collection as an eclectic one, with different schools and communities encouraged to replicate those programs consistent with their own values, norms, and target populations. A complimentary program abstract was developed so that both the approach and the content of the program packages could be perused prior to requesting the program from the archive.

2.4 Timing of Release of Information to an Archive

Holders of data sets and developers of effective programs often, and understandably, want to reap some payoff from their professional investments by keeping the data or programs to themselves until they have published what they wish from the data (or tweaked the intervention program to their satisfaction). The ethical issue arises when this 'private' or 'proprietary' period of time stretches to what the field would view as abnormally long. This is especially true when the data were collected, or the intervention program developed, with government funds. Several US federal agencies are trying to forestall the problem by building resource-sharing ground rules into the original funding award document. Thus, the grant or contract may specify that the data to be generated from a research study will be placed in a public archive two years after the expiration of the project. This solution gives the original developer the fair 'head start' their efforts have earned, while ensuring that the data collected with government funds will be shared with the field before it gets stale.

2.5 Assignment of Due Credit to Both Original Producer and Archivist

Data sets and program materials typically are received by an archive in a format that data developers and their colleagues found workable, but one not yet suitable for public use. The archivist contributes significant additional value in preparing the database for public use. For example, with the approval of the data donor, inconsistencies in the database are eliminated, or at least documented. The documentation is augmented, both at the study level (describing study goals, sampling and data collection procedures) and at the variable level (assigning names and labels for each variable; documenting algorithms for constructed scale variables). Occasionally, the variable and scale documentation is done using the syntax of a popular statistical analysis package such as SPSS or SAS, facilitating future data analysis. Archivists who prepare intervention program packages for public use make analogous contributions. Program materials are edited and 'prettified' for public use. User's Guides and Facilitator's Manuals are created so that the package is replication-ready in the absence of the original developer. In short, the archiving process is best viewed and executed as collaboration between original developer and archivist. Care must be taken to give due credit for the final product to both individuals, teams, and institutions.

2.6 Tension between Fidelity and Usability in the Archiving Process

The collaborative model is productive not only for assignment of due credit but also for joint resolution of the fidelity vs. usability issues that occasionally arise during the archiving process. Should obvious errors in the data-base be corrected or only documented? Should original program materials that were found effective in the developmental site be altered when replication sites find them unclear or when the curriculum they present is based on out of date data? Issues such as these are best resolved on a case-by-case basis by the archivist and original developer working side by side in collaborative fashion.

2.7 Ownership of the Research and Development By-products

The purposes and procedures of the archive accepting the donation should be made clear to the donor at the outset. It should be communicated to data donors that the research by-product they are donating is being put in a public archive whose main goal is the preservation of the resource. Some archives also actively publicize and disseminate their holdings. In addition, as seen above, archives vary in the extent to which they work with the donor in 'upgrading' the material for public use. The donor should be informed in advance of what to expect along these lines. Issues of credit and ownership should also be agreed to before archiving work begins. How will professional credit for the collaborative product be allocated? Will the resultant product be sold to the end user (at cost or for profit) or given away? If the product will be sold for profit, will royalties be given to the original developer? If the product will be sold at cost, will free or discounted copies be made available to the original developer?

3. Conclusion

Social science research yields many by-products that, if properly archived, could be used to further future research, aid policymaking, and foster the development and replication of effective prevention and treatment programs. Several challenges, some with ethical implications, arise in the archiving process. All

are resolvable with good will and commitment to the public good on the part of both original developers and archivists.

Arctic: Sociocultural Aspects

Western curiosity about the peoples of the North can be traced back to the ancient Greeks. Still, the anthropological study of the Arctic as an area of shared cultural traits and environmental conditions hardly predates the year 1900. The early twentieth century paradigms of diffusionism and environmental determinism were instrumental in creating the simplistic notion of a unified Arctic or circumpolar culture (e.g., Bogoras 1929, Hatt 1914). Detailed ethnographic research conducted since that time has demonstrated that variation is an intrinsic characteristic of Arctic sociocultural systems (some of this research is summarized in Berg 1973, Graburn and Strong 1973, Irimoto and Yamada 1994). Nevertheless, this article approaches the subject by focusing on sociocultural similarities, without denying the existence of considerable differences.

1. *The Arctic and Its Indigenous Inhabitants*

Culturally, the Arctic can be subdivided into a North American and a northern Eurasian part. The North American Arctic is primarily inhabited by speakers of Eskimo-Aleut languages. The old collective ethnonym Eskimo is little used today, and commonly replaced by Inuit and Yupik. Aleut, Yupik, and Inuit societies inhabit the coastal areas of northern North America, stretching from southern Alaska to eastern Greenland. Here the geographical boundary between Arctic and Subarctic coincides more or less with the cultural boundary between Inuit/Yupik/Aleut and Athapaskan and Algonquian groups of North American Indians (see *North America and Native Americans: Sociocultural Aspects*).

In the northern part of Eurasia, the physical boundary between Arctic and Subarctic does not coincide as neatly with cultural boundaries. In Siberia, the cultural realm of the Arctic extends into the Subarctic ecological zone, and reaches its limits only in the steppes of southern Siberia. Samoyedic Tungusic, and Paleoasiatic languages are spoken by the culturally 'most typical' Siberians. Speakers of Turkic languages inhabit large parts of the eastern Siberian tundra and boreal forest, but their historical and cultural background points to Central Asia. In northern Europe, where the vegetational and climatic zone of the Arctic is narrow, conventionally only the Saami (speakers of Finno-Ugric languages) are considered an indigenous Arctic people. Other peoples who also inhabit the northern margins of Europe but are organized into large-scale agricultural societies, are not considered in this overview (see *Europe: Sociocultural Aspects*).

2. *Indigenous and Colonial Histories*

Human habitation of the circumpolar North extends over several thousand years. The direct presence of European colonial powers in the Arctic is a relatively recent phenomenon, but findings of iron and other items that were not produced locally attest to long-standing connections with trade centers to the South. The territory of the Saami has a history of almost 2,000 years of outside intervention, as Vikings pushed north along the western coast of contemporary Norway to extract natural resources and to acquire items of Saami production through trade and tribute. Similarly, European expansion into other parts of the North was fueled by the quest for marketable resources. From the seventeenth century onwards, the rich boreal forests of Siberia and Canada became staging areas for the fur trade. The areas north of the tree line were little affected by fur trapping prior to the twentieth century, but the coastal areas of the Arctic close to the Atlantic and Pacific Oceans became important destinations for the Euro-American whaling industry in the eighteenth and nineteenth centuries.

The early days of colonial rule had little direct administrative impact in many areas of the North. Often it amounted to little more than the purely nominal claim to 'owning' the land, and to sporadic resource extraction. In certain areas, however, the state took a more active role in regulating the lives of the indigenous population: For example, in Greenland a particular form of 'enlightened paternalism' was the guiding principle of Danish rule from the eighteenth century onwards. The second half of the nineteenth century was in this respect far more disruptive than earlier periods: The newly emerging ideology of nationalism brought indigenous peoples from northern Scandinavia to Alaska under increasing pressure to adopt the language and culture of the respective dominant societies.

3. Domains of Arctic Sociocultural Systems

The following section will provide a discussion of various aspects of 'traditional' Arctic cultures. Using the turn of the twentieth century as the ethnographic present, the material is organized along topical lines.

3.1 Ecology and Economy

Characteristic of the Arctic fauna is the relative small number of available species, while the number of individual animals at particular times can be high. Similarly, vegetation north of the tree line is sparse, enjoying only a brief but dramatic growing season. Thus, periods of abundance at a particular locale are followed by periods of shortage, and human groups must schedule their movements accordingly. Due to the wide distribution of permafrost, in combination with climatic and vegetational factors, the practice of agriculture was impossible until recently. Thus, all indigenous Arctic peoples practiced foraging forms of subsistence, such as hunting, fishing, and gathering (see *Hunting and Gathering Societies in Anthropology*).

In the tundra zone, collective hunts of wild reindeer (caribou) during spring and fall migrations constituted extremely important subsistence activities. Along the coasts of the Arctic Ocean the pursuit of sea mammals was life-sustaining. Seals formed the staple, and areas visited by migrating whales and walrus had the opportunity to acquire large quantities of meat through one successful hunt. The lower reaches of major rivers provided excellent opportunities for seasonal fishing. The inland areas of boreal forests could generally rely less on one or two major resources, but had to combine hunting (wild reindeer, moose, etc.), fishing, and gathering. The changes brought about by the fur trade triggered dramatic shifts in the seasonal rounds of the peoples inhabiting the Subarctic. The hunt for fur bearers, which previously had been of little significance, became the most important economic activity.

The major form of subsistence outside of hunting/gathering/fishing is reindeer herding, a form of pastoralism (see *Pastoralism in Anthropology*). Reindeer domestication is found in northern Eurasia, from northern Scandinavia to the Bering Strait, but did not penetrate into northern North America until the late nineteenth century. Among the various local forms of reindeer herding, two major types emerge. Small herds of domesticated reindeer are found throughout the boreal forest regions of Siberia; their primary use is for transportation during hunting. Large-scale reindeer herding of the tundra, on the other hand, is geared toward the maximization of animal numbers, and provides the group with meat and other reindeer products. The only pan-Arctic domesticated animal is the dog, which is used for transportation (and sometimes as a sacrificial animal).

Most economic production was geared toward household and community consumption. Sharing of resources within these limits was a consistent feature of Arctic and Subarctic societies. Exchange relations with other communities were often facilitated through ritual partnerships which extended the limits of reciprocity. With the advent of colonialism, production for outside markets commenced: Furs, meat of domesticated reindeer, and other products were individually appropriated; they fueled the emergence of economic stratification.

3.2 Social and Political Organization

It has long been suggested that Arctic societies are characterized by a bilateral type of social organization (Gjessing 1960). Traditional Saami societies, the Paleoasiatic groups of northeastern Siberia, as well as the majority of Inuit and Yupik societies clearly fit this pattern. The societies inhabiting the western, central, and eastern parts of Arctic Siberia, however, display patrilineal types of organization. Given the fact that vectors of cultural influence in Siberia run generally from south to north, it is possible to suggest that unilineal social organization among those groups was stimulated by southern (Central Asian) influences. The unilineal tendencies of certain Yupik and Aleut societies are less easy to comprehend. There are indications of patrilineal 'clans,' sometimes with endogamous tendencies; however, the basic bilateral framework of Eskimo-Aleut societies (privileging horizontal links over lineal ties) is also present in these cases.

It is noticeable that none of the Arctic or Subarctic societies of Eurasia show any traces of matrilineal organization. In Subarctic North America, on the other hand, the majority of northern Athapaskans (including the linguistically related Eyak and Tlingit) are textbook examples of descent reckoned in the female line. Generally speaking, the Subarctic forests are dominated by unilineal kinship systems. However, it is unclear whether there is a causal relationship between unilineality and Subarctic lifeways and between bilaterality and tundra lifestyles. While bilateral systems are more flexible and seem more appropriate for small-scale groups scattered over large territories than more rigid unilineal systems, population densities in the boreal forests were hardly larger than in the tundra. On the contrary, certain Arctic coastal communities (e.g., near the Bering Strait) sustained quasi-sedentary settlements of several hundred inhabitants; other than along the mouths of salmon-rich rivers, no comparable population concentrations are known from the aboriginal Subarctic.

Throughout the circumpolar North, political organization was local-group-oriented and did not entail hierarchies based on hereditary status. Leadership continues to be situational: It is directed toward the solution of group problems, and the decision to

comply is voluntary. In addition to seniority, individual achievements are most relevant in gaining leadership positions. The major exception are the Sakha/Yakut, whose political organization has been characterized as a chiefdom (Graburn and Strong 1973). For the known cases of ranking in the southern parts of Alaska (e.g., Aleut, Alutiiq), influence from the northern northwest coast of North America (especially from the Tlingit) can be conjectured.

Men have often been the only political actors visible to outside observers. Although it is true that many Siberian societies with patrilineal descent have pronounced male-centered ideologies, not all Arctic societies were dominated by 'man, the hunter.' For example, Inuit males, who seemingly provided the large majority of food resources, were entirely dependent on women to process the meat and skin of the slaughtered animals, to make them into usable food and clothing. Thus, the roles of men and women were strongly complementary and did not sustain rigid gender hierarchies.

3.3 *Religion and Worldview*

Shamans and shamanism are probably the most evocative symbols of circumpolar religion and worldview (see *Shamanism*). There is no doubt that—until recently—most Arctic communities had religious functionaries who were able to communicate with and to 'master' spirits. These 'shamans' were engaged in healing and other activities aimed at improving communal and individual well-being. In the small-scale societies under consideration here, these functionaries held extremely important social positions, which sometimes led to an abuse of power. However, the notion of 'shamanism' can easily be misconstrued as a unified system of beliefs, which it never was in the Arctic. Instead, in addition to a limited number of common elements, circumpolar shamanisms show profound differences in the belief systems with which they are associated. Especially in northern Eurasia, elements of worldviews associated with highly organized religions (such as Buddhism or Christianity) found their way into localized forms of shamanism long before the direct impacts of colonialism.

Animism—the belief that all natural phenomena, including human beings, animals, and plants, but also rocks, lakes, mountains, weather, and so on, share one vital quality—the soul or spirit that energizes them—is at the core of most Arctic belief systems. This means that humans are not the only ones capable of independent action; an innocuous-looking pond, for example, is just as capable of rising up to kill an unsuspecting person as is a human enemy. Another fundamental principle of Arctic religious life is the concept of humans being endowed with multiple souls. The notion that at least one soul must be 'free' to leave the human body is basic to the shaman's ability to communicate with the spirits.

Since the killing and consumption of animals provides the basic sustenance of circumpolar communities, ritual care-taking of animal souls is of utmost importance. Throughout the North, rituals in which animal souls are 'returned' to their spirit masters are widespread, thus ensuring the spiritual cycle of life. While most prey animals receive some form of ritual attention, there is significant variation in the elaboration of these ceremonies. One animal particularly revered throughout the North is the bear (both brown and black), as has been demonstrated by Hallowell (1926) in his classic comparative study of 'bear ceremonialism.'

By the twentieth century, hardly any Arctic community had not yet felt the impact of Christian missionary activity. However, there is considerable variation as to when these activities commenced: Christianity reached the Arctic areas of Europe almost 1,000 years ago, while the indigenous inhabitants of the Chukchi Peninsula (Russia) had little first-hand experience of Christianity before the 1990s. Generally speaking, the eighteenth and nineteenth centuries mark the major periods of religious conversion in the Arctic. Although no other major world religion has significantly impacted the North, the spectrum of Christian denominations represented in the Arctic is considerable. There is also considerable variation in how 'nativized' the individual churches have become.

4. *Contemporary Developments*

Throughout the circumpolar North, World War II triggered developments that made the once-distant Arctic frontiers into strategically important areas. The resulting infrastructural and demographic developments altered the social fabric of the North and put an end to official policies of isolationism. The first two decades after 1945 were generally characterized by state policies geared toward 'modernization' and assimilation. It is frightening how similar state policies from Siberia to Greenland were: Native people were relocated from ancient villages to faceless new towns, a new emphasis on 'productivity' favored newly introduced economic activities over traditional subsistence pursuits, and educational systems were reoriented toward non-native knowledge and skills. It may seem ironic that the very same policies provided the educational infrastructure for those native elites who would challenge the political and cultural hegemony of the colonial powers in the years and decades to come.

Between the 1960s and the 1980s, radical political change affected most parts of the circumpolar North. With the exception of the Soviet North, the general tendency was to repeal colonial status and chart a course toward self-determination. In many cases, opposition to large-scale development projects served as a rallying point for newly developing indigenous

movements. For example, the conflict around the construction of the Alta hydroelectric dam in Norway in the late 1970s brought international attention to indigenous causes, and marks a sea change in the political history of the Saami. In Alaska, it was the discovery of oil in 1968 which put the long-neglected topic of native title to land on the agenda. The resulting 'Alaska Native Claims Settlement Act' (1971), which awarded title to 12 percent of Alaska's land, and cash compensation to newly created native corporations, was then considered a spectacular success.

One of the most impressive results of the era was the 1979 passing of the 'Home Rule Act' in Greenland, which provided for far-reaching autonomy within Denmark (control over most public affairs except defense and foreign relations). Between 1973 and 1993, Finland, Norway, and Sweden installed so-called Saami parliaments, which—although only advisory—provide Europe's northernmost indigenous peoples with powerful symbols of sovereignty. The most recent change on Canada's political map is the April 1999 creation of Nunavut, the first and only Canadian territory in which Inuit make up the majority population.

Developments in the Soviet North followed a different pace. The first 'ethnic' administrative units were formed in Siberia in the 1920s, when such events would have been unthinkable in most other countries, but the political conditions of the subsequent decades reduced notions of 'national autonomy' to mere propaganda instruments. Thus, the reforms of the late 1980s, which led eventually to the demise of the Soviet Union, gave hope for advances in the realm of native rights. Although many changes were undoubtedly positive, the social and economic situation of most native communities in the Russian North deteriorated throughout the 1990s. Many Siberian natives have entered the twenty-first century with nostalgic memories of the Soviet period.

The fact that most indigenous Arctic communities have come a long way since the days of colonial rule and outright discrimination should not blind us to persistent problems. Indeed, most communities face a plethora of cultural and social ills, which are enhanced by precarious economic and ecological conditions (see Smith and McCarter 1997). While many of these problems can be attributed directly to the impact of colonization, the option of isolation from global forces has long since disappeared (if it ever existed). Contemporary Arctic indigenous peoples have understood that the challenge is not to choose between 'Western' modernity and 'unchanging tradition,' but to find a livable combination of the two. Given the political sophistication of local communities, to work in the North has become a tremendously rewarding learning experience for anthropologists and other social scientists. No longer content with being mere objects of study but, at the same time, realizing the potential benefits of social science, Arctic communities are engaged in an ongoing process of defining collaborative and mutually beneficial research.

Are

Area and International Studies: Archaeology

Within the realm of formally constituted academic disciplines, archaeology is of relatively recent vintage, although interest in the past is a human universal. Every living society has developed means by which to explain its origin and past, and these conceptions of the past are inevitably used to explain, validate, or challenge current conditions. This interest in the past is an archetypal expression of the human mind and represents far more than idle curiosity about things that are either only dimly perceived or altogether unknown; it is a search for roots that are seen as endowing us with an earned and secure place within our social and physical universe. It is perceived and stated histories that locate individuals and groups within larger social networks and assign to them rights, privileges, and obligations vis-à-vis each other, and the resources they extract from it.

Given the universality of human interest in the past, and the importance concepts of the past have in constituting and validating social frameworks of existence, it is not surprising that the academic elaboration of this interest in the form of archaeology is among those scholarly disciplines that attract great popular interest. By the same token, the pursuit of archaeological studies and the protection of archaeological resources tend to be of interest to governments. Most governments regulate access to archaeological resources (sites, museum collections, etc.) and either directly or indirectly support archaeological research.

Since archaeology deals largely with physical evidence in the form of artifacts, geological sediments, remains of plants and animals, chemical and physical traces in the soil, etc., it is sometimes considered to be closely allied with the 'hard' sciences. In the popular view, the analysis of archaeological data results in establishing factual frameworks of what happened in antiquity with a high level of reliability. To some degree, this view is valid with regard to the most basic level of archaeological information and analysis such as dates based on physical and chemical techniques, descriptive studies of artifacts or features, statistical measures of distribution, etc.

Yet, while archaeology shares many of its primary analytical tools with the physical sciences, its ultimate goal is the interpretation of physical evidence in terms of cultural traditions and social behavior, organization, and structures and the processes and causes of their change. Thus, it is truly a social science and shares with the social sciences an important characteristic: archaeological explanations are formulated within, and are dependent on, conceptual frameworks which, in turn, are derived from, or articulated with, broader social philosophies.

In practice, this conditionality of archaeological explanations means that the results of archaeological research tend to be more or less strongly influenced, and in some cases controlled, by prevailing social and political philosophies. It also means that the regulation of archaeological research by governments provides opportunities for the manipulation of archaeological findings and interpretations for political ends and that archaeology may be, and is, used as an arena for cultural and political contests.

1. *Archaeology and Area Studies*

Since the pursuit of area studies aims at an understanding of the cultural and social conditions in contiguous geographic regions, and since historical constructs play such a central role in the construction of culture and social systems, one would expect that archaeology should play a relatively prominent role in the area studies enterprise. An appreciation of the long-term historical background and context under which artistic, intellectual, and social traditions have emerged, and of the conditions within which they have changed over short and long periods of time, as well as an understanding of autochthonous conceptions of history, should be of profound interest. Also, within the comparative methodological framework of the social sciences, the expansion of the heuristic perspective into ancient history and prehistory should be of great interest inasmuch as it vastly increases the range of variability of the human condition that is the subject matter of social science scholarship.

Among the forerunner disciplines of area studies, research into the ancient history and prehistory of colonial dependencies was a prominent and integral part of the activities of Orientalist and Africanist studies as practiced in the nineteenth and early twentieth centuries by academicians and amateurs tied to the great colonial powers of England, France, and Holland. In Asia, much of this work was carried out under the sponsorship of learned societies such as the Royal Asiatic Society of England, the *Ecole Francaise*

d'Extreme Orient, or the *Koninklijk Nederlandsch Aardrijkskundig Genootschap*, or by researchers and administrators associated with colonial government agencies such as the Archaeological Survey of India or the *Service Geologique de l'Indochine*. As a rule, economic, administrative, and scholarly interests were intermingled in the constitution and operation of these organizations.

The archaeological research carried out in those early years continues to provide much of our basal knowledge of the antiquity of those regions, and its findings and interpretations continue to linger in our contemporary perceptions of the pre-modern civilizations and societies of places like Egypt, the Levant, Mesopotamia, and the Indus Valley. At the same time, research in these places had great impact on the emerging discipline of archaeology itself and helped shape some of its fundamental techniques and methodologies. Further to the east, beyond India, the scope and quality of early archaeological work was somewhat more modest, but even there, it was far from negligible or inconsequential. Scholars of that tradition gave us our first detailed accounts and analyses of the 'classical' Buddhist and Hindu monuments of Burma, Cambodia, Indonesia, and Vietnam. During that period, archaeological research in East and Southeast Asia also penetrated deep into prehistory and provided us, among others, with such enduring concepts as the Dongson civilization of Vietnam, the Yangshao culture of China, the Hoabinhian culture of Indochina, and the Homo erectus-grade hominid fossils of Java, Indonesia, and Zhoukoudian, China.

Curiously, within the context of area studies as it emerged after World War II, archaeology has played a relatively minor role. This is surprising for a number of reasons. For one, the field of archaeology has, over the same period of time, seen exponential growth in terms of developments in method and theory as well as in terms of the number of practitioners. Moreover, the growing wealth of Western nations, together with extensive government support for scientific research, has made it increasingly possible for Western scholars to pursue research in far-flung corners of the globe. Finally, most postcolonial nations of Asia, Africa, and Latin America have developed indigenous cadres of archaeologists who are engaged in research programs within their countries, and sometimes beyond, often supported by their governments. Surprisingly, although our knowledge of the ancient history and prehistory of all parts of the world has increased dramatically over the past five decades or so, neither the pursuit of archaeological inquiry nor its results have attracted much interest in the context of area studies.

The relative neglect of archaeology in contemporary area studies probably has several causes. Among them is the strong social science orientation of archaeologists following the American archaeological tradition, which makes it difficult for humanists in the area studies field to appreciate either the processes or products of archaeological research. By contrast, Orientalists tended to practice archaeology from a humanist perspective, and many of them freely moved among a number of subject areas that we now consider distinct disciplines, including linguistics, philology, archaeology, art history, history, literature, and religious studies. Another likely cause of this neglect is that social scientists among area studies scholars tend to be strongly oriented toward contemporary issues and affairs, thus they see archaeology as of marginal relevance. The questions that emerge, then, are: can archaeology make a significant contribution to area studies? What is the nature of this contribution? And, is this contribution critical to our understanding of the social and cultural dynamics of diverse areas and regions of the world?

2. *Historic and Geographical Continuities and Discontinuities*

On a very basic level, archaeology allows us to reveal the broad historical and geographical continuities and discontinuities in social and cultural histories that underlie the emergence of ancient as well as modern cultures and societies and the political structures within which they are embedded. I mean here, for instance, important historical and prehistoric events that literally remade the human landscape, such as the advance of Neolithic farming populations into Mesolithic Europe beginning during the seventh millennium BC or the great migrations of the early first millennium AD; the Bantu expansion in Africa; the Inca conquests of the first millennium BC in South America; the great Han expansion in China during the early first millennium AD; the emergence of new technologies; the evolution of early cities and empires; the entry of world religions such as Buddhism, Islam, and Christianity into East and Southeast Asia. In all cases, these ancient events laid the foundations for subsequent developments in pre-modern and modern history so that their impact still reverberates today. It would be impossible fully to understand the contemporary face of any world region without being cognizant of this historical and archaeological background.

To some degree, discovery and elucidation of these events is based on sets of empirical data, the reliability of which depends chiefly on the amount and quality of archaeological fieldwork conducted. The interpretation of these events in terms of social process and causation, however, is governed by conceptual paradigms constructed within broader intellectual conventions. A good example of this is the issue of the formation of the early, protohistoric states of Southeast Asia. The evidence of these early states and civilizations is found in monumental architecture, sculptural and other arts, inscriptions, and settlement

patterns. All evidence attests clearly to the presence of cultural, artistic, and intellectual elements derived from India and China. The question is: through which processes, and why, did these elements come into Southeast Asia, and what role did they play in the formation of complex local polities?

Earlier generations of Orientalist scholars, influenced by nineteenth-century notions of the cultural capacity of tropical populations, had variously surmised that the process was one of military conquest, deliberate missionization, or colonization through expansionary trade and involved the imposition of colonial dependencies in Southeast Asia by Indian rulers (cf. Coedes 1968). That view was, at least in part, supported by indigenous historical traditions within the region. Expanding empirical archaeological data uncovered since the 1960s and paradigm shifts within the archaeological community have led to extensive revisions. The view at the beginning of the twenty-first century is that the process of state formation in the region was internally driven, and the acquisition of foreign ideologies and material goods, as well as even the construction of historical traditions claiming foreign descent for local rulers, were the result of competition between emerging indigenous elites (Higham 1996).

In a similar vein, when the Bronze Age antiquities of northern China were first discovered in the 1920s, Western scholars assessed them, correctly, as representing a very sophisticated technology and as being part of a highly developed civilization. Yet, they saw no evidence of gradual local development of either technology or the culture associated with it, and were disinclined on *a priori* grounds to credit early societies in China with such advanced developments. Instead, they sought a putative source in Western Asia, which they thought was the font of Bronze Age civilizations in both Europe and East Asia. More recent archaeological research has generated ample evidence for long-term continuous technological and social developments preceding the Shang state, and a change in archaeological thought has led to proposals that see continuities in Chinese tradition reaching back to prehistoric communities of the Yangshao level (e.g., Chang 1986, Keightley 1983).

It is evident that the broad historical and geographical continuities and discontinuities archaeology can reveal bear on our understanding of the growth and nature of contemporary cultural and social conditions. For that reason alone, archaeology should be an integral part of an area studies framework. Perceived continuities and discontinuities are also invoked in constructing historical consciousness and identity by individuals, groups, and nations, and, because archaeological interpretations are conditioned by given intellectual milieus, become malleable tools in ongoing social and political processes. With this, the conduct of archaeological studies as well as the use of its results enters the arena of contemporary political affairs, which is such an important part of international and area studies.

3. *Interpretive Frameworks and Political Agendas*

The conditionality of archaeological interpretations has become painfully clear in the context of decolonization. Since the 1950s, the conduct of archaeological research outside Europe and North America has increasingly passed from Western scholars to indigenous researchers, and the control of archaeological resources and research has passed from colonial powers to newly established, or re-established, nation states in Asia, Africa, and Latin America. In the process, archaeologists of the new generation have increasingly begun to reject older archaeological reconstructions as rooted in a colonial ideology and are engaging in vigorous revisions of interpretations that had become textbook wisdom in previous decades. A number of non-Western scholars have also argued, explicitly or implicitly, that the pursuit of archaeology should ultimately be restricted to indigenous researchers, not only because it engages their heritage, but, more importantly, it is felt that only indigenous researchers have the cultural knowledge necessary to interpret archaeological findings within their domain properly. The most extreme restriction on foreign archaeological research was probably found in the People's Republic of China, where Communist authorities after 1949 completely outlawed any involvement by foreign scholars in fieldwork. This ban was lifted only in 1990, and archaeological research by non-nationals in China is now permitted under highly regulated and supervised conditions.

While it may be difficult to find many examples of archaeological research projects under colonial rule that were explicitly promoted or conducted to advance colonial political interests, it would be even more difficult to deny that the conduct of research as well as its interpretive results were heavily impregnated by the colonial *zeitgeist* and its views of non-European cultures and societies. Thus, the postcolonial critique is justified in principle. By the same token, however, it must be recognized that the epistemological critique cannot be restricted to colonial contexts only. That is, the conduct of archaeological research (e.g., problem orientation, selection of evidence, etc.) and the interpretation of field data, are subject to influences of dominant social and political ideologies anywhere, including those of postcolonial societies.

In rare circumstances, state ideologies exercise overt control of archaeology, particularly in centralized, autocratic political systems. Egregious examples are found in Germany during the 'Third Reich' (Arnold 1990) and countries under Communist control like Russia, China, or Vietnam (Kohl and Fawcett 1996). In China after 1949, archaeologists were explicitly required to apply Marxist-Leninist theory as well as

Maoist thought in archaeological interpretation (Falkenhausen 1993). They were also told that archaeology, like all science, had to serve the goals of class struggle. Such ideological compulsion had relatively little effect on the reporting of empirical archaeological evidence, but it did force broader interpretive attempts into the procrustean bed of the Marxist-Leninist-Morganian framework of patriarchal, matriarchal, slave, and feudal social formations.

Archaeology is commonly exploited for political purposes in the context of defining and fostering local and national identities, advancing national unity in multi-ethnic states, and promoting national prestige, and in the struggle for supremacy among competing ethnic forces. Examples abound from around the world, including Europe (Diaz-Andreu and Champion 1996), the Middle East (Meskell 1998), and eastern Asia.

Trying to forge a new, postcolonial Filipino identity, President Ferdinand Marcos promoted the notion of an early Malay *barangay* society as the basis for Philippine social organization and projected himself as a personification of an ancient Malay *rajah*. In promoting Islam as the focus of Malay identity underlying the young state, Malaysian political leaders have viewed archaeological research dealing with pre-Islamic antiquities with great suspicion and skepticism. Similarly, the nature of the connection between Kofun and Nara-period Japan and Korea is the subject of heated debate (e.g., Ledyard 1975), and the Japanese government is said to have restricted research access to certain monuments for fear of internal political repercussions over potential findings. Both Vietnam and Korea have had difficulties coming to terms with the role of Chinese elements at the emergence of their civilizations (Pai 1992), and Thai archaeologists argue about the nature of the Khmer foundations of ancient Thai history (Vallibhotama 1996).

Once again, China presents a particularly interesting case in point. Even though Chinese Communist leaders were dedicated to destroying all vestiges of the country's feudal history, they did not hesitate to use the spectacular archaeological treasures discovered in the Yellow River valley for promotional purposes on a global scale and to construct and promote a North China-centered model for the origin and unity of Chinese history and civilization. Mao Zedong is said to have seen himself in line with the famous Qin emperor Shihuangdi, whose stunning tomb had been unearthed at Xian.

In the interest of national identity, unity, and pride, archaeologists in China were also under pressure to find evidence of Chinese chronological primacy in the appearance of important prehistoric technological innovations, and suggestions of external influences in the development of Chinese civilization were officially frowned upon. On the other hand, under the influence of liberalization since about 1985, some archaeologists working in southern China have recently begun to use important Bronze Age discoveries in Sichuan and Yunnan not only to advance a multilinear model of development of Chinese civilization (Tong 1987) but also to promote greater decentralization in contemporary Chinese politics—a reflection of an age-old political contest between center and periphery.

Archaeology, then, relates to international and area studies on two planes. In one sense, it is an extension of history and provides important information on long-term historical relationships that predicate the constitution of contemporary cultural and social systems. It would be impossible fully to understand any culture area without this perspective. On the other hand, archaeological understandings, like historical ones, are constructed in the context of political relationships and contests and frequently are invoked as powerful tools in political processes. Indeed, since archaeology deals with tangible, visible evidence, it often supplies even more powerful symbols than historical characters or events. In this sense, archaeology enters the very core of political processes the study of which is an essential part of international and area studies.

Area and International Studies: Cultural Studies

Area studies has been the site in the United States academy where an in-depth understanding of the languages and cultures of other societies has been nurtured. Its institutional development since World War II has been the product of financial pressures in funding from the government and foundations; its intellectual development has been the product of the changing views of language, discourse, and culture that have now come to be known as the 'linguistic turn' in the humanities and social sciences.

In the new millennium, 'area studies' finds itself at a familiar crossroads between funding pressures and new intellectual issues. The development of area studies has always relied upon a mix of foundation and federal support. In the early part of the twentieth century, the establishment of the great philanthropic institutions such as the Carnegie Foundation for the Advancement of Teaching (1905), the Rockefeller Foundation (1913), and then the Ford Foundation (1936), provided the initial financial base for supporting research and teaching about other parts of the world, often as an adjunct to the foundations' own activities abroad. Particularly important in these efforts was the Rockefeller Foundation whose experiences in China led to its establishment of a humanities program that focused on modern languages and area studies, including the co-funding of an East Asian studies program with the Carnegie Foundation and the American Council of Learned Societies. These activities paralleled the growing public interest in China and Japan; the first area studies organization was the Far Eastern Association (now the Association for Asian Studies), founded in 1943.

World War II would bring government support of area studies for explicitly strategic and intelligence gathering purposes. The Far Eastern Association was created under the specter of World War II, and the prospects of a communist China. The containment of communism required understanding the enemy, and it was in this light that the centers of Russian studies at Columbia and Harvard were established with a mix of government (including 'laundered' CIA funding) and foundation support (Cummings 1997). The Ford Foundation soon became the major private support for area studies. From 1951 to 1966, its International Training and Research Program granted US$270 million to US universities and other institutions, to build research and training programs in area studies. In addition, from 1950 to 1996, it also provided US$87 million to the Social Science Research Council (SSRC) and the American Council for Learned Societies (ACLS) for joint area studies programs.

The key event that changed the public and government perception of area studies was the Soviet launch of the unmanned Sputnik satellite in 1957. The United States was immediately seen as having fallen behind the Soviet Union at every level of education, and by the fall of 1958, Congress was set to pass the National Defense Education Act (NDEA). Under Title VI of this act, funds were set aside 'to teach modern foreign languages if such instruction is not readily available'; in addition to language instruction, the government would provide half of the cost of 'National Resource Centers' devoted to the study of specific languages and areas. From an initial annual appropriation of US$500,000, Title VI would grow to US$14 million in 1966. Despite the failure of Congress in 1966 to pass an International Education Act that would have provided additional support for area studies, Title VI and Fulbright-Hays funding continued to support area research and training, including academic infrastructure and library resources. By 1999, there were 119 Title VI centers divided across 11 areas of the world. These form the backbone for present-day area studies.

By the 1990s, 'area studies' was in crisis. Foundation funding had leveled off, enrollments were declining, and the end of the Cold War eliminated one of the motivations that had played so important a role in federal funding: the containment of communism. At the same time, the intellectual configurations that nurtured area studies were changing. In the early 1990s, the fall of the Soviet Union and a newly emancipated Eastern Europe revitalized interest in civil society and even international civil society, but the initial optimism soon faded with the resurgence of embittered nationalisms. Soon, another term began to dominate discussions of area studies: globalization. The challenge of globalization was soon reflected in the proposed reorganization in 1996 of the joint ACLS and SSRC international program that funded much area research. The following statement, written by the president of SSRC, Kenneth Prewitt, would soon launch a thousand proposals, not only to SSRC, but also the foundations involved in supporting area-based research, such as Ford, MacArthur, Rockefeller, and Mellon.

> Now free from the bipolar perspective of the Cold War and increasingly aware of the multiple migrations and intersections of people, ideas, institution, technologies and commodities, scholars are confronting the inadequacy of conventional notions of world 'areas' as bounded systems of social relations and cultural categories. (Prewitt 1996, p. 1)

Almost at the same time, the Ford Foundation initiated its 'Crossing Borders: Revitalizing Area Studies' initiative, in which it described area studies as being 'at a significant and somewhat tumultuous turning point in its history as it attempts to respond to and illuminate dramatic changes in the world in recent decades and to understand complex relationships between the "local" and the "global".' The program would provide US$25 million dollars over a six-year period in a major effort to respond to the changing conditions that area studies found itself in as it approached the new millennium. By reaching out beyond established area research centers to include colleges and smaller universities, the pool of over 200 proposals provided a snapshot of what were the leading edges of area and international studies in the United States, as they confronted an age of globalization. Summarizing the proposals, the introduction to the project website states:

> The projects described here reveal a multiplicity of approaches to rethinking area studies in the twenty-first century. Some work to reframe the very notion of 'area' by exploring an array of new geographies: diaspora and diasporic communities, links between areas (Africa and South Asia, for example), maritime rather than terrestrial perspectives, challenges to American exceptionalism, or a focus on 'globalized sites.' Other projects begin with transnational themes of compelling interest across regions. The legacies of authoritarianism, human rights, social movements, alternative modernities, the rise of new media technologies, and performance and politics are some of the themes addressed.

The intellectual motivation behind many of the proposals was a rethinking of the very notion of culture and its ties to explicitly national frameworks, as the emphasis on diasporic, ethnic, and transnational phenomena indicates. These interests contrasted sharply with those developing in international relations. There were no proposals that dealt with the two themes highlighted in a controversial collection edited by the international relations experts Lawrence Harrison and Samuel Huntington (2000), *Culture Matters: How Values Shape Human Progress*—civilizational perspectives on culture and globalization as economic development. Just as area and cultural studies have begun to 'deconstruct' notions of shared, national cultures in their attempts to deal with globalization, international relations and development economics have combined theses taken from Max Weber's analysis of the Protestant ethic, added a comparative civilizational framework taken from anthropologists such as Robert Redfield, and made civilization-based cultural differences the sources of development (mainly in the West) and underdevelopment (everywhere else).

The origins of these very different approaches to globalization lie in the historical development of the term 'culture.' One important input into area studies has always been the study of languages, especially those of cultures that had their own written histories and literatures. These language-based approaches focused on the historical examination of texts, and required both philological and hermeneutic methodologies taken primarily from the humanities; the result has been a close tie both in theory and practice between notions of language and those of culture. These concerns often clashed with social sciences-based interests in contemporary societies that focused on strategic issues and economic development, in which language played basically a utilitarian role and was never the source of theoretical insight. An uneasy truce emerged in which area departments were placed in the humanities, while area centers were interdisciplinary and more social science oriented. History departments often acted as a bridge, since they could be located either in humanities or social science divisions.

One result is that department-based language and civilization introductions to world cultures have often been part of the undergraduate curriculum in many colleges and universities as a part of 'general education.' With the support of federal (NDEA Title VI) and foundation funding, area programs, such as those at Columbia, Chicago, Berkeley, and Harvard universities, were typically built around a large library collection, and tried to create 'vertical' depth in language instruction, history, and literary studies. The area committees of ACLS and SSRC were staffed by area experts specializing in particular parts of the world (Eastern Europe, Southeast Asia, East Asia, etc.) and funded research on these regions. The emphasis was not on international relations issues, but more area-specific work that required in-depth language, culture, and historical training. Area research thus tended to draw its theoretical and methodological frameworks from the various disciplines they were historically connected to; theoretical advances made first in the disciplines were then applied to area research. The distinctiveness and autonomy of area studies lay not in its theoretical advances, but in language teaching and the translation and preservation of specialized texts.

On the other hand, international relations programs, especially those affiliated with professional schools such as Woodrow Wilson at Princeton, SAIS at Johns Hopkins, the Kennedy School at Harvard, and Fletcher at Tufts, focus on the economics and politics of nation-states. Professional schools usually exist independently of the intellectual agenda of the university, especially the undergraduate curriculum, and therefore have had little influence on the debates about general education. However, their impact on the undergraduate curriculum is accelerating, as many universities have made 'internationalizing' their institutions a top priority for both research and teaching. International studies majors are proliferating, and often require some mix of economics and area-specific

courses, leading some institutions to see international studies as a way of catalyzing multidisciplinary work.

The close links between traditional area studies and its place within the humanities explains the influence of what has been termed the 'linguistic turn,' in which problems of meaning, interpretation, and discourse became central to much of the humanities and social sciences. The linguistic turn was triggered by the development of structuralism after World War II. In 1969, Claude Levi-Strauss published *The Elementary Structures of Kinship*, which applied the structural linguistics of Ferdinand de Saussure and the Prague School to the analysis of kinship and exchange relationships. The result was what might be called a 'paradigm' shift that would have a profound influence on French humanities and social sciences, influencing several generations of thinkers that included Roland Barthes, Michel Foucault, Jacques Lacan, Louis Althusser, Jacques Derrida, and Pierre Bourdieu. It would serve as a lightning rod for the development of feminist, ethnic, and cultural studies in the 1970s and 1980s.

Structuralism arrived in the United States in the mid-1960s, and in 1966, there was a famous colloquium at Johns Hopkins on 'The Languages of Criticism and the Sciences of Man,' in which Derrida, Barthes, Lacan, Gerard Genette, Jean-Pierre Vernant, Lucien Goldmann, Tzvetan Todorov, and Nicholas Ruwet participated. What was impressive was not only the caliber of thought, but its range, including literary criticism, psychoanalysis, history, philosophy, semiotics, and linguistics. Although united underneath a structuralist banner, the conference also introduced post-structuralist thought to US audiences. Post-structuralism would make its initial beach-head at Johns Hopkin's University and would soon conquer comparative literature departments such as Cornell and Yale where the so-called 'gang of four' of Paul DeMan, James Miller, Geoffrey Hartmann, and Harold Bloom would consolidate what came to be known as 'deconstructionism.'

While structuralism had little direct effect on area studies, the focus on language and meaning would have a huge impact across many disciplines. By the late 1960s, the triumvirate of Noam Chomsky, Jean Piaget, and Levi-Strauss promised to uncover the 'deep structures' of the human mind and society. Analytic philosophy focused on the 'ordinary language philosophy' of John Austin, Ludwig Wittgenstein, and the more formalist work of Quine, Kripke, and Davidson. Besides French-based structuralism and post-structuralism, the more German hermeneutic tradition represented by Hans-Georg Gadamer combined with the Weberian tradition of 'verstehen' analysis to influence thinkers as diverse as Clifford Geertz and Jurgen Habermas. The result was that at some of the leading 'area studies' research universities, such as the universities of Chicago and Columbia, language and discourse became models for cultural analysis. The rise of symbolic anthropology at the University of Chicago quickly set off an 'interpretive turn' associated with such figures as Marshall Sahlins, Victor Turner, David Schneider, Stanley Tambiah, and Clifford Geertz; all except Sahlins would move elsewhere, thereby transforming the field's core from social to cultural anthropology.

At Columbia, the presence of Edward Said and Gayatri Spivak would pave the way for what would become known as post-colonial studies. At Berkeley, Stephen Greenblatt would develop what became known as the 'new historicism,' itself heavily influenced by the mix of history and anthropology developed by Geertz. The interest in meaning and discourse would quickly spread from anthropology and literary studies into area studies as part of what became more generally known as the 'linguistic turn,' a term coined by the philosopher Richard Rorty (1967) and applied first to analytic philosophy. The term was quickly applied to all language-based inquiries, as indicated by Rorty's own work on deconstructionism and Derrida. At the same time, there was a dramatic increase in the number of foreign graduate students, especially from South Asia, East Asia, and Latin America whose interests in contemporary cultural developments in their home countries contributed to the growing interest in popular culture triggered by cultural studies. The relaxation of immigration restrictions in the 1960s also increased their presence among the US faculty.

The introduction of these language and discourse themes in the late 1960s and early 1970s would intersect with the development of new social movements inspired by the civil rights movement and the events of 1968. The rise of feminism and ethnic studies (especially on the West Coast where there were degree-granting programs in ethnic studies) catalyzed research into alternative, nonmainstream histories. Post-structuralist formulations of subjectivity and identity, along with neo-Marxist analyses of culture provided not only new theoretical frameworks, but also new areas of study that challenged traditional area studies. British cultural studies introduced a theoretically sophisticated discussion of the mass media and popular culture, including Althusser's reworking of Marx and Lacanian film analysis. Cultural studies entered the United States through communications programs, most notably at the University of Illinois at Champaign-Urbana. Because of its origins in England (the so-called Birmingham school) and its location in communications studies in the United States, it initially had no impact on area studies or anthropology. However, as it became increasingly apparent (most dramatically by the events of 1989) that popular culture and the mass media were playing a crucial role in the development of societies that were the traditional object of area studies, its influence quickly spread to the point where anthropologists began complaining about how cultural studies was

invading their domain and control of the concept of culture.

Even approaches that were not structuralist or post-structuralist contributed to the linguistic turn. The Frankfurt School critiques of mass culture were updated by Jurgen Habermas' work on the public sphere (Habermas 1989, Calhoun 1992) and then his explicitly linguistically based theory of communicative action (1984, 1987) and his critiques of post-structuralism. His ideas would introduce a distinctly communications-oriented dimension to the civil society discourses that became popular after the downfall of communism. Benedict Anderson (1983) would draw upon Walter Benjamin's work for his provocative theory of the communicative origins of nationalism, while Charles Taylor's hermeneutic explorations into the origins of Western concepts of the self (1989) invited comparative work.

The development of these trends paralleled the expansion of area, ethnic, and cultural studies in the 1970s and 1980s. Yet if the events of 1968 could be said to roughly herald in the linguistic turn in the United States, the events of 1989 would prove to be the beginning of its demise. The downfall of communism began the undoing of not only Marxist discourses, but also the relevance of the more politicized domestic versions of multiculturalism and identity politics for global comparisons. The civil society discourse that seemed to hold such promise at the end of the 1980s would quickly unravel in the 1990s, as the uneven development of Eastern Europe and Russia, the clampdowns in China, and the rise of new nationalisms and fundamentalisms, questioned the viability of the civil society concept in an age of globalization.

Whereas in the 1970s and 1980s, theory was very much the at cutting edge of the linguistic turn, by the mid-1990s, 'globalization' had replaced it, not so much as a theoretical category, but rather as an empirical challenge to the standard disciplines and area studies. The transition from the linguistic turn to globalization formed the intellectual backdrop to the Ford Foundation's Crossing Borders Initiative. The over 200 proposals represented the state-of-the-art in area studies, as it attempted to deal with contemporary global transformations. While there was a large variety in theoretical approaches, none emerged as predominant. Instead, most striking was the range of phenomena that the proposals tried to deal with, from opening up ethnic studies and globalizing identity politics, to reconfiguring notions of areas and regions (e.g., thinking of oceans as areas). One lacuna was particularly noticeable and undoubtedly fed into the crisis feeling about area and cultural studies. Despite the calls for interdisciplinarity, there were no proposals that dealt substantively with the relation between economics and culture.

This problem was not unrelated to the linguistic turn in cultural analysis. Despite some innovative works by the literary scholar Mary Poovey (1998) and the philosopher Ian Hacking (1970, 1975), interpretive approaches developed for and applied to literary and historical texts have not been easily transferred to the analysis of mathematical and statistical data. The inability to treat these discourses as cultural phenomena has heightened the split between economic and cultural analyses, just at the moment when historical economics was being eliminated in many economics departments. This gap was exacerbated by the collapse of Marxism, which in the hands of the Frankfurt School and contemporary thinkers such as David Harvey (1982, 1989) and Frederic Jameson (1998), had at least tried to keep the analysis of the relations between culture and capital alive.

The textual focus also overlooked the dynamics of the circulatory processes in which texts are embedded and transmitted. Text-oriented approaches often assumed the fixity of the text artifact and such categories as the author, reader, audience, and the act of reading itself; even the destabilizing moves of deconstructionism presupposed elitist conceptions of reading and re-reading. The linguistic turn's focus on the interpretation of texts, and discourses and the analytic frameworks derived therefrom, produced a paradox: the more approaches treated texts or discourses as intrinsic objects of analysis, the more difficult it was to understand the norms of the interpretive communities that made such approaches possible, i.e., the context that makes interpretation possible. A focus on texts and discourses *per se* overlooks how they serve as ways of connecting individuals and groups and how these connections create various kinds of interpretive communities. Yet, if contemporary globalization involves the creation of new forms of connectedness through a globalized market, mass media, and new technologies, then it is not surprising that the linguistic turn has become increasingly anachronistic as it confronts these phenomena.

Globalization presents a unique challenge to area and cultural studies. A focus on language and identity leaves economic processes unanalyzed. If the seeming triumph of capitalism indicates that the leading edge of contemporary changes is the spread of homogenizing economic processes, then analyses that focus on the cultural dimensions of identity formation seem doomed to play catch-up with forces beyond their control. The civilizational approaches developing in international relations invoke cultural values to explain the failure to develop, thereby presupposing that economic success depends on adopting what are basically Western cultural values; a holistic conception of shared culture as civilization-based values provides the diacritics for developmental differences. Given the historical trajectory of area and cultural studies, it seems highly unlikely that they can go back to a conception of culture that they have been abandoning over the last several decades.

Instead, there is a growing realization in area and cultural studies that while globalization has produced

many convergences in institutions and practices across societies—market economies, bureaucratic states, parliaments, elections—these differ significantly from society. Unlike the rhetoric of economic development, globalization is not a single process spreading across the world. Instead, it spreads through diffusion, influence, imitation, negative reaction, borrowing, etc. that work across complex circulations of goods, technologies, ideas, images, and forms of collective imagination. At the same time, the velocity, scale, and form of these processes and circulations challenge virtually all existing narratives of culture, place, and identity and the intellectual and academic frameworks used to study them.

The complexity of these global processes suggests that if circulation is to be a useful analytic construct that replaces more traditional notions of shared culture, it must be more than simply the movement of people, ideas, and commodities from one culture to another. Instead, recent work suggests that circulation is a cultural process with its own forms of abstraction, evaluation, and constraints that are created by the interactions between specific types of circulating forms and the interpretive communities built around them; the circulation and interpretation of specific cultural forms creates new ways of connecting individuals and groups that can be the bases for social movements, identity formations, and communities. A much cited example would be Benedict Anderson's claim that novels and newspapers help people imagine forms of connectedness among strangers that are at the heart of the idea of nationalism. However, similar themes run through Habermas' work on the public sphere, the Chartier group on print mediation (Chartier 1989, 1994, Martin 1994), and Arjun Appadurai on global flows and 'scapes' (1996).

The linking of circulation with the construction of different types of imagined and interpretive communities also provides a way of overcoming some of the barriers between cultural and economic approaches to globalization. In much of the contemporary work on globalization, culture is seen as that which is subjectively shared by a community, and therefore local. Economic processes are seen as objective, universal, and global. Often overlooked, however, is the interpretive dimension of economic processes. Global capital flows presuppose the intertranslatability of financial instruments and information technologies while at the same time demanding that 'local' economic activities be translated into cross-culturally comparable statistical categories. The circulation of financial instruments rests upon this work of translation and depends upon an interpretive community of institutions (exchanges, banks, clearing houses, etc.) that understand and use these forms.

What these phenomena share is an internal connection between circulating forms and the forms of connection and community built around them. Communities are built around the ways they connect individuals and groups. The ways they are connected depend upon the circulation of specific cultural forms that both enable and constrain how they are to be used and interpreted. Whether it is the novels, newspapers, magazines, publishing houses and coffee houses and salons of Anderson's and Habermas' accounts of nationalism and the public sphere, financial derivatives or junk bonds, or the architecture and codes of the Internet, interpretation and circulation interact to create new forms of collective subjectivity. Instead of simply being the movement of people, ideas, and commodities from one culture to another, circulation is a cultural process with its own forms of abstraction, reification, and constraint. The circulation of a 'community' of forms creates new forms of community with hierarchies of evaluation, contrast, and difference; what might be called a 'culture of circulation.' A culture of circulation would be a 'translocal' form of connectedness that might have the geographical reach of a civilization, but not its fixity or sharedness. It is from these cultures of circulation that new forms of subjectivity and consciousness arise that are the bases for the political cultures of modernity, including the public sphere and nationalism.

Arjun Appadurai has suggested (1999) that research itself should be thought of as an imagined community that spreads through the global circulations of people and ideas as well as institutions and practices. The peculiarity of area studies is not that it is an interpretive community within the larger cultural circulations that characterize modern research; that would be true of any research community. Instead, its potential as a form of knowledge lies in its self-reflexivity. Its objects of study are the cultures of circulation of which it is a part. Both the objects of study and those who study them are increasingly in motion. This 'double circulation' is already creating new communities of research that challenge traditional models of area study by de-centering the Euro-American Academy as the main source of innovative research; post-colonial studies may be the welcome harbinger of things to come. These confrontations are not simply producing competing hypotheses that can be tested for their validity, but are rather the indices of new research imaginaries in the making. A self-reflexive area studies, instead of just providing the data to test theories generated in other disciplines, would be at the cutting edge of understanding the conditions for the production of knowledge in an age of globalization.

Area and International Studies: Development in Eastern Europe

The very designation 'Eastern' Europe is itself controversial, and closely connected to the broader issue of the under-development of the area. Uneven economic growth on the European continent produced a neatly regressive pattern of political, social, and cultural development running from the north-west to the south and east, and that was already apparent to observers in the late eighteenth and early nineteenth centuries (Dobrogeanu-Gherea 1910) By the end of the nineteenth century, 'East' generally referred to those areas lying east of the River Elbe and within the Danubian basin. Such a description, of course, tended to be a self-fulfilling prophesy in that the newly independent countries that emerged from the collapse of the German, Russian, Ottoman, and Habsburg monarchies after World War I were treated within the international community as being backward. The collapse of the successor states into dictatorship in the 1930s, and their absorption into the communist orbit after World War II tended to reinforce the image of the region as somehow a world apart from the rest of Europe. After World War II, the study of the region in the English-speaking world took place under the aegis of area studies centers funded for the purpose of understanding communist countries, and therefore requiring specialized knowledge and methods that were not easily transferable to other areas of the world. These factors, historical and political, all conspired to create the region that by the 1960s came to be known in common parlance as Eastern Europe. The countries that fell under this rubric at the height of the Cold War were Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Romania, and Yugoslavia, as well as the European areas of the Soviet Union.

1. Debating the Term 'Eastern Europe'

As the communist world slowly unraveled in the 1980s, some students of the region began deconstructing the notion of a unified 'Eastern Europe.' The idea of Mitteleuropa or Central Europe was revived, and analysts debated which countries exactly belonged in this intermediate category. The revival of Mitteleuropa was a project of both East European dissidents, who wanted Western assistance in challenging Soviet hegemony in the region, and British and American social scientists, who genuinely believed in the existence of an alternative political geography of the European continent. The most influential arguments identified the lands of the former Habsburg and German empires—Czechoslovakia, Hungary, and Poland—as genuinely Central European, having more in common with Germany and Austria than with Bulgaria or Russia. Others maintained that even Soviet Ukraine and the Baltic Republics were properly Central European, leaving eventually Russia as the self-affirming 'other,' the sole East European nation. For both political and analytical reasons, after the Cold War many scholars wanted to eliminate the term 'Eastern Europe' altogether.

Eliminating the designation 'Eastern Europe' would indeed make sense if there were no common problems specific to the area. This is not the case, however. Over the twentieth century, scholars both within and outside

Eastern Europe have identified consistently two interrelated features of the region that define it as an object of analysis. The first is the problem of creating a stable institutional order in economically backward countries (a problem of much of the developing world). The second is the problem of importing institutional models developed in different social settings (Gerschenkron 1962). During the twentieth century, Eastern Europe was an ideological and institutional laboratory for every major ideology and institutional order. In roughly chronological order, the countries of the region experienced liberal democracy (1900–30), right-wing or fascist dictatorship (1930–45), Soviet-style communism (1945–89), and once again liberal democracy (1989–the present). Of course, such a periodization is problematic, and misses some important variations within the region. It nevertheless captures much of the reality. With the exception of the present period, the outcome of which is not yet known, scholars have maintained that each of these orders failed due to the relative backwardness of the region, and the corruption of the original institutional design in the face of local resistance or circumstance.

2. *The First Liberal Period*

Even before the collapse of the imperial orders, liberal institutions had been adopted throughout much of Eastern Europe. After World War I, the new post-imperial states (except those in the Soviet Union after 1922) implemented broad constitutional guarantees of freedom of speech and assembly, parliamentary government, near universal male suffrage, and judicial independence. Economic backwardness would be overcome through integrating the economies of these new countries into the broader markets of Western Europe and North America. The rights of ethnic minorities, arguably the most thorny issue in the region, would be guaranteed through a series of treaties and documents drawn up by the League of Nations.

The problem with this institutional design was that liberalism was not home grown. Instead, it had been adopted in order to emulate the West rather than as a response to industrialization and the growth of capitalism. National bureaucracies, for example, developed in anticipation of rather, than in reaction to, increased economic complexity and industrialization. They tended to be overstaffed, inefficient, and corrupt. Although in the Czech lands, due to the particularities of Habsburg economic policy, a native middle class had developed, in most of the other countries of the region, entrepreneurial activity was dominated by ethnic minorities. Even as this situation began to change during the 1920s, as native entrepreneurs grew in numbers, an ethnic division of labor remained in place, and political careers and state employment remained the preserve of the dominant national groups (Janos 1982).

Even more important than the differences in the composition of the middle classes between East and West, however, was the differences in the lower classes, in particular the peasantry. Bloated East European states could only be sustained, and development policies pursued, by extracting resources from an already poor peasantry. Slow industrial development, caused by the economic chaos in Germany after World War I, and disrupted trade after the collapse of the imperial orders, meant that cities could not possibly absorb the huge numbers of landless peasants. Land reform, the initial answer to rural poverty, was largely abandoned, or watered down, in Poland and Hungary in the 1920s, and even where implemented, as in Romania, it tended to create unproductive subsistence holdings whose inhabitants continued to live in squalor (Berend 1996).

Such difficult economic and social circumstances conspired to make liberal democracy an extraordinarily precarious project throughout Eastern Europe. Impoverished peasants, marginalized ethnic minorities, and industrial workers could easily be mobilized into radical, antiliberal politics. Political control and 'democracy' could therefore only be maintained through electoral corruption, 'managed' elections in which certain parties were not allowed to compete, or quasi-military dictatorships (as in Poland after 1926). Liberal political and economic institutions in Eastern Europe were thus corrupted by the circumstances in which they developed.

Even if corrupted, however, liberalism was not abandoned altogether. Elections were fixed in some districts, but they continued to be competitive in others. The police and other state officials sometimes violated rights to free speech and even property, but courts frequently reversed such acts of arbitrariness. Public discourse was often impolite but it continued to exist, and the press remained lively. Not until the rise of the Nazi dictatorship and the presentation of an ideological and institutional alternative did the elites of the region become completely unhitched from their liberal moorings. Even here, however, there are crucial differences among the countries. Czechs, and to a lesser degree Poles, resisted right-wing radicalism because their territory was the immediate object of German revisionist claims. Hungary, Romania, and the Slovak lands, on the other hand, all succumbed to fascist dictatorships, hoping to benefit from Nazi power or at least be spared the more unbearable forms of discrimination that were starting to take shape in the 'new European order' (Polonsky 1975).

3. *Fascism*

There is very little agreement among scholars about the causes or social roots of fascism. Some argue that

it is a form of psychological escape into irrationalism that is inherent in modernity. Others argue that it is the revenge of the middle and lower middle classes on the radical left, a sort of Marxism for idiots (Lipset 1963). Still others maintain that it is in fact a radical form of developmental dictatorship which appears quite regularly in late industrializing societies. Neither East European scholars nor British and North American specialists have been able to resolve the core disagreements on this question. Similarly, regarding fascism's impact on Eastern Europe, economic historians continue to debate whether or not the German economic and trade offensive in Eastern Europe in the 1930s was a net gain or loss for Eastern Europe. In the short run, it appeared to have a positive effect, or at least was perceived to have had one among the East European elites. The design was a simple one and in some ways resembled the arrangements that the Soviets later instituted in the region. East European agricultural goods and raw materials would supply the German military industrial buildup. In return, the countries of the region received credits against which they could buy German industrial goods. Of course, in the long run these credits were all but worthless, and the onset of the war in the east ensured that the Nazis would never repay the debts they incurred in the 1930s. Yet the modest recovery of the East European economies during the early Nazi years could not help but to draw these countries more firmly into the Nazi sphere of influence.

The hope of many regional elites was that Germany and Italy would accept their Eastern neighbors as junior partners as long as their institutional and legal orders mirrored those of the masters. Thus, in Hungary, Poland, Romania, and Estonia, local Hitlers and Mussolinis came to power in the 1930s, and even where they did not come to power they waited in the wings for the day when German or Italian armies would install them at the top of the political pyramid. Of course, the ideological design of the right and its subsequent institutional expressions were far less elaborate or well articulated than the liberal one. This was so not only because it was much newer, but also because most ideologies of the right were explicitly antiprocedural and antiorganizational in nature. The 'little dictators' of Eastern Europe did not, for the most part, share Hitler's racial fantasies, since Nazi ideology had little good to say about the non-Germanic peoples of the area, but they did use the opportunity to free themselves from parliamentary and other liberal restraints in pursuit of economic development and regional power. As in the earlier liberal era, political elites corrupted the pure German or Italian model in an attempt to turn it to their own purposes. Nevertheless, the conflict between the fascist right, which favored a party dictatorship, and the technocratic right which favored a nonpolitical dictatorship was never fully resolved in any country of the region until the onset of the war in the east in 1939.

With the onset of World War II, the scales tilted in favor of the fascist right. An important indicator of these differences can be seen in minorities policies, especially with regard to the Jews. Anti-Jewish laws had been on the books in several countries of the region since the mid-1930s, and in some cases even earlier. By the late 1930s, often under German pressure, but sometimes voluntarily and with a good deal of enthusiasm, they were implemented in full force. It is nevertheless important to distinguish between the institutionalized discrimination of the 1930s and the historical 'revenge' against the Jews that was exacted in horrific form by the Germans and their East European helpers on the fascist right during World War II. From the standpoint of 'development,' the organized massacre of Jews that took place in the region during World War II marks clearly the difference between the corrupted developmentalist model of the East European right during the 1930s, and the antidevelopmentalist bacchanalia of the 1940s. Whereas interwar liberalism had failed in Eastern Europe because it could neither overcome the backwardness of the region nor adapt its institutional order to the problems of scarcity, the fascist order failed because it did not really have an institutional response to backwardness at all. Instead, it retreated into the psychological appeal of glory inherent in war, the pleasure of feeling superior to one's 'inferiors,' or the negative empathy inherent in exacting revenge on one's historical enemies. Although it probably did not appear as such to most East European elites in the early 1930s, by the end of the war it must have been clear that the fascist order ultimately had little to do with development at all.

4. *The Communist Experience*

Although Western scholarly debates on the nature of communism were often influenced by the seminal dissident works of Djilas, Havel, Konrad and Szelenyi, and Solzhenytsin, the political restrictions of Soviet rule in the region meant that the study of Eastern Europe was done mostly from abroad. Two schools of thought dominated the analysis of communism: Totalitarianism and modernization theory.

The totalitarian school was inspired by the writings of Hannah Arendt and Carl Friedrich (Arendt 1966, Friedrich and Brzezinski 1956). Its adherents argued that despite the doctrinal differences between Nazi Germany and communist Russia, they had so much in common that it made sense to group the two dictatorships together as essentially the same. For one thing, both professed an ideology of earthly salvation and were prepared to cast aside conventional moral restraints in order to attain their goals. For another, both destroyed existing civic and personal attachments for the purposes of creating a single locus of devotion. And while the Nazis stressed the importance of the

leader, and the communists the importance of the party, in practice both devolved into personal dictatorships. The Nazis believed in hierarchy, and the communists in equality, but in practice these ideological differences exercised a small impact on political, or even social, organization. Most important, however, these theorists told us, the unprecedented capacity for social control inherent in modern political technologies and bureaucratic organizations render totalitarian orders exceedingly difficult to change. Students of Eastern Europe during the 1950s had little difficulty finding proof of totalitarian parties with instrumental views of their own societies. Private property was expropriated and liberal freedoms were either never restored after the liberation from Nazi Germany or were abolished in steps that culminated with the onset of the Cold War in 1948. Under careful Soviet tutelage, East European secret police forces thoroughly intimidated entire societies. Similar to the Soviet Union of the 1930s, the 'little Stalins' of Hungary, Bulgaria, and Czechoslovakia staged trials of 'traitors' from among the highest ranks of the party, all of whom confessed under duress to having worked for Western intelligence agencies throughout their long careers as revolutionaries.

Although not questioning the characterization of communist politics as essentially antiliberal, scholars inspired by modernization theory in the 1960s began to challenge the totalitarian school's interpretation of the *dynamics* of communism, that is, how it would change over time. The essence of modernization theory is its assertion that, even accounting for broad ideological differences, all societies that industrialize, urbanize, and educate their populations face the same kinds of pressures and will most likely have similar kinds of politics. Furthermore, over time, the functional prerequisites of modern societies produce a convergence of cognitive orientations toward power, politics, and justice. Again, studying the Soviet Union and Eastern Europe after Stalin's death in 1953, and the subsequent critique leveled against Stalin by Khrushchev in 1956, scholars had little trouble finding proof of what they were seeking. The Soviet leadership and its East European counterparts appeared to espouse a more pragmatic, less 'ideological' approach to the problems of their own societies (Hough 1977). No longer were shortcomings the result of 'wreckers' and 'saboteurs,' but rather problems to be dealt with and overcome through the 'scientific technical revolution.' Marxism–Leninism, the official ideology of communist East Europe would not be cast aside completely, but in such highly industrialized countries as East Germany or Czechoslovakia the clash between a mobilizational dictatorship and the prerequisites of industrial modernity would most likely be resolved in favor of the latter.

As it turns out, both schools were wrong. Contrary to the expectation of the totalitarian school, the communist world did change, but it did not change in a direction predicted by modernization theory. Rather than a leadership increasingly infused by rational–technical and pragmatic orientations that would yield policies that worked regardless of ideology, Soviet-style institutions throughout the region produced economic stagnation and widespread corruption. Concerning economic dynamism, the key error of the modernization theorists was to confuse Soviet-style industrialization with capitalist economic development. No Soviet or East European economic theorist was ever able to articulate a nonmarket and post-mobilizational model of economic growth. In fact, the post-Stalinist economists in both Poland, and especially Hungary, articulated quite convincing work which demonstrated just why it was impossible to generate growth based on greater allocative efficiency in a Soviet-type economy. On the question of corruption, in the absence of some mechanism for ensuring the circulation of elites, the end of Stalinist police terror simply turned public offices into private sinecures. Such a possibility was laid out in the early work of Barrington Moore on the Soviet Union and developed into a full-blown Weberian model of 'neotraditionalism' by Ken Jowitt at the beginning of the 1980s (Moore 1954, Jowitt 1992). Jowitt explained the decay of communist rule by the inability of communist leaders to articulate a new, postmobilizational 'combat task' that would have provided a yardstick against which to judge bureaucratic rectitude. Others, mainly Western but also East European economists, began to build related models based on the organizational, as opposed to the ideological, features of the Soviet political economy, which they argued was in essence one giant rent-seeking machine (Kornai 1992).

The Soviet Empire in Eastern Europe underwent significant changes in its 40-year history. As in the interwar liberal and then the fascist periods, local conditions conspired to alter the original institutional design. Communism in the region after World War II began essentially as a classical colonial operation in which local elites were controlled by Soviet supervisors, political direction stemming from of the Soviet embassy, and resources extracted through trade agreements that favored the Soviets. After 1953, however, the various states began to move in their own directions. The essential dilemma for both Soviet and East European elites was that, in order to gain some measure of local legitimacy, policy had to be dictated by local circumstances. These local variations of communism, however, always threatened to go beyond the bounds of what the Soviets wanted in order to maintain a cohesive empire. In 1953 in East Germany, 1956 in Hungary, 1968 in Czechoslovakia, and 1980 in Poland, local communist leaders made concessions to local sentiment by making significant institutional changes. Each time, the logic of these changes led to a weakening of party control, a threat to Soviet hegemony in the country, and, ultimately, a

military crackdown and restoration of communist party rule. During the 1970s and 1980s, the relationship of exploitation between the Soviet Union and Eastern Europe was reversed, with the former subsidizing the latter and shielding it from the full effect of the dramatic increase in world oil prices after 1973.

The growth within Eastern Europe of dissident and antipolitical groupings throughout the 1970s and 1980s, especially the emergence of the revolutionary trade union Solidarity in Poland in 1980–1, unleashed a plethora of interpretations. Some modernization theorists maintained the rise of civil society was the fruit of Soviet-type modernization. After decades of repression, an educated, urbanized, industrialized society had emerged to demand more say in how its affairs were being run (Lewin 1988). Others argued that this really had nothing to do with modernization, but with poor economic performance caused by high level of military spending and dysfunctional economic policy making.

The disagreement was never really settled among academics before the entire system in Eastern Europe began to collapse in 1989. The causes of 1989 continue to be debated. Most scholars point to the importance of Soviet leader Mikhail Gorbachev and his attempt to salvage the Soviet empire by remobilizing society through ersatz democratic structures. Others point to deeper causes: changes in military technologies in the 1980s that effectively bankrupted the Soviet state, the drop in oil prices at the end of the 1980s that depleted hard currency revenues, and the rising cost of empire. Whatever the ultimate reason (or combination of reasons), between 1989 and 1991 European communism disintegrated completely and the states of the region found themselves once again trying to adapt institutions imported from abroad—this time, once again, liberal democracy—to the particular postcommunist conditions of their countries.

5. *Postcommunist Democracy*

Between 1989 and 1991, 27 independent states emerged from the collapse of the Soviet empire and Yugoslavia. A decade later, some of these states had established capitalist economies and meaningful institutions of democratic representation. Others made little progress or quickly slid back into a form of semi-authoritarian democracy. What accounts for the huge differences in outcomes? Some have argued that initial institutional choices shape outcomes in decisive ways. In particular, the choice of strong presidentialism appears to undermine the development of representative programmatic parties, parliamentary responsibility, and civic organization (Fish 1998). Others argue that long-term cultural and bureaucratic legacies affect how willing states are to defend economic and political rights (Kitschelt et al. 1998). Still others maintain that geopolitical position is the main driving factor, especially the capacity of selected countries of the postcommunist world to join the economic and security structures of the West embodied in the institutions of NATO and the EU (Kopstein and Reilly 2000). These highly intrusive institutions have permitted Hungary, Poland, and the Czech Republic to suppress internal disagreements in pursuit of the larger goal of entry to the West. The prospect of being admitted to the West also helped Slovakia and Croatian democrats to overthrow dictatorial postcommunist regimes. East European scholars, now free to contribute to the scientific debates about their own countries, tended to point to a combination of internal and external conditions that determined the initial variation in postcommunist outcomes.

Is history repeating itself? In some ways it is. Once again, the countries of Eastern Europe are attempting to plant the institutions of liberal democracy in unfamiliar soil. Once again, the countries of the region are bit players in the game of international capitalism, trying to 'catch up' with the already developed countries in the West. Yet there are important differences, both internal and external, to Eastern Europe. For the first time in history a select group of East European countries really is now thought of as Western and is being admitted to the economic and security structures of the West. Contrary to the rhetoric of the 1980s, even Poland and Hungary in the pre-World War II era were not really considered fully Western. This has now changed, not only within Europe as a whole but, perhaps more importantly, within these countries themselves. No one doubts any more where these countries are "located". Furthermore, no matter how difficult the transition has been, even for countries such Romania and Bulgaria, there does not appear to be any viable ideological or institutional alternative to liberal democracy. Of course, both of these conditions are subject to change. East and West are not only objective categories but also social constructs. The EU and NATO may close their doors to further membership, or new antiliberal ideological challengers might appear on the new eastern periphery of Europe. If this occurs, one can expect the subversion of liberalism in the region once again.

Area and International Studies: Development in Europe

The field of International studies in Europe today raises the question of boundaries: geographical, territorial boundaries, and disciplinary boundaries. As a matter of fact, the construction of Europe as a new political space introduces *de facto* a fluidity of frontiers, and a multiplicity of approaches which have led to the reconstruction of the social sciences in which all sorts of boundaries are blurred (Bigo 1996).

International studies has a broader scope than international relations since it refers not only to relationships that a state maintains with other states, but also to relationships between states and other societies, other groups and communities that have emerged and have been organized in other political and cultural contexts than its own. It includes studies on migration, on minorities and ethnicity, and the emergence of transnational communities. It refers also to interactions among actors—individuals and/or institutions—each carrying different national identities to be negotiated on a transnational level (Kastoryano 1997, 1998).

In this perspective, Europe constitutes a specific historical and political setting for the analysis of international studies and its development. It is, indeed, in the eighteenth century that the nation-state, defined as a cultural, territorial, and political unity was born (Rokkan, Tilly 1976). The same nation-state is questioned today as a universal political structure and major actor in international studies. It is again in Europe that, because of the project of a new political unit, called the European Union, concepts such as citizenship, nationality, public space (Habermas 1996, 2000), and cosmopolitanism (Held et al. 1999, Linklater 1998), need to be redefined. Furthermore, cultural, sociological, and political plurality within Europe provides empirical evidence for the development of international studies and more specifically for the analysis of the switch from a realist perspective based on the rationality of the state (Weber) to a liberal one where increasing interdependence among states leads to an analysis in terms of integration, both regional and European.

Such a development leads to a methodological confusion and to an obvious interdisciplinarity. History, sociology, anthropology, political science, and juridical studies contribute altogether to the knowledge and understanding of the political structure, the institutions, and the social organization in a comparative perspective, and of course, of Europe as a new political space. Moreover, the increasing complexity of social and political reality and an inevitable interdependence of internal and external political decisions require a combination of various theories and intellectual frameworks of interpretation, methods, and approaches, as well as conceptual tools of analysis.

1. *Europe of Nation-states*

War and peace during the twentieth century have not only changed the political geography within Europe but have also stimulated an interest in international studies. Born as a reaction to World War I, international studies has focused on the relationship among states on the line of the treaties of Westphalia (1648), declaring a territorial sovereignty of all states of the Empire and their right of concluding alliances with one another and with foreign powers. This perspective developed by the 'realist' theory of international relations relies on concepts such as sovereignty, territoriality, and security. In addition to the Weberian definition of the state—a collectivity that within the limits of a given geographical space claims for its own interest the monopoly of a legitimate violence—the 'realists' have considered the state as a homogeneous unit on the international scene. Its action is qualified as 'rational.'

Following the path of positivism in social sciences, the 'realist' approach expressed for the first time by E. H. Carr in 1939, and formalized by H. J.

Morgenthau after World War II aims at 'objectivity.' The analysis of the international scene relies on a sociological and political knowledge that is 'real' and amoral. It brings to light states' interests and a scheme of rational actions that characterize them. Such an approach reminds one indeed of Auguste Comte's formula: 'to know in order to predict.' The sentence illustrates best the link between international studies and foreign policy as well as security issues: to know about other societies, other political systems, other administrative structures in order to protect the nation and define an appropriate foreign policy.

This tradition based on the logic of expertise has guided the area studies in Europe. More than any theoretical considerations, knowledge about other 'places' and other 'customs' have been produced by the military, by missionaries, and by diplomats. Based on their imperial tradition, France and Great Britain have given priority to the study of their colonies in order to understand the functioning of the society and obviously to exercise their power.

National characteristics appear also in their method in connection with the tradition of social sciences in each country. Whereas France has privileged a juridical and administrative approach in the description and analysis of other countries, Great Britain looked for grand strategy through international history of diplomacy, based on the descriptions of British diplomats recalling the methods of social anthropology, and developed theories on international studies along the line of the International Society tradition of the English school.

Enriched by the missionaries and useful for diplomats, the realist vision on international studies meant to fight, during the interwar period, against the idealist approach according to which ideas are more important than states' interests. Away from a Machiavellian logic, their approach, qualified as 'utopian,' was based on juridical analysis and aimed at finding new theoretical models and solutions to avoid conflict by introducing a moral argument in interstate relations (Kant). The confrontation of realists and idealists nevertheless brought a dynamic perspective in the perception of the state, where moral values can generate social change and affect relations among states.

According to the liberal vision developed in the 1960s in the United States, 'the good of individuals has moral weight against the good of the state or the nation' (Doyle 1997). The state is not a homogeneous unit but is split into various interest groups and individuals; it is considered as an actor influenced by rational individuals acting and shaping the institutions and the political decisions (Keohane and Nye 1971, Waever), and the 'competition among states' takes into consideration the relationship within and across societies (Raymond Aron 1962). Liberal economic and political models have been transposed in international studies in Europe with the objective of reducing the risk of war and establishing a permanent 'democratic peace,' a concept that has gained more legitimacy after the end of the Cold War with a new perspective called liberal internationalism.

2. *The Plurality of Civil Societies*

The new dynamic thus emphasizes plurality within civil society. It takes into consideration multiple voices and movements in decision making. It incorporates into its problematic the variable of identity formed in relation to various institutions.

Along the same lines, research on comparative politics has switched from a focus on state and power, social and political organizations, institutions and law, to processes of decolonization, to theories of modernization, to 'models of democracy' (Held et al. 1999), in short from structures to issues following the historical events that caused 'great transformations' (Polanyi 1944). To compare the state–society relationship implied measuring the implications of such an interaction for the definition of a political culture, elite formation, the understanding of civic virtues, the nature and the scope of social movements. Since there is an increasing interdependence of the states on the international scene, the ways in which each of these issues is treated are supposed to affect the power relationship within society and between states.

Disciplinary approaches and theory followed the evolution and the practices. With the development of social sciences in the 1970s and 1980s history, law, philosophy, sociology, and political sciences have completed the 'traditional' diplomatic history and fostered international studies in Europe (Aron 1962). German tradition, more interested in the study of peace and geopolitics, incorporated international studies in its intellectual tradition, developing a university research basis and a highly theoretical perspective in the domain of sociology, law, philosophy, and economy.

Theories, in order to reflect the reality, have to take into consideration the complex interdependence between national and international institutions, between domestic and foreign politics, between local and transnational actors. The evolution led in the 1980s and 1990s to a neo-realist approach combining scientific theories and empirical research to show the 'anarchical nature of the international system' (Waltz 1979), confronted by a neo-liberal one that emphasizes the 'institutionalization of world politics' and its effect on the ways in which states cooperate (Keohane and Nye 1971). Such a dynamic confirms the understanding of an international society, defined by Hedley Bull as a 'group of states, conscious of certain common interests and common values that contribute to the formation of a society in the sense that they conceive themselves to be bound by a common set of rules, in their relations with one another, and share in the working of common institutions' (Bull 1977).

The international society implies therefore the establishment of common norms and conventions, rules of interaction. These principles constitute the basis for 'new institutionalism', an approach developed in studies of the European Union. They rely on the existence and importance of international institutions as an instance of socialization for individuals interacting beyond boundaries, sharing the same norms and values and changing their conception of interest and identity; therefore the interaction between actors and institutions has shaped each other and national society as well as international society. The switch from a state-oriented to an individual-oriented action in international studies, from interstate relations to 'transnational' relations (Keohane and Nye 1971), has been considered more determinant of world politics.

The French version of the analysis of transnational relations introduces the network built by nonstate actors and political parties and unions and their actions (Merle 1974). In any case transnationality refers to the interaction of multiple actors and strategies, leading to a political action beyond boundaries and even to transnational social movements (Tarrow 2001). The tendency in the 1990s had become, however, the intersubjectivity (Habermas 1996, 2000) and the role of agents—in interaction with states—in the definition of political norms beyond institutional frameworks and their diffusion. Categorized as constructivist, this approach privileges the identity issues and claims for recognition in the public sphere and establishes the society as the locus of political change.

All these competing theories (realist and liberal and their neo's) and their variations (institutionalism, neo and liberal) do not remove the state away from international studies. Some include the state into the transnational space and movement of interaction (Bigo 1996, Kastoryano 1997, 1998, Tarrow 2001). What is at stake is the 'absolute' state as a homogeneous actor, its limits, and its capacity to shape the political community, and the future of the nation state as a universal and legitimate political structure.

3. *Transnational Europe?*

This debate is at the core of the construction of Europe. Europe as a geographical setting has switched to an economic community (EEC) and since 1992, with the treaty of Maastricht, to a political unit called the European Union. The transformation had an effect on area and comparative studies within and among member states. Area studies within European countries have become internal to Europe, and comparative analysis emphasizes the convergence among member states on issues such as immigration, demography, family structure, as well as security, environment, welfare, even citizenship and nationality. (Each of these themes constitutes a broad research program stimulated by different European Institutions and mainly from the Commission.) France, Germany, Great Britain, Italy, or Spain related through multilateral conventions constitute all 'parts' of one expected political setting called the European Union.

The European Union as a new political unit has changed the paradigms in social sciences, raising the question of frontiers, territory, identity, migrations, sovereignty, all together linked to the future of the nation state. New paradigms partly inspired by the classical approaches in international studies take into consideration economic, sociological, and political integration where the local is confronted by the global, where territory is replaced by space, where citizenship is detached from nationality. The realist approach based on interstate relations has been replaced by the study of 'intergovernmental' relations (Hoffmann 1994) focusing on the power of each nation state, whereas a neofunctional approach has drawn attention to the emergence of a European space as a new space for political action or mobilization for states, as well as for groups organized in transnational networks throughout Europe. The liberal intergovernmental theory maintains the state as a rational actor, and argues that the power within Europe is the result of bargaining among governments of member states (Moravcsik 1993). On the other hand, the importance of institutions as conceived in the 1990s was re-evaluated by the neo-institutionalists and 'historical institutionalists' who include in the definition of institutions formal rules, and political norms (Pierson 1996). The main issues were public policies, and their harmonization, the definition of common political agendas (Muller), multilevel governance focusing on the effect of various transnational networks built by economic, social, and political actors, and of 'network governance' according to which national, subnational, and supranational institutions. They all constitute a penetrated system for a transnational policy process (Kohler-Kock), and transnational networks built by interest groups and immigrants.

To reduce the construction of the European Union to theories is to neglect all the complexity of its integration. Europe constitutes *de facto* a space of complex interaction among various actors, states, national and European institutions, and of their interpenetration. The outcome is paradoxical: there is on the one hand an emphasis on the national specificity of each nation state expressed in terms of 'models' and projected onto the European level: French model of citizenship, British model of liberalism, German model of democracy, Scandinavian model of a welfare-state … , each of these being projected onto a European level (Schmidt 1997). On the other hand, the European Union stands for the idea of open-minded conciliation and negotiations of all identities—national, regional, ethnic, religious—for an alternative conception of universality.

In any case the construction of Europe as a political unity is a challenge to nation states, leading them to reformulate the founding principles, to revise national rhetoric, and restructure the institutions. As a matter of fact, migrations from within Europe from without have generated scenarios announcing the end of the nation state or at least its weakening (Habermas 1996, 2000) and the 'transformation of the political community' (Linklater 1998), and questions on ways to go beyond national understanding of democracy, citizenship, on the emergence of a European civil society not limited to the market, on the construction of a new political space and on new 'model' of democratic society and political structure, a European state (Ferry 2000)—plural (Mouffe), multicultural (Kastoryano 1997, 1998), or cosmopolitan (Archibugi and Held 1995).

All these questions are related to the question of European identity and citizenship. The answers are normative and come mainly from political philosophers. They have developed in the 1990s concepts such as 'postnational' to underline the limits and the difficulties of nation states facing the changing political context, and suggest a membership beyond the nation state and their nationalist definition of citizenship (Ferry 2000). Habermas on the other hand sees in the 'constitutional patriotism' a way to unify all the cultural diversity in one common political culture, and projects it onto the European context (Habermas 1996, 2000). This model implies the separation between nationality and citizenship linked in the context of the nation state, therefore a separation between feelings of membership carried by national citizenship and its juridical practice that is extended beyond the nation state. These normative views of citizenship nourish discourses and stimulate debate and research for a new model of citizenship, including the nationals and non-nationals—immigrants. The question remains the emergence of a European public space denationalized, integrated into one political culture carried out by voluntary associations representing a multiplicity of interests in a public arena (Habermas 1996, 2000), on the search for a 'political community' where all the internal diversity of Europe coexist in order to produce an European identity, to define the European citizen and insure his (or her) identification with the new political entity. Studies on the European Union, privileging the political philosophy, sociology, and anthropology, converge implicitly or explicitly towards this direction. They question the identification of citizens organized in interest groups on the European level, or of immigrants resident in one of the member states with a European society. Sociological research brings some evidence on transnational networks from professionals, corporations, and voluntary associations, unions that cover the European space like a spider's web, and have introduced a new way of political participation on a national as well as European level. They show that some of these networks stem from local initiatives, but most of the time are encouraged by supranational institutions (Kastoryano 1997, 1998, Tarrow 2001), which mobilize resources for voluntary associations or groups to help them to consolidate their organization based on identity or interest or both throughout Europe, and contribute to the formation of a transnational European civil society. A transnational political participation is a sign of Europeanization of actions and can produce a European political culture shaped by interaction with supranational institutions.

Studies of the political construction of Europe, like the process of globalization at large, reveals paradoxes. Transnational networks contribute to the formation of external communities. At the same time transnational networks are now imposed on the states as unavoidable structures for the negotiation of collective identities and interests.They aim to influence the state from outside and within. Clearly, the objective of transnational networks is to reinforce their representation at the European level, but their practical goal is its recognition at the national level. In other words, the ultimate goal is to reach a political representation that can only be defined at the national level (Kastoryano, 1998).

Such an argument contradicts recent claims of the end of the nation state. Of course, an organization which transcends national borders such as transnational ones brings to the fore the multiple identifications deriving from the logic of a political Europe, and runs against the principle of nation states. Others argue that the relevance of the nation state in a political Europe does not necessarily imply the erosion of the nation state. In reality the state remains the 'driving force' of the European Union. Even submitted to supranational norms, the state keeps its autonomy in internal and international decisions, and remains the framework for negotiations of recognition. Therefore the permanence of the nation state as a model for a political unit in the construction of Europe relies very much on its capacity 'to negotiate' within and without, that is, its capacity to adopt structural and institutional changes to the new reality (Kastoryano, 1998).

This debate is closely linked to globalization, broader but raising the same conceptual questions of multiple loyalties and citizenship that derives from intercultural interaction in a common political space. Liberal universalism sees in this evolution a new commitment of individuals to a project that is cosmopolitan, and an open membership to a global political community (Held et al. 1999).

The evolution of social reality and the dynamics of the international scene have had a great impact on 'area and international studies' in general and more specifically in Europe. The prospect of European integration raises questions about the relevance of the national boundaries and makes interdisciplinary approaches necessary. The insights at 'realism,' which

have been so dominant in international studies, have not been invalidated. However, new perspectives and paradigms emerge in which the state is one political actor among others (e.g., individuals, groups, institutions) and in which interdependence and interpenetration become keys to international studies.

Area and International Studies: Development in South Asia

Development can be understood as an activity, a condition, an event, or a process. In social science, development is most often studied as a complex set of institutional activities that employ both public and private assets for public benefit. It takes many forms according to ideas and environments that guide its conduct and condition its results. Policies, institutions, outcomes, and analysis together constitute development as a process that is distinct from the related processes of economic growth and social progress, because development explicitly includes the activities of state authorities who establish public priorities and implement policy, includes official relationships among people inside and outside the state, includes public assessments of policy, and includes political efforts to change policy.

Objects and trajectories of development are defined and measured variously. There is thus a vast literature on economic, political, social, cultural, industrial, agricultural, technological, moral, and human development. Even economic development can be assessed by different yardsticks: aggregate increases in

national wealth and productivity are common measures; but national autonomy, food security, and social stability are often important priorities; and a particular state regime's stability, revenue, military might, and cultural legitimacy often preoccupy policy makers. Primary, secondary, explicit, and implicit priorities typically jostle in policy making and various measures of success are typically used by various participants in development debates.

Economic development is the subject of this article. Though 'the economy' as studied by economics consists primarily of markets, 'an economy' is a more complex environment that includes natural endowments, social power relations, and political history. Economic development embraces all the institutional and material conditions that constitute specific economies. Because development requires the self-conscious use of power by particular groups in specific contexts, development regimes represent formations of organized power that define the history of development.

In South Asia, premodern regimes developed regional economies before 1800. A modern development regime emerged under British rule after 1800. National regimes took over development after 1945. Since 1970, the leadership capacities of national regimes have declined as international trends have favored global investors and struggles to represent the poor and previously marginal peoples have favored local movements and nongovernmental organizations.

In 1929, an erudite British agricultural officer, William Moreland, concluded from his research that the 'idea of agricultural development was already present in the fourteenth century.' His conclusion can now be extended much further back in time, because now we know that ancient and medieval rulers in South Asia invested to increase productivity, most prominently by organizing irrigation. By the fourteenth century, royal finance and protection were also expanding markets and manufacturing by building transportation infrastructure. By the eighteenth century, state activities that developed agriculture, commerce, and manufacturing flourished around capital cities in Bengal, Gujarat, Punjab, the Indo-Gangetic plains, and the peninsular river basins.

Premodern regimes increased state revenue and enriched bankers, farmers, and manufacturers. But they worked in what Moreland called a 'political and social environment … unfavourable to [modern goals of development],' because, he said, military and political struggles undermined investments in farming, manufacturing, and banking, as pillage and plunder fed destructive armies and rapacious taxation fattened unproductive ruling elites (Moreland 1929).

The British imperial development regime was built upon a pre-modern legacy but introduced new ideas, institutions, and priorities. In 1776, Adam Smith's *Wealth of Nations* became Britain's first modern treatise on economic development. Smith attacked Crown support for monopolies like the East India Company and promoted the expansion of commerce as the nation's top development priority. British conquest in South Asia proceeded from the mid-eighteenth to the late nineteenth century as Britain became the world's foremost industrial nation. Industrialization helped to sustain the imperial enterprise and vice versa. Modern imperialism defined the first institutional framework for modern economic development in the United Kingdom, British India, Ceylon, and other colonial territories.

Until the 1840s, Indian tax revenues were assigned primarily to meet the cost of conquest, administration, and imperial finance. Policy priorities shifted over decades onto *laissez faire* lines to open India for Britain's commercial interests. In 1813, Parliament renewed the Company charter but ended its trading monopoly and allowed private merchants freer access to British territories overseas. In 1833, Parliament made the Company an administrative institution and made English the official language of state law, administration, and education. British India became a territory for imperial development inside a world empire; and in 1833, the abolition of slavery triggered petitions from Caribbean planters that spurred the Indian government to send shiploads of indentured workers from Calcutta to keep English sugar plantations running in the West Indies.

British industrial interests were prominent in imperial development policy. As early as 1793, public debates ensued on how to best manage of 'Asiatic possessions' in the national interest. Increasingly prohibitive tariffs against Indian cloth protected Lancashire, and after 1815, Lancashire sent cloth virtually free of tariffs to India. As Smith predicted, British consumers benefited from commercial imperialism. English merchants sold Bengal opium in China to buy tea and porcelain for English households; sugar from Caribbean plantations sweetened English tea. Monetary policy kept relative prices of the Indian rupee and English pound favorable for English investors, importers, exporters, and consumers. In 1818, James Mill's *History of British India* composed a British national history, justification, and ideology for British governance in India; and English businessmen were soon cutting Indians out of commercial partnerships to garner national benefits from the imperial trades.

The real value of taxes in India rose rapidly as prices dropped from 1823 to 1854. During this long price depression, it became more cost effective to invest Indian taxes in India. At the same time, outlets for British industrial capital were being sought in London and supply systems for industrial raw materials were being developed. In the 1840s, London launched plans for building infrastructure in India to cheapen English supplies of commodities and raw materials, to expand military operations, to increase revenue, and to extend British capital investments in plantations, railways,

cities, roads, ports, shipping, irrigation, and other ventures.

In the 1840s, an irrigation engineer, Arthur Cotton, argued forcefully that Indian crop production and security could be advanced by state irrigation investments that would pay for themselves with higher taxes on more productive land. At the same time, a commission of Parliament met to consider ways to improve supplies of raw cotton to Lancashire mills. Bombay Presidency attracted special attention, along with Egypt. Measures were sought to expand cotton exports from these regions to counterbalance England's dependence on cotton supplies from the American South. When the US Civil War broke out, Egypt and India filled a void in cotton supplies created by the Union blockade of Confederate ports.

A transition to a modern development regime consumed the decades 1840–1880. In 1853, Governor General Dalhousie announced a plan to build an Indian railway with state contracts that guaranteed English companies a minimum 5 percent return; and to secure that return, government kept control of railway construction and management. In 1871, the Government of India obtained authority to raise loans for productive purposes, and large irrigation projects began, following earlier success raising revenues from smaller projects. Development projects were all government endeavors that employed many native contractors and their benefits also filtered down to native owners of land receiving new irrigation and producing commodity crops.

By 1880, regions of specialized production for world markets had been developed in South Asia. Ceylon was a plantation economy. Coffee plantations expanded from 50,000 to 80,000 acres between 1847 and 1857, and peasants devoted another 48,000 acres to coffee for export. Coffee acreage expanded another 35,000 acres in the 1860s. In the 1880s, leaf disease killed coffee cultivation, which was rapidly replaced by tea, rubber, coconut, and cinchona plantations. Ceylon and India replaced China as the major suppliers of English tea. British plantation investors drove out peasant producers and controlled export markets. Labor supplies posed the major constraint for tea planters, and the solution was found in the institution of (eventually permanent) labor migration from southern Tamil districts in British India. British plantations in Malay colonies also depended on migrating Tamil workers.

British Burma and East Africa also developed in circuits of capital accumulation anchored in India. In Burma, Tamil Chettiyar bankers became prime financiers for agricultural expansion in the Irrawaddy River delta, which generated huge exports of rice for world markets, including India, where urbanization increased demand for imported rice. In East and South Africa, merchants from Gujarat and emigrant workers from Bombay, Calcutta, and Madras provided both labor and capital for railway construction and formed urban nuclei for the colonial economy. Between 1896 and 1928, 75 percent of emigrants from Indian ports went to Ceylon and Malaya; 10 percent to Africa; 9 percent to the Caribbean; and the remaining 6 percent to Fiji and Mauritius, which also became island plantation economies.

The Deccan plateau in India's peninsula became cotton country. In 1876, cotton duties were abolished in England to further cheapen supplies from India, and a year later, the biggest famine ever recorded struck Deccan cotton-growing districts. Under *laissez faire* economic policy and imperial bureaucracy, little was done to alleviate famine suffering, but famine sharpened government attention to investments in protective irrigation. Famine commissions and policies were implemented.

By 1914, most goods arriving at South Asia ports were destined for export: cotton, wheat, rice, coal, coke, jute, gunny bags, hides and skins, tea, ores, and wool. Most cotton came to Bombay from Maharashtra. All tea came to Calcutta and Colombo from British-owned plantations in Assam, Darjeeling, and hills around Kandy. Most export rice came to Rangoon. Wheat came primarily from fields under state irrigation in Punjab (60 percent) and the western United Provinces (Uttar Pradesh) (26 percent). Oilseeds came to Bombay from Hyderabad territory (Andhra Pradesh), the Central Provinces (Madhya Pradesh), and Bombay Presidency (Maharashtra). Coal, coke, and ores came from mines around Jharkhand into Calcutta and Bombay, where they stoked local industry as well as exports. Eastern Bengal (Bangladesh) produced almost all the world's jute, which went to Scotland and then to Calcutta, where jute cloth output surpassed Dundee by 1908.

Between 1880 and 1914, industrial development in India took off during decades of low prices in Europe and America when rising prices in South Asia encouraged investments in India by firms producing for Indian markets and for diversified world markets. Commodity prices in India rose with export commodity production until 1929. Imported industrial machinery was domesticated in new Indian factory towns. It 1853, the first Indian cotton mill appeared in Bombay, and the Factory Act (1881) imposed rules on Indian factories to reduce their comparative advantage in virtue of low labor costs and cheap access to raw materials in India. In 1887, J. N. Tata's Empress Mill arose at Nagpur, in the heart of cotton country, in 1887. The Tatas became India's industrial dynasty. Tata Iron and Steel Works at Jamshedpur consumed increasing supplies of ore and coal, which by the 1920s rivaled exports from Calcutta. In 1914, India was the world's fourth largest industrial cotton textile producer: cotton mills numbered 271 and employed 260,000 people, 42 percent in Bombay city, 26 percent elsewhere in Bombay Presidency (mostly Nagpur), and 32 percent elsewhere in British India, at major railway junctures. Coal, iron, steel, jute, and other

industries were developed at the same time, producing specialized regional concentrations of heavy industrial production around Bombay, Ahmedabad, Nagpur, Kanpur, Calcutta, Jamshedpur, and Madras. Jute mills around Calcutta multiplied from 1 to 64 between 1854 and 1914; the number of looms and scale of employment increased twice as fast. In 1913, manufactured goods comprised 20 percent of Indian exports that were valued at 10 percent of national income, figures never since surpassed.

World War One stimulated policies to enhance India's industrialization to make India less dependent on imports, and the Great Depression, 1929–33, again boosted incentives for industrial growth by reducing prices for farm output compared to manufactures. As a result, industrial output in British India grew steadily from 1913 to 1938 and was 58 percent higher at the end of the Depression than at the start of World War One, compared to slower and more uneven rates of growth in the UK and Germany. By contrast, plantations languished from the early 1900s to the 1940s, the major exception being rubber, which benefited from war booms. Native States and non-British firms participated in the industrial trend. In 1902, Mysore government installed an electric generator built by General Electric with techniques and equipment pioneered at Niagara Falls. Bangalore was the first South Asian city lighted with electricity. In 1921, a third of India's industrial production was driven by electricity and Mysore had a higher proportion of electrified industry (33 percent) than British Indian provinces of Madras (13 percent) or Bengal (22 percent).

By 1920, South Asia contained national economies dominated by agriculture but also including large public sectors and major industries. Indian investors and nationalist politicians were by this time vocal advocates for increasing state development efforts. By 1920, British India was also a land of opportunity for global investors. In 1914, the US Consul at Bombay, Henry Baker, had called it 'one of the few large countries of the world where there is an "open door" for the trade of all countries.' England was still India's dominant trading partner, but was losing ground. In 1914, the UK sent 63 percent of British India's imports and received 25 percent of its exports; and by 1926, these figures stood at 51 percent and 21 percent, respectively. By 1926, total trade with the UK averaged 32 percent for the five major ports (Calcutta, Bombay, Madras, Karachi, and Rangoon). Bombay and Rangoon did 43 percent of their overseas business with Asia and the Middle East. Calcutta did a quarter of its business with America.

South Asia's early globalization also appears in migration data. In 1911, the British in British India numbered only 62 percent of all resident Europeans (54 percent in Native States and Agencies). Four times more immigrants came into India from Asia than from Europe and 7 of 10 came overland from Nepal (54 percent) and Afghanistan (16 percent). In 1911, Nepalis entering British India (280,248) exceeded the resident British population by 50 percent; Asian immigrants were three times as many. By 1921, emigration far exceeded immigration. Between 1896 and 1928, 83 percent of 1,206,000 emigrants left British India from Madras (which accounted for only 10 percent of total overseas trade), and they went mostly to work in Ceylon (54 percent) and Malaya (39 percent). Bombay emigrants went mostly to East and South Africa; Calcutta emigrants, to Fiji and the West Indies.

In 1920, Britain still controlled the highest echelons of South Asia's political economy, but process of capital accumulation inside South Asia had escaped British control. Before the war, London's political position in South Asia seemed secure. After the war, London declined visibly in relation to other metropolitan powers and also to cosmopolitan powers in South Asia that were mobilizing for national control of development. A national development regime emerged inside the British Empire. In 1920, the Indian government obtained financial autonomy from Britain.

Indian nationalists focused sharply on economic issues. The Indian National Congress first met in Bombay, in 1885, and then met every year in late December in a different city of British India. Following the Deccan famines, in1879, Dadabhai Naoroji published his influential *The Poverty of India* to document the negative economic impact of imperial policies on India, and he presided at Congress meetings in 1886, 1893, and 1906, where delegates from all the provinces discussed government policy and argued for lower taxes and increased state development expenditure. In 1905, the Congress launched a Swadeshi Movement to induce Indian consumers to buy Indian made cloth rather than British imports.

The Great Depression dramatized the social cost of India's open imperial economy: it sparked peasant and worker's movements demanding economic security and spurred nationalist efforts to make government more responsible for public well-being in India. By this time, government had long experience as an economic manager and investor in infrastructure. Government owned and managed most mineral and forest resources. Government agricultural departments, colleges, and experiment stations supported scientists and engineers who worked on state-funded development projects. The vast state sector of the imperial economy was managed, however, within a *laissez faire* policy framework that favored foreign investors.

In 1930, the new Congress president, Jawaharlal Nehru, announced new ambitions for national development. He took nationalist economic thought in a new direction when he said 'the great poverty and misery of the Indian People are due, not only to foreign exploitation in India but also to the economic structure of society, which the alien rulers support so that their exploitation may continue,' and he went on

to proclaim that 'In order therefore to remove this poverty and misery and to ameliorate the condition of the masses, it is essential to make revolutionary changes in the present economic and social structure of society and to remove the gross inequalities.'

Bitter experience of state failure, social disruption, and mass death during the Great Depression, the Great Bengal Famine (1943–4), and the Partition of British India (1947) laid the groundwork for national planning that stressed national autonomy, security, and economic integration under strong state leadership. In 1951, Prime Minister Nehru chaired India's Planning Commission, and in the 1950s, all South Asian countries wrote national plans stressing self-sufficiency and addressing problems of national economic growth, poverty, and inequality.

Three decades from the start of India's first Five Year Plan in 1952 to the end of its Sixth Plan in 1985 where the heyday of nationally planned development in South Asia. This was also the most creative period for development theory, a practical strain of economic thought devoted to increasing the productivity and well-being in nations emerging from European imperial control.

National planning required the institutional enclosure of national economies. Around the world, national economies were more self-contained in the 1950s and 1960s than they had been in the heyday of European imperialism. Foreign direct investment declined globally from roughly 10 percent of world output in 1913 to less than 5 percent in the 1960s, when the rate of increase in world merchandise exports was well below the 1.7 percent that pertained from 1870 to 1914.

South Asia's national plans focused on national markets. National planners formulated priorities for allocating state resources acquired both internally and externally. External funds came in grants and loans from countries involved in the Cold War as well as from the Bretton Woods institutions sponsored by the richest capitalist countries. National plan allocations for agriculture and industry were intended to enhance private investment. Planning instituted a new public-and-private apparatus for monitoring national economies. Planning agencies organized regional and local initiatives like cooperative societies and community development programs. National governments set up public food procurement and distribution systems to establish a ceiling on food costs for the poor. National health and education expanded. State ownership expanded to basic industries, public utilities, banks, and insurance.

Economic progress became a central feature of national discourse. Public intellectuals and organizations representing farmer, worker, business, and other interests became intensely involved in planning debates as the national public was mobilized politically under the universal adult franchise. In order to address national needs, however, deficit spending increased demands for external funding; and national economic growth depended on private capital rather than poor voters. Finance and politics pushed nationally planning in opposing directions. Popular participation favored citizen groups while financial pressures favored major investors.

Plans initially focused on industrial import substitution and on producing basic goods in public sector enterprises. Even so, eighty percent of India's industrial production remained in the private sector, where public sector output lowered input prices. Protective controls on imports, exports, and operations inside national markets were stricter than ever before and spawned a regulatory bureaucracy as well as black and gray markets. Plan allocations were in practice mixed in with political patronage. By the late 1960s, foreign exchange shortages began to put private and public sector companies into direct competition for funding. Nehru died in 1964. Drought and famine struck India in 1965–7 and the food distribution system relied on US foreign aid. As a result, planners thrust new energy into the Green Revolution, which combined irrigation, pesticides, and high-yielding hybrid wheat and rice seeds. Plans concentrated on extending the Green Revolution by investing in sites of intensive cultivation where well-endowed landowners controlled local labor, finance, and political institutions. Critics called this strategy 'betting on the rich.' Defenders saw the Green Revolution as the foundation of national food security.

During the 1970s, state planning began to lose its grip on development. Policy makers in Sri Lanka, Bangladesh, and Nepal were first to shift priorities away from national autonomy as they sought to meet demands from the urban middle classes and rural landowners by using massive external assistance for large development projects, epitomized by the Mahaveli scheme in Sri Lanka, then the largest irrigation project in the world. New external debt came with new conditions. From 1973, rising oil prices brought recession along with inflation to rich countries in Europe and North America, as it drove up the cost of South Asia's industrial growth, middle class consumption, and the Green Revolution. The effects were most drastic in smaller South Asian countries, which began borrowing on a much higher scale and soon came under structural adjustment policies introduced by the World Bank and International Monetary Fund, where development theory had shifted to focus on government policy reform in borrowing countries. Among economists, a critique of national state control of development became more insistent.

In 1981, India also began to rely more heavily on foreign debt. By 1990, internal pressure from middle class consumers and major industrial concerns combined with conditions imposed by external lenders to force the liberalization of economic policies in favor of freer market operations. State policy shifted away from regulated planning toward institutional reforms,

which have preoccupied government since 1991 and opened India's economy substantially.

The 1980s and 1990s witnessed a profound shift in relationships among participants in development. Dismantling central government controls, opening governments to public scrutiny and popular participation, and making the state more accountable and transparent for private citizens became the order of the day. In India, private capital and state governments gained more independence from a central government that is today composed of shifting coalitions of regionally based parties rather than being dominated by a single national party. State governments gained powers to make contracts with foreign countries and businesses. State Chief Ministers now compete to attract investors. In Nepal, electoral democracy was established in 1991, opening development to wide public debate at the same time as foreign investments grew. In Pakistan, a national government threatened by struggles for regional autonomy also had to absorb disruptions from two decades of war in Afghanistan, leading to more stringent authoritarianism. Since 1981, Sri Lanka has been wracked by civil war over Tamil regional autonomy; and like Bangladesh, it depends on foreign investors while it struggles to resist reforms that undermine national sovereignty.

The problem of governance became increasingly central in debates about development. Since 1980, active institutional participants in development have multiplied in all the countries as global investors have increased their power inside national economies. Together, these two trends have weakened the capacities of national governments to maintain strong leadership. At the same time, government reform and privatization of public enterprise has become a policy priority for international funding agencies. Effective governance in development has scattered and fragmented, while the responsibility of the national state for macro-economic management, property and human rights protection, and political stability has become more demanding.

Development today has no one guiding vision or dominant logic and several contradictory trends are prominent. National economies are more global as are the cultural communications that shape national politics. In the 1990s, television media owned by multinational corporations flooded public information systems. The growth of exports from South Asian countries measured 13.5 percent annually in the 1990s, almost four times the rate of the 1970s. Foreign direct investment (FDI) grew, though it remains a small proportion of India's GDP at 0.1 percent before 1991 and 0.5 percent in 1992–6. In 1990–6, FDI increased (in millions of US dollars) from under 100 to over 5,000 in India, from under 250 to over 650 in Pakistan, from under 60 to over 600 in Bangladesh, and from under 60 to over 2,400 in Sri Lanka. In the first six months of 1996 alone, Korean companies made nine technical and 25 financial agreements in India.

Forging alliances between national and international business preoccupies national policy and linkages between FDI and national investors have increased the pool of investment capital inside national economies. A repeat of the nineteenth century trend that created specialized economic regions is underway. In Nepal, tourism and hydroelectricity attract foreign and domestic partnerships. In Bangladesh, the garment industry has been the fastest growing employer relying on imports for all material inputs and exporting all its output. Sri Lanka is a free-trade zone. The South Indian cities of Bangalore and Hyderabad are growth nodes for high technology and business collaboration. The Sylhet region of Bangladesh specializes in labor exports to Britain.

Globalization has not fostered much cooperation among South Asian countries; rather, national governments and business compete in world markets. More market activity crossing national borders escapes regulation and monitoring. External labor migration has reached staggering proportions but is impossible to assess empirically. The largest overseas flow is to the Persian Gulf, where Bangladesh alone sent 1,600,000 workers in 1995. Available data indicate that only a fraction of remittances are recorded and that most flow through informal channels to finance domestic consumption, investment, and foreign trade in the migrants' home country. Illegal trades also flourish in drugs and arms; organized crime has gone beyond its old interest in black market radios and videos to trafficking in women and child sex-workers.

More citizen groups have become vocal critics of state leadership, priorities, and administrative practice in development. Popular movements against the Narmada Dam in India and against the Arun Three hydroelectric project in Nepal represent many mobilizations to make development more respectful of the environment and responsible to people marginalized and displaced by state development projects.

Countless grassroots movements now seek to wrest control of development from national states. These include regional and local democratic movements fighting for the interests of farmers, workers, industrialists, women, and the poor; they also include the Maoist insurgency that has spread like wildfire in Nepal, Tamil separatists in Sri Lanka, and militant struggles for autonomy among tribal peoples in several mountain regions.

Nongovernmental organizations (NGOs) have become prominent development institutions. NGOs number in the hundreds of thousands. Most are small and locally financed but some have grown huge by combining local initiatives with government funding, international finance, and business activity. In 1976, the Grameen Bank was established by Muhammad Yunnus in Bangladesh to make small loans to poor women and today it counts its clients in the millions

and values its loans in billions of dollars. Despite its size, however, Grameen still reaches a tiny proportion of the rural poor in Bangladesh.

Contemporary development includes contradictory tendencies that do not form one dominant trend. Globalization, regionalism, and localization are progressing at the same time. The conventional use of national statistics to study development has become inadequate as economic conditions have become more disparately local, regional, national, and global in their form and content. Overall economic growth accelerated in the 1990s, but there were also a series of good monsoons, poverty did not decline significantly, and inequalities as well as instability and conflict over development increased.

Who is leading development, who is benefiting, and where today's trends are moving remain debatable. Some analysts have said that development itself is dead. It is more accurate to say that development entered a new phase in the last decades of the twentieth century when increasingly numerous, vocal, and contentious participants organized effectively to pursue disparate, perhaps contradictory goals, including free market globalization, economic growth, ending poverty, and empowering the poor majority of citizens in South Asia who have never had their own effective institutional voice.

Area and International Studies: Development in Southeast Asia

Southeast Asia as a political/geographical entity came into 'existence' during World War II when the Allied Chiefs of Staff divided the world into specific 'war' commands. The Southeast Asia Command covered all the present countries of the Association of Southeast Asian Nations (ASEAN) with the exception of the Philippines. After independence, the Philippines was also included in the 'entity.' Thus, Southeast Asians themselves did not know that they were 'Southeast Asians' until the Europeans and Americans informed them. Consequently, they made little use of this connection, and Southeast Asian scholarship showed no interest in the larger unit other than their individual countries. Nevertheless, in universities set up by the colonial powers, the emphasis was on colonial histories, colonial possessions, and their common heritage.

The defining moment for awareness of being Southeast Asian came with the formation of small regional associations (under the aegis of the former colonial powers) and the larger ASEAN entity in 1967. ASEAN

originally comprised the five most economically advanced countries of Singapore, Malaysia, Thailand, the Philippines, and Indonesia and by 1999 had expanded to include all 10 countries in Southeast Asia. This expansion as a political association or unit also led to an increasing use of the term the 'ASEAN region,' rather than the Southeast Asian region. Indeed, although the former term is widely used in the United States, the United Kingdom, Europe, and Australia, there is an increasing trend to use the latter in the region. The term has been widely adopted by the ASEAN Committee on Culture and Information which has requested that researchers undertaking research programs under its umbrella to concentrate on 'ASEAN studies.' Thus, although ASEAN studies can be considered a specialist area within Southeast Asian studies in general, much like Thai studies, for example, nevertheless it encompasses the entire region. In this article, the term ASEAN is used to denote all countries in the region but the preferred usage is Southeast Asian Studies.

Most of the original members of ASEAN have achieved remarkable economic growth over the last 30 years. Behind this lies high levels of investment, open economies, and 'outstanding' export performance. This stimulated a rethinking of Southeast Asia's history and the meaning and context of the growth, leading to diverse studies of the region. In the 1990s, political change and internal transformations related to 'new' political visions, democratization and civil society, and recently the financial crisis and a slow return to previous levels of prosperity have again focused international attention on the region. While in the past emphasis was placed on the need to synthesize and compare variety and variation in Southeast Asia, the current trend is to see the region as an essential player in the global economy. This growth and change in focus have by no means been confined to 'Western'-based scholarship only. Southeast Asianists themselves have actively participated in the studies of their region in the wider context of the world around them and in the process made efforts to internationalize Southeast Asian studies.

1. *Early Approaches and Frameworks by Specialists Mainly Outside the Region*

There is an important heritage of scholarship relating to Southeast Asia within the Asian region, principally by Chinese and Indian scholars. One focus of Indian scholarship was the Indian Ocean area in the early modern period, the resilience of Asian economic forms and activities, and the relations between the Asians and early Europeans in the region. Chinese scholarship focused on China's tributary state and trading relationships with native rulers, and observations on European colonialism in Southeast Asia, especially in the nineteenth century. This approach essentially viewed the Southeast Asian (and Asian) region in terms of networks of maritime trade and trading ports connected within and across 'national' boundaries.

The internationalization of Asian studies, which commenced with the first International Congress of Orientalists convened in 1873 in Paris, revolved around the needs of textual scholars whose enquiry concentrated on linguistic, religious, cultural, and political pluralisms. Asian diversity was included in all congresses, which were held in rotation in all continents. Contemporary political issues, which had been excluded from the earlier meetings of the congress, were included from 1954. The name of the congress was also changed to CISHAAN (*Congres International des Sciences Humaines en Asia et Afrique du Nord*) in 1973, and in 1983, the English form ICANAS (International Congress of Asian and North African Studies) became official.

In the twentieth century, the development of Southeast Asian area studies was closely related to the European powers' imperial interests in Asia and the need for expertise in the relevant vernacular languages. The work of scholar-administrators in the then Indochina, the Netherlands East Indies, Malaya, Burma, and the Philippines falls within this genre of policy oriented research. After World War II, decolonization, the Cold War politics, and development optimism fostered further policy oriented research in order to contribute to the strategic interests of government and business circles. This research challenged the previous, more conservative work of colonial scholars. At the same time a 'new' generation of Western scholars representing the humanities, particularly anthropology, sociology, history, and the social sciences—political science, economics—ventured into cultural contexts, interactions, power relations, and the state, thus challenging the applicability of overarching grand theories. These scholars fostered interdisciplinary programs and trained a generation of Southeast Asianists. With their legacy of regional, comparative, and disciplinary specialisms they not only sustain interest in the area but also are training a new generation of Southeast Asianists. Their focus has also changed with the redefinition of the region through the expansion of ASEAN and an increasing proliferation of meetings and organizations.

2. *Research by Southeast Asianists: Early Directions*

In the 1960s and 1970s, most Southeast Asianists focused on country studies or sub-regional unit studies. The majority of scholars concentrated on historical research/empirical work to constitute knowledge. History, anthropology, sociology, and

political science represented most of the intellectual streams in the field. The principal institutional setting for these disciplines was the universities that trained students in the humanities and the social sciences, and were the sites of research. Politicians and university administrators, encouraged by nationalist sentiment, fostered awareness of national/Southeast Asian studies, and encouraged the development of research interests on the region. The stronger the identity of the Western 'other' in the mind of the Southeast Asianists, the more inclusive became the notion of Southeast Asia. In turn, as these area studies programs attracted students who believed that their employment prospects were enhanced, so were further research interests in Southeast Asian studies developed. A wide range of professional associations was also set up to sustain the humanities and social sciences.

Historians were in the forefront of change. There was a two-stage move away from colonial and political emphasis to economic and then to social and cultural structures. This in turn brought about a discernible realignment from the social sciences towards the humanities. Historical scholarship was not confined to institutional settings and the discipline was open to contributions from other fields. Apart from national historical associations, state historical societies were also formed and there were cultural organizations like museums, which provided vitality to the discipline. Nevertheless, the encouragement of local history in some cases eroded any systematic attention to historical skills.

3. *Principal Institutional Settings and International Networks*

While university departments offered undergraduate teaching, postgraduate training was principally undertaken in the United Kingdom, the United States, or Australia. This was contemporaneous with two major developments. The first was the emergence of Southeast Asian area studies as the most dynamic branch of area studies in the 1960s and 1970s. The region's increasingly important role in view of the actual and potential Cold War conflicts in the area not only focused media attention on the region but also was assisted by support from two main sources. The first was support from Southeast Asian governments, which established Southeast Asian programs or institutes for policy related research pertaining to self-determination struggles, governance, and state policies that promoted political stability in diverse and plural societies. Support also came from the United States, the United Kingdom, and Australia. These countries not only promoted and established Southeast Asian studies centers as a field of study in their own right but also provided postgraduate training for Southeast Asianists through fellowship schemes. They also served as a source of Western academics that came to the region for teaching and research stints. It must be stressed however, that for the latter, Southeast Asia was still largely viewed from the periphery of Europe, the US, and Australia.

In the US, the Rockefeller Foundation made a grant to Cornell University to establish a center in 1950. Between the late 1950s and early 1970s, there was increased US funding for Southeast Asian study programs at Yale, Michigan, Northern Illinois, and Wisconsin-Madison. Columbia expanded its Southern Asian Institute to include Southeast Asian Studies. In the UK, the School of Oriental and African Studies (established 1938), was followed by a Southeast Asian studies center at Hull and Kent. In Australia, Monash University under the direction of John Legge, became a leading center of Southeast Asian studies, followed later by the Australian National University and others. These centers complemented and networked with the centers set up in Southeast Asia (see section 4 below).

4. *The 'Indigensization' of Southeast Asian Studies*

The formation of ASEAN in 1967, the impact of the Vietnam War, and the withdrawal of the US from Vietnam bolstered new interdisciplinary studies. Subsequently, at ASEAN's first summit meeting in 1976 the promotion of Southeast Asian Studies and the initiation of centers reflected a growing awareness of a wide variety of cross-border commonalities and the need to make greater efforts to understand neighboring countries and societies. The more challenging fields of study were cultural studies, gender studies, and indigenous and postcolonial studies, all of which had their own problems while at the same time, relying on the older disciplinary bodies of knowledge. The courses taught were discipline-based and the scholars regarded as discipline-based social scientists or humanists. They were only regarded as Southeast Asianists outside their countries. Moreover, although many or most of the Southeast Asian universities established courses on Southeast Asia studies, only in Malaysia and the Philippines did these institutions award both undergraduate and graduate degrees in Southeast Asian Studies [during the 1990s in Thailand as well]. Interestingly too, the only 'other' languages widely studied were those of Europe, especially English. Only in Malaysia and Singapore were other Southeast Asian and Asian languages offered to students. In the department of Southeast Asian Studies at the University of Malaya, students are required to take a Southeast Asian language, other than Malay.

The rationale for the promotion and funding of Southeast Asian area studies by most countries in the

region stemmed from the need to contribute to better understanding within the region; generate materials on the region which emphasize cross-border commonalities and shared interests, and establish specializations and the teaching of Southeast Asian languages. Funding for these activities came mainly from the state with additional international funding.

5. *Changing the Balance: The 1980s*

The economic ascendancy of Japan, the rise of the East Asian 'Tigers,' and the greater integration of Southeast Asia into the East Asian region led to changes in the direction of research and emphasis. The 'new 'concerns—industrialization, trade, investment, the sociology of production, and the disciplines of economics and political economy—became the new and international 'focus' areas. In terms of area studies, Japan and East Asia became the new paradigms. The commonality of East Asia's economic success, particularly for the countries that benefited most from it, promoted an awareness of shared values (Asian values), as distinct from 'Western values' and the construction of an Asian identity. Coincidentally, Japan (and to a lesser extent South Korea), became the new 'funding ' players, promoting not only Southeast Asian Studies but also Japanese and Korean studies.

At the same time, social science paradigms developed principally in the West were being modified or even rejected within the region. By the end of the 1980s, most Southeast Asians, in common with other Asians, began to perceive themselves and their countries not as objects but as subjects of study.

Three other concerns stand out during this period: labor, women, and the environment. Their study on a regional basis and through regional projects was promoted by international agencies such as the World Bank, the United Nations Environmental Program, and the United Nations Development Program. Large amounts of money were poured into the region, principally to established centers like the Institute of Southeast Asian Studies, Singapore. This institute has become a major postgraduate studies center for Southeast Asian Studies in the region. It has traditionally had a very active publishing program, its own publishing house for books, and publishes journals, of which Contemporary Southeast Asia and Southeast Asian Affairs is very well known. The new programs of the Institute include the regional economic studies program, which focuses on economic and related issues of the Asia-Pacific Economic Cooperation (APEC) forum, with a special focus on ASEAN, and the East Asian Development Network. Other regional projects included the East Asian Caucus, the expansion of ASEAN membership, and the coordination of Asian positions at the Asia-Europe meetings.

Southeast Asian Studies as area studies programs also advanced with the establishment of the Southeast Asian program at the National University of Singapore and the enlargement of the Southeast Asian Studies program at the University of Malaya into a Department that awarded degrees. In the meantime, in Thailand the Institute of Asian Studies at Chulalongkorn University (established in 1967) also began to focus on Southeast Asian Studies. Thammasart University established an Institute of Southeast Asian Studies in 1986, while the Arts faculty established a Bachelors degree in Southeast Asian studies in the late 1990s. The latter also initiated an important Foundation for the Promotion of Social Sciences and Humanities Textbooks Project. This foundation has produced a large number of books, in Thai, on Southeast Asia. The Institute of East Asian Studies (IEAS) established in 1998 at University Malaysia Sarawak, claims to be the first of its kind in the ASEAN region. Its role 'is to promote a range of interdisciplinary programs and activities to advance a better understanding of the East Asian region.'

The pride of being 'Asian,' sometimes expressed in anti-Western policies such as the Look East Policy, also led to a greater focus on Islamic identity and Islamic values, especially in Malaysia, Indonesia, the Philippines, and Thailand. Since the late 1970s, the region has experienced an unprecedented religious resurgence. The expansion of religious schools, the growth of a market in Islamic books, magazines and newspapers, and the rise of a well-educated Muslim middle class have played a role in the development of Islamic studies and Muslim discourse. Consequently, although Islamic studies in the region had earlier been regarded as at the intellectual periphery of the Islamic world, in the 1980s a systematic understanding of Islam and Islamic civilization has made Islamic Studies an ascendant field of area studies. This has been contemporaneous with increased relations with the Middle East and the Muslim bloc. In Malaysia, where Islam is the state religion, but where Muslims form a small majority only, the state has actively promoted Islamic area studies. In common with other countries in the region, pluralism, intellectualism, and openness to dialog with other faiths and institutions mark the study of Islam. The Malaysian government has also promoted Islamic studies through the establishment of an International Islamic University, an international Institute of Islamic Thought and Civilization (ISTAC), and a Center for Civilization Dialogue. The Islamic University, established in 1983, attracts scholars from the Asian region and elsewhere. ISTAC, which was established in 1991, is a research and postgraduate institution, affiliated to the International Islamic University and offers courses in Islamic thought, civilization, and science. The Center for Civilization Dialogue, which is based at the University of Malaya, was formed to encourage cross-cultural dialog and promote harmonious relations in Malaysia.

Figure 1
Southeast Asia: area and international

Islamic studies therefore form a core research activity in Malaysia and Indonesia with participation from key neighboring countries.

6. *The 1990s, Diversification, and New Research Directions*

The 1990s started with a continuation of the discourse on 'Asianess,' 'Asian values,' and an 'Asian century,' all of which lost overall relevance when the Asian miracle turned to meltdown. National values and national ideologies began to be voiced again, as some countries sought to distance themselves from others. In regional terms, especially over East Timor and Myanmar, there was also a lack of unanimity. Nevertheless, the Southeast/Asian identity in the wider world continued, especially in relations with East Asia, the US, and Europe.

Many of the new directions were in Women's and Gender Studies, Migration Studies, and Environmental Studies and there is not a single discipline in the humanities and social sciences that has remained untouched by these topics. There are many new conjunctions, especially with regard to Women's and Gender Studies, encompassing critical race theory, postcolonial theory, multiculturalism, and cultural, political, and social theory. The tremendous growth in intra-Asian labor migration associated with labor shortages/labor surpluses in the region also provided a new focus of area studies: migration studies. Not surprisingly, the Philippines, which relies heavily on short-term contract labor and remittances, took the lead in promoting migration studies. The Scalabrini Migration Center in the Philippines, which is a branch of the Federation of Centers for Migration Studies, became the focus of migration studies and publishes two quarterlies, *Asian Migrant* and the *Asian and Pacific Migration Journal*. Migration studies programs were also initiated in Malaysia, Thailand, and Indonesia.

After the middle of 1997, the region witnessed momentous and tragic events that led to a substantial decline in the living standards of its inhabitants. Consequently, just as in the 1980s, there was a great emphasis on explaining why the second tier newly-industrializing countries grew so fast, the major preoccupation of economists and political economists was on understanding how and why these economies fell off their high growth trajectories. Since this is not the kind of crisis to which governments and international agencies were accustomed, there was a substantial shift to understanding the crisis. The ASEAN Inter-University Seminar Series, which was launched in 1993, had as its theme Social Development: Post Crisis Southeast Asia for the 2001 Seminar. Two of the key panels included Southeast Asian Families: Surviving the Crisis and The Political Economy of Crisis and Response. The Series focused on common pursuits in the exploration of social issues, with an emphasis on collaboration, mutual understanding, and regional cooperation.

While national and regional studies continue to expand, ASEAN has now found it imperative to gain a knowledge and appreciation of other countries. The changing emphasis is reflected in Fig. 1 below National studies are placed at the 'core' of the Sotheast Asian world and other area studies are positioned relative to their importance to Southeast Asia.This is in keeping with the region's growing ties with the European Community and ASEM initiatives. At ASEM I in 1996, Malaysia took the lead to establish an Asia-Europe University (AEI) for European studies. The AEI is aimed at 'studying the diversities of both Asia and Europe and the forces of integration at work in both regions.' New research directions include an enhancement of Asia-Europe relations and partnerships through dialog and cooperation in the field of higher education, and an advancement of European studies. The Malaysian government funds the AEI, with support from other ASEM partners, international institutions in Europe, and the corporate sector in Asia and Europe. It is sited at the University of Malaya in Kuala Lumpur, and the key topics in this 'new' area studies are policy-related research on Asia, Asian business, European studies, European business, and e-commerce.

Thus while Southeast Asian studies continue to be emphasized, the region is finding it imperative to retain a knowledge and appreciation of other countries in Asia, Europe, the US, and the rest of the world, in that order. This will make Southeast Asian area studies remain competitive and holistic and overcome regional parochialism.

7. Future Directions

The interconnections between area studies and global concerns is shown in the growth of various studies–gender relations, labor and environmental standards and regionalism and trading blocs. This focus on global issues is set to continue in the research agendas of Southeast Asian studies in the third millenium. Consequently, Southeast Asian studies will continue to involve an understanding of the comparative nature of change in the global economy, and it is this comparative aspect that gives the field its intellectual breadth and vigor.

Area and International Studies: Economics

At least since Adam Smith's *Wealth of Nations* (1776) the economics discipline has been concerned mainly with explaining the production and distribution of goods and services through the spontaneous interaction of self-interested demanders and suppliers. Economic 'efficiency' in a market system came to be understood as the condition in which land, labor and capital were allocated so that the largest possible output was obtained of those goods and services desired by consumers. Improvement in efficiency is achieved by extending the market geographically and obtaining thereby both greater competition among buyers and sellers, and reductions in costs of production through specialization and economies of scale. All impediments to extensions of the market, such as barriers to mobility of goods and services and of productive inputs, came to be viewed with suspicion or regret by economists. Nation states with distinct cultures, languages, and bodies of law were clearly sources of potential economic immobility, and economists often arrayed themselves against nationalism and in favor of a cosmopolitan world.

In the nineteenth century the 'marginal revolution' in economic theory formalized, and in some respects simplified, economic thinking; it presumed that all economic agents, regardless of their location on the globe, employed a utilitarian calculus. This undermined the case still more for economists to engage in the sympathetic study of the distinctive or unique characteristics of individual nations and peoples. By the start of the twentieth century, then, economists for the most part held to a universalistic ideology that saw in too much attention to what would become known later as international and area studies the danger that a case would be constructed for intervention in the world economy and an excessive role for the state. Added to this danger was the threat that too sharp a focus on the details of national behavior might lead to disturbing questions about the behavioral postulates of economic agents upon which the theoretical system of economic science now depended.

Nevertheless several special circumstances from time to time drew the attention of economists to area and international studies. These circumstances may be grouped roughly into three categories: first, the existence of empires and the challenge of achieving economic development in poor countries; second, international conflict and the need to understand peculiarities of the 'economic systems' of friend and foe; and finally, the structure of the international economic order, taking into account not only the microeconomic efficiencies that could be achieved therein, but also an increasing degree of macroeconomic interdependence.

1. Empire and Economic Development

In contrast to the Mercantilist Writers who preceded them, Smith and some of the Classical economists suggested that colonies, including those in North America, were likely to cost more than they were worth, and it was better to let them become independent trading partners, in which case there was no particular reason to study them more than any other nations. Regardless of this advice, the major nations of Europe, and even to a degree the USA, 'scrambled' for colonies during the nineteenth and early twentieth centuries. Many prominent economists such as John Stuart Mill and John Maynard Keynes became directly involved in colonial administration and neces-

sarily deepened their knowledge of the dependencies in the process. Some later classical economists, such as Edward Gibbon Wakefield, extolled the economic benefits to both colonizers and colonists of the imperial links; others such as Karl Marx and John R. Hobson saw empire as part of a predatory process into which industrialized countries were inevitably drawn by the unstable nature of their own economic systems, but on both sides of this debate over the value of empire there seemed little reason to examine the peculiarities of the colonies themselves, and arguments were conducted mainly at the level of high theory.

During the nineteenth century, the one notable exception to the general inattention by economists to cultural and societal distinctions was the German Historical School which held, among other things, that the postulation of theory should follow inductive inquiry, and that economic development typically proceeded through successive stages, for each of which different public policies were likely to be appropriate. For example, they asserted that there should be no unqualified endorsement of free trade and prohibition against an active state in the economy. Each case required its own analysis, and in certain circumstances even tariff protection—anathema to most free-market economists—might be appropriate. Friedrich List (1827) described the success of protectionist American development policies after residence in the country. Other Germans—graduate students as well as senior scholars—fanned out around the world to gather information about foreign countries in a way that was never fashionable among British classical political economists.

When empires largely collapsed after World War II, attention among economists shifted toward the developmental challenges of the newly decolonized nations. This attention was especially intense in the USA because of the strong sense of an important new world role for the country. To a degree never attempted before, economists in those years reached out to other disciplines to help explain reasons for stagnation, and to help design policies for the future. To some extent the new field of 'Economic Development' in economics, as it was called, reached back to the interdisciplinarity and multinational orientation of the German Historical School, but now filtered through the distinctive features of American Institutionalist Economics, found in the works of Thorstein Veblen, Wesley Clair Mitchell, and John R. Commons. In teaching and research units devoted to development studies such as those at Yale, Stanford, the University of Wisconsin, and the University of Sussex, and through such periodicals as the *Journal of Development Studies* and *Economic Development and Cultural Change*, economists joined with other disciplines, and especially the other social sciences, to explore developmental strategies and especially innovative roles for the state. Enthusiasm for 'economic planning' in this literature was reminiscent of the excitement felt for the Tennessee Valley Authority in the 1930s. Often leaders in the new development economics, although much honored as individuals, moved outside the mainstream of the discipline. Gunner Myrdal and John Kenneth Galbraith are prominent examples. In some parts of national governments and international organizations, such as the Economic Commission for Latin America under the leadership of Raul Prebisch, there was even wholesale rejection of the free-market model wherein, it was charged, each nation was compelled to accept the economic activities meted out to it by the principle of comparative advantage. This model was pictured as no more than a rhetorical device used by the industrialized nations to keep poorer nations as hewers of wood and drawers of water. Instead, it was said, each nation should select its own development path and seek to limit external dependence by producing its own substitutes for imports (Prebisch 1950, Singer 1950). In that it was predominantly Latin American, and later African, economies that followed this advice—as opposed to Asian economies that focused on expanding manufactured exports—the Prebisch–Singer dependency theory fostered a regionally-defined character of inquiry into the particulars of developing economies.

For the first few decades after World War II the subdiscipline of Economic Development prospered and interacted in complex ways with other disciplines and with international and area studies programs on many campuses and in many countries. Within the discipline, a handful of scholars such as Hirschman (1958) emphasized the importance of understanding the different structural issues of the developing world and advocated country-specific inquiry. Economists became engaged with the details and particularities of the societies of other countries as never before, and often they were involved with the planning and implementation of the policies they held under review. Beginning in the 1970s, however, the subdiscipline came under stress. The tension between its operating assumptions and those of the disciplinary core of economics became obvious and intolerable to some disciplinary leaders. The development economists accepted complex behavioral postulates that were culturally determined, at least in part, in place of profit and utility maximization, and they proposed policy norms that substituted values like independence and cultural survival for consumer sovereignty and market freedom. Perhaps nowhere was the debate as sharp as in research on rural and agricultural development, where the 'efficient peasant' school (Schultz 1964) stood in stark contrast to the view that poor farmers were driven by cultural constraints and 'survival algorithms' (Lipton 1968).

The research style of the subdiscipline of development was also discovered to be very different from that of the 'core,' demanding extensive field work and personal identification with the subjects under study, as well as resort to other disciplines such as anthro-

pology and history. The development economists did not depend upon abstract modeling and empirical testing to the extent that this was prescribed in the canonical methodological essays of the time, such as those by Lionel Robbins (1932) and Milton Friedman (1953).

The methodological debate was rendered moot for many observers of the world economy—within and outside the economics discipline—in the 1970s and 1980s, as the evidence mounted that free markets and free trade had demonstrated conclusively their virtues as the best path to successful economic development; central planning and other forms of public intervention lay discredited. Old-style development studies therefore became associated with the losers in this appraisal of the development race. With the evident failure of the import-substitution strategies of Latin America, as against the success of the export-led growth of east and south-east Asia, it seemed to many observers that the special field of economic development had been a pied piper, and that those poorer countries which had followed the mainstream of the economics discipline, where country-specific knowledge was not required, were better off. With the decline in fashion of old-style development studies in economics there followed a reduction in support for the subdiscipline from charitable foundations, governments, and international organizations, and a decline also of interest among students.

By the 1990s, economic development as a distinct subfield of economics was in many places on the wane, or was moving away from its former distinctive commitment to an area studies approach toward simply the application of the conventional tools of applied mainstream economics to problems of poorer countries. Developing-area data sets were widely supplied by international organizations, but there remained little sense of a need for analytical tools uniquely appropriate to conditions of the 'developing world.'

As consensus built during the 1980s and 1990s on the strength of free-market policies, more and more less-developed countries tried to follow in the path of the Asian economies (some under the express direction of the World Bank and International Monetary Fund) and liberalize their markets. Most of these efforts were profoundly disappointing in terms of economic growth. Evidently, the strict neoclassical paradigm was not a panacea, but neither were the interventionist models it replaced. The search went on for a new explanation, and many focused their attention on political and social institutions and their role in facilitating or hindering economic growth. If now-discredited development studies had an ideological connection to the original American school of Institutionalist Economics, the New Institutional Economics offered a neoclassically credible approach with the study of region- and country-specific structures. Douglas North (1990) and Oliver Williamson (1996), among others, developed an evolutionary approach to the origins of legal and commercial institutions, an approach that resonated with economic historians and those in the field of economic development who remained committed to the differences in, rather than universality of, the countries they studied.

2. *International Conflict and Comparative Economic Systems*

After the problems of economic development in poor countries, international conflict has been the second major stimulus for economists to attend to international and area studies. From the earliest days of the discipline, economists joined their countrymen in speculating about the behavior and motives of their traditional opponents: the British about the Spanish and then the Germans, the Americans about the British, the Canadians about the Americans, and so on. Such speculation required some familiarity with the cultural peculiarities of the antagonists. By the 1930s, traditionally free-market economists concluded that at least two alternative types of economic system had emerged that were a continuing political and economic threat to the very idea of a free society and a competitive market economy. These were represented by the fascist dictatorships of Hitler, Mussolini, and Franco, and by the Stalinist planned economy of the Soviet Union. Attention by economists to these alternative economic systems was strengthened, first by the sense that the world economy had become so interrelated that difficulties in one part, like a recession, or selfish actions in another part, like imposition of a tariff, could injure all. This is partly the reason why John Maynard Keynes paid so much attention to economic development in Germany and the USSR. The second reason for attention to these authoritarian experiments was because they were perceived, correctly, as direct challenges to the general applicability of the competitive market model. Advocates of totalitarian economies claimed that authoritative decision makers could do jobs better than could the free market. The systemic extremes were in a sense locked in a battle for the minds of the modern economic man.

As soon as World War II began, the new economics subdiscipline of 'comparative economic systems' emerged formally as a way for governments of the allied nations to better understand the behavior of both enemies (Germany, Italy and Japan) and allies (the Soviet Union). At the start the 'systems' were seen as divided roughly into two broad categories: authoritarian planned economies on one side and liberal democratic economies on the other, but in the decades after World War II a more fine-grained categorization was attempted between the two extremes, to include across a political spectrum from left to right such

categories as non-communist planned (India and Tanzania), liberal welfare-state (Sweden and the UK) and modified communist (Yugoslavia). All these variants received some attention from economists specializing in economic systems and using an approach that involved area and international studies.

The decline of comparative systems as a subfield within economics parallels that of economic development and is tied up with the same historical and ideological trends. Over the course of the Cold War many economists came increasingly to conclude that all deviations from the competitive market norm were simply short-term aberrations and unworthy of serious scholarly attention. These, they believed, were the work mainly of selfish rent-seekers and bureaucrats and could not long survive in the face of the liberal alternative. Events of the 1980s, and especially the *annus mirabilis* 1989 that saw the collapse of the Soviet system, seemed to bear out this prophesy, but if 1989 brought an end to the study of comparative systems, it launched the (presumably temporary) subdiscipline of 'transition economics,' with its own necessarily regional focus. Economic systems specialists turned their attention to the evolution of post-planned economies toward the final steady state of democracy and free market capitalism (Kornai 1990, Boycko et al. 1995). Free-market transitions, like economic development, have proven both slow and difficult, suggesting that economists will remain a voice in post-Soviet studies for the foreseeable future.

With the declining political threat from the communist world and rising concern over the Middle East, it is perhaps not surprising that economists' interest in regional study has also been focused increasingly on the economics of the Muslim world. Islamic economics, with a focus on the Koran-prescribed rules of financial transactions, has emerged as the most recent comparative system for analysis (Khan and Mirakhor 1987, Kuran 1995). Reflecting perhaps the new interest in social institutions, much of the literature has approached the religious constraints on the free market not as an obvious inefficiency but, in the light of new attention to group-based lending and social capital, as potential corrections to the failures of free-market financial institutions.

3. *The International Economic Order*

A third stimulus for economists to pursue area and international studies was a growing appreciation that since the existence of nation states rendered impossible a truly competitive and unrestrained international economy, it was necessary to think about 'second best' alternatives. Up until World War I the informal Gold Standard seemed to impose a salutary degree of monetary and fiscal discipline on nations engaged in international trade and finance. After the war, however, attempts to recapture the benefits of the Gold Standard through the largely uncoordinated efforts of individual nations were mainly unsuccessful. By the later stages of World War II it was widely agreed, even among prominent free-market economists, that new institutional structures were needed to facilitate international trade and finance and, above all, to prevent the return of the Great Depression. Lord Keynes, Harry Dexter White, and other prominent economists who had risen to high levels in government, were at the heart of the planning at Bretton Woods that led to creation of the International Monetary Fund, the World Bank, and ultimately the General Agreement on Tariffs and Trade. Economists were given prominent roles in all of these, and in many other international organizations that came into being with some jurisdiction over the world economy.

It is hazardous to generalize about as complex phenomena as the place of the economist in the design, construction, and operation of the architecture of the international economic order that has emerged since World War II. But dominant characteristics that were present also in the approaches to economic development and economic systems discussed above, are easily visible here as well: an abiding faith in markets as a solution to economic problems, suspicion of special pleading as the basis for policymaking, skepticism of vigorous governmental action of any kind, and, wherever practicable, a preference for rules over authorities as a fundamental policy posture.

Despite near consensus among the economists on the optimal global architecture, progress toward these goals has been incremental and an ongoing area for research. Efforts to remove barriers to trade and financial integration accelerated in the 1980s and 1990s once developing economies lost whatever special status they could claim for strategies such as import substitution, which required tariff protection. Although much of the literature has been polarized between country-specific perspectives and global ones, recently two phenomena have emerged to refocus attention to regional problems.

First, there have been increasing efforts of governments to reduce trade barriers within regions, if not yet worldwide. Regional trade agreements such as NAFTA have raised concern over trade diversion while resuscitating the debate over regional integration. The prospective benefits of regional integration have been a boon, not just for trade theorists, but also for area specialists with an interest in the historical context as well as the implications for economic development (Collier and Gunning 1995).

Second, a series of regional financial crises, in Latin America in the mid-1990s and in Asia in 1997–8, coupled with plans for currency integration such as the EU have renewed interest in regional currency management and optimal currency zones. As with the with debate on trade, many of these issues have deep historical precursors, and economic historians—whose subdiscipline remains a haven for regional

expertise—have added contextual nuance to the monetary theorist's musings (Eichengreen 1996).

4. Conclusion

Economists have tended to focus their attention on increases in efficiency and competition that arise from the development of markets, and they view with suspicion arguments for intervention that privilege national borders or cultures. They have come to view economic agents as relatively homogeneous in their behavior across the globe. In their view, these agents respond differently mostly because they are faced with different institutions and different incentive structures. The New Institutional Economics has been instrumental in using the standard economist's toolkit to model these differences, allowing behaviors previously thought to be in the cultural domain to be formalized within the neoclassical paradigm.

These new domains may revive interest among economists in studies of areas, but it is unclear whether such interests will fall within the realm of area studies. The regional expertise required to legitimize regionally-oriented work within the economics discipline is of a different character than the expertise required in other disciplines. One notable feature of the debate on regional integration is how many economists are publishing on NAFTA, MERCOSUR, APEC, and the EU simultaneously. There is little incentive to invest in context-specific expertise at the expense of the universally-applicable tools, especially since the empirical record would argue against economists going outside the neoclassical paradigm, especially when offering policy advice. There is a fundamental rift between this view and the original vision of area studies, which has stressed nonuniversality and resisted the 'monoeconomics' standard. This ideological rift threatens to leave area studies without a voice from the economics discipline, while simultaneously removing the voice of regional expertise from the economic arena

Area and International Studies in the United States: Institutional Arrangements

Area and international studies refers to research and teaching about other countries. In the United States, until the 1940s, international studies were simply parts of academic disciplines. Over the past fifty years they have become more distinct, self-aware, and organized. Their growth has paralleled a more general trend toward the internationalization of American universities: the expansion of opportunities for study abroad by students and faculty; bringing more foreign students to the campus; staffing and managing technical assistance programs; developing formal overseas linkages including the establishment of satellite campuses abroad; and durable transnational links between faculty and students in the US and abroad. Here, only those aspects dealing with research and teaching about countries other than the US will be discussed.

As international studies have grown, they have split into a number of specialties which for purposes of

analysis will be divided into two segments; one, those that deal primarily with a single country or region, and the other, those that comprise studies of transnational phenomena. Two examples of studies focused on single countries or regions will be discussed: area studies and risk analysis. With respect to transnational research several overlapping specialties will be discussed: comparative studies, international relations and foreign policy analysis, security studies, peace studies and conflict resolution, and international political economy studies.

1. Studies of a Single Country or Region

1.1 Area Studies

1.1.1 Origins. Of all of the international studies specialties the developmental path of language and area studies is the easiest to identify. The seeds of area studies lay in the 'tiny band' of area-focused scholars who, before World War II, were scattered throughout the faculty of a few universities, primarily historians or scholars who studied the literature of great civilizations. During World War II, the anticipated manpower needs for intelligence and possible military government led to the establishment of a number of prototype area studies programs, Army Specialized Training Programs (ASTP), on 55 American college and university campuses, to train specialists on particular countries or areas. This early emphasis on (a) a perceived national need which was unmet by normal academic processes and (b) remedying a manpower shortage—other programs were established under ASTP for perceived shortages in mathematics, physics, electricity, and engineering—remain until today the core rationales for federal government support of language and area studies programs.

Since the ASTP programs were focused on preparing people to deal with current affairs, the social sciences and the currently spoken languages of the region were added to the pre-existing humanities base on the campuses to create a new academic model. In the initial programs the students were all enlisted in the military. After World War II area studies were gradually incorporated into the general educational mission of universities and colleges. By the 1990s almost half of the universities and colleges in the US offered curricular concentrations focused on one or another world area. The area studies model was also used in various government agencies for training foreign service officers and other personnel preparing for service abroad.

1.1.2 Funding. It was clear from the outset that special financing was needed to sustain and expand these programs. The normal organizational style of universities was inhospitable. The normal priorities of disciplinary departments made it difficult to assemble the requisite specialized faculty in a variety of disciplines. Student demand had to be developed from scratch, and funds were needed to support the added time that language learning and overseas doctoral research demanded. Moreover, expanding and cosmopolitanizing library collections to provide the basis for research and teaching about other countries was costly.

Over the course of the next several decades grants from a number of private foundations—primarily the Rockefeller, Ford, and Mellon Foundations, and the Carnegie Corporation—provided the special support that area studies programs needed. In 1958, private foundation funds were supplemented by funding from the federal government. Following the minor panic that resulted from the Russians' unanticipated launching of the satellite Sputnik, the US government established an annual support program for university-based language and area studies centers under Title VI of the National Defense Education Act (NDEA), later the Higher Education Act (HEA). This governmental funding program has continued uninterrupted for more than fifty years and has played a critical role in the maintenance of language and area programs. However, universities have provided the bulk of the support for area studies programs out of their own funds. Outside moneys rarely cover as much as ten percent of the full cost of programs.

Since a primary goal of area studies has been the expansion of a national cadre of experts it was essential that a steady flow of graduate students be recruited into the field. An early fellowship program—Foreign Area Fellowships—was introduced by the Ford Foundation to provide support for domestic and overseas education of area specialists. Over the years, this program has come to emphasize support for dissertation research overseas. Supplemented by support from other donors, it is now administered jointly by the Social Science Research Council and the American Council of Learned Societies, the primary overarching research organizations in the social sciences and humanities respectively. Subsequently, annual government support for study at area centers was provided as Foreign Language and Area Studies Fellowships under NDEA, Title VI. Support for dissertation research abroad was funded by the US Department of Education under a specifically earmarked section of the Fulbright–Hays Act, and, since 1991, through fellowships made available under the National Security Education Act, administered by the Department of Defense. Over the years, language and area studies centers have received a series of general support and endowment grants from the Ford and Mellon Foundations, as well as a variable flow of project money for individual research projects. In addition to general funding for area studies as a whole, supplementary

support has been made available for specific world areas.

1.1.3 Area Specialists. The term 'area specialist' refers to an individual, most often a scholar, who dedicates most of his or her research and teaching to a particular country or region, possesses a substantial amount of multidisciplinary erudition about that country or region, and is competent in one or more of the languages of the area. While the term can include individuals concentrating on any portion of the world, in practice it tends to be used primarily for those whose area of specialization is in the non-Western world (including Russia and East Europe), plus Latin America. Scandinavian studies is usually included as area studies, but European studies is not.

In the period immediately after World War II, before area studies centers were established, most area specialists were self-recruited and self-trained. Their tended to be recruited through prior overseas residence; in the case of developing societies this was often the Peace Corps. In recent decades, most new area experts have been the products of language and area centers—in universities in the case of academics, in government area training centers for the diplomatic service, the army, the navy, the marine corps, or the various intelligence services.

1.1.4 Organization of area studies education. Growing out of the model established by ASTP, and institutionalized in part by the terms of the annual competition for support under HEA, Title VI, the organizational and curricular style of language and area studies is relatively standardized. Campus-based area centers comprise a set of faculty members whose home affiliations lie in a variety of disciplinary departments. These centers do educate undergraduates who take a major or minor in the study of a particular world area. The area studies undergraduate major or minor usually requires that the student takes a spread of disciplinary courses focused on the area, plus a modern language of the area. However, while centers do provide for undergraduate education, their principal concern is with graduate students training to be specialists on the area. While such students almost always take their degrees in a particular discipline, for certification as an area specialist graduate students are required to spread their course work across a number of disciplines and acquire a high level of competence in a regional language. Moreover, there is an almost universal requirement that dissertation research must be carried out in the area. This supplemental layer of area-specific courses, the time required to gain an advanced competence in a language, and dissertation research abroad normally adds several years of course work to earn a PhD.

Centers vary greatly in their organizational form and degree of cohesion. A few centers are full academic departments, complete with their own faculty, staff, and students. More often, the faculty is scattered throughout the various disciplinary departments, but the center sets the curriculum for area studies majors and certifies degrees or certificates. They also maintain centrally held resources such as area-specific library collections, access to fellowships for domestic and overseas study, auxiliary teaching and support staff, and external programmatic and research funding.

Area studies are now spread throughout higher education in the USA. About half of American colleges and universities provide at least one identified concentration of courses on a country or world region. The major research universities have a number of large, well-organized centers, in some cases as many as six or seven, each one dealing with a different world area. Individual area centers vary in size from a handful of faculty members to very large centers which are staffed by as many as 50 faculty members spread over more than a dozen disciplines. The largest and most developed of the centers are awarded annual program support and a quota of graduate student fellowships under HEA, Title VI.

1.1.5 Organization of area research. While the centers play a key role in the organization of area studies, they tend not to be units of research collaboration. Research is carried out by individual scholars. Collaborative research, where it occurs, tends to link scholars across universities rather than within centers. Facilitating these transinstitutional links and serving as research facilitators and accumulators are national area studies membership organizations: the African Studies Association, the American Association for the Advancement of Slavic Studies, the Association for Asian Studies, the Latin American Studies Association, and the Middle East Studies Association. Individual scholars and students are also served by a series of more focused organizations that represent sub-sections of the constituency—e.g., the American Oriental Society representing scholars pursuing the textualist tradition in the Near and Far East. There are also a series of organizations promoting overseas research, some based in the United States, such as the International Research and Exchange Board (IREX) which awards fellowships for study in Russia, and some based abroad, such as the American Institute of Indian Studies whose headquarters are in New Delhi. Standing committees of the Social Science Research Council and the American Council of Learned Societies, supported largely by the Ford Foundation, annually allocate dissertation-level fellowships and sponsor centralized planning and assessment for each world area.

1.1.6 Geographic coverage. Over the years, the geographic domain covered by each world area, whose boundaries represent 'a residue of colonial cartography and European ideas of civilization,' has remained fairly constant. The established geographic units are Africa, Central Asia, East Asia, East Europe, Latin America, Middle East, South Asia, and Southeast Asia. Programs on smaller campuses may define particular areas more broadly. Scandinavian studies, Central Asian, and Oceanic studies constitute smaller area study groups. Scholars studying one or more Western European countries generally do not consider themselves part of the area studies communities, although West European studies have been added to the list of federally supported area groups.

Within each world area particular countries tend to receive the bulk of scholarly attention: China and Japan in East Asian studies, Mexico and Brazil in Latin American studies, India in South Asian studies, Egypt in Middle Eastern studies, Thailand and Indonesia in Southeast Asian studies, and the former Soviet Union, now Russia, in East European studies. More recently, there has been a tendency among students to direct their studies to other countries within their world area.

World area study groups tend to be almost totally discrete both on the campus and nationally. While there may be several area programs on particular campuses and some faculty members may belong to more than one area studies group, each group has its own organizational style, intellectual tradition, professional association, and scholarly journals. There are recurrent attempts to create new geographic units, e.g., the development of the Pacific Rim studies, diaspora studies, and research on the Muslim world as a whole. More recently, part of the rationale for the Ford Foundation's 'Crossing Borders' funding project is to encourage the linking together of several world area studies groups.

1.1.7 Disciplinary coverage. While area studies conceptually covers all the academic disciplines, they differ in their hospitality to area studies as an intellectual approach. The degree of hospitality is reflected in the representation of members of the various disciplines in area studies. History and language and literature, with their emphasis on substantive erudition, are the most fully represented in area studies, followed by political science and anthropology. Least hospitable to area studies are the 'hard' social sciences, those that emphasize strong methodology, quantitative methods, and abstract conceptualization and theorizing: economics, sociology, psychology, and a major portion of political science. The Ford Foundation, in a program begun in 1990, attempted to remedy these disparities by providing fellowships to allow students specializing in one of these disciplines to add area and language training to their education. It also allowed area studies students who were majoring in one of these four disciplines to add to their area course work advanced theoretical and methodological training in their discipline.

1.1.8 Languages. From the start, the federal government's interest in language and area studies has been primarily in the less commonly taught languages, including the training of specialists and the maintenance of a capacity to teach these languages on a variety of campuses. Of special interest are the least commonly taught languages, for instance, Albanian, Armenian, Azeri, Cebuano, Kaqchikel, Latvian, Somali, etc., for which enrollments are so small that no university is likely to offer instruction in them without outside support. The cost of teaching such a language may be as high as $14,000 per student per year, and if the language is taught at all, an institution will have to offer at least two and probably more years of instruction. Partly as a result of the federal government support program, many major research universities currently teach as many as forty languages other than English. Most of the non-European languages are taught in area studies programs.

The degree of language competence required of area specialists varies by world area. It is greatest among Latin American, East Asian, and East European specialists, and least among students of regions with a large number of languages and/or a widely used colonial language, such as South Asia or Africa. At the same time, the amount of time a student must devote to language training varies considerably by world area from very little for Latin American specialists who tend to bring into the program almost all of the language skills they will need to five years or more of language study for students who must master a non-cognate language like Japanese, Chinese, or Arabic. Several of the world area studies groups maintain a facility overseas for advanced training in languages.

1.2 Risk Analysis

Area studies is not the only intellectual format for the study of single countries and world regions. Much research and teaching still takes place within the established disciplines outside of the area studies community. Several streams of internationally-focused, intra-disciplinary research and teaching have coalesced into distinct specialties. These research traditions tend to develop a special theoretical and analytic approach and to use that approach to describe a particular geographic area. An example of such a stream is risk analysis, a branch of applied economics. It analyzes a specific set of quantifiable demo-

graphic, economic, and political variables to estimate the suitability of a particular country or region for investment. While the origins of much of the theory and analytic methodology of risk analysis was developed within the scholarly community—e.g., probabilistic analysis, game theory, information economics—the developers and users of risk analysis are primarily international practitioners such as commercial banks and multinational corporations.

2. *Transnational Studies*

Area studies and other analyses of a single country or region are not the only styles of internationally-focused research and teaching. A number of international studies specialties, some of them predating area studies, have developed that focus not just on one country or region, but are concerned with a number of countries or regions, or, in some cases, all geographic areas at the same time. As in the case of area studies, these intellectual specialties have tended to separate themselves from the general internationalization of disciplines. Moreover, while there is some overlap with area studies and among the transnational specialties themselves, they have developed into quite separate traditions of research and teaching. Here we can deal with only four styles of cross-country and cross-regional research and teaching: comparative analysis, studies of international relations and foreign policy, security studies, and conflict resolution, peace studies, and international political economy studies.

2.1 *Comparative Studies*

Unlike area studies and risk analysis which focus on a single country or region, in comparative studies a deliberate search is made for uniformities and differences across a number of geographic areas. Sometimes the United States is matched with another country. More commonly similarities and differences among a variety of other countries are examined. Early examples were the numerous essays on differences between East and West. Another common style is the tracing of a single phenomenon across a number of different areas, as in comparative studies of entrepreneurship, or Islam. In a third style of comparative studies a common conceptual and analytic framework is developed, then relevant data are collected in a variety of countries. An example of this approach is the study of comparative political development in which information on a substantial number of political systems, primarily in the third world, was assembled using a common descriptive and analytic format. All of these styles of comparative analysis dramatize one of the major tensions in international studies: the degree to which emphasis should be put on the particularities of individual cases or on bending country idiosyncracies to fit a common conceptual and analytic framework.

2.2 *International Relations and Foreign Policy Studies*

While comparative studies can analyze any or all features of countries or regions, other forms of transnational analysis tend to concentrate on a more limited range of topics. The oldest of such international studies specialities is the study of international relations. It is primarily concerned with relations among nation states, their foreign policies, and the operation of international organizations. On most campuses the study of international relations was initially a sub-division of political science. Gradually, free-standing academic departments of international relations developed on a few campuses. In a number of universities, the study of international relations expanded and crystallized into separate schools of international affairs whose primary mission was the education of MA level students who sought internationally oriented careers. There are now 13 members of the Association of Professional Schools of International Affairs (APSIA) which specialize in international relations. Several of them were established before World War II. In earlier years, these schools served as academic trainers for future foreign service employees. As the government developed its own training facilities the schools broadened their mandate to train for service with international organizations and multinational corporations. At the same time, their curricula expanded from a narrow focus on international relations to a broader range of international studies approaches, with a predominantly academic rather than applied professional orientation. Organizationally, the schools differ in the extent to which they are free-standing within the university with separate faculty and degrees. Several of them serve as administrative homes for the area studies centers on their campuses.

2.3 *Security Studies*

Within the study of international relations, a separate field of research and teaching is primarily concerned with security relations. It covers such topics as military policy, the cold war, and the management and use of nuclear and other high technology. In the early years, security studies analysts were primarily political scientists and physicists, both inside and outside of the government. Analyses tended to concentrate on US foreign policy, or on the international system as a whole. Its purpose was preeminently a practical one, to influence foreign policy decisions particularly with respect to the use of military power. A large part of this

research enterprise was carried out within the government or in academic centers with strong government ties.

In 1984 the Catherine T. McArthur Foundation funded a program through the Social Science Research Council whose goal was to transform the field of security studies. Through the awarding of grants for fellowships, conferences, and workshops, the Foundation and the Council's intention was to engage a broader academic community in security studies, including the diversification of research participants to include more young scholars, more women, more scholars from abroad, and to expand the range of disciplines among the participants. Similarly, the scope of security studies shifted from an exclusive concern with military security and technology to include such topics as environmental issues, nationalism and ethnicity, and the changing nature and role of the state in violent conflicts. Its academic home is in the International Studies Association rather than area studies associations. In fact, most area studies specialists deal with internal affairs in the countries they study rather than their external relations. Moreover, most security analysts prefer to work with entire regions, or with international systems as a whole rather than individual countries.

A substantial portion of security studies was carried out within governmental organizations or in research-oriented centers on campuses with strong links to government.

2.4 *Peace Studies and Conflict Resolution*

In part as a reaction to the perceived militarization of the outlook of security studies, two interrelated research specialties developed which were concerned not with strategies for winning conflicts but with their peaceful resolution or with the avoidance of conflict entirely. Peace studies, like security studies, are primarily concerned with a segment of international relations. War and peace are seen as a continuum in the relations of nation states. The peaceful avoidance or settlement of international disputes, including the role of international organization and international law, are of special interest. More recently, the scope of peace studies has broadened to include factors that are presumed to enhance what is referred to as 'positive peace': human rights, ecology, economic well-being, non-violence, peace movements.

The field of conflict resolution overlaps in part with peace studies in that it is also concerned with the settlement of international conflicts, primarily as case studies. However, its emphasis is on conflict as a more general process, and much of the analysis deals with conflicts that are not specifically international. The study of conflict resolution will also deal with such topics as marital conflict, intergroup relations, race and ethnic conflict, and labor relations.

Organizationally, the study of conflict resolution is carried out by individual scholars who sometimes organize an on-campus center which links together a set of on-going group research projects. It may also provide a curricular concentration leading to a degree or a certificate. Nationally, the field is served by a specialized journal and membership association.

2.5 *International Political Economy Studies*

In recent years another more amorphous specialty has emerged from the combined efforts of economics, political science, economics, and sociology. Referred to as international political studies (IPE) it includes research on the international political economy as a whole. It covers such topics as global capitalism, trade regimes, international commodity flows, transnational crime and policing, intergovernmental mechanisms, and the like.

2.6 *Funding*

Unlike area studies, there is no centralized source of federal government funding for transnational research and teaching. There have, in fact, been two attempts to create such a source. In 1967, the International Education Act which would have provided a general purpose fund for international education was enacted by Congress, but no money was ever appropriated for it. Similarly, under the aegis of the Association of American Universities, the Social Science Research Council and in 1989, 165 academic associations concerned with international education formed a Coalition for the Advancement of Foreign Languages and International Studies (CAFLIS) in an attempt to create a free-standing federally funded foundation to provide broad support for international education. Lack of consensus among the various international studies organizations and the unwillingness of the foreign language scholarly community to support the effort defeated this attempt. In the absence of such an overarching source of funds for international education, the strategy has been to expand the mandate of HEA, Title VI to cover a variety of enterprises beyond language and area studies. It now provides funds for international business programs, undergraduate international education, the cosmopolitanization of university library collections, the introduction of international studies into historically black institutions, research and development in foreign language instruction, and overseas research centers.

Non-governmental support for non-area-oriented international studies tends to be more narrowly targeted by topic and purpose, although on a number of campuses the Hewlett Foundation provided en-

dowment funds in support of international studies broadly defined. Most private foundation funding, however, has been for substantively defined, time-limited projects. In recent years, the leading private donors for international studies have been the Ford, Kellogg, MacArthur, Mellon and Rockefeller Foundations and the Pew Charitable Trusts.

3. Looking Ahead

The forces that will shape future developments within international studies are already apparent. Internally, the various sub-specialties are likely to have different trajectories. International relations will broaden its perspective beyond interstate relations to include international business and other aspects of the global society. Peace and conflict studies, security analysis and risk analysis will come to resemble the other temporary coalitions of scholarly interest in International Political Economy Studies. Comparative studies will lose its distinctiveness.

With respect to area studies, during most of its history area specialists have played an important role in linking the American academic world with events and scholarship in other countries. What made this role possible was the area specialists' combination of language competence, area knowledge, familiarity with forefront disciplinary scholarship both here and abroad, and access to the American academic world. It will be interesting to see whether this role becomes less important as the spread of English becomes more pervasive, as strong academic communities develop within the countries being studied, and as more members of those communities themselves integrate with the American general academic community and with the increasingly interlinked global world of scholarship. These changes are occurring at a different pace with respect to different world areas. European studies never developed an area studies perspective in part because this intermingling of American and European scholarship was already well advanced. Latin American studies is already well along in this loss of the traditional role for area specialists. At the other extreme, in East Asian studies the difficulty of mastering Asian languages and the importance of a knowledge of their cultures will inhibit the transnational homogenization of scholarship. African studies and Central Asian studies are at the very beginning of this cycle. Hanging over all of the components of international studies is uncertainty about the continuation of the external financial support that in the past has underwritten the special costs of international scholarship and, above all, the overseas sojourns of PhD students. It is clear that, in some form, international studies will continue to be a strong component of American scholarship in the behavioral and social sciences.

Area and International Studies in the United States: Intellectual Trends

The fundamental role of area studies in the United States has been to deparochialize US- and Eurocentric visions of the world in the social sciences and humanities, among policy makers, and the public at large. Within the university, area studies scholarship attempts to document the nature, logic, and theoretical implications of the distinctive social and cultural forms, values, expressions, structures, and dynamics that shape the societies and nations beyond Europe and the United States. The broad goals are (a) to generate new knowledge for both its intrinsic and practical value, and (b) to contextualize and denaturalize the universalizing formulations of the social sciences and humanities which continue to draw largely on US and European experience. When successful, area studies research and teaching demonstrates the limitations of analyses of other societies,

based largely on the contingent histories, structures, and selective and often idealized narratives of 'the West.' More ambitiously, area studies can provide understandings of other societies in their own terms, and thus materials and ideas to construct more inclusive and effective tools for social and cultural analysis.

Area studies communities have not always succeeded in this; there have been false starts, dead ends, and other agendas as well. And area studies has evolved over time, and thus must itself be historicized and contextualized. Nevertheless, research and teaching on Africa, Asia, Latin America, the Middle East, and the Soviet Union has become a powerful social and intellectual invention. By generating new kinds of data, questions, and insights into social formations and cultural constructions that undermine received wisdom and established theories, by creating new interdisciplinary academic programs, and developing close collaborations with overseas colleagues rooted in different national and intellectual cultures, area studies scholars have challenged the social science and humanities disciplines to look beyond, and even to question and reconstruct, their initial origins and formulations.

These challenges have often involved sharp intellectual, institutional, and political struggles. Tensions and debates between area studies and the disciplines continue over intellectual issues, economic resources, and the structure of academic programs. To complicate matters, the various area studies fields are not at all homogeneous; there are striking differences in their political, institutional, and intellectual histories, and their relationships with the disciplines.

Area studies can be seen as a family of academic fields and activities with a common commitment to: intensive language study; in-depth field research in the local language(s); close attention to local histories, viewpoints, materials, and interpretations; testing, elaborating, critiquing, or developing grounded theory through detailed observation; and multidisciplinary approaches. Most area studies scholars concentrate their research and teaching on one or a small number of related countries, but try generally to contextualize their work in larger regions of the world (e.g., Africa, Latin America, Southeast Asia), beyond the USA and Western Europe. Those working on the three one-country area studies fields (China, Japan, and Korea), often engage in at least implicit comparisons among them, and often command literatures in languages from two or more of these countries. (Scholars with historical interests in Japan and Korea need to read Chinese. Likewise, serious scholars of China need to read the vast literature in Japanese.) The geopolitical boundaries of all the area studies fields—especially East Europe, Soviet, and Southeast Asia—are historically contingent, pragmatic, and highly contestable. The conventional boundaries have been intellectually generative, but they also clearly have limits.

1. *The Growth of Area Studies*

Prior to World War II, internationally-oriented teaching and research in US colleges and universities rarely went beyond European History and Literature, Classics, and Comparative Religion. At the start of the twenty-first century, thousands of college and university faculty regularly teach on the histories, cultures, contemporary affairs, and international relations of Africa, Asia, Latin America, the Middle East, and the former Soviet Union. Topical courses in the social sciences, humanities, and professional schools now use examples, readings, ideas, and cases from across the world.

Area studies has been institutionalized in US universities in (a) area studies departments, and (b) area studies centers, institutes, or programs. Area studies departments usually offer undergraduate degrees combining course work in the language, literature, history, religion, and sometimes the politics, of the particular region. In general, these departments are multidisciplinary but tilt heavily to the humanities. At the graduate level, area studies departments tend to concentrate on literature and history. In the 1940s and 1950s, these departments were regarded as crucial to training area specialists. However, by the 1960s the overwhelming majority of doctoral students specializing in the non-Western world were being trained and hired to teach in standard social science and humanities departments; anthropology, art history, geography, history, language and literature, music, political science, sociology. At the University of California, Berkeley, for example, since 1946, over 90 percent of the advanced degrees dealing with Southeast Asia were granted from the core disciplines or professional schools. Across the country, however, Psychology was always absent, and Economics has now essentially stopped producing area specialists. Through the early 1970s, small numbers of economists working on Third World development issues counted themselves area specialists. But as Third World development problems turned out to be more intractable than imagined, and as Economics has moved towards quantitative analyses and formal modeling, the subfield of development economics lost status and very few US economists now claim to be, train others to be, or indeed, engage intellectually with area studies scholars. Nevertheless, nearly all area studies faculty have at least double identities; for example, as a historian but also as a China scholar, as a sociologist but also as a Latin Americanist.

While area studies departments generally have declined in their centrality, area studies centers, institutes, and programs have grown dramatically. US universities now house over 500 such units focused on every region and all the major countries of the world. Only rarely are they formal teaching units, and they do not usually grant degrees. Instead, they draw in and on faculty and graduate students from across

the social sciences, humanities, and professional schools by organizing multidisciplinary lecture series, workshops, conferences, research and curriculum development projects, advanced language instruction, publication and library collection programs, and a wide variety of public outreach activities. By these various means, they often become active intellectual and programmatic focal points for both new and established scholars concerned with their particular area of the world.

Despite this dramatic growth, debates continue regarding the adequacy of international content in the curriculum; how it should relate to the undergraduate majors or advanced degree programs; the interests of diasporic populations in the student body; the relationships to 'multiculturalism'; and what, and how, foreign languages should be taught. Equally debated are the most valued topics, theories, intellectual perspectives, and methods for faculty and graduate student research.

The growth and worldwide coverage of area studies scholarship and teaching in the USA has no equivalent elsewhere. Many European universities have, or have had, centers or programs focused on their own colonial or ex-colonial possessions. Japanese and Australian universities have active centers concerned with their neighbors in East and Southeast Asia, but support relatively little scholarship on more distant regions such as the Middle East, Africa, or Latin America. Elsewhere, only a few universities have programs that go beyond their own world region—and the study of the USA or North America. While area studies is growing slowly in parts of Asia and the Middle East, only the USA has numerous universities with multiple area studies programs dealing with several regions of the world. Variously overlapping and competitive, jointly they provide global coverage.

Area studies in the USA began shortly before World War II, when small bands of scholars of Latin America and the Soviet Union joined forces to encourage increased research on those regions. During the war, a large percentage of the few US specialists on other regions became involved in intelligence work and helped to train officers for overseas commands and postwar occupation forces. After the war, some continued with the government but most returned to university life.

In the late 1940s, the Ford and Rockefeller Foundations, and the Carnegie Endowment convened a series of meetings among scholars and government officials in the belief that the Cold War and the prospects of decolonization in Africa and Asia would require the USA to play a vastly expanded role in world affairs. It was felt that the USA would need much more expertise than was currently available, and it would have to cover every region of the world. Such expertise, it was argued, would be needed by policy analysts, diplomats, and development workers, but also by society at large—in business, banking, the media, in primary and secondary education, in the foundation world, and by US personnel in international agencies. It was needed especially in higher education, where such expertise could be generated, mobilized, and directed toward overseas projects, but also be taught and disseminated broadly.

For most Americans at the time, the only familiar area of the world beyond the USA was Western Europe. (In 1951, an SSRC survey was able to identify only 55 people in US universities with expertise on any country in all of South and Southeast Asia. (Bennett 1951)). Most Americans had studied something of Europe in secondary school, some had traveled there, and some had recently fought there. Likewise, the vast majority of faculty and students in US universities came from families of European background. European institutions, politics, economies, cultures, and social formations were at least somewhat familiar from the media, and they were often similar to and sources for their US counterparts. Thus increasing US expertise on Europe did not seem to be of the highest priority. In contrast, US ignorance about the rest of the world was overwhelming. Furthermore, perceived challenges and threats from the Soviet Union, China, and communism generally, suggested that the USA needed internationally oriented economists and political scientists capable of constructing programs to encourage capitalist economic development, 'modernization,' and democracy in order to achieve social and political stability.

At the same time, at least some academic and foundation leaders were aware that the American and Eurocentric knowledge and experience of most US economists and political scientists might not be adequate for understanding the non-Western world. At least some felt the direct application of Western models and examples, and techniques in societies of very different character and history might not work at all. Economist, George Rosen (1985), provides a compelling account of the failures of MIT and Harvard economists in attempting to suggest or impose decontextualized economic development strategies in India and Pakistan during the 1950s and early 1960s. The USA seemed to need expertise in other fields to understand the structures and dynamics of other societies; their social organization, demography, social psychology, cultural and moral values, religious, philosophical and political orientations, economic potentials, international relations, etc.

The lead was taken on the campuses; indeed, the vast majority of support for area studies has always come from the universities through long-term investments in faculty, foreign language facilities, fellowships, libraries, research funding, etc. Nevertheless, external support has been crucial. A small Fulbright overseas teaching and exchange program had begun in 1946. But in 1950, The Ford Foundation established the large-scale Foreign Area Fellowship Program (FAFP), designed to create a much more sophisticated

and knowledgeable cadre of international scholars. FAFP awards provided a year of interdisciplinary and language training on a country or region of the world, plus two years' support for overseas dissertation research and write-up. By 1972, the FAFP had supported the training and research of some 2,050 doctoral students. That year, the FAFP was transferred to the interdisciplinary Area Studies Committees jointly sponsored by Social Science Research Council (SSRC) and the American Council of Learned Societies (ACLS). By the year 2000, with continuing Ford and other funding, the two Councils had provided over 5,000 more area studies dissertation fellowships and postdoctoral research grants. The foundations also provided several million dollars for area studies workshops, conferences, and publication programs at the two Councils and other similar institutions. Between 1951 and 1966, the Ford Foundation also provided $120 million to some 15 US research universities to establish interdisciplinary area studies centers. By 1999, the Foundation had invested on the order of $400 million in area studies training, research, and related programs (Beresford in Volkman 1999).

Although The Ford Foundation was the single most important source of private extra-university funding for the institutionalization of multidisciplinary area studies, other important funding programs followed. The post-sputnik National Defense Education Act of 1957 established the Department of Education's program that helps to support the administrative, language teaching, and public service (outreach) costs of some 125 university-based area studies centers, and the Fulbright Programs were much expanded in 1961. Likewise, the National Science Foundation and the National Endowment for the Humanities fund international research, workshops, conferences, exchanges, and related activities. Private foundations (e.g., Mellon, Henry Luce, Tinker), have also provided major support for area studies programs on particular countries or regions of the world. Still others (the Rockefeller Foundation, Carnegie Endowment for International Peace, the John D. and Katherine T. MacArthur Foundation), have both funded and drawn on area studies scholars for their own topically focused international programs. But it was the long-term, massive, and continuing support by The Ford Foundation at key research universities and through the SSRC/ACLS joint committees that established area studies as a powerful and academically legitimate approach to generating knowledge about the non-Western world. The Ford Foundation's 1997 $25 million 'Crossing Borders' initiative is the latest manifestation of this long-term commitment.

Although Cold War concerns were central to founding US area studies in the late 1940s and early 1950s, the scholars in the universities and SSRC/ACLS area studies committees quickly captured the initiative with broader academic agendas including the humanities, history, and other fields far from immediate political concerns. Indeed, from the 1960s, many area studies scholars criticized publicly the US government's definition of 'the national interest' and its policies and activities in the region of the world they were studying. This was most obvious in the Southeast Asia and other Asian fields during the Vietnam War. But numerous Latin Americanists had long been deeply critical of US policies towards Cuba, the Caribbean, and Latin America. And many South Asia scholars vigorously protested the US government's 'tilt towards Pakistan' during the Indo-Pakistan conflict of 1965. Numerous area studies scholars and organizations criticised US government-sponsored Third World 'development' and 'modernization' programs variously as ill-conceived, unworkable, counter-productive (if not simply counter-insurgency), self-serving, elite oriented, and of limited value to the poor of the countries they were claiming to aid. In effect, in varying but substantial degrees, all of the area studies fields quickly came to include a much wider range of political views and research agendas than their origins might have suggested.

Aside from expanding beyond initial political concerns, each of the area studies fields rapidly took on their own distinctive intellectual and research agendas, debates, and characteristics. US research on Southeast Asia began with heavy emphasis on political issues and the social sciences but then became heavily 'cultural' in orientation. In Latin American studies a variety of political economy frameworks have spiraled through the field influencing heavily political science, sociology, and theories of development generally, far beyond Latin America. From the 1960s to the end of the 1980s the key debates in Soviet Studies turned around whether the USSR could evolve towards more rational sociopolitical forms, or would necessarily degenerate.

African studies is marked by conflicting visions of Africa and divergent research agendas among mainstream (white) Africanist scholars, African-American scholars, and their counterparts in African universities. In contrast, while the South Asia field in the USA was built on nineteenth-century European humanistic studies of Sanskrit religion and philosophy, since the mid-1970s the intellectual life of the field has been redirected by the Subaltern movement and epistemological debate over the position of the scholar, and appropriate categories and subjects for the study of post-colonial societies.

But area studies in the USA has meant more than simply the addition of new research agendas or distinctive scholarly communities in US universities. By generating new data, new concepts, new approaches, and new units of analysis; by legitimating the intrinsic and analytic value of culturally rooted interpretations, and by creating new types of multidisciplinary academic units, area studies scholars have challenged intellectually and structurally, and to some

degree transformed, US universities and the established disciplines.

As Immanuel Wallerstein, as chair of the Gulbenkian Commission on the Restructuring of the Social Sciences, has pointed out (Open the Social Sciences, Stanford 1996) the current disciplinary division of labor in the social sciences was established in the late nineteenth century. A domain in the world, an intellectual discipline, and an academic department were seen to be mutually defining; the market required a discipline and department of economics, politics required a discipline and department of political science, society called for a discipline and department of sociology, etc. Legitimating each other, these hierarchically structured departments became the fundamental building blocks of US universities developing their own agendas, concepts, curricula, jargon, research methods, internal debates, specializations and subfields, journals, national organizations, and intellectual and interdepartmental hierarchies.

In this context, cross-disciplinary or multidisciplinary training and research were always difficult, and often denigrated. At the same time, recognition has grown that this nineteenth-century compartmentalization of the world reflected in twentieth- or twenty-first-century department does not fit current understandings of how societies and cultures actually operate. Not only are specializations internal to departments reducing their coherence, but it become obvious that the market, polity, society, culture, etc.—the domains that once justified current disciplinary boundaries—all penetrate, interact, and shape each other, and cannot be studied in isolation. Scholars now often seek out intellectual colleagues in other departments, and there are frequent calls for greater interdisciplinarity. Institutionally, even if internally riven, most departments remain sharply bounded based on the power to hire and recommend or deny tenure, buttressed by exclusionary discourses or jargons, and in competition with each other for university resources. The resulting tensions and contradictions, and the critiques they engender, have created a 'crisis in the disciplines' (Timothy Mitchell in Szanton in press) at least as problematic as the debates surrounding area studies.

Nevertheless, area studies units are not about to replace the disciplines, or even attain institutional equivalency. Short of an unlikely intellectual revolution and the reconstruction of the social science and humanities departments, area studies units and the disciplinary departments will continue to stand in productive tension with each other. At the same time, by demonstrating there are intellectually, politically, and socially important forms of knowledge, and legitimate modes of generating knowledge that require interdisciplinary collaboration which the traditional disciplines are unlikely to produce on their own, area studies has paved the way for the subsequent creation of women's studies, gender studies, African-American studies, ethnic studies, Asian-American studies, cultural studies, agrarian studies, and numerous other interdisciplinary centers and programs since the 1970s. In effect, area studies has legitimated a series of venues for cross-disciplinary research and debate recognized increasingly as essential for understanding the mutually constitutive elements of any society.

2. *The Critiques of Area Studies*

Despite the relative success of area studies centers in legitimating intellectual and organizational changes in US universities, area studies continue to be critiqued by scholars who define themselves solely, or largely, in terms of a disciplinary affiliation.

First, an unlikely combination of positivist and critical left scholars have charged that area studies was a politically motivated Cold War effort to 'know the enemy,' and with the collapse of the Soviet Union and the end of the Cold War, it is now obsolete. This critique is most frequent from within political science, a discipline currently taken with rational choice theories and also most directly affected by the political rivalries of the Cold War, its termination, and the transitions that have followed. But another version is also heard from the academic left, long opposed to US foreign policy and international activities, which has claimed that area studies has been largely a component of, and aid to, US hegemony, and opposed to progressive change elsewhere in the world. However, as noted above, while Cold War issues provided the major impetus for the development of area studies in the 1940s and 1950s, since that time all of the fields have in fact expanded intellectually and politically far beyond those initial concerns.

Second, others in the positivist tradition have charged that area studies has always been largely ideographic, merely concerned with description, as opposed to the nomothetic, or the theory building and generalizing character of the core social science disciplines. At its worst, this view sees area studies simply as generating exotica, which, however interesting, cannot add up to useful theories. At best, this view sees area studies as a source of data and information, fodder for more universal theorizing by scholars in the disciplines with broader vision, more sophisticated techniques, and greater intellectual skills.

In fact, there is little evidence that area studies research has been any less theory-driven than social science and humanistic research on the USA and Western Europe. Few social scientists or humanists ever propose grand new theoretical statements and proofs. Most, more modestly, see themselves as analyzing an interesting, or to them important, subject or object, in the process testing, critiquing, confirming, elaborating, or refining some presumed understandings or theories. This is equally true of scholars writing

on the politics of Bangkok or the politics of Washington DC, on Russian novels or US novels.

The issue is not the presence or absence of theory, but the kinds of theory being used, and how explicit or implicit, ambitious or modest, scholars are in articulating their theoretical assumptions and concerns. Here there is vast room for variation and debate as theories come and go, attract attention, are tried out against diverse data, materials, and concerns, and are then rejected, refined, celebrated, or absorbed into disciplinary (or common) knowledge. Not only have the area studies fields been thick with theory and theoretical debates, but frequently they have generated theoretical developments and debates within the disciplines. Nor should this be surprising, for, as previously noted, the vast majority of area studies scholars are institutionally located in the core social science and humanities departments. Privileging (or worse, universalizing) theory derived from narratives or analysis of US experience or phenomena alone overlooks the fact that the US is, although 'unmarked' by Americanists, as much a contingent, historically shaped and particular, if not peculiar, 'area' as China, or India, or Latin America. Indeed, on many dimensions, the USA is one of the more unusual and least 'representative' societies in the world—and thus a particularly poor case from which to build generalizing theory. In addition, Area Studies scholars working outside the USA usually recognize, at least implicitly, both the comparative value and the limits of their research arenas. In contrast, Americanists working on similar issues at home often seem to treat the USA as the 'natural' society, theorize, universalize, and advise others freely, and see no bounds to their findings.

A third and more subtle set of critiques of area studies scholars argues that they have absorbed and continue to use uncritically the politically biased categories, perspectives, and theories of their colonialist scholar-administrator predecessors—or indeed, of contemporary US or Western leaders attempting to maintain or expand hegemonic control over the rest of the world. The claim, dramatically put forward by Edward Said (1979), and echoed across subaltern and cultural studies generally, is that despite area studies scholars' evident personal interest in and specialized knowledge of the area of the world they are studying, the conceptualization of their projects, their research agendas, and what they have taken as relevant models of society and social change, remain fundamentally US- or Eurocentric.

In effect, there are two different charges here. One is that area studies scholars have sometimes or often failed to study other societies in their own terms, as social and cultural life and processes are experienced and might be construed, constructed, analyzed, and critiqued from the inside. The second is that they have failed to extract themselves from their conscious or unconscious political biases, and therefore have not framed their analyses adequately in some purportedly more universal theory, whether neoliberal, neo Marxist, postmodern, etc. Instead, area studies scholars are accused of—at best, naively, at worst, intentionally—imposing their own personal and/or national agendas and variously idealized formulations of the historical experience of 'the West,' both to explain, and often in the process, to denigrate, other societies that have almost always been, in one way of another, politically and economically subordinated.

These charges carry weight; political power and position and the generation of knowledge are inevitably entwined. But this hardly limited to area studies scholarship. All social scientists and humanists—both insiders and outsiders to a society—are influenced by their political context and commitments. Implicitly or explicitly, politically freighted categories and theories always shape how issues are framed, what kinds of question are raised, what equally valid questions are ignored, and who benefits from the research.

But the issue is more complex, because the current international economic and political hegemony of the US subtly, or not so subtly, encourages the notion that the research questions, assumptions, concepts, and procedures of US scholars are incontrovertible or irresistible. This can provoke deep resentments in other parts of the world. But it can also generate powerful alternative analytic approaches, for example, subaltern studies. Nevertheless, area studies scholars have one advantage in dealing with this problem. Intensive language- and history-based research conducted outside one's home country, in at least partially unfamiliar settings, is more conducive to a self-conscious recognition of these power issues than research carried out in the familiar USA.

A fourth critique of area studies derives from current fascination with 'globalization.' Although there is huge debate on how new it really is, how to define it, and how to study it, globalization (as financial, population, media, or cultural flows, as networks, 'deterritorialization,' etc.), is seen broadly as erasing boundaries, forcing the homogenization of localities, cultures, and social and economic practices. From this viewpoint, an area studies focus on the specificities or unique dynamics of particular localities is seen as being beside the point—an outdated concern for a world that at best is fading rapidly away.

In fact, globalization, however defined, when examined in particular places is rarely a homogenizing force, or erasing all other social or cultural forms and processes. Not only is globalization producing increased disparities in power and wealth—both nodes of rapid accumulation, and zones of exploitation and poverty—but its particular manifestations are always shaped by local histories, structures, and dynamics. Likewise, the recent growth and virulence of divisive ethnic movements and identity politics often seem both a consequence of, and a reaction to, elements of globalization. In this context the intensive multidisci-

plinary analysis of particular locations and areas—the hallmark of area studies—is even more essential.

In contrast, transnationalism is leading to more significant changes in the conceptualization and procedures of area studies. The geographic regions into which the area studies world was divided in the 1950s—South Asia, Sub-Saharan Africa, Latin America, etc.—were politically defined, and in cultural–historical terms often arbitrary and debatable. At the time of writing, these conventional categorizations are being questioned, and boundaries are being redrawn. Furthermore, recent attention to transnational diasporas is emphasizing the importance of new social and cultural formations cross-cutting previous nation-state and area boundaries. Likewise, Britain and France, as past centers of empires, have been—and continue to be—deeply shaped by their (ex-) colonial activities and subjects—and indeed are now becoming subjects of study by scholars in their ex-colonies. The analytic value of the older geopolitical area studies units has not disappeared completely, but the geographies of power are changing. Many boundaries have become more permeable, and the importance of sometimes new, sometimes longstanding, transnational social, economic, and cultural formations are increasingly being recognized, studied, and becoming the basis for new institutional support and organizational arrangements.

3. *Some Future Directions*

The new geopolitics and softening of area or national boundaries is being reflected in new area studies attention to population diasporas. Once one could study comfortably Southeast Asia, or, for example, the Philippines, Vietnam, or Laos as relatively bounded units. Today, there is growing recognition of the necessity of studying the flows of people from such areas or countries as they spread around the world. The intellectual reasons are several; diasporized populations have numerous feedback effects on the dynamics of their homelands. They drain educational investments, alter the age structure, and reduce population and sometimes political pressures. They also send back remittances, economic intelligence, political ideas, and entrepreneurial skills; and reshape the world views, opportunities, and networks of those remaining at home. Diasporas also often affect the political and diplomatic relations between their host country and original homeland. German relations with Turkey, US relations with Cuba, Chinese relations with Indonesia, etc., are all affected by the immigrant populations from those countries. In addition, in the new setting of a host country, immigrant communities may reveal previously unremarked elements of their homeland—or of the host society and culture. Thus new African and Middle Eastern populations in Sweden have brought out previously unnoticed degrees of racism in that country (Pred 2000). In the USA, the children of historic and current diasporas constitute increasingly large proportions of college and university students. As such, they are demanding new courses on the language, culture, and history of their ex-homelands, on their own diaspora, and critical courses on their relationship to the USA. And the growing numbers of scholars from other regions of the world now in US universities are generating new intellectual approaches, theories, and understandings.

The expanding attention of area studies scholars to diasporic populations is recontextualizing the prior focus on the nation state as the primary actor and natural unit of international analysis. The nation state was a great social invention of the nineteenth century, and since then it has spread across the globe as the seemingly necessary macropolitical unit for organizing societies and interstate relations. Yet public, political, and scholarly interest in nation states has drawn attention away from other powerful world-shaping macro institutions and processes, including the diasporas now coming into focus, the multiple forms of capitalism, and world-girdling institutions and movements, from the World Bank, IMF, and the United Nations and its international conventions to the environmental or feminist movements. These alternative macro-foci to the nation state vary in salience and manifestations in different world areas, but all are variously overriding or circumventing traditional nation state and area boundaries. Their significance, however, requires close analysis of particular manifestations and processes in diverse parts of the world, the classic role of area studies scholarship.

Currently, US area studies is also changing with a growing recognition of the necessity of serious collaboration with scholars in other parts of the world. While well trained area studies scholars, as outsiders, may discern elements of a society or culture that insiders tend to take for granted, as outsiders they inevitably also miss key local understandings and dynamics. Scholars and intellectuals inside those societies have different perspectives, experiences, agendas, and priorities than their US counterparts, and can answer questions, redirect straying analyses, and illuminate unimagined domains. Russian scholars are now working with US, European, and other counterparts to clarify the multiple transitions their society is experiencing. The theoretical generativity of Latin American studies, a field long marked by high levels of collaboration, only underscores this point. And scholars in other regions of the world who command the local historical dynamics, languages, literatures, philosophies, and cosmologies are powerfully challenging Western formulations and presumptions (Smith 1999). Indeed, a major source of new social theory seems likely to derive from efforts to integrate analyses of social experience in a much wider variety of societies than has been the case in the past.

More fundamentally, collaborators abroad assist US scholars in seeing the particularities and limitations of their own US-based agendas, perspectives, and theories. Collaboration and complementarity, engaging the insider's and outsider's views, should provide fuller and more analytically rich and useful accounts of both US and other societies, than either view alone. While this is easy to assert in principle, it is often difficult to achieve in the current global context. European social theorists (Bourdieu, Foucault, Giddens, Gramsci, Habermas, Hall, etc.) and South Asian 'Subalterns' are providing important new perspectives and intellectual frameworks. However, US scholars and universities still shape much world-wide academic (and public-policy) discourse. US views tend to define the key questions, approaches, and methods, and US universities train large numbers of scholars from all over the world, socializing them into the particular assumptions and perspectives of the US disciplines. In this context, genuinely collaborative relationships—most likely led by area studies scholars—drawing on multiple national perspectives, will increasingly be important to avoid reading into other societies the presumptions of one's own.

Although a political impetus initiated area studies in the USA, the character and intellectual agendas of the individual area studies fields have diverged dramatically since the 1950s. They have varied with the shifting mix of the disciplines involved most centrally in particular fields, and the fashions within them; with the difficulty of access and learning local languages and histories; with events in the countries being studied; with US foreign policy, and domestic politics and demography; with funding sources and funders' interests; and with the accumulated prior scholarship of, access to, and collaborative relationships with, scholars in the area being studied. Individually and collectively, however, the area studies fields have played a deeply innovative and generative intellectual and institutional role in US universities. At the start of the twenty-first century, area studies continues to produce intellectual challenges to the humanities and social sciences, structural challenges to the organization of the US university, innovative approaches to the generation of social theory, at least rough translations and greater knowledge of other societies and cultures, and greater comparative understandings of US society and culture as well.

Area and International Studies in the United States: Stakeholders

Area and international studies (A&IS) represent a crossing point between academic disciplines, research and policy institutions, numerous ethnic foreign-language communities, various international exchange organizations, foreign and domestic corporate interests, national security agencies, and issue-oriented oppositional movements. As a result, the A&IS enterprise is contested by shifting coalitions defined by such factors as professional self-interest, intellectual paradigms, national security threats, and ideological agendas.

The various A&IS stakeholder communities can be divided into three major categories: the producers of knowledge (individuals and institutions, as well as the associations that represent them), the consumers of knowledge (in the form information or in the form of A&IS-trained personnel), and the investors (in both production and consumption).

1. *The Producers of A&IS*

The institutional locus of area and international studies varies across nations. This locus is a key determinant of the complexity of the stakeholder community. In many countries, including France, the former Soviet Union, and China, A&IS research and training is located in national academies, or government-funded think tanks (Lambert 1990, pp. 712–32). These are self-contained nonuniversity institutions

whose staff and students are devoted to language training, empirical research, and policy analysis. A variant, most notably in Great Britain, is the free-standing research institute devoted to philology and historical studies of a foreign civilization. Such self-contained institutes are separate, and often distant, from institutions of higher education in their countries. As a consequence, A&IS expertise in these countries is generally not conducted with reference to the standards of the academic disciplines, but represents a nondisciplinary or multidisciplinary tradition that serves as its own point of reference. The stakeholders are basically limited to the area specialists in the national academies and their client government agencies with foreign diplomatic, economic, military, or national security concerns.

In contrast, A&IS in the United States are found in institutions of higher education, particularly in the research universities. The standard organizational model consists of a coordinating center or institute that offers the less commonly taught languages (LCTLs), while the more commonly taught languages and relevant courses in the various academic fields are offered by the disciplinary departments. The area and international studies faculty are employed by these departments and judged by them for tenure and promotion. As a result, research and teaching in A&IS are judged primarily by disciplinary standards. Faculty in A&IS programs have primary appointments in disciplinary departments, teach courses in those departments, and conduct research in those disciplines. Thus, while the A&IS programs are interdisciplinary inasmuch as they list faculty and courses from different disciplines, A&IS teaching and research are almost exclusively disciplinary in nature.

A&IS graduate degrees, especially PhDs, are therefore normally conferred in a discipline. Department of Education data for all graduate degrees produced by federally-funded comprehensive A&IS centers in the 1991–4 period show that 91.5 percent received disciplinary or professional degrees, while only 8.5 percent received areas studies degrees,and these were largely at the MA level (Schneider 1995a, p. 9, Table C). Even those programs that award a graduate degree in study of a foreign area do so through a curriculum based on disciplinary courses offered by departments, usually with a disciplinary major.

Because of this integral relationship to higher education, A&IS studies are far more developed in the United States than in other countries. In the year 2000, federal funding through Title VI of the Higher Education Act supported 113 comprehensive (graduate and undergraduate) A&IS centers at colleges and universities, another 57 undergraduate centers, 26 undergraduate international business programs, 25 graduate centers for international business education and research, 7 foreign language resource centers, 11 overseas research centers, and one program to recruit A&IS students at minority-serving institutions. A&IS programs that do not receive federal funding are far more numerous, at least four times the number receiving aid. The total number of formally organized A&IS programs in the USA is probably in excess of 500.

The A&IS stakeholders in the US system are far more varied than in countries with the national academy model. The faculty members involved in the academic programs are usually members of disciplinary associations (such as the American Historical Association), and members of A&IS professional associations (such as the Latin American Studies Association and the International Studies Association), which means that these associations are stakeholders.

The membership of the A&IS professional associations are a guide to the size of the knowledge producer population. Although only about two-thirds of the area studies association's membership are faculty, not all foreign area studies faculty belong to these associations. Past studies have therefore estimated that total membership in the area studies association provide a good approximation of faculty employment in foreign area studies (Lambert et al. 1984, p. 13). The total membership of the five major area studies associations, which cover Africa, Asia, Latin America, the Middle East, and the former Soviet Union and Eastern Europe, was approximately 16,000 in 1990 (NCASA 1991). This compares with a 1979 membership in all area studies associations of about 18,000. If the 1990 memberships of the smaller area studies associations such as Brazilian, Canadian, European, and Caribbean studies are added to those of the five major associations, the total remains approximately 18,000, about the same as in 1979 (Barber and Ilchman 1977, p. 15). Membership in the International Studies Association adds another 3,000 persons, for a combined total of 21,000. Another faculty stakeholder group is foreign-language and literature teachers, for whom two sources of information exist, membership in professional organizations, and surveys of the National Center for Education Statistics of the US Department of Education. Using these two sources, a recent study estimated a total 36,000 post-secondary language and literature faculty (Merkx 2000, pp. 93–100). Added to the previous groups, the estimated total of faculty stakeholders is 47,000 persons.

Campus units that support A&IS, such as the library and the language departments, have an investment, which means that their professional organizations (such as the Association of Research Libraries or the National Council for the Less Commonly Taught Languages) are also involved. The numerous academic disciplines that contribute to A&IS programs, including foreign languages and literature, have an interest. Likewise, those universities whose prestige and enrollments reflect success in A&IS programs have a stake, as do the presidential associations that

represent their interests in Washington (such as the Association of American Universities (AAU)).

Campus-based components of A&IS face internal rivals on campus, however, and these rivalries may be reflected in division within their respective associations. Within key departments, such as history or political sciences, there may be struggles for resources and faculty lines with non-A&IS factions. Within the library, the A&IS collection effort competes with other collection priorities. The language department may be unwilling to offer foreign languages that are needed by A&IS programs but attract low enrollments. The entire A&IS community of a university must compete for funding against student aid, faculty compensation, science and technology programs, and other priorities. Even at the national level, the associations and organizations representing the A&IS campus-based community may face internal conflicts over competing priorities, or find themselves lobbying at cross-purposes. In turn, collaboration or conflict at the national level has a significant influence on levels of investment in A&lS.

Additional A&IS knowledge is produced in the USA by government intelligence agencies, military institutions, government-sponsored think tanks, and risk analysts employed by corporations. This information is generally not accessible to the public, and hence is a relatively minor component of A&IS knowledge. These agencies and institutions are important stakeholders, however, as consumers of A&IS information and training, and to a lesser extent, as funders.

2. *The Consumers of A&IS*

A second category of stakeholders is constituted by those institutions that need A&IS information or need A&IS-trained personnel. These can be divided in turn into three broad sectors: government, business, and education.

There is a surprising consistency over time in estimates of US government manpower needs for foreign-language and area-trained personnel. The most cited and thorough study is that of James R. Ruchti of the US Department of State, prepared in 1979 for the Perkins Commission, which surveyed more than 25 agencies and concluded that the federal government employed between 30,000 and 40,000 individuals whose jobs required competence in a foreign language, and that, of these persons, between 14,000 and 19,000 were in positions that required skills in the analysis of foreign countries and international issues (Ruchti 1979, cited at length in Berryman 1979, pp. 75–114). Although estimates of declining government employment have been assumed to reduce the need for foreign language skills in the federal government, this was not evident in the mid-1990s. The most recent survey of foreign language needs at 33 federal agencies, undertaken by Stuart P. Lay in 1995, concludes that these agencies have over 34,000 positions that require foreign language proficiency, of which an estimated 60 percent are found in the defense and intelligence community (Lay 1995). Anecdotal evidence suggests that reductions in force since 1995 may have lowered these figures in the nondefense government sectors, but the preponderance of defense and intelligence employment would reduce the effect of such reductions. If 30,000 positions are taken as a possible lower end estimate to account for reductions, and it is assumed that because of the relatively high turnover of military personnel 20 percent of the federal positions will require replacement in any given year, a replacement need of 6,000 government positions per year can be estimated.

Business demand is hard to estimate. Anecdotal evidence suggests that the US business climate has an increased need for A&IS information and skills. In the 1970s, US business was widely seen as uncompetitive on world markets and lagging in productivity. A survey from this period indicates that less than 1 percent of jobs at 1266 US firms, which accounted for the great majority of industrial exports, required foreign language skills. Nevertheless, there were 57,000 jobs at these firms that required or benefited from foreign language skills (Wilkins and Arnett 1976). Given the predominance of employment in small firms as opposed to large industrial firms, this was clearly an underestimation of private-sector demand at that time.

Adding an equal-sized small-firm component leads to an estimate of about 100,000 positions, which with a 10 percent turnover would have required replacement of 10,000 positions per year. Since the 1970s, the share of the US gross national product resulting from international trade has quadrupled. It is therefore reasonable to assume that employment in the private sector of personnel with foreign language and area skills has increased by several magnitudes. Even if such employment has only doubled since the 1970s, the business sector would need to fill 20,000 positions per year involving foreign language and area competence.

Educational demand for A&IS has been better studied, but not without controversy. The 1970s recession in higher education employment, combined with the Nixon-inspired drop in Title VI funding, led to gloomy projections about the future academic demand for language, international, and area-trained personnel (see, for example, the extended discussion in Berryman et al. 1979, pp. 30–74). There was also a concomitant reduction in the production of international and area studies PhDs, compared with the 1960s. However, the optimistic projections of the Barber and Ilchman study of 1977 proved more accurate: they noted that tenured area studies faculty were significantly older than the general tenured faculty population, and predicted a surge of retire-

ments over the following ten years (Barber and Ilchman 1977). The academic employment market for language and foreign area specialists was indeed strong during the 1980s.

Another dimension of change in higher education created additional need for foreign language, international, and area studies faculty, namely the expansion of public-sector undergraduate teaching institutions, most notably community colleges and branch campuses. The growth of this sector included a substantial and largely unforeseen growth in international education activities, including the teaching of language, international, and to a lesser extent, foreign-area content courses. By the end of the 1980s a sizable proportion of members of the foreign area studies association were located at undergraduate teaching institutions.

During the 1990s the demand for post-secondary faculty strengthened, and this has contributed to a sense of crisis in the Title VI community. Unemployment among PhDs dropped by more than one-third in the mid-1990s, and all major professional associations, including those in foreign language and area studies, reported increased postings of job announcements. In part this reflected the retirement of faculty hired during the higher education boom of the 1960s. Because area and international studies grew even more rapidly than higher education as a whole in the 1960s and 1970s, the job market for these specialists will be strong through the first decade of the twenty-first century.

Detailed projections of retirement patterns based on the age cohorts of the area studies association's membership were prepared in 1991 by the National Council of Area Studies Associations, which represents the five major area studies associations. Exit rates of present humanities and social science faculty were based on respondents' plans to retire, estimated at 16.9 percent for 1997 through 2001, and at 16.8 percent for 2002 through 2007, for a total of 33.7 percent, or one-third of current faculty. These estimations do not include projections of exits due to morbidity or mortality based on the age structure of the cohorts, which would, if included, lead to an overall exit rate of approximately 40 percent. Using the latter figure and assuming that exiting faculty are replaced but there is no growth in academic demand, 40 percent, or 7,000, of the current 18,000 area studies faculty will need to be replaced in the first 10 years of the twenty-first century, or 700 positions per year. An additional 1,200 positions will be opening in international studies, or 120 faculty positions a year.

Another faculty stakeholder group consists of foreign-language and literature teachers, for whom two sources of information exist, membership in professional organizations, and surveys by the National Center for Education Statistics of the US Department of Education. Using these two sources, a recent study estimates the combined foreign language and literature faculty in higher education at the start of the twenty-first century at 36,000 persons. If the exit projection of 40 percent for area studies faculty over the first decade of the new century is applied to the estimated total of 36,000 post-secondary language and literature faculty, an additional 14,000 positions would need to be filled.

3. *Demand and Supply*

The demand in federal government, business, and higher education for personnel who have foreign language skills, and international and foreign area knowledge will be substantial in the coming decades. Additional demand from state and local government and from secondary education may also be expected. Overseas employment offers another, as yet unexplored, source of demand. Annual demand for the first decade of the twenty-first century is estimated at 20,000 business jobs, 6,000 government jobs, and 10,000 education jobs, for a total of 36,000 foreign-area, international, and language-trained personnel.

The supply side of the equation is far simpler to estimate, as are the implications for Title VI legislation. The number of federal Foreign Language and Area Studies (FLAS) Fellowships awarded annually through Title VI of the Higher Education, which was 600 in 2000, does not meet even the academic demand, although it is a stimulus for recruiting superior students. The overall annual production of PhDs by Title VI centers was about 1,400 per year in the early 1990s. Beginning in 1993 there was a substantial increase in the number of universities receiving NRC or FLAS funding, leading to a jump of PhD production to about 1,900 language and area trained personnel (Schneider 1995b). These numbers, which have since been stable, are less than the estimated annual higher education demand for 2,100 foreign language or area studies faulty over the first decade of the twenty-first century.

The production of MA degrees by Title VI centers is higher, averaging about 6,000 per year in the 1990s (Schneider 1995b). That number is far below the annual combined demand for about 14,000 persons coming from the K-12 education sector and the federal government. Production of BAs by Title VI centers approximated 27,000 students annually by the early 1990s, of which an estimated 6,000 enter graduate school, and 21,000 of the BA graduates enter the job market. Of the 6,000 MA recipients, about 2,000 continue graduate study and 4,000 enter the market. Thus a combined total of 25,000 BA and MA graduates with foreign language or area training enter the job market, compared with a demand from business, government, and K-12 education estimated above at 34,000 positions. These positions must be filled by persons trained in other programs or on the job.

As a consequence of the shortfall of trained personnel, the federal government spends considerable sums of money on in-house training programs, such as the Department of Defense's Defense Language Institute (DLI), the National Security Agency's National Cryptologic School (NCS), and the Department of State's Foreign Service Institute (FSI). The DLI and the NCS together train about 4,600 students annually. The Department of Defense alone spent over $78 million to train linguists to meet its need, considerably more than the cost of all Title VI programs (Lay 1995, p. 1). In-house foreign language training at the FSI cost an additional $10 million. These figures do not include the salaries of the personnel who are being trained.

It should be noted in passing, however, that at least two Department of Defense programs draw on institutions of higher education to meet future needs for foreign language and area competence. The US Army Foreign Area Officer (FAO) Program annually sends approximately 100 mid-career officers to Title VI centers to obtain graduate degrees in preparation for overseas assignments in embassies, foreign war colleges, or military aid missions. The National Security Education Program provides on a competitive basis portable scholarships and fellowships to students undertaking foreign language and area training, as well as grants to enhance the institutional capacity for such training.

4. *The Investors in A&IS*

Investment in area and international studies in most of the world is supported almost exclusively by national governments. In the United States, funding for A&IS has come from the federal government, but also from two other sources—private foundations, and from colleges and universities themselves. Title VI of the Higher Education Act (HEA), formerly the National Defense Education Act (NDEA), administered by the Department of Education, has been the primary instrument through which the federal government supports A&IS (cited in McDonnell et al. 1981, p. 11). Beginning in the mid-1990s, the National Security Education Act provided additional support through the Department of Defense.

The history of A&IS been something of a roller coaster. Federal funding was critical to the development of A&IS in the United States, but has been threatened or reduced a various times. Foundation funding was highly important at one time, but was later reduced to modest levels. Despite this variation of support through time, the commitment of higher education institutions support for A&IS, once established, has proven relatively constant.

The original rationale for NDEA as a whole was narrow and clearly articulated: 'To insure trained manpower of sufficient quality and quantity to meet the national defense needs of the United States' (cited in McDonnell et al. 1981, p. v). In the post-Sputnik atmosphere of concern about Soviet achievements in science and technology, the NDEA legislation focused primarily on training in the physical sciences and engineering. However, *prior* to Sputnik the US Office of Education had prepared draft legislation on foreign language and area training. This legislation, according to one contemporary official, had been drafted because, 'By the mid-1950s responsible people in the Government were beginning to realize that university resources in non-Western studies were wholly inadequate to meet present and anticipated national needs. Some measure of Government assistance to language and area studies seemed essential' (Mildenberger 1966, pp. 26–9). Kenneth W. Mildenberger organized and headed Title VI programs following passage of NDEA.

The Office of Education's foreign language and area studies draft was incorporated in the NDEA bill as the result of negotiations between Assistant Secretary of Health, Education and Welfare, Eliot L. Richardson, on behalf of the Eisenhower Administration and the sponsors of the legislation, Senator Lister Hill and Representative Carl Elliott (Clowse 1981). Like all sections of NDEA, the original Title VI emphasized training, in this case of individuals in modern foreign languages 'needed by the Federal Government or by business, industry, or education' and 'not readily available in the United States.' Such individuals were also to be trained 'in other fields needed to provide a full understanding of the areas, regions, and countries in which such language is commonly used,' including 'fields such as history, political science, linguistics, economics, sociology, geography, and anthropology' (National Defense Education Act of 1958, as Amended, reproduced in Bigelow and Legters 1964).

The original NDEA Title VI legislation envisioned a 50–50 partnership in which the costs of foreign area centers would be divided equally between the universities and the federal government (a munificent arrangement in comparison to the 20–1 ratio of university to federal support for Title VI centers at the time of writing) (McDonnell et al. 1981, p. 38). Federal support for foreign area studies was augmented by sizable investments from the philanthropic community, led by foundations such as Ford, Rockefeller, Mellon, Carnegie, and Tinker. The Ford Foundation alone contributed about $27 million annually between 1960 and 1967 for advanced training and research in international affairs and foreign area studies, more than federal appropriations for Title VI in the same period.

The establishment of foreign-area programs was a costly venture for universities even with federal and foundation subsidies. Yet universities responded to NDEA Title VI with enthusiasm. This reflected a consensus between academia and government on

national needs in the field of international education, forged by World War II and reinforced during the early stages of the Cold War. Many, if not all, foreign-area scholars, university administrators, and foundation executives had served in State Department, intelligence, or military positions during World War II or the Korean War. The boundaries between government and academic institutions were permeable and amicable. The relatively small size of the community of foreign area specialists inside and outside government meant that people knew one another. Perhaps most important of all, they shared a similar perspective on the US role in world affairs. The alliance between academia and government for foreign area training and research was a natural outgrowth of these affinities.

The Title VI experiment proved highly successful. Within a decade the United States had established a network of centers covering most foreign areas, generating unprecedented quantities of research, and producing substantial numbers of new foreign language and area specialists. Ancillary institutions such as foreign-area studies associations and research journals multiplied quickly. The prestige and the funding conveyed by Title VI designation continued to be rewarded by university administrations (Merkx 1990, pp. 1, 18–23).

Following the promising early start of Title VI came the Vietnam War, which by the late 1960s led to funding freezes and then to declines. Moreover, the Vietnam War itself produced a significant deterioration in the relationship between government and academia. Academic dissent from US foreign policy in South-West Asia began to grow during the Johnson Administration and reached high levels during the Nixon Administration. The events of Watergate did little to increase academic confidence in government. Resentment by government officials of criticisms from academia, including from some of the very foreign area specialists trained under Title VI, grew as well. The gradual retirement of the World War II generation of leaders further contributed to the growing gulf between academic and government cultures.

The Carter Administration made some effort to improve relations with the academic community. Carter appointed a Presidential Commission on Foreign Language and International Studies (known as the Perkins Commission), which in 1979 issued a strong call for increasing federal support of international education to more than three times existing levels (US Department of Health, Education, and Welfare 1979). Among its recommendations were the establishment of undergraduate and regional foreign area centers as complements to the Title VI national resource centers, and the provision of annual federal grants of $50,000 to each of the national resources centers for library costs. However, the timing of the Perkins Commission report was not propitious. Double-digit inflation and high interest rates were leading to reductions, not increases, in federal expenditures.

A more successful initiative by the Carter Administration was to repeal NDEA and incorporate its Title VI functions in a new Higher Education Act (HEA). This step ratified the separation of university-based foreign area studies from the national defense needs that had been the original justification for federal funding. While pleasing many campus-based area specialists, the change of name made Title VI a more vulnerable target for those in the next administration who were to argue that federal subsidies were no longer in the national interest. HEA was also accompanied by the controversial establishment of the Department of Education (ED) as a cabinet-level institution, despite strong objections from the Republican minority in the Congress.

Within months after the establishment of the Department of Education, President Carter lost the 1980 elections to Ronald Reagan. The Department of Education and Title VI were among the targets singled out by the incoming Republican administration. Reagan's Office of Management and the Budget (OMB) recommended elimination of all Title VI appropriations and continued to do so for all of the first seven Reagan budgets, even after the White House had conceded defeat on its goal of eliminating the Department of Education. University–government relations were not enhanced by faculty criticisms of the Reagan Administration's increased emphasis on defense expenditures and its aggressively interventionist stance in Third World zones of conflict, nor by administration insinuations that foreign-area specialists were unpatriotic partisans of the countries they studied.

Thus the early years of the Reagan Administration represent the nadir of the partnership between academia and government in foreign area studies. Due to the high inflation of the late 1970s and early 1980s, and essentially level funding in current dollars, Title VI appropriations in real terms were at their lowest level since the inception of the program, falling to well below half their 1967 high point. The Administration was formally opposed to the program. Higher education in turn was suffering from the consequences of inflation, the growth of university enrollments had taken a sharp downturn for demographic reasons, and foundation support for international education had evaporated.

Nonetheless, the partnership between government and academia survived. Support for Title VI came from three directions. A few well-placed government officials recognized the value of Title VI research and training, and were moved to intervene on its behalf. Perhaps the most famous example is the letter of 11 March 1983 sent by Secretary of Defense, Caspar Weinberger, to Secretary of Education, Ted Bell, with a copy to OMB Director, David Stockman, requesting reconsideration of the zero-funding of Title VI.

Weinberger noted, 'My concern is shared by other officials within the Department of Defense, and members of the academic community on whom we depend for both a solid research base in area studies, as well as for production of foreign language specialists.' The Deputy Director of Central Intelligence, Rear Admiral Bobby Inman, was another outspoken defender of Title VI programs.

A second source of support came from the directors of Title VI-funded area centers, who were galvanized by the realization that the survival of Title VI programs could no longer be taken for granted. The second-generation center directors of the 1980s lacked the Washington contacts and political knowledge of the founding generation. They were forced, however, to increased activism by the disastrous implications of a total cut-off of federal support for their programs. After the failure of their efforts to reverse the Reagan Administration zero-funding of Title VI in the early 1980s, the center directors focused on the Congress. (The author, for example, met with Vice President Bush's chief of staff, Boyden Gray, in 1981 to submit several proposals concerning Title VI funding and administration, which were then transmitted to the Vice Present in writing, eliciting from him a pleasantly noncommittal response.) These early attempts at congressional relations were for the most part uncoordinated individual initiatives, but were not without effect. Congress proved more responsive to the universities than the administration had been, and Title VI funding survived, albeit at the relatively low levels of the Carter period.

The third source of support came from individuals outside of government and academia that were affiliated with institutions involved directly or indirectly with international education, such as the major foundations, higher education associations, and professional organizations. Some of these persons had served on the Perkins Commission. Others were involved with the successful effort to obtaining funding for Soviet Studies that led to the passage of the Soviet–Eastern European Research and Training Act of 1983 (Title VIII of the Department of State Authorization Act). From this sector came two important studies calling attention to inadequacies in the US international studies, the *Report of the Task for on National Manpower Targets for Advanced Research on Foreign Areas* (NCFLIS 1981) and *Beyond Growth: The Next State in Language and Area Studies* (Lambert et al. 1984).

The growing sense of shared concern about the chronic underfunding of international education in general, and the threat to Title VI in particular, coalesced in an initiative that began with a dinner at the Smithsonian Institution in late 1984 'to discuss what might be done to stabilize long-term federal support for international studies and foreign language training' (Prewitt 1986, p. v). Several foundations funded, under the aegis of the Association of American Universities (AAU), a study which resulted in the monograph *Points of Leverage: An Agenda for a National Foundation for International Studies* (Prewitt 1986, p. v), accompanied by the recommendation of an AAU advisory committee chaired by Kenneth Prewitt of the Rockefeller Foundation (AAU 1986). The Prewitt committee offered draft legislation for the establishment of a National Foundation for Foreign Languages and International Studies. The intent of the proposal was to centralize federal support for international education in a single entity, as opposed to the existing 196 international studies and exchange programs in 35 departments of the federal government. It was thought that this would allow supporters of international education to focus their advocacy on a single, high-profile institution that would be analogous to the National Science Foundation or the National Endowment for the Humanities.

The AAU Legislative proposal was intended to serve as a rallying point for the various international education constituencies. It had the opposite effect. The proposal was viewed with suspicion as being the product of the elite institutions associated with the AAU. It was widely misinterpreted as constituting a threat to existing programs. The process by which the proposal was developed was criticized for having too narrow a base and not including a sufficiently broad spectrum of international education interests. Perhaps the most positive thing that can be said of the reaction was that its vigor reflected the growth of concern about the future of the US international education effort.

In a constructive response to these criticisms, the AAU obtained additional foundation support to broaden the dialogue about international education needs, establishing in 1987 a two-year effort known as the Coalition for the Advancement of Foreign Languages and International Studies (CAFLIS). An open invitation to participate was sent to virtually every type of group that might be interested. Ultimately, some 150 organizations participated in one or more stages of CAFLIS discussion, including most higher education associations, area studies associations, language groups, organizations engaging in foreign exchanges, peak organizations in the social sciences, and professional associations.

Despite, or perhaps because of, the inclusive nature of the process, CAFLIS ultimately ended in failure. The various constituencies represented in the CAFLIS process had different agendas and found difficulty coming to an overall agreement. A fundamental cleavage existed between those groups that emphasized the need for increased investment to meet the original Title VI goals of advanced training and research in foreign language and area studies (a focused and less costly agenda), and those who were advocating federal subsidies for language training in primary and secondary schools, for internationalization of undergraduate education, or for adding

international dimensions to professional training in fields such as business, medicine, and engineering (a diffuse and more costly agenda). Even after the recommendations of the three CAFLIS working groups were watered down and widened to satisfy groups dissatisfied with the original Title VI agenda, some of these groups refused to ratify the final recommendations, which appeared in late 1989 (CAFLIS 1989). The result was a proposal for a new federal foundation that would not incorporate existing federal programs but merely add to them, an agenda that failed to generate a congressional response.

The disappointing outcomes of both the AAU legislative proposal and the CAFLIS process led the core A&IS groups to refocus attention on Title VI. The Higher Education Act was to expire in 1990. The Association of American Universities, the National Association of State Universities and Land Grant Colleges, and the other higher education presidential associations organized a series of meetings on Title VI reauthorization that culminated in the appointment of an Interassociation Task Force on HEA–Title VI Reauthorization. The directors of foreign area centers receiving federal funding formed a Council of Title VI National Resource Center Directors (CNRC). The foreign-area studies associations organized a coordinating group of executive directors and presidents known as CASA (Council of Area Studies Associations).

This resurgence led to a strategy of building support for Title VI programs in particular, and A&IS in general, by mobilizing the campus-based core constituencies, their professional associations, and national organizations such as the AAU. At the invitation of CNRC a meeting of all these groups took place at the Library of Congress in 1991, for the purpose of defining a common agenda with respect to Title VI reauthorization. When the final law reauthorizing HEA was approved by the Congress in 1992, Title VI incorporated, virtually intact, almost all of the recommendations of the Interassociation Task Force which had been supported by the core constituencies.

This success of the 1991–2 reauthorization effort resulted in the establishment of the Coalition for International Education, which includes 26 national organizations representing the various A&IS stakeholder communities. This membership includes six higher education associations representing college and university presidents, two associations of international education administrators, four associations of Title VI-funded program directors (representing area centers, business centers, language centers, and schools of international administration), two library associations, two international exchange associations, one council of overseas research centers, one area studies association, a social science association, a humanities alliance, an overseas university, and an association of graduate schools.

Federal funding for A&IS reached a low point in constant dollars during the mid-1980s. Since the establishment of the Coalition for International Education, it has grown steadily, if modestly. Adjusted for inflation, funding for Title VI grew 6.5 percent between the 1994 and 2000 federal budgets. The original Title VI programs, such as the area centers, are funded at about one-half their constant dollar figures of the late 1960s. The overall International Education and Foreign Language Studies account in the year 2000 federal budget was approximately $70 million.

5. *Overview*

Area and international studies constitute a diverse and often fractious group of stakeholders in academia and government. In the country where they are most developed, the United States, area and international studies are divided by disciplinary, geographic, linguistic, professional, and institutional fault lines, and face a constant struggle for resources with competing academic fields. Until the 1990s, the different A&IS stakeholders failed to cooperate effectively. Since that time a working alliance has been effective in lobbying for continued government support. Demand for graduates with A&IS training is strong and growing, which appears to account in part for healthy enrollments and continued support by colleges and universities. The post-Cold War increases in international trade and other forms of globalization suggest that area and international studies will remain a growing component of both the humanities and social sciences, despite internal rivalries and external competition for scarce academic resources.

Area and International Studies: International Relations

1. *Origins of Area Studies*

Area studies originated from American frustration over the inadequacies of European-originated social sciences, which focused primarily on European and North Atlantic societies for a long time. In other words, the discipline arose because of the frustration of many Americans in coming up with relevant knowledge of and insights into non-Western societies in the twentieth century (Hall 1948). First of all, empirical data were pitifully scarce. Second, European-originating social sciences did not seem to give credence to their own propositions about economic development, democratization, and rule of law. Third, for their war effort, at first, and then later for their own vision of global governance, the Americans needed broader coverage of social sciences over the globe. Area studies was born of such factors in the USA.

At first, area studies focused on local societies, local dynamics and local logics, and tried to accumulate 'thick description' as described above. The Human Relations Area Studies File compiled at Yale University is one of the best examples of such efforts. It is an overwhelming, detailed ethnographic work covering the beliefs, customs, and social practices of many societies in the world, carried out mostly by anthropologists and geographers (Murdoch 1981). Another, far lesser known, example is the file of food patterns compiled under the auspices of the United Nations University in Tokyo. It details the range and nature of food intake in a vast number of places in the world in relation to the anticipated needs for food assistance, training of personnel for the preservation of health and sanitary conditions, and technical assistance in canned food. This type of area study has long been carried out by anthropologists and geographers alike.

But in the 1950s and 1960s a number of leading economists, sociologists, and political scientists felt compelled to come up with empirically testable propositions about such general subjects as economic development and democratization. This ushered in the heyday of the American-originating modernization theory which tried to give guidance to developing countries as well as to the US government on to how to proceed with the task of economic development and democratization, with US experiences portrayed as the best example. The most notable authors in this area are Walt W. Rostow and Seymour Martin Lipset (Rostow 1991, Lipset 1981). Those social scientists thirsty for generalizable propositions about economic development and democratization did not dismiss area studies at all. For them, area studies are good data basis for social scientific endeavor. Moreover, they were eager to collect evidence that accorded with their own generalizations about economic develop-

ment and democratization, i.e., their various versions of modernization theory. Therefore area studies expanded dramatically in terms of staff appointment and student enrollment in the 1960s.

As area studies became more systematized and theorized under the influence of American-centric modernization theory, many of the themes associated area studies were incorporated into the ordinary social sciences. Thus, textbooks of comparative economic systems included chapters on market economies, centrally planned economies, and developing economies, the last of which was a generalized treatment of those economies which were normally covered by area studies. Likewise, textbooks of comparative politics consisted of chapters on industrial democracies, communist dictatorships, and developing authoritarianism, the last of which was a general treatment of those political systems normally covered by area studies (Eckstein A 1971, Eckstein H and Apter 1963). At one point in the 1960s it seemed as if area studies had merged happily with ordinary social science with the injection of American-centric modernization theory into area studies. However, the picture changed fairly soon as the American experience in Vietnam in the late 1960s through mid-1970s failed to give credence to the American-centric modernization theory (Packenham 1973, Latham 2000). Furthermore, the end of the Cold War in the early 1990s drastically altered the pictures of the world those textbooks portrayed. More fundamentally, the three trends of digitalization, globalization, and democratization have started to alter the whole framework and tenets of comparative economic systems and comparative politics (Inoguchi 2001).

With these three trends steadily intensifying, the framework and tenets of ordinary social science, which focused on the nation-state, the national economy, and the national culture, has begun to look slightly too narrow to deal with increasingly globalized, localized, and trans-nationalized economic transactions and political interactions (Inoguchi 1999, Katzenstein et al. 1998). Therefore, from the late 1990s onwards textbooks of comparative economic systems were replaced by those of the more open or less open economies under the globalizing market system. Likewise, textbooks of comparative politics categorizing regimes into industrial democracies, communist dictatorships, and developing authoritarianism were replaced by those categorizing regimes into established democracies, newly emerging or transitional democracies, and non-democracies and failed states (Sachs 1993, Kesselman et al. 1999). It was clear that by the start of the twenty-first century the two benchmarks—well-functioning market economies and well-functioning democracies—have prevailed as the organizing principles of mainstream social sciences. Thus the subject of comparative market systems such as the Anglo-American model, the Continental European model, and the Japanese model has become fashionable. Likewise, the subject of comparative democratization has become a commonplace (Thurow 1997, Rose and Shin 2001, Inoguchi 2000, APSA 2000).

What, then, has become of area studies? Area studies looks now as if it has been submerged by ordinary social sciences focusing on market and/or democracy. However it seems that, with these terribly simplified frameworks, some have been left uncertain and uneasy and have tried to come up with tighter and more readily fathomable concepts on which to focus. Their solutions are the rule of law and 'high trust.' Such authors as David Landes, Eric Jones, Francis Fukuyama, and Robert Putnam all seem to be saying that how ready people are to observe the rule of law and maintain high trust in human interactions and common endeavors makes a difference, and these things are fathomable only through historically and culturally sensitive understanding of the collective activities of human beings (Landes 1998, Jones 1979, Fukuyama 1996, Putnam 1994, 2000). To sum up, area studies has been largely incorporated into ordinary social sciences under the rubrics of market and democracy while the remaining huge residues are to be understood by the resort to history (Putnam 1994, Inoguchi 2000). So, ironically, area studies is now played down institutionally and in terms of flows of money. However, the tasks assigned to area studies as envisaged by Americans in the 1940s and 1950s remain to be solved.

2. *Origins of International Relations*

International relations as a discipline was born after World War I in Europe. All the major European intellectuals pondered on the causes and consequences of the most disastrous war ever experienced. Most of them were historically oriented, and yet such authors as F. H. Hinsley, David Wight, and Edward H. Carr all argued that the notion of international society that had been long held by major European powers had been disrupted in the course of the twentieth century and that may be regarded as the basic cause of such a war (Hinsley 1986, Wight 1991, Carr 1939, Bull 1977). Yet the discipline of international relations was brought into its own by the Americans. Overcoming the idealism and isolationism that characterized the USA through the early part of the twentieth century, the country started producing works that became the classics of the international relations genre in the 1940s and 1950s. Realism and internationalism became the dominant modes of American thinking about international affairs by the 1940s. Such authors as Hans J. Morgenthau, George Liska, and Arnold Wolfers were representative authors (Morgenthau 1978, Liska 1977, Wolfers 1962). At the same time behavioral, i.e., systematic and empirical, examinations of international relations were produced the 1940s by, among others, Quincy Wright and Harold

Lasswell and his associates (Wright 1942, Lasswell et al. 1980). Furthermore, area studies occupied an important place in the study of international relations most broadly defined. The study of international relations covered not only inter-state relations but also anything that took place outside the USA. All in all, Americans dominated the field of international relations studies by the 1950s (Hoffmann 1977). Most intellectual currents were represented by their writings, while the new mode of analyzing international relations in the framework of behavioral science and the new area of study called 'area studies' that was attached to the study of 'international relations' prospered in the USA. American dominance was reflected by the salience throughout the world of the US publications *Foreign Affairs* and *World Politics*; journals representing the policy-oriented establishment and the academic establishment respectively.

3. *Intersection of Area Studies and International Relations*

The place of area studies in the study of international relations has always been ambiguous. Initially it was simple and clear. From the dominant US perspective, anything that took place outside the USA was defined as international affairs, and that presumably included all subjects that also came under 'area studies.' However, as the study of international relations became more diversified and as the study of comparative politics encompassed much of area studies as it applied to developing countries, at one point in the 1960s it seemed as if international relations and area studies were to be isolated from each other. International relations focused on realism of various kinds and area studies focused on politics in developing countries, which was then referred to as political development in the Third World—Asia, Africa, and Latin America. Yet the isolation of the disciplines turned out to be short-lived. The key concepts giving coherence to international relations and political development respectively, i.e., state sovereignty and modernization, came to be more easily compromised by such forces as economic interdependence and the nonlinearity of the move from economic development to political development, which became more pronounced in the 1970s through the 1980s. From the 1970s onward those forces that undermine the system of international relations under the guidance of state sovereignty—such as economic interdependence and transnational relations—became so pronounced that they came to be widely regarded as concepts that shape international relations no less than the traditional concepts of state sovereignty, popular sovereignty, and the loss of sovereignty (Inoguchi 1999). This way, international relations have come to be called global politics, encompassing international relations, domestic politics, local politics, and all transnational relations. Here again, the relationship between international relations and area studies has been blurred (Baylis and Smith 1997, Held et al. 1999, George 1994).

In terms of institutional arrangements, area studies and international relations have a similarly ambiguous relationship. When 'area studies' meant studies of developing countries including colonies and when international relations meant foreign affairs taking place outside the USA, their relationship was not an issue. That was the case indeed in those years before 1945. In Japan their relationship is not a big issue. International relations means more or less everything that is taking place outside Japan, and area studies means studies of foreign countries including developed countries (Inoguchi and Bacon 2001). Area studies occupies an important place in the Japan Association of International Relations. Area studies and diplomatic history are two of the three major categories of academic genre along with international relations theory in terms of the number of members. In terms of academic training of graduate students, path dependence of a sort is easily discernible. First, those graduate students with a social science background focus on international relations theory. Second, those graduate students with a history background focus on diplomatic history. Third, those graduate students with the background of foreign languages focus on area studies. Since these three major kinds of training all produce graduate students of international relations, all the three major genres are quite evenly represented in the Japan Association of International Relations. In the USA, area studies and international relations are both fully under the department of political science. Many area studies programs may have disappeared, but language and history departments continue to give training to those political science graduate students needing some area-specific knowledge and training. International relations has been studied mostly within the department of political science, and therefore, given the theory-driven nature of American international relations, a vast majority of students are exposed to theories of international relations, whether they are structural realism, constructivism, critical theories, or behavioralism (Weaver 1998).

Reference to journals and their subject areas helps provide an understanding of the ever-self-differentiating drive of American journals. *Foreign Affairs* and *World Politics*, mentioned above, both have very large circulations, in part because of their wide coverage of everything pertaining to US foreign affairs. Besides these two, *International Organization* is the most highly ranked journal in the field. It focuses on international political economy, and is intensely theory-driven. It is quintessentially 'American.' *International Security* is another highly regarded journal

focused on international security. It is both theory-oriented and policy-oriented. *International Studies Quarterly* is the most behaviorally oriented of major American international relations journals. It is sustained by a large number of professionally trained academics in behavioral science. *Journal of Conflict Resolution* is the highest-ranking journal with a peace research orientation and behavioral approach. It is multidisciplinary with psychology, formal theory, sociology, political science, and social psychology all well represented. *International Studies Review* focuses on critical review essays on international relations, with emphasis on multidisciplinary contributions, which its editor believes are not well represented in either *International Organization* or *International Studies Quarterly*.

Outside the USA, the following journals stand out: *Review of International Studies*, *European Journal of International Relations*, *Journal of Peace Research*, and *International Relations of the Asia-Pacific*. *Review of International Studies* focuses on theories and historical events of international relations. It presents a good mix of theory, history, and philosophy. *European Journal of International Relations* focuses on theoretical and philosophical analysis and reflections on European and international affairs. *Journal of Peace Research* is a highly respected peace-oriented journal with a predominantly behavioral orientation. *International Relations of the Asia-Pacific* is a new journal focusing on the Asia-Pacific area. It covers contemporary events and actors in the region from the points of view of theory, history, and policy.

The above comparison of major journals conveys a sense of the various components of international relations studies. On the other hand, those products of area studies (whether it is single-country-focused or comparative) are accommodated in a very different set of journals. They are either flagship journals of national political science associations (and their equivalents) or area-studies-focused journals. The former includes *American Political Science Review*, *American Journal of Political Science*, *Political Studies*, *British Journal of Political Science*, *European Journal of Political Research*, *Comparative Politics*, *Comparative Political Studies*, *Government and Opposition*, *Asian Journal of Political Science*, and *Japanese Journal of Political Science*.

A quick survey of major journals of international relations and political science seems to give a sense of separation between area studies and international relations mentioned earlier, but the major trends are in fact 'comparative' and 'global' (McDonnell 2000). 'Comparative' is understood to mean that they provide in-depth comparisons of two or more political systems rather than focusing individually on single countries. This is, incidentally, a trend that the United States Social Science Research Council wishes to promote at a time when area studies programs and funding have been steadily disappearing. 'Global' studies aim to treat all politics within a larger framework of co-existence on the planet. This is an inevitable and irreversible trend that the neat distinction between domestic politics and international relations cannot properly tackle. One should gain consolation from the meaning behind the word 'area studies.' Clearly for Americans, Japanese politics is the right subject of area studies, whereas for the Japanese, American politics is the right subject of area studies. American funding on area studies may be receding, whereas some other countries' funding on their respective national politics may be on the rise.

Area studies is an important area of social science research. Its relationship with the field of international relations varies from one country to another. In some countries such as Japan, area studies and international relations more or less go together or even sometimes merge with one another. In other countries such as the USA, area studies and international relations are not regarded as overlapping subject areas.

Area and International Studies: Law

Soon after the beginning of twentieth century, the Carnegie Endowment for International Peace concluded a report on the teaching of international law in the United States by suggesting that although data on student enrollment in such offerings 'probably convey a favorable impression with respect to the extent to which International Law is taught in the … United States … [a] closer examination … will, however, make it clear that a relatively small number of students actually take the courses offered' (Carnegie 1913). Shortly before the twentieth century's end, a study based on a survey conducted by the American Bar Association subtitled 'Plenty of offerings, but too few students,' concluded that '[w]hile international law offerings have exploded since the 1960s, the percentage of students taking these courses has remained relatively constant' (Barrett 1997). Although US law school offerings in international law are just one facet of the broader question of the relationship between area and international studies and law, these two studies, conducted, respectively, prior to World War I and following the Cold War, suggest that the relationship has been a complex one, surprising at times even to those engaged professionally in the intersection of these different fields.

After a brief discussion of definitions, suggesting the capaciousness of the relevant terms, this article examines the relationship of area and international studies to law, with particular attention being paid to the serious questions that efforts at integrating them raise about the nature of each field of inquiry. It argues that one cannot appreciate fully the history of such efforts, nor the directions in which they might proceed, without taking full account of the tensions that exist between the particularity in which area studies is grounded, and the purported universality of law.

1. *The Relevant Terms*

There is no single agreed-upon definition of what constitutes either of the terms central to this article, be it from a purely scholarly or a more practical perspective. This article treats area and international studies as the intensive cross-disciplinary study of a

region or of the global system that is centered typically in history, language, literature, and/or the social sciences, and regards law as that field of inquiry concerned with the rules, formal and informal, that societies create at a variety of levels (such as the national, subnational, international, and transnational). Its principal emphasis will be on ways in which, within the legal academy, the former subject has—and has not—informed the latter, as manifested most concretely through foreign, comparative, and international legal studies, although it will also discuss briefly the treatment within area studies of law.

2. *A Selective History*

At least in terms of concrete indices, the period since the conclusion of World War II, and especially the last three decades of the twentieth century, witnessed a marked increase in attention to area and international studies in the legal academy. In the United States, the extent and range of legal scholarship that might be said to incorporate some dimension of area and international studies has grown enormously at both elite and other institutions. So, too, have the number of specialized law journals, dedicated research centers, course offerings, foreign visiting faculty, exchange programs and other opportunities for study abroad, and the like. For example, there are today scores of journals focused on international, comparative, and foreign law, and associated issues, few of which can trace their history as far back as the 1960s (Crespi 1997).

Western European legal education has taken on a decidedly more comparative and international, flavor, especially as concerns issues raised by European integration. In its most pronounced form, this is leading to academic programs (such as those of the European University) and scholarship intended to create 'European,' rather than national, law and lawyers.

In East Asia, the idea of university legal education from its outset approximately a century ago drew heavily on foreign and particularly German and French civil law models. This arguably has imparted a significant, if not always fully acknowledged, area and international studies tinge to legal studies and scholarship. More recently, the growing global concern with foreign and international legal studies has been accompanied in many parts of East Asia by a conscious attempt by some to recast the legal academy (and profession) along so-called American lines. This has been evidenced for instance, by an emphasis in pedagogy on what are said to be practical, problem-solving skills and enhanced student participation, as opposed to more abstract, doctrinally focused lectures. And throughout much of the developing world, particularly beyond universities with an Islamic mission, there has been an upswing in scholarly and curricular concern with international issues, if not with area studies more generally.

Potential explanatory factors abound. Perhaps most significantly, global economic integration, as manifested in the expansion of international trade (at a postwar rate four times that of overall economic growth), of foreign direct investment, and of the transborder flow of capital, technology, information, and personnel has generated changes in legal institutions, law, and the legal profession warranting greater attention in the legal academy to area and international studies, broadly defined. With respect to institutions, for example, the European Coal and Steel Community and the General Agreement on Tariffs and Trade have become the European Communities and the World Trade Organization. In the process, each has expanded substantially in scope, membership, and global importance, building an increasingly elaborate jurisprudence and institutional structure worthy of serious study by legal scholars that many would agree is abetted by familiarity with fields of international studies such as international relations and international institutions, and of studies of at least some areas. As regards the law itself, the growing fragmentation of production across national borders and the concomitant tendency to see the corporate form as plastic, rather than fixed (in the sense, suggested by the new institutional economics, of readily adding and shedding functions) has, for example, heightened scholarly, as well as more practical, interest in contract law in both transnational and various foreign national settings. And the legal profession itself also reflects this phenomenon. This is evident not only in the much publicized growth of so-called mega law firms with hundreds of attorneys scattered in dozens of satellite offices circling the globe, but increasingly, even for those lawyers anchored firmly in their domestic legal setting (still the vast majority worldwide)—all 'justifying' greater concern with the foreign and international in legal studies.

There is much more involved, however, than global economic integration. Politically, the second half of the twentieth century witnessed a marked expansion of bodies of law—such as international human rights and international environmental law (with close to 200 international agreements in the latter discipline)—that barely existed as formal doctrine prior to World War II. And the end of the Cold War, the collapse of apartheid, and the changes under way in China, together the associated rise of legal development as an instrument of broader developmental work (of the type sponsored by institutions such as the United Nations Development Programme) and of foreign policy more generally, have all drawn academics from granting, recipient, and other countries into law reform work that highlights the significance of area and international studies (Alford 2000). Demo-

graphically, the professoriate in both the developed and developing world has changed in ways that would seem to make it potentially more receptive to incorporating area and international studies in its work. The percentage of legal academics in nations such as the US with serious training in a social science has expanded in recent years, as has the number of their developing-nation counterparts educated abroad (with, for instance, the master's and doctoral programs at most American law schools comprised predominantly of foreign students). And, finally, there is a need to take account of broader academic institutional considerations, as the funding that governments, foundations, businesses, and others have provided for area and international studies has not gone unnoticed by law schools, much as the desire of universities to accentuate their international character via exchange programs and the like has increasingly reached professional education.

Much of the preceding discussion has focused on the impact of area and international studies on law (perhaps a cost of the author's principal disciplinary affiliation), but we ought not to neglect the converse. Growing legalization requires that at least some area and international specialists be attentive to law in ways that may not have previously been the case. As both the substantive doctrinal rules and the dispute resolution processes of regional and multilateral bodies become more elaborate and have greater effect (as, e.g., the WTO's more adjudicatory mode of settling disputes replaces the GATT's more negotiation oriented format), scholars whose principal concerns lie in fields such as area studies, diplomacy, or international economics increasingly need to pay the law greater heed. One would be hard put, for instance, to appreciate changes in the Mexican polity, or to assess the economic implications of intellectual property protection without some understanding, respectively, of the North American Free Trade Agreement and the Trade Related Intellectual Property agreement of the WTO's Uruguay Round. Somewhat analogously, the increasing transformation of what were once moral or political claims into rights with at least some potential of legal enforcement is leading not only students of international affairs, but also growing numbers of philosophers, historians, and others having an area focus into the language and argumentation of law, as evidenced quite graphically by the international dialogue between scholars of Confucianism and human rights launched by the distinguished sinologists William Theodore deBary of Columbia University and Wei-ming Tu of Harvard University (deBary and Tu 1998). And law has been critical to the blossoming since the 1980s of fields such as social history and cultural studies, among others, given how valuable a source legal materials have proven to be for primary data on the lives of ordinary citizens and efforts at state control (leading, for instance, to a recasting of the conventional wisdom that major East Asian societies had an aversion to formal legality) (Huang 1996, Macauley 1998).

3. *Still at the Margins*

As suggested by the quotations in the introduction to this article, for all the impressive growth in foreign, comparative, and international legal studies, and notwithstanding the rationale for law taking area and international studies seriously, at the dawn of the twenty-first century, the notion of 'plenty of courses, but too few students,' and the more general marginality it implies remain apt, at least as concerns American legal academe. Each of the major schools of legal thought prevalent in the US—law and economics, critical legal studies, and more traditional doctrinalism—in its own way, offers a universalist paradigm (of, to put it crudely, economic analysis, critical thought in the manner of deconstructionism, and what, for lack of a better term, is often described as 'thinking like a lawyer,' respectively) in which there is little room for, or for the most part, even interest in the particularism of area and international studies. Accordingly, only rarely does what is seen as cutting-edge mainstream scholarship touch upon foreign, comparative, or international law, or life beyond the US more broadly. Even when it does, typically it provides an application of, or otherwise confirms, established signature theoretical positions. Moreover, the focus of most legal scholarship on formal rules may lead even comparative legal scholars to lose sight of one of the key lessons to be gleaned from area studies—namely, that the extent to which public, positive law is relied upon to address certain concerns may vary enormously between societies.

Much the same pattern is replicated in other dimensions of US legal academe. The most prestigious and widely read of law journals (such as the *Harvard Law Review* or *Yale Law Journal*, and other 'flagship' general reviews edited by students at the leading law schools) address only very sporadically foreign or international subject matter. Such concerns are relegated to more specialized journals (the advent of which, arguably, has had the unintended consequence of isolating work in these fields from a general audience). The first-year law school curriculum, which remains substantially what it was in the late nineteenth century at most American schools, incorporates foreign, comparative, or international law marginally, if at all, and is not accompanied by any requirement that students in their final two years do coursework in these areas. As a result, most of the enrollment in such offerings consists of 'repeat players' who, arguably, are those who are already most open to perspectives other than that of their own nation, while at least two-thirds and perhaps as many as three-quarters of all law students, even at institutions that extol their inter-

national programs, graduate with no curricular exposure to these areas (Barrett 1997). Faculty members specializing in foreign or comparative law (who often form one-person 'departments' responsible for whole continents, if not most foreign legal systems) are, by their own statement, on the periphery, rather than at the center, of their institution's intellectual life (Reimann 1996). Increasingly, they are called upon to generate a fair degree of their own financial support, typically (and unfortunately in terms of its potential for at least the appearance of conflicts of interest) from the very nations that are the subjects of their scholarship. And in a similar vein, in a manner anomalous in American graduate education, the overwhelming majority of foreign students are directed into a one-year master's program that is neither their institution's principal or most prestigious degree, nor intended primarily to lead to further academic or professional study.

Comparative law scholars in particular have tended to respond to this marginality with intimations that those who set intellectual trends in legal academe are less worldly than they might be (Berman 1989), expressions of concern about isolation (Merryman 1999), and even calls for the end of comparative law as a distinct field (Reimann 1996). Yet, arguably, area and international specialists bear some responsibility for their plight. However strong it might be on its own terms, comparative legal scholarship is rarely viewed as making major contributions of a broader theoretical nature while all too frequently it is seen as inaccessible to nonspecialists, and more than occasionally so obscure as to deter the type of engagement that over time builds an ongoing scholarly dialogue. Moreover, recent critiques from the vantage points of both law and economics, and critical legal studies suggest that some comparative law scholarship suffers from a disingenuousness or inattention to issues of power, invoking cultural difference in an ill-defined manner that may obscure, rather than clarify (Ramseyer and Nakazato 1998, Kennedy 1997), and, according to some, paying insufficient heed to the political implications of its treatment of the 'other' (Riles 1999). International law scholarship may speak to a broader range of readers, focused as it has done increasingly on more readily comprehended projects of international governance and regulation. But in the minds of some observers, it may be insular in its own way, containing, as noted with respect to American work, 'very few references to non-American writings, even in English, let alone in French or German' (not to mention other languages) (Gross 1989). Curricular offerings in comparative and foreign law face a tension between striving to be comprehensive, and endeavoring to avoid being superficial. And notwithstanding the heightened attention to legal issues in area studies, many historians and social scientists continue to portray the law in excessively formalistic, overly literal terms, evidencing little appreciation of scholarly debates about the nature of law that would suggest the malleability with which law might be interpreted (Alford 1997).

There is no shortage of proposals in this 'age of globalization' as to how better to accommodate the foreign, comparative, and international with legal studies. And yet, even the most sophisticated of these may not grasp the heart of the problem. Although law might seem a grounded discipline, given how anchored it would appear to be in the soil of a single nation, ultimately it has universalist presumptions and aspirations (at least with respect to methodology), which do not accommodate comfortably the particularism of area and international studies as they (and especially the former) have for the most part been practiced. The effort, in a sense, is akin to that of trying to bring disciplines such as philosophy and anthropology together, leading some to suggest that before legal academe can engage the history and sociology of law in other societies effectively, it needs first to do so more thoroughly for its own society (law, having as a discipline, been surprisingly inattentive to the ways in which the rules of which it is comprised actually work in practice).

Of course, the universalist presumptions and aspirations of American law, by way of example, are at some level grounded in the experience of a particular society, even if not always fully appreciated as such by their proponents. Particularly in the current era of triumphalism, with its suggestions of an inevitable convergence of law and other institutions along what are said to be American lines, this blurs the distinction between what might genuinely be termed universal and what might be more specific to the United States, thereby complicating serious efforts to incorporate more fully other area perspectives into thinking about law in general (Ackerman 2000). These difficulties are, arguably, further exacerbated by the nature of law as both an academic and a practical discipline, housed in the United States (and increasingly elsewhere) in a professional school. This means that most faculty members do not have formal academic training beyond their professional degrees, may be participants in that about which they are writing, and, principally, are teaching practically-oriented students who will work chiefly within a single jurisdiction.

To acknowledge the foregoing challenges is not necessarily a counsel of despair. Spurred by the globalizing considerations discussed above, legal academe, particularly beyond the United States, is taking fuller account of foreign, comparative, and international law, even as newer work in area and international studies, in the manner examined in the *Area and International Studies in the United States: Intellectual Trends*, is imbuing what has long been a field rich in description with a keener appreciation of the importance of theoretical engagement.

Area and International Studies: Linguistics

In most of the world, 'you are what you speak,' because national identity is often aligned with linguistic identity. Geopolitical regions are partially defined in terms of language, and the subject matter of area and international studies is embedded in local languages. Despite the importance of linguistic expertise for understanding the peoples of a region and accessing primary material, linguistics is typically regarded as a peripheral discipline for area and international studies, relative to 'core' disciplines such as political science, history, economics, anthropology, sociology, and geography. This peripheral status results from (largely correct) perceptions that linguistics is highly technical and impenetrable, that linguistics is theoretically fractured, and that most linguists in the US are not interested in topics relevant to area and international studies. However there is evidence of renewed linguistic interest in issues of language in the contexts of geography, politics, history, and culture, as well as a commitment to be accessible to other disciplines and language learners.

1. Linguistics and Area and International Studies

Linguistics is directly relevant and beneficial to area and international studies:

(a) when it contributes to understanding the geographical distribution of peoples (by means of typology, dialect geography, historical linguistics, fieldwork, and language planning and intervention);

(b) when it contributes to understanding the different world views of peoples (by means of linguistic anthropology, discourse analysis, literary analysis, and poetics); and

(c) when it contributes to language learning (through the development of pedagogical and reference materials).

Linguistics can also achieve an area or international studies dimension in other endeavors (for example, the development of formal theories) when there is sustained focus on a given language group.

2. A Brief History of Relevant Linguistic Developments

In the early part of the twentieth century (approximately 1900–40), linguistics was dominated by Sapir and Whorf, whose objective was to explore how languages reveal people's worldviews and explain cultural behaviors. This view of language as a direct artifact of the collective philosophy and psychology of a given society was inherently friendly to the goals of understanding nations and their interactions. The Sapir-Whorf emphasis on the relationship between language and its socio-geographical context (later retooled as 'functional linguistics') might have engendered significant cross-disciplinary efforts, but unfortunately, its heyday was largely over before area and international studies became firmly established as academic disciplines.

By the time the US government made its first Title VI appropriations in the late 1950s, a landmark event in the founding and building of area and international studies as known at the end of the 1990s, linguistics had moved on to a fascination with mathematical models that would predominate (at least in the US) well into the 1980s. The theoretical purpose of an algebraic approach to the explanation of grammatical phenomena is to provide a formal analysis of the universal features of language. This theoretical perspective of 'formal linguistics' marginalizes or excludes issues relevant to area and international studies since language context is not considered a primary factor in language form. The relationship of pure math as opposed to applied mathematical sciences (economics, statistics, etc.) is analogous to the relationship between formal and functional linguistics and their relative sensitivity to contextual factors: the objective of both pure math and formal linguistics is analysis independent of context, whereas functional linguistics and applied math make reference to concrete domains (extra-linguistic or extra-mathematical).

The popularity of mathematical models was widespread in the social sciences in the late twentieth century, creating tension between the so-called 'number-crunchers' and area and international studies scholars, and disadvantaging the latter in hiring and promotion. Formal linguistics has played a similar role in the broader discipline of linguistics and yielded a framework that does not focus on language pedagogy or the geographic distribution and differing worldviews of peoples. Formal linguistics has been primarily inspired by the work of Noam Chomsky, whose framework has been successively known as generative grammar, the government binding theory, and the minimalist program. Other important formalist theories include relational grammar and head-driven phrase structure grammar.

Since the 1980s there has been renewed interest in the relationship between language function and language form, known as 'functional linguistics.' Though functionalist approaches are not a retreat into the past, they comport well with pre-Chomskyan theories, enabling linguists to build on previous achievements. Functional linguistics is also more compatible with many linguistic traditions outside the US, especially in areas where Chomsky is not well known (for example the former Soviet Bloc countries, where Chomsky's linguistic work was banned in reaction to his political writings), or in areas where there has been sustained focus on mapping and codifying indigenous languages (such as Australia, Latin America, and the former Soviet Union). The most significant functionalist movement is known as cognitive linguistics, and has George Lakoff and Ronald Langacker as its primary proponents. Cognitive linguistics has rapidly gained popularity in Western and Eastern Europe, in the countries of the former Soviet Union, Japan, and Australia. In addition to cognitive linguistics, many traditional sub-disciplines of linguistics continue their commitment to functionalist principles, among them dialectology, discourse analysis, historical linguistics, and typology. These traditional endeavors and cognitive linguistics bear a mutual affinity since both focus on language-specific data (as opposed to language universals). Because the context of language and its role in meaning are central to the functionalist view of linguistics, the potential contribution of functional linguistics to area and international studies is great. And because functionalist linguistics tends to avoid intricate formal models, it is more accessible to specialists in other disciplines, and its results are transferable to language pedagogy.

At the time of writing, formalist and functionalist linguistics are engaged in an often-antagonistic competition. (For further information on the history and present state of formal vs. functional linguistics, see *Generative Grammar*; *Functional Approaches to Grammar*; *Cognitive Linguistics*; *Sapir-Whorf Hypothesis*; and Newmeyer 1998, Lakoff 1991, Croft 1998).

3. Linguistic Contributions to Area and International Studies

Many time-honored endeavors of linguists (investigation of unknown languages, research on the relations among languages, preparation of descriptive and pedagogical materials) yield valuable results for area and international studies. Relevant methods and results are discussed under three broad headings below.

3.1 Contributions to Understanding the Geographic Distribution of Peoples

Linguists use the empirical methods of fieldwork to discover the facts of existing languages, recording features of phonology (language sounds), morphology (shapes of words), syntax (grammatical constructions), and lexicon (meanings of words). Investigation of how these features vary through space is known as dialectology, and each line on a map corresponding to one of these features is known as an isogloss. Isoglosses usually correspond to geographic (mountains and rivers), ethnic (often religious), or political (more often historical than current) boundaries. Despite the use of scientific discovery procedures, linguists do not have an operational definition for language as opposed to dialect.

Language is often closely tied to national identity, and the cohesiveness of a given speech community is often more dependent upon the sociopolitical imagination of speakers than on the number of features they share or the number of isoglosses that divide them. Chinese, for example, is a remarkably diverse linguistic entity that elsewhere in the world would probably be considered a family of related languages.

There is only a gradual cline rather than a bundle of isoglosses between Macedonian and Bulgarian, and the speakers do not agree on the status of their distinction: Bulgarians believe Macedonians are speaking a 'Western Bulgarian dialect,' whereas Macedonians assert they are speaking a distinct language. Minor dialectal differences are sometimes amplified for political gain. The various ethnic groups in the former Yugoslavia that speak the language historically known as Serbo-Croatian have used relatively minor distinctions as flags of national identity, claiming distinct languages in order to fracture the country and justify seizure of territory.

The aim of historical linguistics is to discover relationships among languages. Historical linguistics uses two methods to arrive at a description of historical changes and their relative chronology. The first method is internal reconstruction, which compares linguistic forms within a single language in an attempt to reconstruct their historical relationships. The second is the comparative method, which compares cognate forms across related languages in an attempt to arrive at how modern forms developed from a shared proto-language. Any given language change usually spreads gradually across the territory of a language. Over time this yields isoglosses, the primary material of dialect geography, and these isoglosses reflect the relative chronology of historical changes. Thanks to historical linguistics, we know a lot about how languages are related to one another, information valuable for understanding the history, migrations, and ethnic backgrounds of peoples.

Despite considerable removal in both time and space, linguistic relationships continue to inspire political and other behavior. During the Cold War Ceaucescu's communist regime raised money by selling babies for adoption to infertile French couples; this plan played upon a desire to procure genetically related offspring, since both Romanian and French are Romance languages. The notion of Slavic unity was used to justify much of the Warsaw Pact, and after the break-up of the Soviet Union Solzhenitsyn suggested that the Belarussians and Ukrainians join Russia to form a country based upon the relation of their languages (since Belarussian, Ukrainian, and Russian constitute the East Slavic language subfamily).

Languages in contact can influence one another regardless of any genetic relation. As a result, groups of contiguous languages tend to develop shared features, known as areal phenomena. The languages of the Balkans include a variety of South Slavic and other very distantly related Indo-European languages, among them Serbo-Croatian, Albanian, Macedonian, Romani, Greek, and Bulgarian. Together they share certain features, pointing to a greater unity of the Balkans that transcends their diverse heritage. Sustained or intensive language contact can result in the creation of new types of languages.

This takes two forms: one is 'creolization,' two or more languages melded into a new language; and the other is 'pidginization,' a simplified version of a language (often borrowing words from another language). An example of a creole is Papiamentu, a mixture of Spanish, Portuguese, Dutch, and indigenous languages, spoken in the Dutch Antilles; pidgin English is a language of trade created in Asia and the South Pacific for communication between indigenous peoples and outsiders. A further type of linguistic coexistence is 'diglossia,' the use of one language for spontaneous oral communication, but another language for formal and literary expression. For example, after two centuries of German domination removed Czech from the public arena, the Czech National Revival resurrected a literary language from an archaic Bible translation. As a result, there is a significant gap between spoken Czech and the Czech literary language.

Typology compares the structure of both related and unrelated languages. Typology suggests a positive correlation between the severity of geographic terrain and the density of linguistic diversity (Nichols 1990). Perhaps the best example is the Caucasus mountain region, arguably a part of the world with more languages per unit of inhabitable surface area than any other, predictably matched by a high level of ethnic and political tension. Global linguistic diversity is threatened by the phenomenon of language death, and it is predicted that 90 percent of the world's languages will disappear by the end of the twenty-first century (Krauss 1992, p. 7). Endangered languages are those of minorities who must acquire another language (of a politically dominant group) in order to survive. Protection of minority rights requires protection of minority languages, and can entail fieldwork and the preparation of pedagogical materials. Another significant language-planning issue involves the status of languages in the Central Asian republics of the former Soviet Union. After decades of Russian domination, the majority languages of these new countries are being elevated to the status of official literary languages.

3.2 Contributions to Understanding Behaviors and Worldviews

People use language to describe their experiences of reality and to make hypothetical projections from those experiences. Human experience is mediated by both perceptual mechanisms and conceptual systems. Though much of human perceptual ability is universal, input can be both ambiguous and overly detailed. Perception provides much more opportunity for distinction than any one language can codify in its grammar or any human being can meaningfully attend to. The highly textured world of perception does not suggest any unique strategy for carving nature at its

joints. Thus, perception is inseparably joined with conceptual decisions concerning what to ignore and what goes with what (Talmy 1996 has coined the term 'ception' to describe the concurrent operation of perception and conception). If, as functional linguists believe, linguistic categories are conceptual categories, and can be specific to a given language, then linguistic categories should reveal important facts about how people understand and interact with their world. Time, for example, is a phenomenon that human beings do not have direct experience of, because humans perceive only time's effects on objects and events. It is therefore possible to conceive of time in different ways, and a plethora of tense and aspect systems present artifacts of varying conceptions of time. The relationships that exist between beings, objects, and events can likewise be understood in many different ways; a testament to this is the variety of case systems and other means that languages use to express relationships.

Language is the essential vehicle of a number of cultural phenomena, ranging from the daily rituals of oral communication, the subject of discourse analysis, through the artistic use of language that is the subject of literary analysis and poetics. Linguistic analysis of use of metaphor and poetic structure can be valuable in interpreting literary culture.

3.3 Contributions to Language Pedagogy and Reference

Linguistic expertise is essential for the production of effective language textbooks, reference grammars, and dictionaries, tools that enable area and international studies scholars to gain language proficiency. Academic promotion procedures fail to recognize the exacting scholarship and creative thinking that pedagogical authorship and lexicography require. In the US, there is not enough of a market for publications in languages other than French, Spanish, and German to provide financial incentive to take on these tasks. As a result, linguists are reluctant to author textbooks and reference works, and materials for lesser-taught languages are usually inadequate or absent. Faced with financial crises in the 1990s, some colleges and universities acted on the popular myth that native ability is the only qualification needed to teach language, and replaced language professionals with part-time and/or adjunct native speakers. Although it now has competition from functional linguistics, formal linguistics continues to dominate the field, and its findings are not generally relevant or transferable to pedagogy and lexicography (since this is not the aim of formal linguistics). Collectively, academic bias, small market share, de-professionalization of language teaching, and theoretical focus greatly reduce linguists' impact on language pedagogy and reference materials.

For detailed treatment of the above topics and for further references, see *Linguistic Fieldwork*; *Dialectology*; *Historical Linguistics*; *Internal Reconstruction*; *Comparative Method*; *Areal Linguistics*; *Pidgin and Creole Languages*; *Diglossia*; *Linguistic Typology*; *Language Endangerment*; *Language Policy*; *Language and Literature*; *Language and Poetic Structure*.

4. Probable Future Directions of Theory and Research

Internet technology provides instantaneous access to vast quantities of language data, an unprecedented resource that linguists are only beginning to use. A large number of national language corpora, even for lesser-taught languages, are now available on the Web. There are also search tools, such as google.com, that are extremely useful to linguists researching the use of forms and constructions (at least in languages with Latin alphabets; despite the advent of Unicode, fonts continue to pose some of the most intractable technological problems linguists face). The sheer quantity and availability of language-specific data seems guaranteed to facilitate research relevant to area and international studies. Perhaps the best example of how corpora and technology can be integrated into linguistic research is Charles Fillmore's FrameNet, a digital dictionary of the grammatical constructions of a language, based on a language corpus. Originally developed for English, FrameNet is now being expanded to other languages, and promises to be a valuable tool for linguistics and language pedagogy. Perhaps projects like these will raise awareness of the need for lexicographical and other reference materials, and enhance the prestige of such endeavors.

Funding always plays a crucial role in guiding research trends. The US Department of Education and the National Science Foundation are the greatest sources of support for linguistic research, and both agencies fund projects relevant to area and international studies. While linguistics plays merely a supportive role in US Department of Education Title VI National Resource Center grants, it is a central player in Title VI Language Resource Center (LRC) grants. There is a new trend for LRC grants to focus on a region of the world. In 1999 three LRC grants were awarded for projects with areal focus: the National East Asian Languages Resource Center at Ohio State University, the National African Languages Resource Center at the University of Wisconsin, Madison, and the Slavic and East European Language Resource Center at Duke University-University of North Carolina, facilitating the creation of technologically enhanced pedagogical materials and area-specific linguistic research. The launching of LRCs focused on world regions is a major step forward in fostering linguistic projects that are responsive and responsible to area and international studies. Continued attention and funding may enable the relationship between area and international studies and

linguistics to realize its potential, much of which today remains untapped.

Area and International Studies: Political Economy

Modern 'political economy' explores relationships among economic and political organizations (e.g., states, corporations, unions), institutions (e.g., laws and practices regulating trade and competition), policies (e.g., restrictions on international capital mobility), and outcomes (e.g., rates of economic growth, political regime stability). Political economists differ along several important dimensions, as discussed below. This essay offers an overview of the evolution of competing versions of political economy, and their relationship to Area and International Studies, since World War Two.

1. The Fordist Moment

The classical political economists of the late eighteenth and nineteenth centuries—Smith, Ricardo, Malthus, Marx, and J. S. Mill—addressed fundamental questions such as the appropriate economic role of the state, the implications of trade liberalization for the economic fortunes of different economic classes, the ecological constraints on continuous economic growth, and the economic and political contradictions of different modes of production, including capitalism.

In the first quarter-century after World War Two, some of these questions remained at the center of debates between modernization theorists (Rostow 1960) and dependency theorists (Cardoso and Faletto 1979) who argued about the logics of, and possibilities for, economic and political development in what the Cold War framed as the Third World. Marxist versions of political economy became the new orthodoxy in the Second World, which soon encompassed most of Eastern Europe and much of Asia. In the First World, however, most students of market dynamics within Economics departments began to abandon political economy approaches. Prior to World War Two, when institutional economics remained the dominant tendency in the economics departments of the United States, this break with the core assumptions and research agendas of political economy had gone furthest in the United Kingdom. However, after the war, British neo-classical microeconomics and Keynesian macroeconomics gained ground rapidly in the United States. In the Cold War context, the dominant theoretical orientations of the US hegemon exerted a powerful gravitational pull on social science in the academies of the First World.

The new mainstream economists had a much narrower intellectual agenda. At the micro level, they drew on the pioneering work of Marshall and Pareto in an effort to demonstrate by formal, mathematical means the superiority of competitive markets as efficient allocators of resources. Arguments for trade liberalization and critiques of most forms of state intervention in market allocation processes were developed in this spirit. At the macro level, in First World economies, the new mainstream drew on Keynes in an effort to theorize how best to employ fiscal and monetary policies to reduce the amplitude of business cycle fluctuations. There were significant tensions between these micro-and macro-economic agendas, but they only became salient toward the end of this period.

Most of the new mainstream economists—whether micro or macro in focus—sought quasi-natural laws governing market dynamics regardless of time and place. They paid little attention to the political and institutional parameters within which markets existed or to the balance of power among social forces that shaped these parameters. There was an irony here. The divorce between politics and economics in First World academic economics was possible because a new kind of political economy—sometimes called 'Fordism' (Lipietz 1987)—was developed after World War Two.

The institutional and political details of Fordist regulation varied from country to country but everywhere it represented a fundamental shift away from wage regulation through competitive labor markets maintained by the repression of worker rights, to form democratic unions and engage in collective bargaining. Fordist institutions linked national real wage growth to the expansion of national labor productivity through some combination of collective bargaining (e.g., pattern bargaining in the United States) and state regulation (e.g., minimum wages) (Piore and Sabel 1984). Fordist regulation generated higher rates of economic growth and distributed the gains from that growth more broadly among the workforce than any form of economic regulation before or since (Marglin and Schor 1990). These successes contributed to the depoliticization of economic policy, which could more easily be seen as an administrative matter to which there were technical answers. This facilitated the shift away from political economy's focus on the reciprocal relationship between political power and economic outcomes.

Non-Marxist versions of political economy remained a significant current within the comparative politics subdiscipline of political science in this period. In the Cold War struggle, a great deal of public research funding was made available to those pursuing such studies (Gendzier 1985). Area Studies encompassed the countries of the Second and Third Worlds, where the influence of Marxist political economic analysis was strong among state elites, academics, and organizations such as unions and co-operatives. So First World academic analysts found it necessary to engage questions of class power, organization, and institutions in studying these countries. To this task most brought Weber and Durkheim, as interpreted and synthesized by Talcott Parsons, under the rubric of modernization theory (Leys 1986).

Area Studies thus helped to preserve political economy when it was marginalized in the Economics departments of the First World countries in which it had originated. In turn, political economy offered a coherent basis for distinguishing among different areas. Latin America, for example, made sense as a region to be contrasted with others because most of its states shared a particular kind of political economy. In the nineteenth century, the countries in this region were characterized by primary commodity production for export, and republican regimes that secured their independence from Iberian empires. In the crisis of the 1930s, most of these countries embraced a particular kind of economic development strategy—import-substitution industrialization—that gave rise to parallel economic and political dynamics, including the rise of a significant industrial working class, and the formation of corporatist political systems.

There was no parallel symbiosis between political economy and the International Relations (IR) subdiscipline as it existed in US political science in this period. IR was dominated by international security debates between those who supported a *realpolitik* firmly rooted in a narrow account of national self-interest and those who asserted that international cooperation rooted in shared liberal values was a surer guide to national security and world peace. IR paradigms, particularly as they were formalized by Waltz and his followers, took it as axiomatic that states were highly autonomous from the domestic societies in which they were embedded, at least as regards the formation of foreign policy (Waltz 1959). On this view, the international distribution of state power resources (e.g., concentrated in two rival superpowers versus dispersed more evenly among leading countries organized into alliances), and differences in state elite strategies for realizing their power maximizing objectives, were the main explanations for variations in state behavior and resulting international dynamics (Krasner 1976). States might liberalize trade as part of their grand strategies for enhancing their power relative to their rivals, but there was little reciprocal causality in this model. That is, neither international economic dynamics, nor classes defined in economic terms, had much impact on state goals or strategies.

Beyond IR as practiced in the United States, International Studies in these years was roughly equivalent to diplomatic history. Greater methodological and theoretical eclecticism created more space for recognizing the significance of domestic factors in international relations. A few approached these matters from standpoints that paid greater attention to the kinds of factors highlighted by political economy. Still, most studies of international diplomacy remained in the realm of 'high politics,' and so had only passing contact with the methods and concerns of political economy.

2. *The Neo-liberal Moment*

As the Fordist economic order began to disintegrate in the late 1960s, many argued that both the causes of the crisis and the remedies for it lay in changes in the balance of economic and political power among nations, between labor and capital within nations, or both (e.g., Gourevitch 1986). Economics and economic policy were thus repoliticized as an intense political struggle over how to understand and respond to the crisis of Fordism under way. In this context, rival strands of political economy emerged, each associated with advocates of a different response to the crisis. Critical political economists—a diverse group influenced in varying degrees by Marx, Weber, and Polanyi—were concentrated in political science and sociology departments. This strand of political economy was strongest among area specialists who focused on Latin American, Asia, and Western Europe and among students of peasant rebellion and social rev-

olution. Their diagnoses of the crisis tended to support policies that would reinforce and extend the basic principles of Fordist regulation, or a move beyond capitalism to some form of democratic socialism.

Neoclassical political economists began from the premise that neoclassical accounts of economic dynamics were basically sound, as were capitalist economies. The problem as they saw it was how to develop an equally sound science of political dynamics, a science that would explain why state intervention could seldom improve on market outcomes, even when market failures were acknowledged. Some sought to build a new political science on the 'rational choice' premise that all individuals and organizations are instrumentally rational, self-interested actors (Alt and Shepsle 1990). Others were less programmatic, turning traditional analytic tools to the service of policy goals deriving from neoclassical economics. The first strategy generated theories of 'rentier' states and 'political failure' paralleling the theory of market failure that justified Fordist regulation on efficiency grounds (Kruger 1974, Bates 1988). These analyses, together with neoclassical micro-economic doctrines, provided the intellectual rationale for 'neo-liberal' policy prescriptions—that is, the redefinition as the primary economic role of the state as the creation and maintenance of competitive markets. The second strategy generated (among other things) assessments of strategies for implementing structural adjustment policies successfully in democracies where popular opposition to such policies was widespread. The neoclassical strand of political economy was concentrated in economics and political science departments (particularly in the United States).

The neoclassical approach to political economy was very much in tune with the neo-liberal response to the crisis of Fordism championed by the United States under Ronald Reagan and the United Kingdom under Margaret Thatcher. The third world debt crisis soon facilitated the export of neo-liberal policies, via conditions imposed on debtor nations in return for assistance in restructuring their loans. In this context, neoclassical political economy became the more prominent of the two approaches, particularly among policy élites and in the United States. However, there were important intellectual innovations within both tendencies. The result was a renaissance of political economy analysis in the neo-liberal era, with both the form and the implications of that analysis intensely contested.

World systems theory was an important strand of the critical political economy analysis that emerged in this period (Wallerstein 1976). While influenced by earlier dependency theories, world systems theory was distinctive in two ways: the degree to which it treated the international economy as a system governed by its own systems-level logic, and the degree to which that logic was seen to determine the development possibilities of the nations whose system functions marked them as peripheral or semi-peripheral. World systems theory took hold primarily in sociology departments, where Marx enjoyed more equal status with Durkheim and Weber.

A second strand of critical political economy, with institutional roots in sociology and political science, emerged under the banner of 'bringing the state back in' (Evans et al. 1985). This strand explored the significance of national differences in state characteristics and relations between the state and societal actors, factors that were treated as secondary in most world systems analyses. Within the Third World, critical political economists began to explore the social and political consequences of structural adjustment policies in Africa and Latin America in the wake of the debt crisis (e.g., Bierstecker 1995). There was also increased interest in the role of 'developmental states' in enabling a small number of countries—concentrated in Asia's Newly Industrializing Countries—to escape the travails of the debt crisis and successfully reorient national economies to an export-driven model of industrialization (e.g., Evans 1995). Finally, a literature emerged on the export processing zones created in many countries subject to neo-liberal restructuring, and on the international supply chains that linked them to First World corporate producers and retailers (Gereffi and Korzeniewicz 1994).

A strand of neoclassical political economy also focused on the world system. Most important here was the 'hegemonic stability' theory advanced by the self-styled neo-realists and their neo-liberal interlocutors. These analysts, located within international relations sections of political science departments, mainly in the United States, debated the extent and significance of the decline of US economic hegemony evident by the late 1960s. Hegemonic stability theories asserted that, without disproportionate US economic power, the international monetary system created at Bretton Woods and multilateral trade liberalization under the auspices of GATT would not have been possible (Gilpin 1987). They interpreted the collapse of fixed exchange rates and an alleged shift toward protectionism in the form of 'nontariff barriers,' as evidence that the postwar international economic regimes constructed by the United States were indeed unraveling.

Neo-liberals such as Keohane drew on game theory to argue that states *qua* rational actors might choose to support and extend trade liberalization and other aspects of international regulation out of an enlightened sense of self-interest, even in the absence of a hegemon, under certain conditions (Keohane 1984). Other neoclassical political economists took a different tack, identifying a variety of societal, institutional, and ideological factors that might explain why the US state maintained its trade-liberalizing trajectory in the 1970s and 1980s, despite declining US economic hegemony and rising social costs (e.g., Goldstein 1993). Among neoclassical political economists fo-

cusing on the global South, attention was devoted to explaining the wave of democratization that began in the late 1970s, particularly to possible links between economic liberalization and democratization.

In the 1990s, the end of the Cold War and the acceleration of the economic globalization—by which analysts generally meant increased international trade and capital mobility, and sometimes also neo-liberal policies such as privatization and deregulation—shifted the focus of research and the terms of debate. The concepts of the Second and Third Worlds were rendered obsolete; many analysts began dividing the world into the 'global North' (i.e., rich capitalist democracies) and the 'global South' (i.e., all others). An important debate developed concerning whether there was anything sufficiently novel about the international economy of the 1990s to warrant the use of the term globalization (Held et al. 1999). There was also great interest in the causes and consequences of economic globalization. Neoclassical political economists tended to take a positive view of economic globalization and often treated that the process as natural and/or inevitable. Critical political economists typically saw the shift as the product of power politics within and among nations and its negative affects as more substantial (Cox 1994). There was great interest in whether this new economic order was significantly narrowing state policy autonomy, forcing governments toward a more *laissez-faire* model of economic organization regardless of their political stripe and the preferences of voters (e.g., Rodrik 1997). There was also interest in the implications of economic globalization for the power of organized labor (e.g., Kitschelt et al. 1999). Finally, there was growing interest in the origins and character of organized resistance to the neo-liberal model of globalization, a discussion leavened with the insights of social movement theory (e.g., Castells 1997), as well as more traditional political economy approaches (Arrighi et al. 1989).

These developments had important implications for the evolution of area and international studies. The resurgence of political economy strongly legitimated international studies' supra-national and interdisciplinary character and added another important approach to how such work might be organized. As to area studies, political economy may afford new grounds for drawing area boundaries. For example, since the passage of the North American Free Trade Agreement (NAFTA) in 1993, Canada and Mexico have become much more integrated with the US economy. For many of the questions of interest to political economists, it now makes sense to treat North America as a region to be studied as a unit. This contrasts with the old area studies practice of studying the United States in splendid isolation, Mexico as part of Latin America, and largely ignoring Canada. Similarly, as more East European countries join the European Union (EU), it will become sensible to frame many political economy questions in terms of a new EU region that straddles what were once regions in the First and Second Worlds.

Area and International Studies: Sociology

Area studies brings many disciplines to bear on the study of one geographic or cultural area, such as Latin America, the Middle East, East Asia, or Japan. International studies is a collective term for area studies, but also refers to the study of processes, institutions, and interactions that transcend national boundaries. Sociology is one of several disciplines that may be incorporated into area and international studies. Sociology encompasses the general study of society, including large-scale processes of social change, the organization and functioning of whole societies, social institutions, processes, and groups within societies, and social interaction. There is both synergy and potential for conflict in the relations between area and international studies and sociology.

1. Differences of Perspective and Points of Intersection

Areas studies and sociology constitute two different academic communities with their own sets of assumptions and criteria for evaluating scholarship. These criteria in turn affect the training of graduate students, availability of research support, issues of intellectual interest, infrastructure for research cooperation, venues for presenting research papers, and outlets for publication. Understanding these differing professional perspectives provides a foundation for examining how the two communities relate to each other and how their interaction may stimulate new intellectual contributions.

1.1 How Area Studies Fields View Sociological Research and Contributions to Knowledge

From the perspective of area and international studies, sociology contributes certain ways of analyzing a society or interpreting social phenomena. Sociological research is useful to the extent that it reveals interesting things about the area, which in turn may clarify or extend the existing multidisciplinary body of area knowledge.

Since the aim of area studies research is to contribute to knowledge of the area, scholars are expected to be familiar with the current state of that knowledge in order to identify appropriate research questions. In areas with a strong indigenous research community, the current state of knowledge may encompass both the research literature produced by scholars inside the area and published in their own languages, and the research literature published outside the area in other languages.

The questions that build on this body of area knowledge may be pursued using whatever research materials, opportunities, and strategies are available in the area's research context. Some sophisticated sociological research methods may not work well within particular area studies communities. Rather than collecting new data systematically for quantitative analysis, in some research environments it is more feasible and more appropriate to use observational field methods and interviews, or available documentary sources. These approaches often receive a more favorable reception within the community of area scholars, as well as from local gatekeepers of research access.

Observation, interviewing, and documentary research methods place a premium on language facility rather than on the skills of formal quantitative analysis. In many areas of the world such research requires speaking or reading ability in local vernacular languages, the language of a former colonial power, or some other commercial or regional *lingua franca*. Consequently, area studies scholars place considerable value on appropriate language competence as a basic qualification for scholars and a fundamental tool of scholarly research. If the linguistically competent scholar has mined the available resources appropriately, the resulting research contribution will be evaluated on the basis of its analytical power and the degree to which the findings resonate with what is already known about the subject.

The audience for area studies research is broadly interdisciplinary and may also be quite international. The lines between academic disciplines are much less significant than the period, geographic area, or specific topic of study. Consequently, the most knowledgeable

audience emphasizes the contribution of the research toward understanding of the particular issue or phenomenon within its natural social and historical context.

Theory is relevant in this research environment to the extent that it elucidates the particular case, or conversely, when the evidence from the area refutes a prevailing theory developed elsewhere. However, an area-based case study may generate theory that can then be applied in other settings. Similarities and differences with other cases in other geographic areas are of relatively lesser interest to area studies scholars, although implicit comparisons between the observer's home country and the area of study often underlie (and may distort) the analysis. Hence the theoretical contributions made by area specialists often need to be noticed and utilized by scholars who are not specialists in the original area in order for their general relevance in the social sciences to be recognized.

Area studies scholars evaluate sociological research about their area in terms of its contribution to substantive knowledge of the area, and its ability to provide interpretive frameworks that clarify the social patterns and processes they encounter. Formal training in area studies emphasizes the application of the findings from many disciplines to knowledge of the area, but pays less attention to the theoretical and methodological underpinnings of those disciplines. Hence area specialists without training in a specific discipline may have ample empirical knowledge but lack the tools to conduct empirical research or to draw analytical conclusions. Among area studies scholars who do have disciplinary training in sociology, participation in the interdisciplinary area studies community broadens perspectives and provides additional tools and resources for research, as well as offering an audience that can appreciate and evaluate new research findings about the area.

Sociologists have made major intellectual contributions to area studies in virtually every area of the world. In East Asia, for example, these include the work of Ronald Dore (1958, 1959), Ezra Vogel (1963, 1969), and William Parish and Martin White (1984). Most of these studies are better known among area specialists than among sociologists.

1.2 How Sociology Views Area Studies Research and Contributions to Knowledge

Theory and methods hold pride of place in the discipline of sociology. The aim of sociological research is to contribute to the developing body of sociological theory, rather than to empirical knowledge of a particular place. Sociology tends to view area studies as a collection of available knowledge that can be mined as a resource by scholars who want to pursue theoretical ideas through comparative analysis. This produces a different set of criteria for the conduct and evaluation of research, and can create difficulties for the scholar who wishes to be both sociologist and area studies scholar.

Sociological theory is supposed to be general, though not necessarily universal. That is, it should specify the conditions under which certain results ought to occur (prediction) or explain the processes that operate in a particular case (explanation), by reference to more general concepts that presumably would apply in other similar cases. The theories themselves concern the relationships between such general concepts, which are subject to testing to find out if they continue to hold true or can be rejected on the basis of empirical evidence. New theories can be proposed or old ones elaborated through empirical research, but the findings of empirical research must be couched in theoretical terms.

The habits of thought that are cultivated in the study of sociology thus emphasize extracting from the particular case those properties that can be compared or generalized. Such properties are conceptualized as belonging to limited sets of alternatives, or constituting points on a continuum. The logic of research is then to identify circumstances in which the crucial properties vary, either through internal variation within a large sample or by the selection of cases for systematic comparison, in order to test the validity and limits of the theory. It is also common practice to undertake a single case study, either to apply an existing theory and assess its explanatory power, or to generate new theoretical ideas out of the intriguing properties and dynamics of the case.

Research questions derive from the current state of sociological theory and substantive knowledge about some social phenomenon, abstracted from its geographic location. For the audience of professional sociologists, empirical research contributions are valued to the extent that they are methodologically rigorous and contribute to the advancement of sociological theory. However, there is lively debate within the discipline of sociology about the relative merits of different styles of theory and consequently about the most appropriate research approaches. These methodological orientations also reflect different levels of sociological interest in how well research represents and illuminates the actual cases under study.

The development of sophisticated multivariate methods for analyzing quantitative data has encouraged sociological research to move toward internal comparison of subgroups that cluster or diverge on certain variables within a single dataset. This approach shifts attention toward the proper execution of methodological procedures, and away from the assumptions, operational definitions, and methodological decisions that connect the quantitative research findings to the underlying social reality they claim to measure. Moreover, in international research, the

common framework for data collection may distort findings in favor of the theoretical assumptions of the dominant party, regardless of their relevance in other cultural contexts.

Although qualitative research methods have a long history in sociology and at the beginning of the twenty-first century are enjoying a resurgence in popularity, the predominance of quantitative methods raises standards for qualitative sociological research as well. Qualitative researchers may feel obliged to build internal comparisons into their research design with multiple research sites and subgroups, or to include some systematic quantitative analysis to bolster their qualitative arguments. These demands increase the methodological rigor of qualitative research and the discipline's receptivity to it. However, they may also greatly extend the time required to conduct the research, which is usually a solo undertaking, and may distract the researcher's attention from the contextual analysis that is the hallmark of good qualitative research.

Since in many research contexts serious qualitative research requires strong facility in a vernacular language, the potential range of applicability of the researcher's skills for comparative work becomes a function of the geographic range of the language he or she commands. Hence a specialist with language competence in Spanish, Russian, Chinese, or Arabic may have a potentially wider range of comparative possibilities than someone whose language competence is in Japanese or Hungarian.

The sociologist who is linguistically qualified to do independent area studies research represents only one of several strategies for utilizing area knowledge in sociology. A sociologist who does not have an area studies background may decide that the properties of some society fit the conditions needed for testing an idea in a comparative study. Depending upon the study design and methods to be employed, this might require one or more of the following research strategies: working with sociologists from the area as collaborators in a joint project involving systematic data collection in two or more countries, using common instruments; using the research literature on the area as a secondary resource, to the extent that it exists in a language the sociologist can read; hiring research assistants from the area to gain access to vernacular resources; or going to the area to conduct research, either independently or with the assistance of translators and interpreters.

Such research might result in a multinational comparative study that uses specific countries to represent particular structural conditions, a study using intra-area or intra-country comparisons to highlight variations on a particular theme, a study that compares a phenomenon found in one country with a similar phenomenon found previously in another setting, or a study that explores in detail an institution or phenomenon that appears to produce different results from those found elsewhere. These forms of research are most likely to be presented to a sociological audience, and to be couched in theoretical language as general contributions to the discipline of sociology rather than as contributions to understanding of the area.

Despite the strong demand for theory-driven research, in fact many sociologists initially become intrigued by some social situation or research opportunity, and then develop a theoretical rationale for pursuing it. The key lies in linking the situation to a sociological question of current interest to the discipline. However, the most intriguing issues or research opportunities in an area studies context may not mesh well with the current theoretical concerns of the discipline. The relevant subfield may espouse a theory that asks different research questions, or the area case may contradict the dominant theory, whose advocates may be more inclined to dismiss the troublesome case than to reject their theory.

Conversely, an awareness of current issues in the discipline of sociology may lead area studies researchers to explore new questions that have previously been ignored or even deliberately avoided because of their sensitivity in the cultural context. For example, American sociologists have raised research questions concerning the status of women and minorities in many world areas where local scholars had previously ignored them. Greater interaction across the area studies–sociology divide can thus challenge received understandings and lead to new intellectual developments on both sides. In addition, as sociological theories fall in and out of favor, or conditions in the area change, different area studies concerns may gain new sociological relevance and vice versa.

2. *A Brief History of Area and International Studies in Sociology*

While some of the tendencies discussed above may be found in other social science disciplines, particularly in recent years, the deep concern with both theory and methodology is characteristic of sociology as a discipline and has left its mark on the relations between area and international studies and sociology. The history of area studies within sociology reveals how these potential synergies and conflicts have fluctuated over time and in different contexts.

2.1 *The Global Perspectives of Sociology's Nineteenth-century Founders*

The European founders of the discipline of sociology viewed the world as a laboratory in which similarities between societies offered evidence of general laws, while differences between societies provided clues to the large-scale processes of social change that were sweeping nineteenth-century Europe and America. In

their search for general laws and processes, they made extensive use of available research materials about other societies, even if they did not venture into the field themselves. Area and international studies as known today did not yet exist, but there was considerable information available even on very remote societies. Created partly as a result of colonial relations, these materials included scholarly research by historians, philologists, geographers, and anthropologists, translations of major cultural texts, and reports from colonial administrators, missionaries, and adventurers.

Emile Durkheim made extended use of anthropological research on totemism among American Indian tribes and Australian aborigines to propound the theory that the social order itself was the symbolic focus of religious rituals (Durkheim 1912). Karl Marx and Friedrich Engels used historical and anthropological materials, as well as participant observation of contemporary social life and political events in several countries, to analyze the development of capitalism and its transformation of social relations (Engels 1884, Marx 1852).

Max Weber made even more extensive and systematic use of the historical, anthropological, and cultural materials of particular world areas in his ambitious comparative study of religion and society in India, China, the ancient Middle East, and early modern Europe (Weber 1922a, 1922b). Although Weber's focus was on the link between religious beliefs and economic behavior, his comparative studies constituted a thorough examination of the legal institutions, political order, economic institutions, social structure, and social stratification of each society and how it had changed over time. Some of Weber's interpretations have been superseded by new scholarship, but his comprehensive approach to the understanding of particular societies remains a strong model for both sociology and area studies today.

2.2 Isolation and Internationalism in Twentieth-century American Sociology

While this broad international and historical perspective continued in twentieth-century European sociology, a new generation of American sociologists turned their attention to the social institutions and social processes developing within American society. In a young society whose cities were absorbing millions of immigrants even as the population pushed westward to settle a still-open frontier, American sociologists relied increasingly on observation, interviews, and surveys to analyze the social dynamics swirling around them. They theorized about people who created their own social rules and meaning through social interaction, rather than living with centuries of custom and inherited position. There was little inclination to look to history or other countries for evidence when comparative cases for analysis could be found in subcultures right at home.

As American sociology came into full flower in the 1950s, its insular tendency was further reinforced, despite the influence of many European émigré scholars and the continuing tradition of comparative international research as exemplified by the work of S. N. Eisenstadt (1963) and Seymour M. Lipset (1959). The field was soon dominated by functionalist theory, which emphasized analysis of how the internal components of a society work together to produce a smoothly functioning and stable whole, based on a common set of values. This perspective generated a flood of research on various aspects of American society, couched as general contributions to sociological knowledge. Sociological methodology flourished as well, with increasing emphasis on quantitative analysis of survey data on attitudes and reported behavior, which fit neatly into the assumptions of functionalist theory.

Yet during the same postwar years, new programs of interdisciplinary language and area studies were being developed at large American universities, with strong financial support from the federal government and private foundations. The impetus for the development of area studies came from a combination of America's experience of World War II, and the subsequent Cold War. Acutely aware of the nation's lack of citizens with foreign-language skills and useful knowledge of particular world areas, the US government sought to create such a reserve for future national defense needs. The resulting government-funded program provided general infrastructure support to develop interdisciplinary area studies programs with course offerings in language and various academic disciplines, plus fellowships that the institution could award to graduate students willing to undertake the new courses of study, which required intensive foreign-language study (Lambert 1973).

The funding encouraged the development of area studies programs at the master's level, but the intent was also to encourage and support students who continued with doctoral-level studies in a discipline, in order to staff the continued expansion of international studies in colleges and universities. Major foundations contributed to the government-led effort with additional programs of infrastructure and research support for international studies, including fellowship programs to fund dissertation field research in foreign areas. Among the research support institutions that provided infrastructure for the area studies initiative were the American Council of Learned Societies (ACLS), which provides national-level leadership and coordination in the humanities, and the Social Science Research Council (SSRC), which plays a similar role for the social sciences. These two institutions provided the infrastructure for a series of national-level research planning committees for specific world areas, which in turn served as re-granting bodies for large block grants

of research and research training funds for area studies research provided by major private foundations.

Under these public and private initiatives, academic institutions were encouraged not only to utilize existing staff, but to hire new faculty to broaden their interdisciplinary offerings. The willingness of academic departments to accommodate area specialists depended to a considerable extent on whether the discipline's internal intellectual organization recognized geographic or cultural areas as natural subdivisions. Sociology was particularly resistant to the notion of area specialists, because its internal intellectual organization was oriented to specialization in particular social institutions and processes, and the discipline as a whole was heavily oriented to universalistic theories.

However, the growing dominance of modernization theory in American social science during the 1950s and 1960s lent indirect support to area studies research. Modernization theory was an American elaboration of evolutionary and Durkheimian ideas about how societies could make the transition from traditional to modern, based on a model of full modernity epitomized by the contemporary United States. In sociology, the functionalist model of internally differentiated, modern American society was projected backward to a theoretical model of an undifferentiated traditional society based largely on kinship and holistic communities bound together by shared religious beliefs (Lerner 1958). Indicators were then developed to measure the progress of societies along the road from traditional to modern (Inkeles and Smith 1974), which in many cases also corresponded to prescriptive programs for American assistance to less-developed countries.

Area specialists could apply modernization theory to the area they studied, and in some cases they could also find employment designing and evaluating modernization programs for the area. For areas that were already defined as modern or nearly so, the task was to show how well the theory predicted their trajectory. Unfortunately, the assumption was that the theory must be correct; any misfit between case and theory was either forced to fit, or dismissed as an irrelevant case for sociological study because of its exceptionalism.

In addition to the small cohort of American sociologists trained as area specialists, American postwar affluence and various development programs for other parts of the world were also drawing foreign nationals into American graduate programs in sociology in growing numbers. These young scholars came specifically to learn the theories and methods of American sociology, and were eager to participate in large, multinational studies directed by their American mentors. If they had reservations about the relevance of the survey questions or the applicability of the theory, modernization theory could also subtly imply that this reflected a deficiency in the foreign student's understanding or the backwardness of the native country, rather than a flaw in the theory.

By the 1970s, as funding for area studies programs was drying up, disillusionment with modernization theory was growing among younger sociologists. A cluster of new approaches to development issues emerged, prompted in large measure by scholars with area studies interests. Scholars of Latin America embraced the alternative of dependency theory, which argued that the lagging development of Latin American countries was the result of colonial relations and economic dependency on northern hemisphere countries, rather than on the traditional values and internal backwardness posited by modernization theory (Frank 1967, Cardoso and Faletto 1979). This resonated well with the broader world systems theory propounded by Immanuel Wallerstein, who theorized that the development of capitalism was not a phenomenon that took place within individual nations, but rather was an international set of processes that profoundly altered relationships within the world system of states. In a multivolume study informed by historical area studies research, he traced the decline of Africa and Eastern Europe to dislocations in agricultural markets and trade relations as capitalism expanded around the globe (Wallerstein 1974, 1980). World systems theory offered a new set of transnational variables for studies of development within countries, and focused attention on the international ties of different segments within a society. The theory attracted both scholars with particular area studies interests, and those who wanted to study transnational processes on a more general level.

Attempts to apply world systems theory in Asia were not particularly fruitful, but by the 1980s Japan had risen to a position of economic rivalry with the United States, which prompted new interest in Japanese methods of business organization and industrial production. Although area specialist sociologists of social organization and industrial sociology analyzed the Japanese methods, it was schools of business administration rather than sociology departments that were most eager for their research. Sociological interest deepened as it became more apparent that other Asian countries were following a Japanese model of state-directed, export-led development. This did not fit any of the earlier development theories, but resonated with new theoretical interest in relations between state and society (Skocpol 1979).

In the post-Cold War 1990s, language and area studies programs came under heavy attack from social science disciplines as a relic of the Cold War (see Samuels and Weiner 1992). In sociology this did not signal a return to American isolation so much as a general internationalization of the discipline, in which the many alternate ways of accessing area knowledge made the trained area studies specialist less significant as a gatekeeper for that knowledge. Ironically, in

Japanese studies, by the 1990s the postwar investment in language and area studies scholars had produced a large enough body of area studies research in English to support secondary research by sociologists without Japanese language skills.

Sociology was also becoming more internationalized through a new wave of European postmodern and poststructural theories that called attention to nuances of culture and symbolic language even as they emphasized the internationalization of popular culture and the breakdown of stable cultural systems of meaning (Bourdieu 1977, Foucault 1975). In drawing closer to new European theories, American sociology was also reconnecting to the relatively unbroken European tradition of sociology as a discipline interested in area-specific knowledge about the whole world.

3. *Institutional Relationships between Sociology and Area and International Studies*

Sociologists are organized internationally through the International Sociological Association, and nationally through national or regional disciplinary associations, while area specialists are organized in North America, Europe, and elsewhere through interdisciplinary professional associations that are area- or region-specific, such as the Association for Asian Studies, the African Studies Association, the Latin American Studies Association, the European Association of Asian Studies, and the American Studies Association in Japan.

The International Sociological Association is structured around a series of international committees representing subfields of the discipline, which facilitate the interaction of scholars from different countries who work on similar issues. The implicit assumption is that scholars do research in their own areas to contribute to collective sociological knowledge, and area-specific research or knowledge has no independent significance. Conversely, sociology as a discipline has little visibility in area studies associations, which tend to have strong representation from history and literature along with many social science disciplines.

In the mid-1990s the International Sociological Association organized a series of regional conferences to consider the state of sociology from the perspective of each region. The resulting publications reflect the substantive issues most relevant to each region, including in some cases a strong desire to develop new theories out of regional experience or a regional and linguistic community of sociologists. The base, however, remains sociologists *from* the region as opposed to sociologists *of* the region (see Wallerstein et al. 1998).

As the ISA has taken up regional concerns, the large American Sociological Association is becoming steadily more international in the scope of its membership and its concerns. The ASA has long had an institutional committee devoted to international ties, which in the early 1990s voiced concern over the widening gap between area studies and the social sciences. Rather than leading toward greater integration of area studies scholars into sociology and other social science disciplines in the United States, this concern combined with serious financial exigencies fed into the decision of the Social Science Research Council to dismantle its long-standing infrastructure support for specific area studies committees in favor of very broad regional committees composed of American scholars and scholars from the region. The change was intended to encourage research across regions and on transnational processes, but it also reflected the growing hostility of the social science disciplines to area specialists and the enterprise of interdisciplinary area studies.

Internally, the ASA has made international or comparative sociological studies the thematic focus of several recent annual meetings, and its journals publish international research regularly. Since the 1970s several ASA sections have formed with explicitly international interests, including sections on Asia and Asian America; Comparative and Historical Sociology; International Migration; Latina/o Sociology; Peace, War, and Social Conflict; and Political Economy of the World System. Although their themes are not as explicitly international, some other sections, such as Collective Behavior and Social Movements, have also become thoroughly international in scope. The two explicitly area-focused sections of the ASA combine an interest in a world area with an identity community of sociologists who have ethnic roots in the area but do not necessarily study the area itself. Many smaller interest groups for particular areas and countries also sponsor gatherings at the ASA annual meetings, which help to link area studies, area nationals, and sociology, but also may blur the intellectual focus on the sociological study of each area.

While tensions remain between area and international studies and sociology, the discipline is international in scope and is getting better at accommodating area and international research. Still, the gap remains wide enough that scholars who hope to combine area specialization with sociology must be prepared to navigate between two academic communities with different standards and expectations. The potential rewards of doing so promise to strength en area studies with the theoretical and methodological rigor of sociology, and to challenge sociology with the theoretical insights of research that is deeply contextualized by interdisciplinary area studies knowledge.

Areal Linguistics

Areal linguistics is concerned with the diffusion of structural features of language among the languages of a geographical region. Various linguistics areas are exemplified in this article and the importance of areal linguistics to the study of linguistic change in explained.

1. *Linguistic Areas*
