According to Barley (1991), one common misapprehension about the nature of organizational conflict is indicated by our tendency to 'bracket' it. By this Barley means that we see conflict as somehow being outside the usual day-to-day events of organizational life. It is to be seen as a special case to be treated in special ways. Barley considers this bracketing to be, indirectly, an artifact of the psychological discipline of conflict and negotiation studies: seeing the world through eyes used to studying dyadic negotiations in laboratory settings predisposes us to look for self-contained conflicts with well-defined antecedents and a limited life span. Barley argues that we need to bring the study of conflict back from the margins and place it at the heart of the quotidian experience of organizations. This means rejecting ideas of utility maximization and individual cognition in favor of an anthropology of specific conflict processes; an approach that involves developing an 'ethnography of disputing.' Barley regards the advantages of this approach to be the historicizing and contextualizing of the eternal conflict between organizational actors trying to make sense of their position in a negotiated order. Barley's position relies heavily on the work of Anselm Strauss and his earlier studies of the unstable divisions of labor found in many organizations. Strauss and his collaborators found that, rather than following externally imposed standardized rules and procedures, individual tasks and duties were more the product of bargaining and negotiation between the staff themselves (see *Organizations: Negotiated Orders*; *Individual Identities in Organizations*).

In general, an anthropological approach to organizational conflict places a good deal of emphasis on the social/cultural context in which the disputants find themselves. These include: socially constructed identities (especially 'insider' vs. 'outsider' status); the size and complexity of networks of dependency relations; the historical nature of social norms (especially those that define what a 'dispute' is and the rules by which it is handled); as well as the resources that actors who are seeking to influence the trajectory of a dispute have at their disposal (Barley 1991). Overarching these dimensions is an appreciation of the semantic and material implications of the language of conflict; in this way, the anthropological approach shares a number of methodological similarities with Actor Network Theory (Law 1994) and Domain Theory (Gray 1989).

The anthropological approach, as depicted by Barley, serves the important purpose of showing us that we do not have to think of conflict exclusively in psychological terms. Breaking the tyranny of the anthropomorphized dyad allows us to think about conflict as a complex nexus of social relations and avoids the functionalist view that it must be doing some 'good' somewhere. Nevertheless, the anthropological study of conflict still remains under-theorized. Indeed, it remains largely an empirical exercise and little theory is at work, an observation that is particularly striking when considering the dimension of power in shaping the antagonistic relations of everyday social settings. For example, Barley's (1991) conception of power extends little beyond the distribution of 'resources' available to parties to influence outcomes in competitive relations, a view that is also evident in some explicitly 'sociological' treatments of conflict (e.g., Tolbert 1991). Thus, it is little different from social psychological approaches in dealing with the complexities of the power relations mediating organizational conflict. Recently, several authors have addressed this shortcoming in anthropological studies of conflict: for example, Sarat and Felstiner's (1995) application of Michel Foucault to their studies of divorce negotiations. Nevertheless, the general lack of nuance in the treatment of power by theorists concerned with organizational conflict points to an area where studies can be greatly enriched.

The conceptual arena of power underwent profound changes in the late twentieth century, shifting from arid behaviorism to arcane abstractedness, before finally settling into fine-grained analysis (see Flyvbjerg 1998; also see *Organizations: Authority and Power*; *Organizational Control*). In part this shift was symptomatic of a return to a less moralistic and more Machiavellian view of power. We shall return to these themes in the last section of this article.

3. Organizational Conflict and Neo-Darwinism

The basic premise of neo-Darwinian approaches to human behavior, such as the Evolutionary Psychology movement (e.g. Buss 1995), is that the human mind is stuck in the prehistoric African Savannah of our hominid ancestors. Behavioral traits—for example, human aggression and a predisposition toward intersubjective conflict—survived because they conferred adaptive advantage on us as a species. Thus, we can established *ex post facto* explanations for almost any empirically observable form of behavior—on the basis of natural selection then, if it was not adaptive, it would have been bred out. Nicholson (1997) suggests that common characteristics of organizations, such as a predilection for gossip, the love of ritual, and even the existence of hierarchy, can be traced to biologically determined human nature.

The increasing influence of the neo-Darwinian approach (incidentally, a viewpoint that is opposed by many evolutionary biologists who see it as a misappropriation of Darwin's ideas) is already being felt in studies of organizational conflict. For example, Ehin (1995) considers the tension between conflict and cooperation to be part of our biological destiny. Moreover, he contends that, by studying the mutual dependence systems of our hunter-gatherer ancestors, we are able to define a set of desirable social principles for current organizations that are '…more congruent with human nature' (Ehin 1995, p. 667). Adopting a dualistic model of innate characteristics, Ehin argues that humans display either *agonic* (aggressive, individually territorial, and hierarchical) or *hedonic* (mutually supportive, group-centered, and egalitarian) tendencies. The extent to which we display one or the other is determined by context and, citing studies of chimpanzee behavior as evidence, Ehin contends that, if we can return to our 'natural' settings, the hedonic predisposition will prevail. It is only when we are removed from this setting—in this case, placed in a hierarchy of work organization—that we tend to display agonic characteristics. This work stands as the intellectual equivalent of Hobbes' primitive ruminations and the organizational implications are clear. First, conflict is an evolutionarily advantageous response to many 'unnatural' forms of organization and, second, if only we can return to a more natural form of organization, then conflict will be, to all intents and purposes, banished as we revert to our hedonic state. This reflects an increasingly popular view that presence of cooperation and the absence of conflict are not just virtuous aspirations within the modern society, they are biological necessities that ensure the continuation of our species (Fukuyama 1999). Not only is this view naive with respect to issues of power, it is also a contestable interpretation of Darwin's idea of natural selection. In particular, to two specific objections can be laid against it.

The first is fundamental: according to Darwinian adaptation, evolution occurs through random mutation rather than strategic intent and anything that involves intent cannot be explained by Darwinian ideas. Of course, axiomatically this rules out all social situations, including those where parties are in conflict over the relative moral status of competing norms or the distribution of resources (see *Industrial Relations and Collective Bargaining*). But, as if this misinterpretation of Darwin was not sufficient, such studies can never satisfy the requirements of evolutionary science. This point has been particularly well made by de Jong and van der Steen (1998) who persuasively demonstrate the inability of any psychological study to establish that anything so abstract and socially constructed as a behavioral trait (for example, a predisposition toward conflict) could be advantageous from an evolutionary perspective. Few would deny that heredity plays *no* part in behavior but it is stretching it beyond the conceptual and methodological bounds of Darwinism to suggest that the dynamics of organizational conflict will be *determined* by human genetics.

4. A Neo-Machiavellian View of Organizational Conflict

By control to the previous approaches to organizational conflict, we wish to offer a fourth framework for thinking about the problem. Our starting point is that we must acknowledge that conflicts matter in any organization and we are all players—even in the face of denial or ignorance (being devious or stupid does not disengage one from conflictual processes). There are four basic ways in which the political maneuvering of organizational conflict proceeds. The first three of these invariably lead to protagonists being ousted in conflict. The organizational agent who is not politically skilled will fail. Returning to the Machiavellian theme, the key implication is that skill in the arts of political engagement, strategy, and discourse should be central to organizational competencies.

The first typical mode is to be *in denial* of conflict. We can characterize this as unrealistic, for few rational actors could be insensitive enough to their organizational surroundings to survive in this state for long. Second, there is *passive acceptance without resistance* of what one is in conflict with. This is naive: it accepts what it does not seek to understand or counter. Third, there is *active recognition without action*, where one realizes the nature of the conflict but proposes no strategic counterpoint for dealing with it. We may characterize this as incompetent. Finally, there is *strategic cognition and treatment*, where one recognizes the phenomenon as conflict and treats it appropriately through devising strategies to manage it, with and through the use of power. We may characterize this,

after Buchanan and Badham (1999), as developing 'power-assisted steering.'

Essential to these competencies is the ability to be able to creatively improvise around organizational conflicts, through developing a diverse repertoire. This includes: image building; selective information release and dissemination; scapegoating of conflictual others; building formal alliances with potential allies; networking with friends and enemies of enemies; striking up appropriate compromises where necessary; being able to manipulate rules, and being ruthlessly pragmatic. Such tactics require deployment in specific organizational contexts, characterized by diverse stakeholders and variable political entrepreneurship. The exercise of power, in ongoing action, will be accomplished through the production of plausible accounts, the creation of viable reputations for political operators, and the achievement of outcomes regarded as 'wins' (Buchanan and Badham 1999). Essential to these capabilities is a capacity to analyze strategies of power discursively. Those who would be players need to be able to ask questions about the extent to which their power games—actual or projected—will be characterized as ethically acceptable, contextually reasonable, and plausibly accountable? What will the consequences be for those whose reputations are involved in the stakes: who will be weakened, strengthened, or unchanged?

Organizational life involves developing and deploying *political competence*. (The theoretical derivation of this view of organizations are elaborated in Clegg [1989] and Buchanan and Badham [1999].) Sometimes the skill will be in containing conflict or nipping it in the bud, other times ensuring where and when it flares, in what arenas, and with what participants. Conflicts represent opportunities for honing the skills of political competence in whatever normative order the organization constitutes. Clearly, these are highly variable—but even the most sacred may be as readily characterized in these terms as may be the most profane—as any reader of Trollope's 'Barchester' novels could attest. Political strategy does not depend on the normative environment in which it is lodged so much as the strategic capabilities deployed. On this reading, Machiavellian skills are appropriate in any organizational context.

Conflict Sociology

When two or more social actors pursue incompatible interests they may be said to be in a relationship of conflict; such conflicts may remain potential, or they may result in various kinds of overt behavior. The sociological study of conflict is concerned with all these possibilities, though the study of the most extreme form of conflict—actual war—is usually the province of political science and international relations. The subject has been treated in diverse ways in sociological theory. These will be analyzed in terms of two sets of variables: conflict as exceptional or endemic; and as momentous or mundane.

1. Major Axes in the Analysis of Conflict

There are two central choices for sociological theory in the treatment of conflict. First, should it be treated as exceptional or as endemic? In the former case, the

theory assumes that normally social life will proceed without conflict, or at least without its overt expression in hostile actions. If conflict becomes evident, this is a sign that some or other institution is not functioning properly. Conflict is therefore seen as pathological. Alternatively, a theory may assume that social relations are likely to exhibit conflict at many points, and its expression will be expected to be frequent. In some cases the absence of conflict might be seen as pathological.

A second choice is whether, when conflict does occur, it should be regarded as of momentous importance, likely to result in major upheaval and possibly radical change; or whether it should be treated as mundane, that is, merely part of the events of everyday life, without particular moment.

These are by no means the only issues which have to be addressed by theories of conflict, but the two-by-two matrix which they form provides a useful heuristic for studying the position of different schools of thought (see Fig. 1).

Figure 1
The main axes of sociological theories of conflict

2. *Conflict as Momentous—Whether Exceptional or Endemic*

The following discussion is organized in terms of the momentous versus mundane dimension, the second dimension being examined within this one. This is purely for convenience of presentation and does not imply any priority of importance.

2.1 *Conflict as Momentous and Exceptional: Functionalist Approaches*

Functionalist theories, particularly in the structural functionalist form which dominated US and much other sociology in the first two postwar decades, are clear and strong examples of the treatment of conflict as momentous and exceptional (see *Functionalism in Sociology*). These theories, particularly those of Talcott Parsons (in particular, Parsons 1964), have often been accused of an incapacity to analyze conflict. This is not true. As Parsons once remarked, he was aware of the enormous capacity for conflict in social relations and was surprised that so much cooperation in fact took place. The purpose of his theories was therefore to demonstrate how it was that, in practice, conflict did not overwhelm social relations. As a result, the emphasis of the theoretical tradition he launched was on how conflict was rendered exceptional.

Functionalism views social institutions as overwhelmingly interconnected and equipped with integration mechanisms. While for most of the time conflict does not occur, social relations are highly vulnerable should it do so. It is a sign that something is malfunctioning, that something pathological is occurring, and major disorder, possibly leading to change, can be expected (Cohen 1966). Structural functionalism fits box I of Fig. 1.

2.2 *Conflict as Momentous and Endemic: Marxist Approaches*

During the 1960s and 1970s there was a major polemical confrontation between structural functionalist and Marxist theorists, in both western Europe and the USA (see *Marxism in Contemporary Sociology*). For Marxists, conflict is endemic to all significant social relations, because these embody in various ways the class relations that are fundamental to social life and that are based on opposed interests. Marxist writers have therefore been unhappy with behaviorist approaches to social conflict, which regard a conflict as existing only when it is openly manifest. According to Marxists and other critical sociologists (see *Critical Theory: Contemporary*), this conceals from view conflicts of interest which the weaker parties to a relationship are powerless or fearful to express. Convinced that the conflict will in principle be there, such sociologists search for subtle and implicit expressions of it (Lukes 1974).

To take a simple example, a functionalist sociologist carrying out research on a factory or office would regard evidence of conflict between management and workers as evidence that something was wrong, that institutions governing social relations in the workplace were not operating correctly. A Marxist sociologist, on the other hand, would regard such instances of conflict as evidence that the reality of the relationship between management and workers was revealing itself; it would be the absence of conflict in such a

relationship that would require explanation as something denying that fundamental reality.

However, opposed as functionalism and Marxism might be, they are in fact agreed on the momentous–mundane dimension. For Marxist sociology as much as for functionalist, conflict is likely to be momentous in its consequences, bringing widespread and uncontainable disorder before it ushers in social change. This is because for Marxists conflict is the way in which the underlying contradictions of the class relations on which the social order rests are finally and catastrophically resolved. Marxism occupies box II in the matrix.

Therefore, contrary to initial appearances, structural functionalism and Marxism are not diametrically opposed in their treatment of conflict. One ironic consequence of this has been the way in which Marxist accounts of an ongoing social order—one in which the fundamental flaws have not yet been revealed—sometimes resemble functionalist ones. For both schools all social institutions are interconnected and, to the extent that (for Marxists) class domination is operating effectively, all institutions tend towards maintenance of the stability of the existing order. This inherent functionalism of much Marxist theory became particularly evident in the structural Marxism which developed in France during the 1970s, exemplified by such writers as Althusser (1968) and Poulantzas (1968). These depicted the totality of capitalist domination in such a way that social conflict seemed almost impossible.

3. *Conflict as Mundane—Whether Exceptional or Endemic*

An important development in the study of social conflict emerged during the 1950s with the idea of the institutionalization of conflict (e.g., Harbison 1954). This involved the hypothesis that, if mechanisms existed which separated different institutional areas from each other, conflicts appearing in one would be prevented from spreading into others, and conflict would therefore be limited. The idea can best be understood through an analogy with insulation or isolation in electricity. The cable wrapped around an electrified wire prevents the current from jumping from the wire to objects alongside it, which it might damage. Interest then focuses on what kinds of social mechanisms might serve as isolators separating one social area from another. If such isolators exist, then individual outbreaks of conflict are unlikely to have momentous implications for the wider society.

Interest in institutionalization developed from the turmoil of the first half of the twentieth century, which had seen considerable disruption caused by two political forces—communism and nazism–fascism—which owed their success, in part, to a capacity to amalgamate disparate issues into totalities that pitched whole groups of populations against each other. There was particular interest in mechanisms which might separate political from industrial conflict, this combination being seen as crucial to the success of communism.

In a closely related development, political sociologists were interested in ways in which different conflictual identities might either run together or cross-cut one another (Lipset 1964). In the former case conflicts might be expected to spread across whole institutional areas and to be intense. In the latter, conflicts between groups defined according to a particular characteristic would be offset and thereby contained and diminished by cross-cutting identities. For example, a society in which most blacks were Roman Catholics and also manual workers, while most whites were Protestants and bourgeois, would be expected to generate deeper and more intransigent conflicts than one in which ethnicity, religion and class divide the population in different ways.

These approaches made it possible to conceive of conflict of no major macro-social importance as mundane.

3.1 *Conflict as Mundane and Exceptional: Micro-functionalism and Applied Sociology*

Theories of conflict institutionalization often overlapped with the functionalist approach to conflict as pathological, and many writers in that school were concerned, both intellectually and in practice, to combat Marxism. The idea of institutional isolators was also quite compatible with the functionalist approach, such mechanisms being among the devices by which social integration was ensured. On the other hand, a stress on institutional separateness could lead theorists away from the emphasis on the overall interconnectedness of social institutions which was distinctive of structural functionalism.

As sociology expanded from the 1970s onwards, and spread into a large number of specialized subsectors, many practitioners of the discipline lost a sense of connecting their work to an overall perspective on society, not necessarily because they did not believe in such a perspective, but because the need to develop knowledge within specialisms required its neglect. Institutional separateness was pragmatically reinforced, even among those who maintained an essentially functionalist standpoint. Their theoretical stance becomes one of micro-functionalism. Functionalism's sense of conflict as exceptional and pathological is therefore not necessarily lost. These approaches therefore occupy box III in Fig. 1. The occurrence of strikes, divorces, crime, outbursts of violence and terrorism, can still be seen as empirical indicators of malfunctioning; but it is malfunctioning of a mundane kind. This is particularly likely to be the case with applied sociology, designed to be used for

the study of perceived social problems, in such areas as the sociologies of working life, ethnic relations, the family and marriage, poverty, social movements, crime and deviance.

3.2 Conflict as Mundane and Endemic: From Critical Sociology to the Normalization of Conflict

By no means all students of specialized fields in which conflicts may occur necessarily share a view of it as pathological. Some may be close to a Marxist or other radical position, likely to see expressions of conflict as demonstrating the realization of certain fundamental contradictions within institutions. This is, for example, likely to be the perspective of feminist sociologists on family conflict, or of observers from a number of perspectives on ethnic conflict. Work of this kind therefore marks a movement towards box IV (Fig. 1): conflict perceived as normal and mundane. However, to the extent that these approaches retain something of a Marxist or more generally 'critical' idea of conflict revealing inherent contradictions, they are unlikely to remain fully at the level of the mundane; conflicts will be expected to involve major disruption and possibly change. For example, if growing family conflict (both divorce and difficult intergenerational relationships) are seen as evidence of challenges to patriarchy, they are unlikely to be mundane conflicts that just rumble along without coming to some kind of crisis.

These differences in the extent to which conflict could be regarded as fully mundane and containable can be seen from contributions made to the study of industrial conflict by British sociologists. These have contrasted a unitary approach to industrial relations, characterized by implicit functionalist assumptions, with a pluralist one (Clegg 1975, Fox 1973). Under the former it was assumed that management and employees shared interests; as a result conflict was treated as pathological, something that should always be prevented. Under the latter, it was taken for granted that employers and employees had partially opposed interests; as a result conflict between them was endemic, and its occasional manifestation should be regarded as normal. There is then however disagreement among those who regarded such conflict as thoroughly containable and who belong fully to box IV in Fig. 1 (Clegg 1975), and those who took a more Marxist position and saw potentially momentous possibilities (Fox 1973, Hyman 1975).

More abstract theories and approaches to conflict belong fully to box IV (Fig. 1). As the Conclusion below will suggest, pursuing this path leads eventually to the disappearance of conflict sociology as such. However, the journey towards that position has involved some important contributions to the study of conflict.

Already in the late nineteenth century, Georg Simmel had pointed to a paradoxical way in which conflict might actually strengthen social ties: parties to a conflict had a stronger relationship than total strangers (see *Simmel, Georg (1858–1918)*). Many conflicts, even full-scale wars, were governed by minimal sets of rules and mutual understandings. From these insights developed the idea that conflict might be functional to social relationships. In the 1950s, Lewis Coser (1956, 1965) developed from Simmel a general theory of the functions of social conflict. At the macro-theoretical level, this was a direct challenge to the dominant view of conflict as pathological, while remaining within a broadly functionalist approach. More generally, it contributed to the perception of conflict as both endemic and mundane.

Also starting in the 1950s was a series of major contributions by Ralf Dahrendorf (1957, 1972), which took theory a significant step further. Not only could conflict be functional, but perhaps social order was actually sustained by conflict. Such an approach first required the concept discussed above of the institutionalization of conflict. Provided individual conflict zones could be mutually segregated in the way this concept anticipated, the open expression and working out of differences, difficulties and contradictions was the way in which people innovated, developed institutions and actually sustained social relations. If conflict was bottled up, there were no possibilities for doing this, relations would fail to be open and honest, and innovation would not take place. In radical contradiction with structural functionalism, this approach contended that it was the endemic and mundane character of conflict which ensured social order.

Dahrendorf was writing with the tragic history of his native Germany in the first half of the twentieth century very much in mind (Dahrendorf 1966). To that extent, his work can be seen as part of a more general tendency in postwar German sociology to stress open dialogue and communication, which necessarily implies the working out of conflicts (Habermas 1981). Conflict became normalized further by developments in the 1960s and 1970s which drew on the legacy of Max Weber (see *Weber, Max (1864–1920)*). There was for a long time a struggle between functionalists and others over who were the true heirs of Weber's approach, particularly in the English-speaking world where Parsons had been influential in the translation and interpretation of the German scholar's work Parsons 1937, Weber 1947).

As more thinkers came to read the original, as German sociology re-emerged during the post-war era, and as more neutral translations appeared, so Weber's legacy was prised away from functionalism. Weber had neither ignored conflict nor had a special theory of it. Conflict was there as an integral part of the collection of social phenomena that resulted from different actors pursuing their own interests as they defined them. Weber had not taken the functionalist step of trying to find overall integration processes that

would somehow bind these conflicting interests into a wider whole. Conflicts could rumble on indefinitely. If order was achieved, it was most likely to result from one group being able to impose its interests on others through the exercise of *Herrschaft*. This word translates easily as 'domination,' though Parsons had preferred the circumlocutory 'imperative co-ordination.'

Weber had also differed from Marxists in that he did not reduce social relations—including their conflictual aspects—to those of material class interests, nor indeed of any other essentialist forms. Conflict might be about class interest, but might also be about idealistic beliefs and symbolic orders. None were treated as ontologically privileged.

This interpretation of Weber became increasingly useful to those trying to avoid the hegemonic tendencies of grand theory. A good example is the work of John Rex (1961, 1981). Of political leanings which led him towards Marxism, Rex had been born in Zimbabwe (then Southern Rhodesia), and was preoccupied with racial and ethnic conflict. He spent most of his career in the British midlands, also a region of considerable ethnic complexity and, sometimes, tension. Marxist insistence on reducing all conflicts to class did not appear to him to cope with the independent reality of these issues. He found Weber's ideas of variously rooted status groups, and their use of a diversity of means to maximize their interests, far more useful. Ethnic relations, and by derivation many others, could therefore be seen as incorporating conflict as an intrinsic and normal aspect of attempts at interest definition and maximization.

4. *Conclusion: The Disappearance of a Distinctive Conflict Sociology*

Now that the great edifices of structural functionalism and Marxism seem finally to have collapsed, the agnostic, non-essentialist approach implied by the idea of conflict as endemic but mundane has probably become the dominant one in Western sociology. Yes, conflict is always likely to be a part of human relations; it can be 'about' almost anything; it does not necessarily have to be absorbed and tamed for some kind of social order to survive; it is not a special aspect of social life, but just a part of it. Research and theory based on assumptions of this kind cluster around the bottom right-hand corner of box IV (Fig. 1). Weber, perhaps along with Simmel, is probably the founding father whose approach to conflict appears most comfortable to contemporary sociologists. As heirs to the Marxist tradition seek to salvage something while dropping the dogmatism and historical certainty, they reach similar conclusions.

The more normal that conflict is seen, the more a specific conflict sociology will cease to exist. This becomes particularly true as sociological theory turns increasingly to theories based on models of rational action by calculating actors—approaches which are also found in Weber and Simmel (see *Rational Choice Theory in Sociology*). In these models actors are always depicted as having interests; and where there are interests, conflicts among them are normal and taken for granted (for example, Knight 1992).

For conflict sociology to continue to exist, the various specialisms of the discipline would need to draw on similar ideas and hypotheses when they come to instances of conflict within their particular area. This does happen to a limited extent. For example, studies of how protest groups engaged in difficult conflicts sustain their morale and endurance can be extended across from ethnic to industrial or environmental movements. Studies of the role of violence and the effect of violence on perpetrators, victims and outsiders may also be able to share knowledge across conflicts concerning very different issues. Beyond this however not much survives.

It has been noted at several points above how sociological approaches to conflict have often reflected developments in the world at large: obsession with society's capacity for upheaval after the first half of the twentieth century; Dahrendorf's concern to treat conflict as normal in the light of the German past; Rex's African concern to study racial conflict. Today's postmodern, post-Cold War world presents a scene in which conflict seems at once endemic but directionless, and sociological theory is reflecting that. Were the heartland of theoretical development to lie, not in the so-called 'advanced' societies, but in parts of the world where religious and ethnic struggles are fundamental to social life, the situation would probably be rather different (Ratcliffe 1994, Venkateswarlu 1992). And since it must not be expected that social change in the advanced societies has come to an end, it may well be that after a number of years the emphasis of the above account will appear very dated.

Conformity: Sociological Aspects

Conformity is a central pattern of social life since it appears that individuals often behave in a similar way in similar circumstances. Why do they do so? Is it because there is some social force acting behind them, or is it because they can be seen as rational, this rationality being linked to some common tendency to act in a definite way in given situations?

1. *Conformity, Similarity, and Dissimilarity*

Conformity depends directly on the degree of similarity between an individual action and another, those actions being more or less frequent in a group. Tarde (1962) tries to stress the importance of imitation to explain such similar behaviors in social life. Imitation appears to him as a constant attitude which explains all social phenomena: all fields of action are involved, and innovation, or dissent, depends always on previous imitations. But imitation has such general contents that it is not very useful to explain the peculiarities of different situations. Durkheim (1982) does not accept this rather general idea of imitation. But for him, there is a similar strong social tendency toward the building of common patterns of behavior: moral, religious, linguistic, or esthetic rules express in a common way the fact that society is built up on the necessity of integration of individuals throughout shared values. Despite any subsequent difference of attitudes, conformity is an essential feature of society.

More or less supported by explicit values, or norms, conformity is strengthened by unequally strong rewards and sanctions. From death penalty to intellectual dissatisfaction, from imprisonment to snobbery, conformity is most often reinforced by social actions in different ways. But it is also observable that conformity can occur when no sanction at all is observable, for instance, people's breakfast habits, which differ from one society to another, this difference being related to a group attitude.

Moreover, when there is a claim to conformity, and sanctions (or rewards) towards potential conformists or deviants, the size of the reference group can have a variable extension (Mead 1962): for a Catholic, or a believer in human rights, humanity as such should comply with some specific norms, whereas the follower of an elitist fashion will stop liking it when the number of followers has reached a certain size (Coleman 1990).

Conformity is related to beliefs and to justifications: people are conformist or deviant because they believe they should be so, and others are asked to behave in the same manner when they are thought to belong to the relevant group to which the norm that introduces conformity should apply. Therefore, a study of the conformity problem must include the motives for which a justification is accepted or rejected. People can obey a norm because they believe the norm is valid, or because they are forced to comply with it. But they can refuse to obey a norm not because they do not acknowledge the validity of the norm, but because they have a stronger interest against conformity. On the other hand, people can refuse to obey a norm because they believe it is unfair, or useless, or unnecessary, or inadequate.

Compliance with similar patterns of behavior can be related to personal or group circumstances: people may think that a norm is illegitimate from the point of view of their position in society. For instance, those who cannot through their personal effort achieve a social promotion, will tend to believe that, since they do not have such opportunity, they cannot have any faith in a social order that builds its legitimacy on this

very self-promotion through effort (Merton 1957). Those conditions can be related to the position of an individual within a group, or to the members of a group within a larger group. Finally, there is a problem of comparison among completely different groups when it appears that they have completely different systems of values.

Because of this wide variety of situations, it seems difficult to accept only one general trend towards conformity or deviance, whether it should be located at an individual level (imitation) or at a social level (social integration). It is more promising to distinguish several fields where the conformity issue can be described in significantly different ways.

2. *Positive Beliefs*

A first domain for conformist attitudes is that of positive beliefs. In this field there is a strong claim to conformity when there are epistemic norms that are recognized from a universal point of view. If there is a norm of validity for the description of a fact, or a set of facts, it is not surprising that rational people will acknowledge the evidence regarding this norm. Conformity has no negative connotation in this case. For sociologists, who believe in science and the validity of their academic enterprise, it would be difficult, and arguably inconsistent, not to believe in such a norm. Subsequently, they will be interested, regarding positive descriptions and beliefs commonly shared by people, in the frequency of typical errors. The sociologist has many devices to explain such widely spread errors.

Tocqueville (1966), for instance, explains that people need general ideas to achieve their ordinary actions, but they do not have the means to verify the validity of all the beliefs they will refer to. In a society based on the dismissal of all authority, the majority of people will think that the most acceptable belief is the one that is commonly shared by others. There will be a tendency towards conformity since the adoption of majority's voice is less costly, both from an intellectual point of view and from a social point of view. Boudon (1990) has studied various ways social errors are built up on a rational basis.

3. *Social Rules in Moral, Political, and Religious Fields*

As previously mentioned, conformity implies a problem of legitimacy. There are strong social norms regarding social practices in moral, political, and religious fields. These norms tend to vary in a significant way from one society to another, and there is a historical evolution that must be taken into account. Sociologists can consider that this variety must lead to a complete relativity of values. But they can try also to pay attention to the reasons that lead to the acceptance or to the refusal of norms.

First of all, it seems that there are four relatively constant norms throughout all cultures (Cusson 1983): incest between mother and son, father and daughter, or brother and sister; rape of married women; murder, meaning the voluntary act of killing someone who belongs to one's own group; theft. Of course, the last case is the less accurate since the definition of legitimate belongings can vary in such a way that property itself can be seen as a theft.

If we depart from those universal features, labeling theorists (Becker 1963) interpret conformity as the result of a power relationship: the powerful impose on others conventions that are arbitrary. Arbitrary conventions have two effects. First, some people are labeled as deviants whereas others are praised as conformists. This expresses the structure of power in society, certainly not an intrinsic validity. Second, once people have been labeled as deviant, this label reinforces by stigmatization their deviant situation, since others can no more accept them as nondeviants. This narrows the range of actions that are available to them; eventually the stigmatized can themselves believe that they are deviants.

It is obvious that two situations can frequently appear. Some people tend to impose on others a norm that cannot be valid to them, and depend only on a power relationship. For instance, it is clear that a racist norm can hardly be seen as legitimate by its victims, since it has no other ground than the relation of power. But on the other hand, people tend to impose norms that they try to legitimize. The claim of the stigmatized must necessarily be a change of norm, that is, the replacement of a nonvalid norm by a valid one. For instance, critics of racism will support the idea that there is no legitimate ground for racism, and they will try to set up a norm against racism: if they succeed, racists will become deviants. If labeling theorists maintain the idea that there is never any intrinsic value to certain rules, they will have no basis for the replacement of a racist rule by a nonracist rule, and they will treat in the same manner the deviant who does not accept a prevailing racist norm and the deviant who does not accept a prevailing nonracist norm.

Therefore, historical evolution must be taken into account as it can be related to the relative strength of different arguments regarding norms. If we consider, for instance, norms regulating sexual behavior, Christian religious belief tends to condemn, on a metaphysical basis, premarital sex, divorce, homosexuality, and pedophilia altogether. In a society where people are submitted to such norms, if they do not share the religious beliefs, they might consider themselves as victims of arbitrary norms. In such an instance they might believe that they have a right to do whatever they wish to do, in spite of those forbidding norms. It can be noticed, therefore, that when there is

no consensus on religious norms for sexual behavior, the only path to maintain a legitimate norm that will be valid for everyone will be to accept the principle of personal choice. Religious people will act according to their choice, and the nonreligious to their other choice. Modern societies increase the principle of personal choice, and diminish the authority of traditional or religious norms. The evolution is significant: divorce tends to be widely practiced, and homosexuality is increasingly legalized. But one significant aspect of this evolution is that norms against pedophilia tend on the opposite to be strengthened in a liberal society. This is easy to explain, on one side, divorce or homosexuality are related to a freedom of choice among consenting partners. If a marriage is a contract between two adult persons, the notion of agreement can imply that the contract should be dismissed if the two partners do not agree any more, even if this is considered to be a failure from another point of view. On the contrary, pedophilia is definitely rejected because it involves children, legitimately seen as victims because of their lack of free choice.

Therefore it cannot be said that a labeling theory is the last word on the problem of conformity or deviance. Both depend on beliefs and possibilities of legitimacy. In other words, norms depend on reasons (Boudon 1990). In this case, if strong norms depend on religious beliefs, when they are imposed on others who are nonbelievers, there is a problem of legitimacy if those beliefs cannot be proved to be right or wrong. Therefore, rationalization will tend to lead to a situation where such norms will apply only to believers. In this case, the principle of choice tends to legalize some practices, and to reinforce the fact that others are forbidden.

According to Boudon's latest works, we can try to find the reasons for the acceptance or the rejection of a norm. Dissatisfaction can occur when there is a rejection of the elements on which the norm is based, or when the norm can be seen as valid in general, but not in the situation where the actors find themselves. Once again, according to Merton's description, someone will tend to reject a social order based on the idea of self-promotion through effort when it cannot be really achieved. Here a problem of consistency is faced: the norm is valid under certain conditions, but ceases to be so when those conditions are not met.

Hence, conformity should not be seen as static. Many norms depend on beliefs that are submitted to rationalization. One of the aspects of this rationalization is that some norms cannot be valid to certain people: for instance, if there is a norm supporting slavery, it will tend to be withdrawn in the long run since it is inconsistent with the source of any legitimacy for individuals, their ability to accept a norm, which implies a certain amount of freedom of choice. Some norms are seen as oppressive which were not before, because the belief on which they were based is no longer shared.

From a rationalistic point of view, there can be a discussion that shows that conformity or deviance depend on the perception of the validity of norms. It can be said that norms tend to be rejected in four major cases: when they just express a power relationship that is disguised in some other value; when they are grounded on false beliefs; when they are grounded on beliefs that cannot be proved and which have no self-evidence—in this case, they cannot be imposed on someone who does not share such beliefs; finally, a norm is not valid when it cannot be applied to someone's situation.

4. *Norms of Culture*

In the two previous sections, I have tried to isolate norms that can be discussed among people from the standpoint of their validity. But there are other norms that are connected to strong conformity that do not seem to be negotiated in terms of validity. For instance, Japanese women tend to walk in a way significantly different from European women. On one hand, there is no obvious reason to consider one way as better than the other; on the other hand, such behaviors express conformity, since they are group behaviors. How should we give an account of such attitudes applied to food, language, dress, architectural habits, etc.?

Three major elements can be stressed regarding this type of conformity. First, it can be related to practical constraints. A language must be shared among people to be efficient for communication. Here, conformity is just the result of the nature of the practice. There cannot be a private language (Wittgenstein 1967).

Second, similarity can express integration to a group. For instance, it is obvious that religious dress is linked to the sense of belonging to a community which can be turned into strategic devices. People tend to adopt some features to show that they belong to certain groups (Simmel 1923). This can be done because belonging to a group is seen as important, or because belonging to a group is a consequence of a common faith or a common goal, or because there is some sort of distinction that is looked for (Veblen 1953).

But finally, it must be said that in these fields conformity tends to be linked to innovation. It is obvious in the esthetic field: on the one hand, there is a huge amount of conformity, that is observable in the constituency of local schools, such as the general use of Romanesque architecture during certain periods in Europe. This conformity, however, does not exclude innovation; Gothic style sooner or later replaces the Romanesque. It would be too difficult in this article to assess all the elements that play a role in such an evolution. It is clear at least that the previous ones are important: interactive constraints, and the sense of

belonging to a community. But these allow the evolution of behaviors and the place for innovation.

Congress: United States

Among the world's national legislatures, the United States Congress stands out as far and away the most powerful. It is distinctive in its independence from the executive, its complex internal organization and procedure, and a capacity to develop its own legislative proposals.

Congress is composed of two chambers: a Senate, in which each state has two senators; and a House of Representatives, in which the number of representatives from each state is determined by population. There are 100 senators and 435 representatives. To become law, bills must be passed by both chambers and be signed by the president. Bills vetoed by the president can become law, provided two-thirds of both the House and Senate vote to override; but that is rare. Senators are elected for 6-year terms, with a third of senate seats being filled every 2 years. Representatives are elected to 2-year terms, and all come up for re-election simultaneously.

1. Congressional Elections

Senators are elected at large from their states, while representatives are elected from single member districts (see *First Past the Post, in Politics*, and, by contrast, *Proportional Representation*. Also see *Apportionment: Political*). The 2-year terms of Representatives are the shortest term of any national legislature. The authors of the Constitution intended the House to be the 'people's' chamber, and meant to keep them on a short leash. The 2-year term does this most effectively. Members of the House are for practical purposes always running for reelection, and they must constantly pay attention to constituency concerns. Indeed, it is widely accepted that the desire of members to be reelected has a vast influence on congressional structure and policy making (Mayhew 1974, King 1997).

1.1 Primary Elections

In nearly all places in the United States, party nominations of candidates for Congress are done by means of primary elections, not by party committees or conventions. In other words, the party organizations have almost nothing to do with who runs for Congress under their banner. This system provides members of Congress with a degree of freedom from their party not enjoyed by members of the European parliaments. Members of Congress who fail to follow their leaders are not subject to the ultimate sanction of being denied renomination by their party. Instead of being constrained to satisfy their party, members of Congress are most concerned about pleasing their constituents (see *Primary Elections*).

1.2 Incumbency Advantage

Members of Congress enjoy a substantial 'incumbency advantage' that enables them to be reelected at high rates. Typically, 90 percent or more of House incumbents who seek re-election win. Senate incumbents are somewhat less successful, but still manage to be reelected with great regularity. Incumbency advantage stems from the greater name recognition that incumbents enjoy compared to challengers, from their ability to do favors for constituents, and, perhaps most importantly, from their superior ability to raise money to finance their campaign. Congressional campaigns have become extremely expensive in recent decades,

with the victorious House candidates spending on average $664,000 in 1998, and victorious Senate candidates spending on average $4.8 million (see *Political Money and Party Finance*). According to Jacobson, there is a self-fulfilling quality to the high reelection rate of congressional incumbents. The seeming invulnerability of incumbents, and the daunting challenge of raising the money necessary to mount an effective challenge, discourage many would-be challengers, leaving incumbents to face incompetent, underfunded challengers who have little or no chance of winning, thus further inflating re-election rates (Jacobson 1997).

2. *Internal Organization*

The United States Congress has a complex internal organization that has a great influence on how it translates the preferences of its members into legislation. Congressional organization is dominated by two partially competing institutions—committees and parties. Congress emerged more or less in its current, modern form at the end of the nineteenth century by means of a process of institutionalization (Polsby 1968). Boundaries were established as once rapid turnover declined; internal complexity developed as standing committees became more firmly established; and universalistic decision-making criteria developed as seniority took hold (see *Institutionalization*).

2.1 *Committees*

Both the House and the Senate have a set of standing committees with fixed legislative jurisdictions. Normally, all legislation, once introduced by a representative or senator, is referred to a committee with jurisdiction over its subject matter. All members of Congress are assigned to committees. Senators have three or four committee assignments, while representatives have one or two. The party organizations in Congress make assignments to committees, but generally members are placed on committees where they have some interest. Some committees have more important jurisdictions than others, and members naturally seek to be assigned to those committees. Seats on committees with jurisdiction over spending and taxation are among the most sought after, and the hardest to get.

Committees have great influence in shaping legislation and in determining what legislation will reach the floor—a bill is seldom considered by the entire House or Senate chamber unless it has been recommended favorably by the committee with jurisdiction. Committees do not have the power to force Congress to adopt legislation that its majority does not prefer, but they can block legislation a majority would favor, and thus they serve as an important veto point in the legislative process.

In both the House and the Senate, the chairperson of each committee is normally chosen according to a norm of seniority, whereby the member of the majority party with the longest continuous service on that committee is selected as its chairperson. The seniority norm is violated occasionally, especially when the majority party has just experienced a large influx of new members who have little commitment to seniority. This was the case in both 1975 and 1995, occasions on which the seniority norm was violated in three instances.

There is substantial debate among scholars about the consequences of delegating power to committees. One prevalent view holds that, because the members of a committee may not reflect the views of the entire chamber, they write legislation that advances their own interests, and not those of Congress as a whole. Another view holds that the chamber as a whole would not allow itself to be cheated in this way, and has tools to keep its committees in line and working for the benefit of the whole institution (see *Delegation of Power: Agency Theory*).

The committee system of Congress is commonly believed to strengthen Congress vis-à-vis the executive branch by encouraging its members to specialize. As issue specialists, members of Congress can better resist the executive branch, develop their own legislative proposals, and transform proposals submitted by the executive (Polsby 1975).

2.2 *Party Organization*

Nearly all members of Congress belong to the Democratic or Republican parties. Party is an extremely important aspect of congressional action, but political parties do not command the same degree of loyalty in Congress that they do in most other national legislatures. Party leaders in the House and Senate have a great deal of influence over the agenda, helping to determine what legislation will come to the floor, and when.

Recent party leaders have been motivated by varying conceptions of the leader's role. Newt Gingrich, Speaker of the House from 1995–8, saw it as his responsibility to articulate a vision for the Republican party, and he expected his party to follow him. This was an unusually expansive notion of congressional party leadership, and one which his party was not willing to support indefinitely. His replacement, Dennis Hastert, also a Republican, has returned to a more traditional leadership posture of seeking to identify a set of positions that unite his party, and endeavoring to pass bills that accomplish those purposes. Parties and their leaders sometimes try to enforce party discipline by threatening wayward members with loss of committee assignments, chairmanships, or loss of other perquisites, but this is unusual, and sometimes drives dissidents into the

waiting arms of the other party. The leaders' job might be better described as discovering rather than creating an agenda for the party.

The power of party leaders is limited by the willingness of party members to grant them power. With the members of Congress always eager to appeal to their own unique states and districts, they are reluctant to grant party leaders much power, for that might limit their own ability to pursue initiatives beneficial to their constituents.

To a substantial degree, the power of committees and party leaders is contradictory. To the extent that party leaders are able to increase their power, they do so at the expense of committees and committee chairs. When party leaders seek, as Gingrich did, to determine themselves what the agenda of the House will be, and what legislation will look like, they arrogate to themselves powers that committees and their chairpersons cherish.

2.3 Legislative Procedure

Because of their very different sizes, the House and Senate have fundamentally different procedures. In both, however, the rules of procedure have a profound impact on the legislative product. The House of Representatives, with its large size, cannot tolerate as much individual expression of its members as the Senate can, and its procedure is designed to ensure that the majority prevails. Consequently, the minority party and individual members often feel that they have been crushed by a legislative steamroller. The smaller Senate can more readily accommodate the peculiarities of its members, and accordingly it allows far more freedom for debate and amendment.

2.3.1 House procedure. After important bills are reported favorably from committee, they normally go to the Rules Committee. The Rules Committee drafts a resolution, called a 'special rule,' that, on adoption by the House, determines the conditions under which the bill will be debated, amended, and voted upon. The power and flexibility of special rules to alter, amend, and waive the rules of the House is staggering. Special rules can either make no amendments in order (a closed rule), or place no restrictions on amendments (an open rule). Alternatively, they can make a specified list of amendments in order, they can declare amendments adopted without a vote, or they can amend amendments without the permission of the amendment's author. Special rules can alter or waive the rules of the House for the purposes of considering a particular bill. In short, special rules are infinitely flexible, limited only by the creativity of the Rules Committee, allowing the majority to do nearly anything it wants. Rules written by the Rules Committee must be adopted by a majority vote of the House. In general, the majority party members work closely with their party leaders to ensure that the position preferred by the party is able to prevail, and that potentially troublesome amendments are either forbidden, or considered in such a way that they will do the least possible harm to majority party control.

2.4 Senate Procedure

While action in the House is structured closely by its extensive rules, the Senate, by contrast, has relatively few rules and frequently ignores what rules it has. The Senate gives individual senators an almost unbelievably large amount of discretion and power. This has the predictable consequences sometimes of paralyzing the Senate. The House works by assembling majorities and voting, but the Senate must work by a process of accommodating the individual senators, not by forming majorities, but by working to overcome the objections of individual senators.

The central feature of Senate procedure, around which all else is organized, is the possibility of the filibuster. Filibusters are efforts to defeat bills, not by voting them down, but by means of delay. The goal of filibusterers is to convince supporters of legislation that it will take so much time to pass the bill that they would be better off dropping it and moving on to something else.

Filibusters are possible because of three glaring omissions from Senate rules. The Senate lacks any means of limiting debating time; it lacks a 'germaneness' rule for interventions and amendments; and it lacks a previous question motion. Because the House rules have all of these key features, dilatory tactics are not possible there. The usual filibustering tactics include so-called 'extended debate,' whereby senators talk endlessly, and not necessarily about the bill in question, offering numerous amendments, which need not be germane to the bill, and offering numerous motions, such as suggesting the absence of a quorum, intended only to delay action. Filibusters can be ended by means of the 'cloture' process. If 60 senators are willing to vote for cloture, debate can be ended, but only after all amendments have been disposed of, and all senators have had an additional opportunity to speak for an hour.

Because even a single determined senator can cause a lengthy delay, losing the Senate the opportunity to consider other important legislation, the focus of Senate activity is not on breaking filibusters through cloture, but rather on avoiding them altogether. In advance of bringing legislation to the floor, bill sponsors often engage in extensive discussions with their colleagues in an effort to anticipate and satisfy objections. Most legislation passes the Senate with only minimal objection, in part because of efforts to build consensus early.

3. Congress and the President

By dividing the legislative and executive powers into separate branches, the authors of the US Constitution sought to encourage friction and disagreement in government. This plan has worked well for over two centuries, as Congress remains determinedly independent. Congressional independence is nowhere better demonstrated than in its handling of the federal budget. By statute, the president is required to submit to Congress each year a detailed budget proposal. Nothing, however, requires Congress to pay much attention to presidential proposals. Commonly in recent years the president's budget has been declared 'dead on arrival' at Capitol Hill, and Congress has gone on to draft its own, different budget, relying on its budget process, its committees, and its own budget agency. The president has influence over members of Congress, especially those from the president's own party; however, even members of the president's party are influenced strongly by their constituencies.

4. Congress and Foreign Policy

Congress defers to the executive branch to a great extent in foreign policy, but with important exceptions. Even though the Constitution gives Congress the power to declare war, power over warmaking drifted away from Congress to the president over the twentieth century, in part because of a need for speed and secrecy, and in part because of an unwillingness in Congress to challenge the president over the war power. In trade policy, Congress has since the 1930s mostly ceded trade negotiation power to the executive branch, but periodically becomes involved in trade issues such as automobiles or steel, especially when domestic jobs are threatened by imports.

5. Democratic Accountability

Ideally, individual members of Congress should be held accountable for the collective actions of Congress, but this does not necessarily occur (Arnold 1990). While members of Congress sometimes campaign for reelection by proclaiming the major legislative accomplishments of Congress, often they detach themselves from the institution as a whole and seek reelection for particular services rendered to the district or state. Adopting pork barrel projects such as dams, roads, and parks can help to make individual members popular, but the appearance of waste and venality can make Congress less popular. Fenno argued that representatives and senators distance themselves from Congress as an institution and seek to promote themselves separately, often at the expense of Congress as a whole (Fenno 1978). The accountability of Congress to voters is inherently difficult because Congress acts as an institution, but its members are judged individually.

Conjoint Analysis Applications

1. Introduction

This article provides a general discussion of CA applications and identifies and reviews principal contributions, streams of research, and applications within the overall field. CA is a generic term for methods developed to model and measure preferences and trade-offs that share several common features:

(a) independent variables or 'attributes' that explain preferences are identified and defined (e.g., bus travel times and fares; MHz and prices of PCs);

(b) attribute 'levels' relevant to the research are assigned (e.g., 30, 60 min travel time or \$1, \$3 fare for buses; 600, 733 MHz and \$2,500, \$2,850 prices for PCs);

(c) statistical design techniques are used to combine the attribute levels and create descriptions of options (e.g., 15 min travel time for \$2 or 733 MHz for \$2,850);

(d) a sample of individuals evaluate all or a subset of the descriptions;

(e) individual- or group-level models are estimated from the evaluation data (e.g., transport modes or PC options); and

(f) the estimated models are used to measure subjective quantities (e.g., the subjective value of 600 vs. 733 MHz or implied willingness to pay to save 30 min travel time).

Despite commonalities, CA methods also differ in experimental designs, response tasks, model form(s), and measurement of subjective quantities. For example, initial CA applications were based on an axiomatic theory of the behavior of a ranking of all possible combinations of a discrete set of attribute levels (e.g., Krantz and Tversky 1971). All possible combinations of attribute levels are given by complete factorial enumeration, such that if $A_1(I)$, $A_2(J)$, ..., $A_N(N)$ represent the number of levels of attributes 1, 2, ..., N, then all combinations are given by the expression $I \times J \times \cdots \times N$. Thus, in a full factorial experiment the total combinations equal the product of the levels of each attribute. For example, if the attributes (levels) are bus fare (3), travel time (3), and service frequency (3), then there are $3 \times 3 \times 3$ (or 3^3) = 27 possible bus descriptions.

If a subject ranks all designed descriptions in order of preference (or another subjective dimension), and certain axiomatic conditions are satisfied, the ranking can be represented by an algebraic model defined by marginal and joint attribute effects. For example, for two or more factors, a ranking of a factorial set of options is additive in the attribute effects, if, and only if, the effects of all attributes on the ranking are independent of one another and there are no joint attribute effects (i.e., only marginal effects apply). That is, an additive process underlying a ranking of all combinations of, say, the ith, jth, and kth levels of attributes A_{1i}, A_{2j}, and A_{3k}, respectively, can be expressed as:

$$V_{ijk} = c + v(A_{1i}) + v(A_{2j}) + v(A_{3k}) \tag{1}$$

where V_{ijk} is the overall value of attribute level combination ijk, c is a constant that sets the response scale origin and $v(A_{1i})$, $v(A_{2j})$, and $v(A_{3k})$ are values of the ith, jth, and kth levels of each attribute.

Statistically, if the underlying process is additive, all attribute interactions will be nonsignificant. If the underlying process is multiplicative, the model is as follows:

$$V_{ijk} = c^* + v(A_{1i})v(A_{2j})v(A_{3k}) \tag{2}$$

where all terms were previously defined, except c^*, a constant to set the scale origin. Equation (2) requires all attribute main effects and interactions to be significant. Early applications lacked error theories, hence used goodness-of-fit tests to evaluate and compare models.

Full factorial designs proved too large, so ways to reduce numbers of combinations were proposed, such as fractional or other partial factorial designs, ranking all pairs of attribute levels or using incomplete block designs to select attributes and levels (e.g., Green 1974). Most applications rely on non replicated fractional factorials that cannot be used to test model forms and produce few observations relative to parameters for individuals (Louviere 1988). However one can estimate individual models if response, design, and model assumptions are satisfied (e.g., equal interval response scales, insignificant interactions, independent and identically distributed normal errors).

A new paradigm emerged when McFadden (1974) developed computationally tractable extensions of RUT to the multiple-choice case. This provided ways to estimate and test choice models with a formal theory of errors based on RUT. RUT assumes an unobservable value, U_i, for each of $i = 1, 2, \ldots, I$ options that is a sum of observable (explainable) and random (unexplainable) components:

$$U_i = V_i + \varepsilon_i \tag{3}$$

where V_i and ε_i are, respectively, observable and random components. RUT assumes that individuals try to choose their preferred options, but the random component implies that choices are inherently stochastic from a researcher's perspective: that is, the probability that a subject will choose an option from a set of options is predictable, not the exact choice. If $P(i|C)$ is the probability of choosing option i in set C, and Max = maximum operator, then

$$P(i|C) = P[(Vi + \varepsilon i) > \mathrm{Max}(Vj + \varepsilon j), \text{ for all } j \text{ options in } C] \tag{4}$$

Different discrete choice models are derived by making assumptions about the distributions of the ε's. For example, McFadden (1974) derived the multinomial logit model (MNL) by assuming that the ε's were independently and identically distributed Gumbel random variates. MNL choice probabilities have a simple closed-form, but if the ε's are non-independently and identically distributed normals, the nonclosed form multinomial probit (MNP) model results.

Louviere and Woodworth (1983) integrated RUT-based choice models with CA, and proposed ways to design choice experiments consistent with RUT-based choice models. This choice-based (CB) approach designs attribute level combinations (to estimate evaluation/utility functions) and selects choice sets in which they appear (to satisfy properties of choice models), and the error theory is used to select and test model forms. The CB approach typically estimates models from samples of subjects because individuals provide too few observations to satisfy asymptotic theory and obtain reliable model estimates.

Choice experiments mimic real choice situations. For example, to model choice of travel mode to work, one designs experiments to offer commuters sets of mode choices; to model choice of health insurance plan, one designs experiments that offer subjects sets of health insurance options. Thus, the CB approach designs attribute level combinations to describe sets of options (say M of them). If $M = 1$, subjects evaluate each option separately, making M binary choices (e.g., will/will not choose); if $M > 1$, subjects evaluate sets of multiple options (say S of them), making S multiple choices (Louviere and Woodworth 1983, Louviere et al. 2000).

Significant progress has been made in linking behavior in choice experiments and real environments. Specifically, in RUT models the magnitude (or 'scale') of the parameters are inversely proportional to choice variability. For example, if we denote the scale as λ, it can be defined as follows for MNL models (Ben-Akiva and Lerman 1985 pp. 104–5): $\lambda^2 = \pi^2/6\sigma_\varepsilon^2$ (π is the natural constant; σ_ε^2 = error variance). In empirical applications, analysts estimate the quantities $\lambda\beta_k$, not β_k (β_k is a k-element parameter vector associated with design matrix, X_{ki}, and the ith choice option).

Thus, λ is not identified in any one data source, and typically is set equal to one for convenience. Ben-Akiva and Morikawa (1990) showed that ratios of λ's can be identified and estimated from two or more choice data sources; hence, if experimental and actual choices differ only in response variability, parameters estimated from each will be proportional. Empirical tests in several fields suggest that parameter proportionality often holds to a close first approximation (see Louviere et al. 1999).

This property of RUT-based choice models allows many sources of preference and choice data to be compared, including traditional CA data. For example, one can transform CA ranks into implied choice sets by 'exploding' subjects' complete or partial orders into one or more choice sets (Louviere et al. 2000). That is, for a ranking of M options, the first is preferred to the other M–1, the second to the remaining M–2, etc; hence M rankings yields M–1 choice sets (if A, B, C, D are ranked 1, 2, 3, 4 the first set contains A, B, C, D with A chosen; the second set contains B, C, D with B chosen; etc). Such explosions transform preference responses into discrete choices that can be compared using RUT-based statistical models (e.g., Louviere et al. 2000). Recently Bayesian methods have been used to estimate individual-level parameters (Wedel et al. 1999), but the pros and cons of these methods in CA and CB applications have not been fully explored.

Statistical properties of choice experiments also remain elusive. In particular, humans interact with CA and choice experiments and particular designs can impact response variability. Statistically efficient designs may require many choices, which may increase choice variability; increases in choice variability may offset higher statistical design efficiency. Hence, research into behavioral impacts of designs and effects of non design issues like task layouts, formats, response tasks, etc, on choice variability also are needed.

Connectionist Approaches

1. Definitions

To facilitate the following discussion, it will be helpful to first define some terms. A typical connectionist network comprises a (potentially large) number of simple processing *units*. The units are often called (artificial) neurons, but that terminology begs the question of their relation to biological neurons, so it will be avoided in this article. In the most common case, the units form a weighted sum of their (quantitative) inputs and pass the result through a simple, nonlinear activation function, which limits the range of possible outputs. The resulting value is considered the activity of the unit, which may be transmitted to other units (through outgoing connections). In some cases the activity of a unit is a combination of its inputs and previous activity, which provides a kind of 'short-term memory' residing in the collective activities of the units.

The weighted sum results from the fact that each connection in the network has an associated weight (analogous to synaptic efficacy in biological neural networks), which multiplies the quantity transmitted by that connection. Positive weights correspond to excitatory connections and negative weights to inhibitory; zero-valued weights correspond to the absence of a connection. Mathematically, connection weights are often treated as a weight matrix **W**, with element W_{ij} being the weight of the connection to unit i from unit j. Learning and adaptation take place by modification of the weights according to some learning algorithm (Sect. 3); thus the connections constitute the network's 'long-term memory.' 'Connectionism' derives its name from the fact that knowledge resides in the patterns and weights of the connections.

Many connectionist networks are organized into layers, analogous to functional areas in the brain; information usually moves in lockstep from layer to layer. Although many networks are feed-forward, that is, the information moves through successive layers from input to output, other networks are recurrent, which means that there may be feedback connections from a layer to itself or to earlier layers. Recurrent networks are able to recognize and process temporally-extended patterns, that is, sequences of related inputs.

It must be stressed that there are exceptions to all of the preceding general statements about connectionist networks, and 'connectionist approaches' are best viewed as forming a Wittgensteinian 'family resemblance.'

2. History

A short history of connectionist approaches will be presented: first in the narrower context of cognitive science and artificial intelligence; then in the broader context of epistemology, linguistics and the philosophy of mind. Although the size of this article does not permit detailed citations of the literature, many of the seminal articles are collected in Anderson and Rosenfeld (1988) and Anderson et al. (1990). (See *Cognitive Psychology: History*; *Cognitive Science: History*.)

2.1 Narrower History

According to the second edition of the *Oxford English Dictionary*, the term 'connectionism' was first used by E. L. Thorndike, in his *Fundamentals of Learning* (1932), to refer to the reduction of mental processes to the connections between stimuli and responses (that is, to a form of associationism), and so connectionist theories have been set in opposition to cognitive theories. The term is used somewhat differently now (so that 'connectionist cognitive science' is not an oxymoron), but retains some similarities to associationism. However, to understand the relation it is better to look at connectionism from the perspective of neural network models of cognition.

In the early 1940s W. S. McCulloch and W. Pitts investigated the computation of logical functions by simple neuron-like elements; in effect they showed that these elements could compute logical 'and,' 'or,' 'not,' and so forth. In his *Organization of Behavior* (1949) D. O. Hebb suggested that learning takes place by the formation of cell assemblies and that this occurs through the strengthening of connections between simultaneously active neurons in neural networks, which are initially randomly connected. His description of this process inspired one of the simplest connectionist learning rules (Sect. 3.1).

In the late 1950s F. Rosenblatt began to investigate the application of simple neuron models called perceptrons to perceptual problems such as classifying printed letters (see *Perceptrons*). He developed a learning algorithm for simple (single-layer) perceptron networks, which iteratively adjusted the connection weights whenever the network made a mistake. He proved that, if the network were capable of solving the problem at all, then the algorithm would eventually find the connection weights to solve it. However, there

are many problems that a single-layer network cannot solve, and Rosenblatt never succeeded in finding a multilayer learning algorithm.

A key event in the history of connectionism was the publication of M. Minsky and S. Papert's *Perceptrons* (1969), which demonstrated limitations of simple perceptron networks. Specifically, they proved that single-layer perceptron nets could discriminate only those categories that are linearly separable (see *Linear Algebra for Neural Networks*; *Perceptrons*). Their proof did not apply to multilayer nets (for which there was still no learning algorithm), but they suggested that similar limitations would be found for these too. Nevertheless, their book was widely interpreted as showing the impotence of neural networks in general, and is commonly blamed for discouraging research in the field for a decade. (The extent to which it actually did so is, perhaps, a topic for historians of science.)

It will be worthwhile to comment on the role of holography in the development of connectionist approaches. As early as 1929 K. S. Lashley had conducted experiments suggesting that individual memory traces were not localized in any one place, and that degradation of memory was proportional to the amount of cortical mass destroyed, thus implying that individual traces were distributed over large areas of cortex. In his well-known 1950 paper, he despaired of ever understanding how such a nonlocal memory could operate. The principles of holography had been described by D. Gabor in 1948, but it was not until the advent of optical holography in the early 1960s that it began to be seen as a solution to Lashley's dilemma. Although an analogy between holography and memory had been suggested as early as 1963 by P. J. van Heerden, the 'holographic hypothesis' has been developed most extensively by K. H. Pribram and his colleagues since 1966 (see, e.g., Anderson et al. (1990), ch. 7). In the late 1960s and early 1970s holographic and holography-inspired models of associative memory were also investigated by H. C. Longuet-Higgins, D. J. Willshaw and others (Hinton and Anderson, 1989). Some connectionists were influenced by the critiques of traditional, rule-based AI by the phenomenologist philosopher H. L. Dreyfus (*What Computers Can't Do* 1972). Although he stressed the limitations of rule-based systems, he also suggested that some of these limitations would not apply to analog systems operating on principles similar to holography (see *Cognition*, *Distributed*).

Although a number of investigators (including J. A. Anderson, S. Grossberg, and T. Kohonen) continued connectionist research through the 1970s, the field was rejuvenated by the work of D. E. Rumelhart, J. L. McClelland, and other members of the 'PDP (Parallel Distributed Processing) Working Group,' many of whose publications were collected in a widely-read two-volume set (Rumelhart et al., 1986). The credibility of connectionist approaches was also enhanced by J. Hopfield's publication in 1982 of a simple recurrent net capable of associative memory and pattern completion.

2.2 Broader History

Although connectionism can be viewed as an approach to knowledge representation and inference that is of relevance only to cognitive science, in fact it has much broader implications, for it challenges assumptions about knowledge that have been largely unquestioned since ancient Greek philosophy. Already in the philosophies of Socrates, Plato, and Aristotle there is a preference for knowledge expressed as logical relations among discrete, language-like structures, and for a view of cognition as mechanized deduction. These ideas influenced many later philosophers, including Hobbes (who equated thinking with computation), Leibniz (who experimented with formalized systems of knowledge representation and mechanical deduction), and Boole (who invented mathematical logic).

These ideas were also influential in the development of logical positivism, which dominated the philosophy of science in the first half of the twentieth century. The idea persisted in the assumption that there must be a 'language of thought,' because no alternative is imaginable, and it is 'the only game in town.' Similarly, most research in artificial intelligence (AI) took for granted that intelligence resides in the structures of a *knowledge representation language*, and in deduction-like formal rules for their manipulation. Throughout the 1970s (the 'connectionist dark ages'), AI researchers concentrated their attention on expert systems, which depended on expertise represented symbolically (see *Expert Systems in Cognitive Science*). Disappointment with the performance of these systems was one of the motivations for the connectionist renaissance.

In summary, the Western tradition (with some exceptions) has displayed a kind of 'linguistic chauvinism,' which presumes that all knowledge and cognition can be expressed in language-like structures. Knowledge is expressed at a symbolic level, that is, in terms of atomic (indivisible), word-level categories related by sentence-like logical structures. On the other hand, most connectionist approaches represent knowledge at a *subsymbolic* level, that is, in terms of minute, quantitative features related by low-level, often statistical, connections. In other words, knowledge is more akin to an *image* than to a *sentence* (see *Imagery versus Propositional Reasoning*; *Mental Imagery, Psychology of*). Therefore, some of connectionism's advocates see it as a fundamentally new view of knowledge and cognition, which is leading to a paradigm shift in cognitive science and philosophy and is engendering a 'new AI.' Specific innovations of the connectionist approach are discussed in Sect. 5.1. See *Artificial Intelligence: Connectionist and Symbolic Approaches*; *Knowledge Representation*; *Production Systems in*

Cognitive Psychology; *Schemas, Frames, and Scripts in Cognitive Psychology*.

3. Mechanisms of Adaptation and Learning

Virtually all connectionist approaches incorporate adaptive mechanisms or learning algorithms, which allow the network to improve its performance; here a few will be discussed briefly.

3.1 Correlational Learning

Correlational learning ('Hebb's rule'), the simplest connectionist learning algorithm, takes its inspiration from Hebb's hypothesis that the simultaneous activity of two neurons strengthens the connection between them. It makes a change in connection weight proportional to the product of activities of the units it connects. Thus, the change in the weight W_{ij} of the connection to unit i from unit j is proportional to $y_i x_j$, where y_i is the activity of unit i and x_j is the activity of j. This learning rule can be viewed as a highly simplified model of long-term potentiation. See *Long-term Potentiation and Depression (Cortex)*; *Learning and Memory, Neural Basis of*; *Synaptic Efficacy, Regulation of*.

The effect of this rule is that the weight becomes a correlation coefficient between the activities of the units it connects. That is, the connection will become stronger (more positive) to the extent that the units are simultaneously positive or simultaneously negative. The connection will become more inhibitory (more negative) to the extent that one unit is positive while the other is negative. If there is, on average, no systematic relation between the activities of the two units, then the weight will tend toward zero, effectively disconnecting the units.

The correctional learning rule is the basis of a simple associative memory known as a *linear associator*. In this connectionist network, there are two layers of linear units, an input layer and an output layer; each input unit is connected to every output unit, so that the output is a linear function of the input, $\mathbf{y} = \mathbf{W}\mathbf{x}$. A series of pairs of pattern vectors $(\mathbf{y}_1, \mathbf{x}_1), \ldots, (\mathbf{y}_p, \mathbf{x}_p)$ may be presented to the input and output layers of such a network and the weights adjusted according to the learning rule. The goal of the linear associator is that the network associate each $\mathbf{x}_k$ with the corresponding $\mathbf{y}_k$. In fact it can be shown that if the set of input patterns is orthogonal, then the output $\mathbf{W}\mathbf{x}_k$ will be proportional to the desired $\mathbf{y}_k$ (see *Linear Algebra for Neural Networks*).

3.2 Delta Rule

An improvement called the delta rule can be made in the linear associator; it illustrates a fundamental approach to connectionist learning. The idea is to define the error, as a function of the weight matrix, as the sum of the differences between the desired and actual outputs of the network, $E(\mathbf{W}) = \sum_{k=1}^{p} D(\mathbf{y}_k, \mathbf{W}\mathbf{x}_k)$. The weight matrix is then changed by gradient descent which means that the elements of $\mathbf{W}$ are changed in the relative proportion that causes a maximal incremental decrease of $E(\mathbf{W})$.

If the difference between patterns is measured by Euclidean distance squared, $D(\mathbf{y}, \mathbf{y}') = \|\mathbf{y} - \mathbf{y}'\|^2$ (that is, the sum-of-squares error), then the delta rule is essentially equivalent to linear regression. If the input patterns are linearly independent, then the delta rule will converge to a weight matrix that associates perfectly, $\mathbf{y}_k = \mathbf{W}\mathbf{x}_k$. If they are not, then the weight matrix will be that which minimizes the total error; that is, it will be the best linear prediction of the output patterns from the input patterns (see *Linear Algebra for Neural Networks*).

The delta rule also illustrates an important characteristic of most connectionist networks: their ability to *generalize* to inputs other than those upon which they have been trained. The delta rule provides only linear generalization, but other algorithms, such as backpropagation (Sect. 3.3) can make nonlinear generalizations. Typically, connectionist categories are represented by concrete prototypes rather than by definitions in terms of necessary and sufficient conditions or other abstract symbolic structures. Network behavior then depends on similarity to the prototypes rather than on formal manipulation of symbolic structures.

3.3 Backpropagation

Gradient descent may be applied also to multilayer networks of nonlinear units, so long as the activation function is differentiable. The backpropagation algorithm (also called the *generalized delta rule*) efficiently computes the weight changes by starting with the last layer and working backward layer by layer. It has been rediscovered a number of times, perhaps first by P. Werbos in 1974, but its importance in connectionism began with its rediscovery in the early 1980s. There are also special adaptations of backpropagation for recurrent networks. Backpropagation has a number of limitations, including: (a) it may be quite slow, (b) it does not necessarily take the shortest path to an error minimum, and (c) it may get trapped in local minima. Nevertheless, it remains a fundamental learning algorithm and has been subject to many practical improvements.

3.4 Other Learning Algorithms

The preceding are examples of supervised learning procedures, which means that the 'correct answer' $\mathbf{y}_k$ is available for each training input $\mathbf{x}_k$. Although this is appropriate for modeling some cognitive processes and for many practical problems, for others unsupervised learning is preferable. In these procedures, the

network is not trained to produce any specific outputs, but it allowed to group or categorize inputs according to standards inherent in its design. Thus unsupervised learning is often equivalent to some kind of statistical clustering. Between these two extremes is reinforcement learning, in which the algorithm is told whether or not the output is correct, but not what the correct output is. In unsupervised and reinforcement learning, as in supervised learning, the network is normally expected to generalize reasonably to novel inputs. There are now hundreds of connectionist learning algorithms, of greater and lesser relevance to cognitive science and neuroscience, but this must suffice for an introduction.

4. *Example: Learning Past Tenses*

Since the early 1980s, connectionist networks have been used for an enormous number of practical applications and for modeling many aspects of cognition. One notable example must suffice here; see Rumelhart et al. (1986) for additional examples.

Rumelhart et al. (1986, Vol. 2, Chap. 18) trained a connectionist network to produce the past tenses of English verbs. The inputs were vectors representing phonological features of the present tenses and the outputs were vectors representing the phonological features of the corresponding past tenses. Learning was observed to pass through three stages. In the first stage, the most common verbs were learned, essentially by rote as individual special cases. In the second stage, the network learned how to form regular past tenses (for it was able to generalize to novel regular verbs), but over-generalized by treating the (previously correctly processed) irregular verbs as though they were regular. In the third stage, the network (re)learned the correct formation of the irregular past tenses without losing its ability to form regular past tenses. It is interesting and highly suggestive that children pass through these same three stages; the model also exhibited errors of the same kinds made by children.

Although this experiment can be (and has been) criticized on a number of grounds as a model of language learning, it is perhaps more valuable as a demonstration of how a connectionist network can exhibit apparently rule-like behavior, but not be following any explicit rules. In particular, exceptions to the rules are handled automatically without explicit accommodation. Thus it is paradigmatic of connectionist cognitive models.

5. *Issues*

5.1 *Connectionist Representations*

Connectionist approaches represent and process information in a way that is fundamentally different from *symbolic* approaches, in which knowledge is represented in discrete structures relating atomic lexical-level features (i.e., categories of the sort for which natural languages have words). In symbolic approaches, information is processed by formal logic-like rules, which rearrange these atomic units of meaning. In connectionist approaches, on the other hand, information is represented by patterns of activity distributed over large numbers of units, which individually have no lexical-level meaning. The latter are often termed microfeatures, but they are fundamentally different from features, which are supposed to be complete, context-free units of meaning. Microfeatures are just components of distributed representations and are usually individually uninterpretable.

Instead of rules, connectionist information processing is defined by quantitative connections between microfeatures and takes place at a subsymbolic level (Smolensky 1988). Cognition then is an emergent effect of large numbers of these interactions (which therefore constitute the microstructure of cognition). Indeed, according to this account, apparent symbolic processing is just such an emergent effect of these subsymbolic interactions.

Traditional (symbolic) models of knowledge have been criticized for their *brittleness*. For example, when a set of rules is formulated in an attempt to model the behavior of some expert, it is generally found that the rules do worse than the expert, since the expert applies rules flexibly and makes *ad hoc* exceptions to them as required by the particulars of the situation. Of course, additional rules can be formulated to cover the exceptions, but then these are likewise found to have exceptions, and so forth. The attempt to reduce flexible behavior to inflexible rules leads to a combinatorial explosion of possibilities which exceeds the capacities of brains and computers.

Connectionist approaches seem better able to account for the flexibility and context-sensitivity of natural intelligence. This is because the connection weights function as a large number of soft constraints, none of which is individually necessary or sufficient to produce a result. Therefore connectionist networks can accommodate inputs that are exceptional in various ways, either by ignoring the anomalous aspects, or by corresponding adjustment of their output. As a consequence, their performance is also robust in the face of noise in the input or damage to the network. Further, to the extent that microfeatures of the environment are represented in the input, the network can process information in a way that is sensitive to the context. (See *Artificial Intelligence: Connectionist and Symbolic Approaches*; *Knowledge Representation*; *Production Systems in Cognitive Psychology*; *Schemas, Frames, and Scripts in Cognitive Psychology*.)

5.2 *Criticisms*

Connectionist networks have been criticized for their *opacity* or *uninterpretability*. That is, when a connec-

tionist network has been trained to perform some task, it is difficult to extract human-interpretable rules from the network; although the network performs correctly, one cannot understand the 'rules' it is apparently following. The reason of course is that it is *not* following rules, and the individual units and weights represent microfeatures and constraints that are lexically meaningless (i.e., have no lexical-level meaning). There are mathematical procedures for extracting rule-like information from networks, but they give only approximations to the network's behavior. This is analogous to what has been observed during 'knowledge acquisition' for expert systems: after the fact, human experts can account in terms of rules for their decision making, but the rules do not account adequately for the expert's future decisions.

Quite naturally, some of the severest criticisms of connectionism have come from linguists and other cognitive scientists committed to a 'language of thought,' that is, to the hypothesis that cognition must be understood in terms of the manipulation of propositional or sentential symbolic structures. These criticisms have focused on the alleged inability of 'flat' connectionist representations to capture the rich hierarchical symbolic structure of human language and propositional attitudes, and the related sensitivity of cognition to their constituent structure. However, experiments in 'connectionist symbol processing' have shown that connectionist networks can be sensitive to the constituent structure of representations without explicit representation of that structure and without the use of explicit symbolic rules (e.g., Sect. 4). There is much more to the issue than this, however, and the early collection by Pinker and Mehler (1988) is still a good introduction to the anti-connectionist position. (see *Connectionist Models of Language Processing*).

5.3 Computability

If connectionism is viewed as a fundamentally new approach to information representation and processing, then the question arises of its power relative to conventional digital computation, as modeled by the Turing machine. At a basic level this question is easy to answer. On one hand, since connectionist networks are routinely simulated on digital computers, it is apparent that they have no greater power than a Turing machine. On the other hand, researchers have shown that various sorts of connectionist networks can simulate Turing machines, which therefore have no greater power than the networks. The conclusion would seem to be that connectionist networks are equivalent to Turing machines in computing power.

However, at a deeper level the question is problematic, for the Turing machine model is based on certain idealizing assumptions about what is significant and insignificant in models of computation, assumptions that are questionable when applied to connectionist models. In particular, the Turing machine model is based on the assumption that computation proceeds by the recognition of atomic tokens of definite type according to the discrete application of finite, definite rules; these processes are assumed to operate with complete reliability. These assumptions are a poor match to connectionist approaches, in which information is represented in distributed patterns of continuous activity, and in which recognition is a matter of degree. Nevertheless, questions of computability are also important in connectionism, but relevant answers may require the development of a new theory of computation that makes idealizing assumptions more relevant to connectionist approaches.

5.4 Relation to Biological Neural Networks

Connectionist networks are often called 'neural networks' and described in terms of (artificial) neurons connected by (artificial) synapses, but is this more than a metaphor? Generally, connectionist models have reflected the contemporary understanding of neurons. For example, McCulloch and Pitts focused on the 'all or nothing' character of neuron firing, and modeled neurons as digital logic gates. Newer connectionist models have had a more analog focus, and so the activity level of a unit is often identified with the instantaneous firing rate of a neuron. However, these models still ignore many important properties of real neurons, which may be relevant to neural information processing (Rumelhart et al., 1986′, vol. 2, Chap. 20). As a consequence neuroscientists have stressed the differences between biological neurons and the simple units in connectionist networks; the relation between the two remains an open problem. Nevertheless, it is much easier to envision neural implementations of connectionist networks than of symbol-processing architectures.

See Churchland (1986) and Quinlan (1991) for an introduction to connectionist approaches in philosophy and psychology. See *Connectionist Models of Concept Learning*; *Connectionist Models of Development*.

Connectionist Models of Concept Learning

A category is a collection of objects or events. Concepts can be seen as mental representations of categories, and concept learning can be defined as learning to assign objects or events to categories. The study of concept learning has a long history in psychology. Experimental research on concept learning has revealed several regularities, which seem to apply across a wide range of stimuli and learning conditions. These regularities must be explained by any valid model of concept learning. A detailed overview of basic findings on concept learning is provided in *Concept Learning and Representation: Models*. Recently, connectionist models of concept learning have become particularly popular (e.g., Ashby et al. 1998, Gluck and Bower 1988a, 1988b, Kruschke 1992). In connectionist models, it is assumed that concept learning involves the development of associative links between objects and categories. These links form the basis of categorization, which is the process of assigning an object to a category. In this article, the basic principles of connectionist models of concept learning are presented, and their empirical and theoretical merits are discussed. There are so many different connectionist models of concept learning that it is impossible to cover them all here. Instead, the article will focus on a few models, which are well established and have been particularly influential. The discussion starts with a simple model of concept learning (the delta-rule model), which has formed the basis of much research on connectionist models of concept learning. Next, the fundamental limitations of the delta-rule model are highlighted. Finally, a recent alternative to the delta-rule model is presented.

1. The Delta-rule Model

One of the simplest and best understood learning rules in connectionist models is the so-called delta rule, which was proposed by Widrow and Hoff (1960) and which is formally equivalent to the learning rule in Rescorla and Wagner's (1972) model of associative learning (see Sutton and Barto 1981). The delta rule is an error-correcting rule. It assumes that feedback is available on the classification performance of a network, and that this feedback is available for each stimulus that must be classified. A learning scheme that fulfills this condition is called a supervised learning scheme.

To illustrate the delta rule, assume that we have the following simple model of concept learning (Fig. 1). The model takes the form of a connectionist network, with two connected layers of processing units. The input layer is used to represent or encode the stimuli

Figure 1
Delta-rule network architecture

that can be presented, whereas the output layer represents the response alternatives (in a categorization context, each response alternative typically corresponds to a single category). Input coding is achieved by a number of units, each of which corresponds to a single feature or dimension of the stimulus. Furthermore, each input unit is connected to each output unit. The connections in the network have associated strength values. The strength of a connection determines the effect that activation of its source or input unit has on its output unit. In a network of this form, category learning is assumed to involve the modification of the strengths of the connections between input and output units, in such a way that presentation of a stimulus to the input units will give rise to the activation of the output unit that corresponds to the category to which the stimulus belongs.

The input to the network on a given trial is represented by the pattern of activation across the input units. Suppose that each input unit represents a stimulus feature that can either be present or absent (such as 'red,' or 'large'). The set of features that characterizes a stimulus can then be represented by setting the activation of each input unit that corresponds to a feature that is present to 1, whereas the activation of the other units can be set to 0. Of course, other representation schemes are possible, depending on the nature of the stimuli and the requirements of the learning task.

Upon presentation of a stimulus, the activation of the output units is computed, as follows:

$$a_o = \sum_i w_{io} a_i \tag{1}$$

in which a_o is the activation of output unit o, a_i is the activation of input unit i, and w_{io} is the strength of the connection between input unit i and output unit o. Next, feedback about the network's output activation pattern is provided, and the discrepancy between the current output pattern and the desired output pattern is computed. In a concept learning task, the desired output would typically be that one output unit (corresponding to the correct category) is activated, whereas the other units remain inactive. For each output unit, an error value e_o is computed:

$$e_o = d_o - a_o \tag{2}$$

in which d_o is the desired output value for unit o. Finally, the connection strengths in the network are modified, as follows:

$$\delta w_{io} = \lambda a_i e_o \tag{3}$$

in which δw_{io} is the change in the connection strength and in which λ is a learning rate parameter.

After a number of presentations of the entire set of stimuli in a category-learning task, the delta rule is guaranteed to produce a set of connection strengths that is optimal for the category-learning task at hand, within the constraints imposed by the architecture of the network (Kohonen 1977). For some category structures, the simple network in Fig. 1 is sufficient to achieve perfect categorization of all stimuli. If perfect categorization is impossible (for reasons that will be explained below), the delta rule still converges upon a set of connection strengths that produces the best performance that can be achieved with the network to which it is applied.

2. *Evaluation of the Delta-rule Model*

Delta-rule networks have been evaluated in a large number of empirical studies on concept learning (e.g., Estes et al. 1989, Friedman et al. 1995, Gluck and Bower 1988a, 1988b, Shanks 1990, 1991), with considerable success. However, although the delta-rule model can explain important aspects of human concept learning, it has a major weakness: It fails to account for people's ability to learn categories that are not linearly separable. In a network of the kind described above, the activation of any output unit is always a weighted sum of the activation of the input units. This implies that the network can only learn categories that can be separated by a linear function of the input values. In human concept learning, linear separability does not appear to be an important constraint. It has been shown repeatedly that people can learn nonlinearly separable category structures without difficulty (e.g., Medin and Schwanenflugel 1981, Nosofsky 1987).

There are several ways in which delta-rule networks can be modified to handle nonlinearly separable categories. One way is to augment the input layer of the network with units that only become active when particular combinations of two or more features are present in the input (e.g., Gluck and Bower 1988b, Gluck 1991). If enough configural units are present (and if they encode the correct combinations of features), such networks can be made to learn any category structure using the delta rule. However, it is not clear that learning in such networks corresponds well to human learning, or that configural cue networks explain categorization after learning (Choi et al. 1993, Macho 1997, Nosofsky et al. 1994, Palmeri 1999). Moreover, the number of possible configural units grows exponentially as the number of stimulus dimensions becomes larger. Configural cue models are therefore not particularly attractive as models of human concept learning.

A second way of modifying delta-rule networks so that they can learn nonlinearly separable categories

involves the use of a layer of 'hidden' units, between the input units and the output units. Rumelhart et al. (1986) proposed a generalization of the delta rule for such networks. This back-propagation-of-error rule is used to determine how much the connection strengths between input and hidden units, and between hidden and output units should be changed on a given learning trial, in order to achieve the desired mapping between input and output. If the units in such multilayer networks have nonlinear activation functions, back-propagation networks can learn nonlinearly separable categories; in fact, they can learn arbitrary mappings between inputs and outputs, provided that they contain a sufficient number of hidden units (Hornik et al. 1989).

Despite their intuitive appeal and obvious computational power, backpropagation networks are not adequate as models of human concept learning (e.g., Kruschke 1993). Their most important shortcoming is that they suffer from 'catastrophic forgetting' of previously learned concepts when new concepts are learned (McCloskey and Cohen 1989). To overcome this difficulty, Kruschke (1992) has proposed a hidden-unit network that retains some of the characteristics of backpropagation networks, but that does not inherit their problems.

3. *ALCOVE*

ALCOVE (Kruschke 1992, 1993) is a connectionist network with three layers of units: an input layer, a hidden layer, and an output layer (see Fig. 2). The model is based on an exemplar theory of concept learning and categorization, Nosofsky's (1986) Generalized Context Model (GCM; see *Concept Learning and Representation: Models*). Each input unit i of ALCOVE encodes a single stimulus dimension and is gated by a dimensional attention weight α_i, which reflects the relevance of the dimension for the learning task at hand.

Each hidden unit has a 'position value' on each stimulus dimension, which means that each hidden unit corresponds to a particular stimulus or exemplar. Whenever an input pattern is presented to the network, each hidden node is activated according to the similarity between the stimulus it represents and the input pattern. In ALCOVE, similarity is defined as in Nosofsky's GCM:

$$a_j^{hid} = \exp\left[-c\left(\sum_i \alpha_i \,|\, h_{ji} - a_i^{in} \,|^r\right)^{q/r}\right] \tag{4}$$

in which a_j^{hid} is the activation of hidden unit j, h_{ji} is the position of hidden unit j on stimulus dimension i, c is a positive constant called the specificity of the hidden unit, a_i^{in} is the activation of input unit i, and where r and q determine the similarity metric and similarity gradient, respectively.

Figure 2
Architecture of the ALCOVE model of concept learning

Each hidden unit is connected to output units that correspond to response categories. The category units are activated according to the following rule:

$$a_k^{out} = \sum_j w_{kj} a_j^{hid} \tag{5}$$

in which w_{kj} is the association weight between hidden unit j and category unit k. This is the same activation rule used in the simple delta-rule network discussed above (see Eqn. (1)). Finally, category unit activations are translated into response probabilities by the rule

$$P(K) = \exp(\varphi a_K^{out}) \Big/ \sum_m \exp(\varphi a_m^{out}) \tag{6}$$

where φ is a scaling constant. ALCOVE employs a variation of the backpropagation learning rule to adjust dimensional attention weights α_i and association weights w_{kj} in the course of learning (see Kruschke 1992, for details of the learning rule). As a result of these adjustments, the network will eventually learn to classify each stimulus into the correct category.

ALCOVE has great advantages over the simple delta-rule network for concept learning. The model is not affected by the linear separability constraint. Like standard backpropagation networks, ALCOVE can

learn arbitrary mappings between stimuli and categories. Moreover, ALCOVE does not suffer from catastrophic forgetting (Kruschke 1993). Most important, however, is the close correspondence between ALCOVE's predictions about concept learning and human performance. In a large number of experiments, the model has been tested successfully (e.g., Choi et al. 1993, Kruschke 1992, 1993, Nosofsky et al. 1992, Palmeri 1999). ALCOVE ultimately derives its strength from its combination of the principles of exemplar-based processing with those of associative learning.

4. Conclusions and Future Directions

Whereas connectionist models such as ALCOVE can explain many important aspects of human concept learning, it is becoming increasingly clear that they also have fundamental limitations. The models that were reviewed here all assume that concept learning is an associative process, in which links between stimulus and category representations are modified. There is little doubt that many concepts are learned in this way. However, the associative model does not apply to the learning of all concepts. Some concepts are learned by a process of rule discovery, which has characteristics that are very different from those of connectionist models of learning. An important challenge for the future will be to determine when associative models and rule-based models of concept learning apply. There have been some recent attempts to develop hybrid models, which combine associative and rule-based learning principles (e.g., Erickson and Kruschke 1998), and it is likely that such models will become increasingly prominent.

Connectionist Models of Development

Connectionism is a style of computational modeling inspired by principles of brain functioning and by the mathematics of statistical mechanics. It is implemented as networks of interconnected units, where units correspond roughly to neurons and connections correspond roughly to synapses. Momentary patterns of activity in units can be interpreted as cognitions or percepts; weighted connections between units can be viewed as long-term knowledge, modifiable by learning. Since the late 1980s, cognitive modelers have become interested in applying such neural networks to data on psychological development in children. Among the attractive characteristics of neural networks are graded knowledge representations, capacity for change and self-organization, feasibility of studying environment–heredity interactions, and neurological plausibility. This article reviews developmental connectionist models, showing how various modeling techniques have contributed to the understanding of a variety of developmental issues in cognitive and perceptual development.

1. *Techniques*

There are several neural network techniques that have been applied to developmental issues. Virtually all of them employ layered, feed-forward networks in which activation is passed forward from input units to hidden units and on to output units. Sometimes there are multiple layers of hidden units, other times no hidden units at all. These networks learn by processing examples of input–output pairs. Presentation of an input vector of activation results in a vector of output activation. Hidden and output unit activations are typically determined by summing the products of sending-unit activations and incoming weights and passing this weighted sum through a nonlinear activation function, such as a sigmoid or hyperbolic-tangent function. A linear activation function typically is used for continuous outputs.

In supervised learning, error at the output units is computed as the sum of squared differences between outputs and targets. Weights are adjusted to reduce this discrepancy, using the delta rule in which weight change is proportional to error. In multilayer networks, error is typically propagated backward to earlier layers of weights, a technique known as back-propagation. Unsupervised learning can also occur, without output targets, as networks learn to group together similar input patterns.

Networks can be designed by hand and remain static, or generated by a learning algorithm. One such generative algorithm, called cascade-correlation, grows by recruiting new hidden units that have learned to be active when the network is experiencing a high degree of error. Back-propagation of error is unnecessary here because incoming weights to a recruited hidden unit are frozen when training of the single-layer of output-unit weights resumes. Unit recruitment corresponds roughly to the formation of new neurons and new synapses.

A few developmental models employ auto-associator networks, in which units are fully interconnected (no layers) and learning occurs with either the delta rule or Hebb rule (in which weights are strengthened in proportion to the product of the activations of the sending and receiving units).

2. *Cognitive Stages and Perceptual Effects*

One of the first developmental connectionist models concerned a task that has become a benchmark for modeling developmental stages—the balance beam. Here a child is presented with a rigid beam on which a number of equal-sized weights are placed at certain positions to the left and right of a central fulcrum. The child is asked to predict which way the beam will tip when supporting blocks are removed, or whether the beam will remain balanced. A back-propagation model trained on examples of balance beam problems captured the first three stages observed with children (the use of only weight information, distance information when both sides have equal weight, both weight and distance information without resolving conflicts), but failed to settle into the final stage of mostly correct solutions (McClelland 1989).

A cascade-correlation model progressed through all four stages of balance beam performance and also captured the effect that problems with small weight × distance differences from one side to the other are relatively difficult at each stage (Shultz et al. 1994). Such perceptual effects are pervasive in cognitive tasks, but have not been comprehensively explained. Connectionist models produce these effects naturally in their method of passing activations.

There are several of these perceptual effects in the vast literature on conservation acquisition: the problem size effect (small number problems are easier than large number problems), length bias (nonconservers

choose the longer row as having more), and the screening effect (even nonconservers assume conservation when the transformation is hidden from view). A cascade-correlation model of conservation captured these phenomena, along with natural conservation acquisition and sudden spurts in performance, while showing how perceptual and cognitive information, although initially in conflict, are eventually integrated (Shultz 1998).

A modular cascade-correlation model of seriation (sorting) captured all four stages that children go through (random performance, partial sorts, complete trial-and-error sorts, and systematic sorts) as well as the fact that smaller differences between items make the task more difficult (Mareschal and Shultz 1999).

3. *Transition Mechanisms*

Perhaps the most difficult issue in developmental psychology concerns how children progress from one stage to the next. The longstanding debate on nativism vs. empiricism has been enlightened by connectionist analyses of different ways in which innate influences can be implemented—as neural representations, architectures, or timing of development (Elman et al. 1996). Interactions between learning and inheritance have been modeled by having successful neural networks reproduce over generations, showing that evolutionary progress is enhanced by learning ability (Nolfi et al. 1994). This belies the common assumption that connectionist approaches to development are strictly empiricist.

A constructivist approach to development has been implemented in several simulations using the cascade-correlation algorithm. These simulations show that it is possible to escape from Fodor's paradox of cognitive development—that experiential accounts of development are incoherent because it is computationally impossible to learn anything genuinely new. Generative networks escape from this paradox by increasing their computational power when needed (Mareschal and Shultz 1996).

4. *Non-normative Stages*

A curious feature of development is the presence of early nonnormative stages. Why would children regularly construct incorrect solutions to a problem? In one example, length bias in nonconservation resulted from a correlation between number and length for transformations that preserve density (Shultz 1998).

A cascade-correlation model of the integration of velocity, time, and distance cues for moving objects progressed through the non-normative stages observed with children on their way to the normative integration based on products and ratios of cues (Buckingham and Shultz 2000). For example, children first view velocity as being proportional to distance traveled, then as the difference between distance and time, and finally as the ratio of distance to time. Such stages are a natural consequence of the growth in computational power in cascade-correlation networks. Initially, these networks lack the power to represent the nonlinear relations among velocity, time, and distance and the ability to simultaneously represent the various directions of inferences based on these equations. Static feed-forward networks that adjust their weights, but do not grow, are unable to capture these stages.

5. *Developmental Lags*

Different methods of assessing stages in children sometimes produce different results. One example concerns the age at which infants develop the notion of permanent objects, objects that continue to exist even when they are no longer being experienced. Piaget had found that infants below about 9 months would not retrieve an object from under a screen, but Baillargeon has found that infants as young as 3.5 months look longer at events in which a moving object violates permanency, such as failing to emerge between occluding screens. A modular network model of infants' visual tracking of moving objects learned to predict the emergence of an object from behind an occluding screen (Mareschal et al. 1999). An unsupervised module learned to recognize objects, a recurrent back-propagation module learned to predict object trajectories, and another back-propagation module learned to retrieve objects by integrating information from the other two modules. The developmental lag was explained by noting that reaching requires integration of information about both the location and the nature of the object, whereas prediction requires only information about its location.

6. *Modularity*

With verbal theorizing, it is difficult to know when to claim that the operation of distinct modules is required for cognitive processing. Computational modeling suggests modularity whenever a homogenous processor fails to learn the task or capture the psychological data. Modular systems are known to simplify learning and processing of particularly difficult tasks.

Another example of modularity is a model of word learning using an unsupervised network to learn categories and an auto-associator network to learn category names (Schyns 1991). The output of each module served as input to the other. This model captured several phenomena in children's concept learning: strong recognition of a previously unseen

prototype, semantic overextension, interword competition, faster learning of a label for a distinctive category, and faster learning of a category with a distinctive label.

The seriation model presented earlier provides a third example of modularity, with one network module selecting a stick to move and another selecting a destination. Homogeneous networks did not progress through the proper psychological stages and did not learn to sort successfully.

7. *Self-organization*

Self-organization refers to spontaneous ordering tendencies in complex systems. Both brains and artificial neural networks, because of their complex dynamics, parallelism, and responsiveness to feedback are likely candidates for self-organization. Indeed, neural network models can be used to investigate self-organizing properties of the brain.

An example is a model with only input and output layers, a Hebb learning rule, and competition among output units that simulated the formation of ocular dominance columns in visual cortex (Miller et al. 1989). Groups of neurons in visual cortex eventually organize themselves into columns responding to information coming from one eye or the other.

8. *Integration of Diverse Findings*

Some connectionist models have been able to integrate large areas of psychological literature that have resisted the explanatory efforts of verbal theories. Examples of conservation and seriation were noted earlier. Another example is a cascade-correlation model of shift learning (Sirois and Shultz 1998). In shift learning, subjects learn a discrimination problem and are then shifted to another related problem to determine what was learned on the first problem. The network model integrated diverse developmental findings on a variety of shifts that could not be accounted for by any one of several verbal theories. The model was based on the idea that older children and adults spontaneously overlearn these problems.

9. *Explanation of Mystery Effects*

In smaller, contemporary literatures, there are often results that are difficult to explain. One curious finding concerns asymmetric exclusivity effects in infant habituation to categories of pictures, namely that dogs are not included in the category of cats, but cats are included in the category of dogs. This was captured by a back-propagation encoder network, and subsequently explained by determining how these effects arose within the model (Mareschal and French 1997). Encoder networks learn to reproduce their inputs on their output units using a smaller number of hidden units. A stimulus is recognized as familiar if it can be encoded onto the hidden units and then decoded accurately onto the output units. Habituation to repeated stimuli results in a decrease in network error; recovery of error to a new stimulus is interpreted as an indicator of novelty. The asymmetric exclusivity effects were explained in terms of the distribution of stimulus features. Because some cat-feature values are inside the range of dog-feature values but not the reverse, a system learning these statistics would naturally view cats as a subset of dogs.

10. *Resolution of Theoretical Disputes*

Theoretical disputes are often difficult to resolve at the level of verbal theories. One such recurrent debate concerns whether human cognition is based on symbolic rules and variables, or on sub-symbolic connections. Infant habituation and recovery to sentences in a simple artificial grammar have been covered by variety of standard neural models, without explicit rules and variables that others had argued were required (e.g., Shultz 1999, Sirois et al. 2000). Similar theoretical disputes have been addressed by models of conservation, seriation, and the balance beam presented earlier.

11. *Conclusions*

Connectionist models have simulated large varieties and amounts of developmental data while addressing important and longstanding developmental issues. Connectionist approaches provide a novel view of how knowledge is represented in children and a compelling picture of how and why developmental transitions occur. Like other modeling techniques, connectionism has increased the precision of theorizing and thus clarified theoretical debates.

As these models become more widely known, it is likely that many more of their predictions will be tested with children. It is also likely that connectionist models will be extended to a wider range of developmental phenomena. Although it is not yet clear whether these models will be able to cover phenomena in social development, there is a promising connectionist model of imprinting (O'Reilly and Johnson 1994). Much of the connectionist developmental literature concerns language acquisition, which is covered in another article. Some features lacking in current models will continue to receive attention: explicit rule use, genotypes, multitask learning, impact of knowledge on learning, embodiment, and neurological realism.

Connectionist Models of Language Processing

All connectionist models have in common that they consist of subunits that can, in one way or another, be likened to brain structures. The neuroanatomical structures the network elements stand for are either large brain regions and the pathways between them, or local clusters of neurons and their mutual connections, or individual neurons and the web of fibers in which they are embedded. There are at least three major meanings of the term 'Connectionist model': (a) *Classical connectionist models* proposed by nineteenth-century neurologists specify centers and pathways that are analogous to cortical areas and fiber bundles most relevant to language, and related modern *neurobiological approaches to language* propose intensely connected cell assemblies with different cortical distributions as the brain basis of language; (b) *Symbolic connectionist models* suggest single artificial neurons corresponding to linguistic units (language sounds, words, etc.); and (c) *Distributed connectionist models* represent such linguistic entities by activity vectors involving numerous neuronal elements. This article will explain these three different notions by introducing the respective research areas (Sects. 1–3). In the final Sect. (4), recent trends in the research on connectionist models of language will be highlighted.

1. Neurological and Neurobiological Models of Language

In the second half of the nineteenth century, connectionist theories were proposed by neurologists to summarize and model the effect of brain lesions on cognitive functions (Caplan 1987). The underlying idea was that local processing systems, so-called centers, specialize in particular cognitive processes. These were thought to be autonomous processors. The centers were linked through so-called pathways which allowed for information exchange between them. The pathways had their analogue in fiber bundles in the white matter of the brain. The most famous classical neurological model of language goes back to Wernicke (1874) and Lichtheim (1885). This model explains basic features of organic language disturbances, *aphasias*. The main proposal of the Wernicke–Lichtheim model was that there are two centers for language processing, one mainly involved in speech production and the other primarily contributing to language comprehension. This hypothesis could be confirmed by a wealth of clinical studies. It is now well-established that, in most right-handed subjects, the main or core language areas are located in the left inferior frontal lobe (Broca area for speech production) and in the left superior temporal lobe (Wernicke area for speech comprehension).

In the light of modern neuropsychological and neuroimaging research, early connectionist models turned out to be too crude to explain many patterns of brain activation induced by language processing, and the more fine-grained aspects of language disorders caused by brain lesions. It now appears more likely that the 'language centers' of Broca and Wernicke are not functionally independent but that they are mutually dependent when functioning properly. Furthermore, while these core language areas are certainly important for language, they are certainly not the only cortical areas contributing to and necessary for language processing. This is demonstrated by neuroimaging research (EEG, fMRI, MEG, PET) showing that, in addition to the core language areas, other areas light up when specific language stimuli are being processed, and by converging neuropsychological reports about patients with lesions outside their core language areas who showed category-specific linguistic deficits. These studies show that, in addition to the core language areas, there are additional or complementary language areas that are activated during language processing and whose lesion causes deterioration of aspects of language processing.

Mutual functional dependence of the core language areas and the category-specific role of complementary language areas are explained by a neurobiological model postulating that words and other language elements are cortically organized as strongly connected assemblies of neurons whose cortical distributions vary with word type (Pulvermüller 1999). Accordingly, concrete words referring to objects and actions are organized as widely distributed cell assemblies comprising neurons in sensory and motor areas involved in processing the words' meanings. In contrast, highly abstract grammatical function words and grammatical affixes are proposed to be more focally represented in the left-hemispheric core language areas of Broca and Wernicke (Pulvermüller 1999). In summary, neuron sets in core language areas appear to be relevant for all types of language-related processes, and complementary neurons in areas related to actions and perceptions regularly involved in language use may contribute to category-specific language processes.

2. *Symbolic Connectionist Models of Language*

According to modular approaches to cognitive psychology, the mental language processor consists of quasi-autonomous subprocessors or modules, and language processing therefore is being considered the result of quasi-autonomous subprocesses. The subprocesses envisaged to be involved in language comprehension are, for example, input-feature analysis, letter or phoneme analysis, word form processing, and semantic analysis (Morton 1967). These processes are assumed to occur sequentially or in a cascaded manner. A similar but reverse cascade has been assumed for the putative subprocesses of language production which finally results in movements of the articulators or the (writing) hand (Garrett 1984).

In symbolic connectionist models, the subprocessors of modular models have been replaced by layers of neuron-like elements, the assumption being that individual artificial neurons represent acoustic or visual features, phonemes or graphemes, word forms, and word meanings (see, for example, McClellend and Rumelhart 1981). Symbolic connectionist networks have been applied with some success to the modeling of word production (Levelt et al. 1999) and word recognition (Norris et al. 2000), as well as other language phenomena, for example speech errors observed in normal speakers and language-impaired neurological patients (see, for example, Dell 1986).

A still open issue is whether information should only be allowed to flow in one direction between the subcomponents of the postulated networks, from input to semantics in comprehension and from semantics to output in production. As an alternative, reciprocal connections and thus bidirectional information flow has been proposed to take place between the layers of the networks.

3. *Distributed Connectionist Models of Language*

The distributed network type most commonly used to model language resembles symbolic networks, because both network types are made up of layers of neurons and connections between layers. An important difference is the following: Symbolic networks include local representations—usually single artificial neurons—that represent elementary features of the input and output as well as more complex entities such as, letters, phonemes, and words. In contrast, distributed networks use activity vectors over large sets of neurons in a given layer to represent words and other more complex linguistic structures. The distributed networks most commonly used in language simulations do not include direct connections between the neurons of one layer. The active neurons defined by an activity vector are therefore not connected to each other and do not form a functionally coherent system. This distinguishes them from cell assemblies with strong internal links. However, as a consequence of associative learning, artificial neurons in different layers may strengthen their connections to neurons in other layers indirectly linking the active neurons defined by individual activity vectors.

The classical type of distributed network, the perceptron, consists of two layers of neurons. Each neuron in layer one is connected to each neuron in the second layer, though connection strengths (or weights) vary as a function of associative learning of pairs of input–output patterns. In the 1960s, Minski and Papert (1969) proved that perceptrons can learn to solve only a certain type of classification problem

called linearly separable. In the 1980s, Rumelhart and McClelland (1986a) showed that the addition of one 'hidden' layer of neural units between the input and output layers, and extension of the learning rule, allows for overcoming this limitation. The networks were now able to learn to solve more complex classification problems and this led to a strong interest in three-layer neural architectures. Three-layer perceptrons were used with some success to model language: There are models that classify speech signals (e.g., Waibel et al. 1995); others that mimic important aspects of the infant's learning of language specific information as described by elementary rules (e.g., Hare et al. 1995); simulations of the effects of focal brain lesions on language functions (e.g. Plaut and Shallice 1993) and of the recovery of language functions after stroke.

For solving more complex problems posed by syntax, the network architecture had to be modified once again. Three-layer architectures do not allow for keeping information in memory for a longer time span, but this is necessary for assessing syntactic dependencies between temporally distant language units as, for example, between the first and last words of a long sentence. To solve this problem, a 'memory layer' allowing for reverberation of activity and information storage has been added to the three-layer-architecture (Elman 1990). Such networks including an additional memory layer can be shown to be more powerful than three-layer perceptrons in storing serial order relationships. They are capable of learning subsets of syntactically complex sentence structures, for example aspects of so-called center-embedded constructions.

4. *Current Trends*

After introducing three types of connectionist models, the article will now highlight selected topics in connectionist research, where the three approaches offer somewhat different views and where the divergence in views has actually led to productive research.

Recent trends in connectionist research on language include the more detailed modeling of syntactic mechanisms and attempts at mimicking more and more properties of the actual neuronal substrate in the artificial models (Elman et al. 1996). Multidisciplinary research across the computational and neurosciences is necessary here. The strategy to copy the brain's mechanisms into the artificial neural network may be particularly fruitful for implementing those higher cognitive functions that, if implemented in the biological world, only arise from specific brain types. The brain's structure is information that may be of relevance for neuronal modeling.

The modeling of rule-like verbal behavior is an illustrative example for successful multidisciplinary interaction in connectionist research on language. It is sometimes assumed that symbolic algorithms are necessary for explaining the behavior described by linguistic rules. For producing a past tense form of English, one would, accordingly, use an abstract rule such as the following addition rule scheme:

$$\text{Present stem} + \text{Past suffix} = \text{Past tense form}$$

In particular, an algorithm of this kind could model the concatenation of the verb stem 'link' and the past suffix 'ed' to yield the past tense form 'linked,' and, in general, it could be used to derive any other regular past form of English. However, it is difficult to see how an irregular verb such as 'think' or 'shrink' could yield a past form based on a similar rule. In the extreme, one would need to assume rules for individual words to provide algorithms that generate, for example, 'went' out of 'go.' This would require stretching the rule concept, and linguists have therefore proposed that there are two distinct cognitive systems contributing to language processing, a symbolic system storing and applying rules and a second system storing relationships between irregular stems and past forms in an associative manner (Pinker 1997).

From the perspective of neural networks, however, one may ask whether two separate systems, for rules and exceptions, are actually necessary to handle regular and irregular inflection. Rumelhart and McClelland (1986b) showed that an elementary two-layer perceptron can store and retrieve important aspects of both past tense rules and exceptions. It can even produce errors typical for children who learn past tense formation, such as so-called overgeneralizations (e.g., 'go*ed*' instead of 'went.')

From a linguistic perspective, the two-layer model of past tense proposed by Rumelhart and McClelland has been criticized, for example because it does not appropriately model the fact that rule-conforming behavior is by far most likely to be generalized to novel forms. The past form of a newly introduced verb, such as 'dif,' will thus almost certainly receive an 'ed' ending if one intends to use it in the past tense ('diff*ed*.') This is even so in languages where most verbs have irregular past forms and only a minority of the verbs conform to the rule. The rule is nevertheless used as the default and generalized to novel forms and even rare irregular items. This is a problem for a subset of connectionist models, because the strongest driving forces in associative networks are the most common patterns in the input.

However, there are distributed three-layer networks that solved the problem of default generalization surprisingly well (Hare et al. 1995). An important determinant is that rule-conforming input patterns are maximally *dissimilar*, while the members of an irregular class resemble each other. Consider the different regular forms *to watch*, *talk*, and *jump* in contrast to the similar members of an irregular class

to sing, *ring*, and *sting*. Because the regulars are so heterogeneous, they occupy a wide area in input space. The representation in input space of a novel word is thus most likely to be closest to those of *one of the many different* regular forms, and this is one important reason why so many new items are treated as regular by the network. On the other hand, if a newly introduced item happens to strongly resemble many members of a regular class, for example the pseudoword *pling*, it is, in many cases, treated as regular. These observations may lead one to redefine one's concept of regularity: A rule is not necessarily the pattern most frequently applied to existing forms, but it is always the pattern applied to the *most heterogeneous set* of linguistic entities. The heterogeneity of the regular classes may explain default generalization along with the great productivity of rules.

The simulation studies of the acquisition of past tense and other inflection types by young infants suggest that neural networks consisting of one single system of layers of artificial neurons provide a reasonable model of the underlying cognitive and brain processes. In this realm, the single system perspective appears equally powerful as an approach favoring two systems, one specializing in rule storage and the other in elementary associative patterns.

Neuroscientific data and theories have recently shed new light on the issue of a single-system versus a double-system account of rule-like behavior. Important was the discovery of patients with brain lesions who were differentially impaired in processing regular and irregular past tense forms. Patients suffering from Parkinson's disease or Broca's aphasia were found to have more difficulty processing regulars, whereas patients with global deterioration of cortical functions as seen, for example, in Alzheimer's Disease or Semantic Dementia showed impaired processing of irregulars (Ullman et al. 1997; Marslen-Wilson & Tyler, 1997). This double dissociation is difficult to model using a single system of connected layers, but is easy to handle if different neural systems are used to model regular and irregular inflection.

Another argument in favor of a double system account comes from neurobiological approaches proposing that words and inflectional affixes are represented in the cortex as distributed cell assemblies. In this case, past tense formation can involve two types of connections, local within-area connections in the core language areas and long-distance links between the language areas and outside. It is known from neuroanatomy that two adjacent neurons are more likely to be linked through a local connection than are two distant neurons to be linked by way of a long-distance connection. This situation can be modeled by two pathways connecting the neuronal counterparts of present stems and past forms, for example a three-layer architecture with two pathways connecting input and output layers, one with higher and the other with lower connection probabilities between neurons in adjacent layers. Parameters are chosen appropriately, the two pathways or systems will differentially specialize in the storage of rules and irregular patterns. Similar to a two-layer perceptron, the low-probability system is best at storing the simple mapping between irregular present forms that resemble each other and their past forms. In contrast, the complex mapping between the heterogeneous regular stems and their past forms is best accomplished by the three-layer component with high connection probabilities. When the two components are differentially lesioned, the network produces the double dissociation between regular and irregular inflection seen in neuropsychological patients. This approach explains the neuropsychological double dissociation along with aspects of the acquisition of past tense formation by young infants (Pulvermüller 1998). This explanation is based on principles of cortical connectivity.

Together, the neuropsychological double dissociation and the neurobiological consideration argue in favor of a two-system model of regular and irregular inflection. In contrast to the modular proposal that each of two systems are exclusively concerned with regular and irregular processes, respectively, the neuroscientific variant would suggest a gradual specialization caused by differential connection probabilities. The ongoing debate between cognitive neuroscientists favoring single- or double-system accounts of rule-like knowledge clearly proves the importance of multidisciplinary interaction between the linguistic, cognitive, computational, and neurosciences.

Conscious and Unconscious Processes in Cognition

Everyday experience suggests that we often seem to know more than we can tell. Riding a bicycle, playing tennis, or driving a car, for instance, all involve mastering complex sets of motor skills, yet we are at a loss when it comes to explaining exactly how we perform such physical feats. These dissociations between our ability to report on cognitive processes and the behaviors that involve these processes are not limited to action but extend to higher-level cognition as well. Most native speakers of a language are unable to articulate the grammatical rules they nevertheless follow when uttering expressions of the language. Likewise, expertise in domains such as medical diagnosis or chess, as well as social or aesthetic judgments, all involve intuitive knowledge to which one seems to have little introspective access.

We also often seem to tell more than we can know. In a classic article, social psychologists Nisbett and Wilson (1977) reported on many experimental demonstrations of the fact that accounts of our own behavior frequently reflect reconstructive and interpretative processes rather than genuine introspection. In one such study, Nisbett and Wilson asked patrons of a department store to choose the best-quality item among four identical pairs of nylon stockings in the context of what subjects believed was a consumer survey. There was a strong position effect: items located on the right, which were inspected last, were chosen much more often than items in other positions. Yet, when asked what motivated their choice, not a single subject mentioned position as a relevant factor, and many denied that it might have had an effect when asked directly about it. More generally, while it is usually agreed that cognitive *processes* are not in and of themselves open to any sort of introspection, Nisbett and Wilson further claimed that we can sometimes be '(a) unaware of the existence of a stimulus that importantly influenced a response, (b) unaware of the existence of the response, and (c) unaware that the stimulus has affected the response' (Nisbett and Wilson 1977, p. 231).

Just as for knowledge of our own cognitions, our knowledge of the world turns out to be much less complete that it might appear, thus further deconstructing Cartesian conceptions of cognition in which conscious awareness reigns supreme. In change blindness and inattentional blindness experiments, for instance, people are surprisingly often unable to detect large changes in visual stimuli that they are allowed to observe at their leisure. One such experiment (e.g., Simons and Chabris 1999) involved watching a movie depicting two teams of three basketball players and counting the number of times that a ball was passed between the players of each team. Under these conditions, that is with attention fully engaged in tracking one of the two balls, people often failed to notice that, halfway through the movie, an actor dressed as a gorilla appeared on the right of the screen and walked slowly towards the middle of the scene, where he repeatedly banged his chest, subsequently resuming his stroll to disappear on the left!

Demonstrations of dissociations between conscious awareness and stimulation and/or behavior have now been reported in many domains of psychology. Frith et al. (1999) have suggested organizing paradigms through which to study the 'neural correlates of consciousness' in nine groups resulting from crossing two dimensions: (a) three classes of psychological

processes involving, respectively, knowledge of the past, present, and future—memory, perception, and action, and (b) three types of cases where subjective experience is incongruent with the objective situation—cases where subjective experience fails to reflect changes in either (i) the stimulation or in (ii) behavior, and (iii) cases where subjective experience changes while stimulation and behavior remain constant.

Among such paradigms, the study of dissociations between conscious and unconscious perceptual processes has by far the longest history, extending back to the beginnings of scientific psychology in the nineteenth century. Subliminal perception (see Dixon 1971) is said to occur when stimuli presented below the threshold of awareness influence information processing, emotion, or action. In a classic but highly controversial series of studies, Anthony Marcel suggested that semantic priming, that is, the facilitation of decisions about semantic aspects of a target stimulus when it follows a related stimulus (the prime), can occur in conditions when the prime is presented so rapidly that subjects fail to be able to decide whether it was present or not (e.g., Marcel 1983). While many subsequent studies have reported similar findings with different stimuli such as spoken words or faces, many have also failed to replicate such findings, and the domain remains highly controversial (Holender 1986). Nevertheless, it appears that considerable information can be perceived and processed in the absence of conscious awareness when it is assessed through subjective measures: people can believe that they are guessing, yet perform better than chance would predict in a variety of tasks involving semantic and affective decisions.

Some forms of learning and memory can also be unconscious. Memory for previous events can be expressed explicitly, as a conscious recollection, or implicitly, as automatic, unconscious influences on behavior. Numerous studies have demonstrated dissociations between implicit and explicit memory. Amnesic patients, for instance, who exhibit severe or total loss in their ability explicitly to recall previous experiences, nevertheless retain the ability to learn novel procedural skills (Milner 1962) or to exhibit sensitivity to past experiences of which they are not conscious (e.g., Warrington and Weiskrantz 1968). Some studies have explored the extent to which patients undergoing general anesthesia are able to learn novel associations, and one study has even demonstrated learning in fetuses (Van Heteren et al. 2000).

Similar dissociations can be observed with normal subjects (see Cleeremans et al. 1998). Arthur Reber, in a classic series of studies conducted in 1967, first suggested that learning might be 'implicit,' to the extent that people appear to be able to learn new information without intending to do so, and in such a way that the resulting knowledge is difficult to express. In Reber's seminal study of artificial grammar learning, subjects were asked to memorize a set of meaningless letter strings generated by a simple set of rules embodied in a finite-state grammar. After this memorization phase, they were told that the strings followed the rules of a grammar, and were asked to classify novel strings as grammatical or not. In this experiment and in many subsequent replications, subjects were able to perform this classification task better than chance would predict, despite remaining unable to describe the rules of the grammar in verbal reports. This dissociation between classification performance and verbal report is the finding that prompted Reber to describe learning as implicit, for subjects appeared sensitive to and could apply knowledge (the rules of the grammar) that they remained unable to describe and had no intention of learning.

In a series of experiments that attracted renewed interest in implicit learning, Berry and Broadbent (1984) showed that success in learning how to control a simulated system (e.g., in one set of experiments, a system described to subjects as a 'sugar factory') so as to make it reach certain goal states was independent from the ability to answer questions about the principles governing subjects' inputs and the system's output: practice selectively influenced ability to control the system, whereas verbal explanations about how the system works selectively influenced ability to answer questions.

At the turn of the twenty-first century a third paradigm—sequence learning—has become dominant in the investigation of implicit learning. Nissen and Bullemer (1987) first demonstrated that subjects asked to respond as fast and as accurately as possible to a series of visual events learned progressively about the sequential structure of the stimulus sequence in spite of showing little evidence of being aware that the material contained structure. Numerous subsequent studies of this effect have indicated that subjects can learn about complex sequential relationships despite remaining unable fully to elicit this knowledge in corresponding direct, explicit tasks (e.g., Cleeremans and McClelland 1991).

One of the most convincing demonstrations of dissociations between conscious knowledge and behavior was obtained in an eye-blink conditioning situation (Perruchet 1985). In this experiment, people were exposed to a series of identical tones, 50 percent of which were followed after a short interval by an air-puff directed at the left cornea. Immediately after each tone was presented (and before the puff occurred in reinforced trials), people were asked to indicate the extent to which they expected the tone to be followed by an air-puff on a 0–7 points scale. A trial-by-trial analysis of the results indicated that eye-blink responses were increasingly more likely to occur after presentation of a tone, if the corresponding trial had been preceded by a series of reinforced trials (i.e., trials during which the tone had indeed been followed by an air-puff). In stark contrast, however, people's

subjective expectancy of the occurrence of an air-puff tended to *decrease* with the number of reinforced trials that preceded the trial under consideration. In other words, people's eye-blink responses were completely dissociated from their conscious expectations about when each tone would be followed by an air-puff.

Finally, the neuropsychological literature also contains many striking cases of dissociation between subjective experience and behavior. In addition to the dissociations exhibited by patients with amnesia, other syndromes have also attracted attention over the last decades. Blindsight patients, for instance, suffer from damage to the primary visual cortex, and report being unable to see in some portions of their visual field. Larry Weiskrantz (1986) showed that such patients are nevertheless often able to act appropriately when stimulated in their blind field, for instance by initiating correct reaching or grasping movements toward a target. Likewise, the study of patients with form agnosia or neglect has offered valuable insight into the neural correlates of consciousness. For instance, Milner and Goodale (e.g., 1995) have described a patient, D.F., who, while unable to offer verbal or manual reports on the orientation of a slot, nevertheless retains the ability actually to insert a card in it, accurately preparing her movement well before the slot is reached. These observations led Milner and Goodale to suggest that distinct 'what' and 'where' processing pathways exist in the human visual system, and that only one of these pathways (the ventral 'what' system) is associated with conscious visual experience.

1. *Consciousness and Theories of the Psychological Unconscious*

These different findings all suggest that unconscious influences on behavior are pervasive. This raises the question of how best to characterize the relationships between conscious and unconscious processes, and in particular whether one should consider that mental representations can be unconscious. The idea that mental life includes both conscious and unconscious events has been expressed most clearly by Freud (e.g., 1949), whose psychoanalytical theory has influenced profoundly both scientific thought and public conceptions of the mind. Even though one can find earlier characterizations of cognition in which computations that are not accompanied by awareness contribute to conscious decisions (e.g., Leibniz 1981, De Biran 1929), most thinkers up until Freud, including René Descartes and, arguably, William James, considered that mental life consists exclusively of conscious events. This position is still endorsed by some authors today, even though there is wide consensus about the idea that cognitive processing is largely unconscious.

Freud's characterization of the 'dynamic unconscious,' however, makes very specific assumptions—specifically that there exist unconscious mental representations, and that these representations can reflect semantic and affective dimensions of processing. Further, the unconscious, as Freud depicted it, is as dynamic and causally efficacious as the conscious—it is a mental bubbling cauldron of sorts, replete with repressed instincts, thoughts, and feelings vying to get access to awareness. Few thinkers would endorse Freud's characterization of the unconscious in full today—often choosing instead to deny its existence altogether, or considering that only shallow aspects of processing can take place unconsciously. In particular, while popular belief has often tended to ascribe powerful abilities to the unconscious, empirical exploration of the level of analysis at which processing occurs in the absence of consciousness has failed to offer convincing demonstrations that unconscious processing can be as flexible or as deep as conscious processing. Rather, the evidence suggests that unconscious processing can bias conscious processing in a way that reflects strong or habitual responses.

An important issue in this context is to determine the extent to which conscious and unconscious processing depend on separable neural systems, and what their relationship should be. Contemporary theories of consciousness make widely different assumptions about its underlying mechanisms. Atkinson et al. (2000) proposed to organize such theories along two dimensions defined by (a) whether the theory assumes that consciousness depends on the involvement of certain *processes* or rather on the properties of certain mental *representations*, and by (b) whether the theory assumes that consciousness depends on the involvement of *specific modules* or whether it *can occur anywhere in the brain*. Computational models of information processing play a significant role in fostering the development of novel theories of consciousness. In neural-network—or connectionist—models, for instance, task-relevant knowledge is embedded in the same structures that support processing itself. In contrast to traditional information-processing frameworks, knowledge is thus implicit in such models to the extent that it cannot be separated from the mechanisms that subserve processing.

If consciousness does not depend on neural systems specifically dedicated to subserve subjective experience, but should instead be viewed as an emerging property of the processing conducted by many different regions of the brain, one might expect to find indications that consciousness fails to be a unified, all-or-none phenomenon. Marcel (1993) described a relevant series of experiments probing the unity of consciousness in normal subjects. In these experiments people were asked to detect changes in the luminance of very faint stimuli in three different ways: by blinking, by pressing on a button, or by a verbal response ('yes'). When these responses had to be produced simultaneously, they often tended to be dissociated, with subjects answering positively, for

instance, through a blinking response, but negatively through the other modalities. Another experiment indicated that the probability of correct guessing varied significantly across modalities, thus suggesting that they each afforded varying degrees of availability to conscious awareness.

2. *Methodological Challenges*

Because there is no accepted operational definition of what it means for an agent to be conscious of something, complex measurement challenges arise in the study of the relationships between conscious and unconscious cognition.

First, consciousness is not a single process or phenomenon, but rather encompasses many dimensions of experience. A first important challenge thus arises in delineating which aspects of consciousness count when assessing whether a subject is aware or not of a particular piece of information: awareness of the presence or absence of a stimulus, conscious memory of a specific previous processing episode, awareness of one's intention to use some information, or awareness that one's behavior is influenced by some previous processing episode. Different aspects of conscious processing are engaged by different paradigms. In subliminal perception studies, for instance, one is concerned with determining whether stimuli that have not been consciously *encoded* can influence subsequent responses. In contrast, implicit memory research has been more focused on *retrieval* processes, that is, on the unintentional, automatic effects that previously consciously perceived stimuli can exert on subsequent decisions. In studies of implicit learning, it is the *relationships* between ensembles of consciously processed stimuli that remain purportedly unconscious. These subtle differences in which specific aspects of the situation are available to awareness illustrate the need to distinguish carefully between awareness during encoding and awareness during retrieval of information. Further, both encoding and retrieval can concern either individual stimuli or relationships between sets of stimuli, and both can either be intentional or not.

A second important challenge is to devise an appropriate measure of awareness. Most experimental paradigms dedicated to exploring the relationships between conscious and unconscious processing have relied on a simple dissociation logic aimed at comparing the sensitivity of two different measures to some relevant information: a measure *C* of subjects' awareness of the information, and a measure *P* of behavioral sensitivity to the same information in the context of some task. Unconscious processing, according to the simple dissociation logic, is then demonstrated whenever *P* exhibits sensitivity to some information in the absence of correlated sensitivity in *C*. There are several potential pitfalls with the simple dissociation logic, however. First, the measures *C* and *P* cannot typically be obtained concurrently. This 'retrospective assessment' problem entails that finding that *C* fails to be sensitive to the relevant information need not necessarily imply that information was processed unconsciously during encoding, but that, for instance, it might have been forgotten before retrieval. A second issue is to ensure that the information revealed through *C* is indeed relevant to performing the task. As Shanks and St. John (1994) have suggested, many studies of implicit learning have failed to respect this 'information' criterion. For instance, successful classification in an artificial grammar learning task need not necessarily be based on knowledge of the rules of the grammar, but can instead involve knowledge of the similarity relationships between training and test items. Subjects asked about the rules of the grammar would then understandably fail to offer relevant explicit knowledge.

A third issue is to ensure that *C* and *P* are both equally sensitive to the relevant information. At first sight, verbal reports and other *subjective measures* such as confidence ratings would appear to offer the most direct way of assessing the contents of subjective experience, but such measures are often difficult to operationalize in a sufficiently controlled manner. For instance, people might simply refrain from reporting on knowledge held with low confidence, or might offer reports that are essentially reconstructive in nature, as Nisbett and Wilson's experiments indicate. For this reason, many authors have advocated using so-called objective measures of awareness. *Objective measures* of awareness include forced-choice tests such as recognition, presence–absence decisions, or identification.

Even if these different conditions are fulfilled, however, it might be elusive to hope to obtain measures of awareness that are simultaneously *exclusive* and *exhaustive* with respect to knowledge held consciously. In other words, finding null sensitivity in *C*, as required by the dissociation paradigms for unconscious processing to be demonstrated, might simply be impossible because no such absolute measure exists. A significant implication of this conclusion is that, at least with normal participants, it makes little sense to assume that conditions exist in which awareness can simply be 'turned off.' Much of the ongoing debate about the existence of subliminal perception can be attributed to a failure to recognize the limitations of the dissociation logic.

It might therefore instead be more plausible to assume that any task is always sensitive to both conscious and unconscious influences. In other words, no task is *process-pure*. Two methodological approaches that attempt specifically to overcome the conceptual limitations of the dissociation logic have been developed. The first was introduced by Reingold and Merikle (1988), who suggested that the search for absolute measures of awareness should simply be abandoned in favor of approaches that seek to

compare the sensitivity of *direct* measures and *indirect* measures of some discrimination. Direct measures involve tasks in which the instructions make explicit reference to the relevant discrimination, and include objective measures such as recognition or recall. In contrast, indirect measures, such as stem completion in memory tasks, make no reference to the relevant discrimination. By assumption, direct measures should exhibit greater sensitivity than, or equal sensitivity to, indirect measures to consciously held task-relevant information, for subjects would be expected to be more successful in using conscious information when instructed to do so than when not. Hence, demonstrating that an indirect task is more sensitive to some information than a comparable direct task can only be interpreted as indicating unconscious influences on performance.

The second approach—Larry Jacoby's 'Process Dissociation Procedure' (Jacoby 1991)—constitutes one of the most significant advances in the study of differences between implicit and explicit memory. It is based on the argument that, just as direct measures can be contaminated by unconscious influences, indirect measures can likewise be contaminated by conscious influences: particular tasks can simply not be identified with particular underlying processes. The process dissociation procedure thus aims to tease apart the relative contributions of conscious and unconscious influences on performance. To do so, two conditions are compared in which conscious and unconscious influences either both contribute to performance improvement, or act against each other. For instance, subjects might be asked to memorize a list of words and then, after some delay, to perform a stem completion task in which word stems are to be completed either so as to form one of the words memorized earlier (the *inclusion* condition) or so as to form a different word (the *exclusion* condition). If the stems nevertheless tend to be completed by memorized words under exclusion instructions, then one can only conclude that memory for these words was implicit, since if subjects had been able consciously to recollect them, they would have avoided using them to complete the stems. Numerous experiments have now been designed using the process dissociation procedure. Collectively, they offer convincing evidence that performance can be influenced by unconscious information in the absence of conscious, subjective awareness.

3. *Treating Consciousness as a Variable: Qualitative Differences*

Rather than pursuing the elusive goal of demonstrating unconscious cognition, a more fruitful approach to exploring the relationships between conscious and unconscious cognition thus consists of treating consciousness as a variable, that is, of exploring the functional, neural, and computational differences that exist between tasks performed with awareness and without. This leads to the design of experiments in which qualitative differences between cognition with and without awareness can be established in carefully controlled conditions. In this respect, the 'contrastive approach' advocated by Baars (1988) and Frith et al. (1999) offers great promise in helping to solve the methodological challenges described above. Numerous qualitative differences between conscious and unconscious processes have been reported. For instance, based on behavioral methods, Arthur Reber and others have suggested that implicit cognition involves processes that are more resistant to insult or injury, that tend to be less sensitive to individual differences or affective state, and less sensitive to attentional demands. Recent advances in brain-imaging methods make it possible to go beyond purely behavioral methods and to integrate different *online* measures of awareness and of brain activity when attempting to contrast conscious and unconscious cognition. One of the most interesting paradigms through which to combine so-called first-person (subjective) and third-person (objective) methodologies is binocular rivalry—a phenomenon that takes place when different images are shown to each eye. Under these conditions, one's perception of the stimulus alternates spontaneously between the complete perception of one stimulus and the complete perception of the other. Using functional brain imaging, one can then correlate people's subjective reports of what it is they actually perceive at each point in the experiment with the cerebral regions that are most activated, and in so doing establish which of these regions correlate most with the unchanging stimulus and which correlate most with perception as assessed by subjective reports.

Numerous studies combining various online measures of brain activity have likewise attempted to identify which regions of the brain are most involved in processes such as conscious recollection, intentional retrieval, or nonconscious influences in different memory tasks (see Shacter et al. 1998 for a review). While it is too early to draw definite conclusions from such studies, it appears, for instance, that anterior prefrontal regions of the brain appear to be most clearly associated with processes of effortful, conscious retrieval. This and similar findings should help us further to develop theories of consciousness that have a firm rooting in our knowledge of the brain.

4. *Conclusions*

The study of differences between conscious and unconscious processing is a major endeavor for the cognitive neurosciences. Conscious and unconscious processing differ on several dimensions, including depth and specificity of processing. Action can be initiated without consciousness, and some aspects of

perception or memory can also take place without consciousness. Such unconscious processing always tends to reflect habitual or strong responses. From this perspective, unconscious processing is best characterized as the indirect effects of conscious processing. The extent to which conscious and unconscious processes involve distinct brain regions remains an open issue, but it is clear that some regions of the brain tend to be more associated with conscious processing than others. The distinction between conscious and unconscious processing thus appears to involve both a graded and a dynamic continuum (in terms of the underlying mechanisms) and a dichotomy (in terms of subjective experience). Functional brain-imaging methods, when used together with sufficiently sensitive behavioral methods, offer the promise of combining first-person and third-person perspectives to elucidate the relationships between conscious and unconscious processes in cognition.

Consciousness and Sensation: Philosophical Aspects

1. Types of Consciousness

The term 'consciousness' picks out several different aspects of mental functioning. Though these aspects are related in various ways, it is crucial for any theoretical understanding of consciousness to distinguish the different things to which we apply the term.

The oldest and most widespread use of the term is to describe people, and other sentient creatures, as being awake and receptive to sensory input. This is also the least problematic mental phenomenon we refer to as consciousness. The term is used in this case simply to mark the distinction between a person or other creature being in an ordinary waking state and its being asleep, knocked out, anesthetized, or failing for some other reason to interact mentally with its environment in ordinary ways. The distinction between these conditions is doubtless to be explained in large measure in biological terms. Because this first notion of consciousness applies to people and other sentient creatures, we may refer to it as creature consciousness.

A second notion of consciousness has to do with a person or other animal's being conscious or aware of something, or its being conscious or aware that something is the case. A person is conscious of something when that person sees or hears it or perceives it in some other way. Following on that perceptual model, we also count a person as being conscious of something when that person has a thought about that thing as being present. Finally, a person is conscious that something is the case when that person has a thought that it is the case. This second notion of consciousness again applies to people and other creatures, but we describe this kind of consciousness in terms of some object of which a person or other creature is conscious. For that reason it is convenient to refer to this second kind of consciousness as transitive consciousness.

A third notion of consciousness applies not to people or other creatures at all, but to their mental states, states such as perceiving, sensing, thinking, desiring, and feeling. A mental state is conscious just in case one is conscious of it in a way that seems spontaneous and unmediated. An important theoretical question, taken up in Sect. 4, is how to explain the way one is conscious of one's mental states when those states are conscious. But it seems clear that no mental state counts as being conscious if the subject is in no way conscious of that state. Because this third use of the term 'consciousness' applies to mental states, rather than people or other creatures, it is useful to refer to it as state consciousness.

Some theorists have insisted that a person is never in any of these states without being conscious of them. This claim is perhaps best represented by philosophers such as René Descartes (1596–1650) and John Locke (1643–1704), although many thinkers today also hold this. One reason many find this claim tempting may be that in ordinary situations we care relatively little about any mental states that the subject is wholly unaware of. It seldom matters to anybody if a person thinks or feels something without being in any way aware of doing so; still less in the case of other creatures. But the temptation to insist that we are conscious of all our mental states also seems to reflect a certain confusion. When a person perceives something or has a thought about it, that person is in a state of being conscious of that thing. It may seem an easy step to pass from somebody's being in a state of being conscious of something to that state's being a conscious state.

But it is crucial to preserve the distinction between the things one's mental states are about and 'the mental states that are about those things. It is one thing to have a thought or perception of something and another altogether to be conscious of that thought or perception. Even if the thought or perception is not conscious, because one is in no way conscious of it, one's having that thought or perception will still make one conscious of whatever the thought or perception is about. One will then be conscious of something, but not consciously so. We mark this distinction by a third use of the term 'consciousness,' on which a mental state is conscious if one is conscious of that state in a spontaneous, seemingly unmediated way.

The condition about seeming to be spontaneous and unmediated is important. A thought or perception is not conscious if one is conscious of it by applying a theory to oneself, or because one takes somebody else's word for it. One must be conscious of oneself as being in the state in question without seeming to infer that from anything else.

In ordinary waking life, many mental states are conscious, but normally they are not conscious in any reflective or attentive way. When one focuses attentively on one's conscious states, so that one's interest is in the mental state one is in rather than on whatever that mental state makes one conscious of, one is said to introspect the mental state under scrutiny. In these cases one is not only conscious of the mental state one is in, but conscious also that one is conscious of that state. Ordinary state consciousness is not at all reflective in this way.

Both creature consciousness and transitive consciousness can be understood only if we first understand what it is to perceive and think about things. A person or other creature is conscious only if it is mentally responsive to its environment, and one is transitively conscious of something only if one is in a suitable kind of mental state. To understand state consciousness, by contrast, requires something in addition. One must understand what it is to think about or perceive something, and also understand the difference between thinking and perceiving consciously and doing so in a way that is not conscious. Because of disagreement about how to understand that contrast, state consciousness continues to provoke considerable controversy in psychological and philosophical theory, and seems to some even to resist scientific explanation altogether.

2. *Sensations and Consciousness*

The most difficult theoretical issues surrounding state consciousness arise in connection with the conscious-

ness of sensations. Sensations fall into two groups: bodily sensations and perceptual sensations. Bodily sensations include such mental states as pains, aches, tickles, itches, and feelings of nausea, dizziness, and the like. Perceptual sensations, by contrast, include those which pertain to the five exteroceptive senses of sight, hearing, taste, touch, and smell.

There are two additional kinds of sensation, which provide instructive borderline cases. Proprioceptive sensations pertain to the motions and position of our limbs, and enteroceptive sensations pertain to the feelings of our viscera and other internal organs. These two groups resemble bodily sensations in having to do with bodily conditions, but they also resemble perceptual sensations in providing information about the conditions of things, in this case one's own body. The existence of these borderline cases suggests the hypothesis, defended by some theorists (e.g., Armstrong 1962), that bodily sensations, along with proprioceptive and enteroceptive sensations, are simply perceptual sensations that are involved in perceiving bodily conditions. Pains, for example, reveal bodily damage, aches reveal bodily strains and stresses, and so forth for other types of bodily sensation.

Traditional theorists have usually distinguished between sensations and perceptions, though this distinction has been drawn in a variety of different ways. Some theorists have isolated sensations as states that occur in earlier stages of perceptual processing. But this is unhelpful unless one can specify exactly where in the early processing stream sensations are supposed to occur. Some theorists have sought to meet this difficulty by holding that sensations occur early enough in perceptual processing to represent things accurately, whereas perceptions may reflect distortions due to subsequent mental processing. But this is still unsatisfactory, since some distortion occurs even in the earliest stages of sensing. In any case, work on visual processing suggests that the early stages involve nothing that would ordinarily be called a sensation (Treisman 1986). An altogether different approach to the distinction holds that perceiving involves some conceptual content, whereas sensing has only qualitative character and no conceptual content. Even if sensing, so understood, often does not occur as a separate stage of visual processing, one can still abstract the purely qualitative aspect of perceiving and refer to that as sensing.

Conscious sensations exhibit characteristic qualitative character; for every type of conscious sensation, there is something it's like to have that sensation consciously. Many theorists hold that no informative account is possible of this conscious qualitative character, that what it's like to have a conscious sensation resists theoretical treatment of whatever sort (e.g., Chalmers 1996, Nagel 1974, Levine 1993, McGinn 1991). No theoretical treatment could capture or convey the knowledge of what it's like to have any particular type of conscious sensation; the only way one can come to have that knowledge is by having the conscious sensation itself (Jackson 1982).

Other theorists, however, have argued that one can give an informative, theoretical account of what it's like to have particular types of conscious sensation. Sensations play distinctive a role in perceiving and the various types of perceptions and perceptual beliefs are keyed to specific types of perceptible property. So it may be possible to give an informative theoretical treatment of the various types of sensation in terms of characteristic causal connections sensations have with perceptions and perceptible physical objects (e.g., Shoemaker 1975, 1984 and Sellars 1963, Chaps. 2, 3, and 5). Such an account fits well especially with the hypothesis that bodily sensations are a special case of perceptual sensations.

There are two ways theorists seek to distinguish among types of sensation: in terms of the characteristic role they play in perceiving and in terms of what it's like for one to have them. Some have held that these two ways of taxonomizing sensations might give different results. Consider sensations that play the same role in perceiving, say, sensations that result from visual stimulation by a ripe tomato in good lighting. Perhaps what it's like for one person to have such a sensation is different from what it's like for another person to have a sensation picked out by that perceptual role. Perhaps, more generally, what it's like for somebody to have a sensation bears no predictable relation to the characteristic perceptual cause of that type of sensation. The possibility that what it's like for different people might be independent of characteristic perceptual cause is known as the possibility of qualia inversion. (Qualia, singular 'quale,' are the conscious qualitative properties of sensations.) If such inversion occurs, what it's like for one person to have a sensation characteristic of seeing a ripe tomato might be the same as what it's like for another to have a sensation characteristic of seeing grass.

It may seem that such qualia inversion occurs all the time, since people do see things slightly differently. But these ordinary differences are readily detectable, relying only on the way people describe the things they see in perceptual terms. So these differences can be treated as a function of the perceptible properties people take physical objects to have. Qualia inversion would occur, by contrast, if what it's like to have various sensations were wholly independent of the connections those sensations have to perceptible properties. One would therefore be unable to detect such qualia inversion by reference to the way people describe their experiences in perceptual terms. If what it's like for people to have the relevant sensations were independent of the properties they perceive objects to have, people would use the same words to describe the objects they perceive, but what it would be like for them to perceive those subjects would be different.

It is unclear, however, that such undetectable inversion could occur. It is arguable that we are

conscious of our sensations in respect of the role they play in perceiving objects of characteristic sorts. But what it's like for one to have a sensation is a function of how one is conscious of that sensation. One can, for example, be conscious of sensations in more or less fine-grained ways; the visual sensation one gets from seeing a particular red object might be conscious just as some indiscriminate shade of red or as a highly specific shade, depending on factors such as how carefully one is attending, how alert one is, and so forth. If what it's like for one to have a sensation is a function of how one is conscious of it and one is conscious of one's sensations in respect of their role in perceiving, what it's like for one to have a sensation will not vary independently of that role in perceiving (Rosenthal 1999).

Mental states such as thoughts and beliefs do not exhibit qualitative properties, and some theorists insist that sensations and perceptions also exhibit no qualitative properties. This view, known as representationalism, holds that the only qualitative properties involved in sensing and perceiving are the qualities we take physical objects and processes to have (Dretske 1995, Harman 1990, Lycan 1996).

It is clear that no mental states have the qualitative properties of color, sound, and so forth that we perceive physical objects to have. But that does not show that sensations do not have a distinct, mental version of such qualitative properties. We do describe sensations in qualitative terms, visual sensations as being red and green, for example, and pains as being sharp or burning. These qualities of being red, green, sharp, or burning are not the same type of property that physical objects have, but sensations do fall under different types in respect of having one or another type of qualitative property.

It is likely that our grasp of the distinguishing properties of sensations trades on connections those properties have to perceptible properties of physical objects; red sensations occur in response to red objects, and so forth. But sensations sometimes occur in the absence of any objects of the kind that characteristically occasion them. So the sensations themselves must have distinguishing properties that parallel those of the objects that typically occasion them. These distinguishing properties are the qualitative properties of sensations.

3. *Do Mental States Ever Fail to be Conscious?*

It is generally recognized that some types of mental state can occur without being conscious. Thoughts, desires, wishes, expectations, and other such states all sometimes occur without the subject's having any conscious access to them. Indeed, novelists and playwrights have long described their characters as thinking and wanting things that they are sometimes wholly unaware of thinking and wanting.

Freud's theoretical and clinical arguments for positing unconscious thoughts and desires can be seen as continuous with this commonsense recognition of such unconscious states. Unconscious thoughts and desires, according to Freud, often make possible explanations of behavior that seems inexplicable by reference to conscious thoughts and desires (Freud 1915/1966–74). The unconscious thoughts and desires he posited interact to cause behavior in just the way that corresponding conscious thoughts and desires would to cause that same behavior.

Much in Freud's clinical and theoretical thinking remains controversial, but the general point seems sound. There are theoretically neutral examples of the operation of such unconscious thoughts and desires; verbal slips, for example, which Freud called parapraxis, sometimes provide evidence of thoughts or desires of which the subject is wholly unaware (Freud 1915/1966–74, pp. 166, 168–9).

More dramatically, work in social psychology has shown that people often report having thoughts and desires that it can be established experimentally they do not have (Nisbett and Wilson 1977, White 1988). Subjects in these cases confabulate thoughts and desires that seem to make *ex post facto* sense of their behavior, by rationalizing some situation or conforming to expectations or preconceived ideas that they or others have. When subjects confabulate thoughts and desires in this way, they typically remain wholly unaware of the thoughts and desires that actually cause that behavior. Experimental work on metacognition, which is how much subjects know of their own cognitive states and processes, also reveals nonconscious cognitive states (Metcalfe and Shimamura 1994 and Nelson 1992).

Even if thoughts and desires occur without being conscious, some theorists continue to doubt that this is possible with qualitative states, such as sensations. Even Freud held that, because of their qualitative nature, feelings and emotions cannot occur without being conscious (Freud 1915/1966–74, p. 177, 1923/1966–74, pp. 22–3).

There is something it's like for one to be in a qualitative state, such as an emotion or sensation, only when that qualitative state is conscious. When one is in no way conscious of a sensation, there is nothing it's like to have it, that is, nothing it's like for the subject. So, if we taxonomize sensations only in respect of what it's like for one to have them, sensations would have to be conscious to have the distinguishing characteristics of sensations at all. No state would count as a sensation or other qualitative state unless it was conscious.

But if we taxonomize sensations at least in part by reference to their role in perceiving, there is no reason to deny the occurrence of nonconscious sensations, since it is experimentally demonstrable that perceiving occurs without being conscious. It is well-established, for example, that when subjects are presented very

briefly with visual or auditory stimulus material followed by a second stimulus, the second stimulus may mask the first, blocking conscious access to it. Nonetheless, it can often be shown in these masked-priming experiments that the first stimulus has a distinctive perceptual effect (e.g., Marcel 1983a, 1983b).

Research on some subjects with a part of the primary visual cortex destroyed yields similar results. When such subjects are presented with visual stimuli in the area of the visual field served by the damaged part of the cortex, they report seeing nothing at all. Some subjects, however, can guess the visible characteristics of the stimulus with startlingly high accuracy (Weiskrantz 1986, 1997). This phenomenon is known as blind sight. In these cases and in masked-priming experiments, subjects' guesses, often in forced-choice experiments, are highly accurate in the absence of any relevant conscious mental states. Such experimental work leaves little doubt that nonconscious perceiving occurs and that whatever sensations occur in such perceiving also fail to be conscious.

4. *Theories of Consciousness*

A mental state is conscious only if one is conscious of that state in a way that seems to one spontaneous and unmediated. We do not regard as conscious any state the subject is in no way conscious of being in, or conscious of being in only as a result of inference or observation.

Theories of state consciousness differ chiefly in how they seek to explain the way people are conscious of their conscious states. As noted earlier, there are two ways one is transitively conscious of things: by sensing them and lay thinking about them as being present. Corresponding to those two ways of being transitively conscious of things are two hypotheses about the way we are conscious of our conscious states.

On one hypothesis, we are conscious of our conscious states by sensing them. This theory has a long history in philosophical writing. Aristotle's claim that we always perceive that we perceive (Aristotle 1968, 425b12) was developed by John Locke (1700/1975) and Immanuel Kant (1787/1998) into a theory of consciousness as a kind of 'inner sense.' On this view, represented by such contemporary writers as Armstrong (1978) and Lycan (1996), a mental state is conscious if one perceives that state. Because perceiving something seems to make us directly aware of that thing, if we perceive our conscious states, that would explain why it seems that we are directly aware of those states.

But we are also conscious of things when we think of them as being present. So it may be that a mental state is conscious if one has a thought to the effect that one is in that state (Rosenthal 1986, 1997). We would seldom be aware of such higher-order thoughts about our mental states, since they would not themselves be conscious thoughts unless we had third-order thoughts about them, which would be unusual. Very likely that would occur only when we are introspectively conscious of our conscious states. On this hypothesis, higher-order thoughts arise independently of any conscious inference, that is, any inference of which we are conscious. That would explain, without appeal to the apparent immediacy of perceiving, why it seems we are directly aware of our conscious states.

A variant of this model holds that actual higher-order thoughts are not required for a state to be conscious; all that is needed is that one be disposed to have a higher-order thought about that state (Carruthers 1996). But this is less satisfactory, since being disposed to have a thought about something does not result in one's being conscious of that thing, but only in one's being disposed to be conscious of it.

The higher-order thought model has certain advantages over the inner-sense hypothesis. Perceiving always seems to involve mental qualities, but we are never aware of any higher-order mental qualities. In addition, mental qualities all fall into families corresponding to the various sensory modalities, such as sight, hearing, bodily sensations, and so forth. But it is difficult to imagine what sensory modality could be involved in higher-order sensing or perceiving.

Another issue that divides theorists is whether our being conscious of our conscious mental states is intrinsic to the mental states we are conscious of. Looked at from the point of view of the person whose mental states are conscious, the property mental states have of being conscious seems to be intrinsic to those states, and it seems that they could not have occurred without having that intrinsic property. Accordingly, some theorists have adopted a model on which the higher-order thought or sensing in virtue of which we are conscious of our conscious states is intrinsic to those states (Brentano 1874/1973).

Most contemporary theorists, however, argue that a more satisfactory theoretical model results from assuming that the relevant higher-order states are distinct from the states they make us conscious of. It is well known, moreover, that commonsense impressions about which properties are intrinsic and which are relational are often wrong. As with physical properties such as weight, properties that initially seem to be intrinsic often turn out to be relational. So being conscious may well not be an intrinsic property of conscious states, despite its seeming, from the point of view of the person whose mental states are conscious, that it is.

Not all theorists appeal to inner sense or higher-order thoughts to explain how we are conscious of our conscious states. Some suppose that we are conscious of those states in some third way that is unique to being conscious of mental states. Such theorists often

appeal to metaphor to capture this third way of being conscious of things, these as a search light that illuminates mental states, thereby making them conscious. Such metaphorical description makes it difficult to evaluate these proposals. In the absence of some clear account of this third way of being conscious of things, it is likely that positing such a third way is simply a label for the problem of explaining how we are conscious of our conscious states, rather than a substantive explanation.

Some have gone farther, and reject even the commonsense idea that one is conscious of one's conscious mental states (Dretske 1995, Searle 1992). On this view, a mental state's being conscious consists not of one's being conscious of that state in some suitable way, but rather of its being a state in virtue of which one is conscious of something. But all sensing and perceiving and much if not all thinking makes one conscious of things. So this account of what it is for a mental state to be conscious obliterates the distinction between mental states that are conscious and those which are not.

Some theorists distinguish various ways in which mental states can be conscious. On one of the most influential accounts, a state's being access conscious consists of it being poised to play an active role in rationally guiding action, speech, and reasoning, whereas a state has phenomenal consciousness if it has qualitative character (Block 1995).

It is unclear, however, that either notion does justice to our pretheoretic, commonsense idea of a mental state's being conscious. Many states that are poised to guide action, speech, and reasoning are conscious states, but many are not. Nonconscious states often play an important role in the rational guidance of action, speech, and reasoning. So a state's being poised for these tasks cannot subserve that state's being conscious; intuitively, it is necessary also that one be in some way conscious of the state.

As for phenomenal consciousness, a state's simply having qualitative properties cannot ensure that the state is conscious; as masked-priming experiments and work on blindsight show, qualitative states occur without being in any intuitive way conscious. In addition, if phenomenal consciousness were just having qualitative properties, sensations could not occur without being conscious, since they cannot occur without qualitative properties. This sense of consciousness would again obliterate the distinction between a state's being conscious and not being conscious.

5. *Consciousness and Interpretation*

We often determine what thoughts and desires other people have by inferring from what they do to the thoughts and desires that would best explain or make sense of that behavior. Sometimes people also say what they think and desire, but often all we have to go on is that seeing others as having particular thoughts and desires would make sense of their behavior.

Daniel Dennett has argued attributing beliefs and desires to others in this requires seeing others as being rational in doing what will get them what they want, given what they believe. He argues that this explanatory strategy is effective with much behavior that cannot readily be explained by the physical stance, which appeals to how something operates as a physical object, or the design stance, which regards objects as well-designed machines. This explanatory framework, which Dennett labels the intentional stance, seeks to rationalize the behavior of people and other creatures by seeing that behavior as due to their thoughts and desires (Dennett 1987).

Dennett has developed a theory of consciousness, on which consciousness in effect results from people's adopting of the intentional stance toward themselves. A person's conscious thoughts and desires are those one is disposed to report having or in some other way takes oneself to have, thereby making sense of one's behavior. Consciousness is a matter of our spontaneously interpreting ourselves as being in various mental states. So there are, in this view, no determinate facts about consciousness beyond such self-interpretive behavior (Dennett 1991).

Spontaneously interpreting oneself as being in some mental state can be seen as resulting from one's having a spontaneous higher-order thought to the effect that one is in that state. So Dennett's view has much in common with the higher-order-thought model. But there are important differences. Dennett takes self-interpretative behavior to be the last word about what conscious states we are in. But because such behavior cannot by itself explain how one is conscious of one's conscious states, the higher-order-thought model takes that behavior to be a mere symptom of the higher-order thoughts in virtue of which one is conscious of those states. So on that model there will be determinate facts about consciousness independent of self-interpretative behavior.

Spontaneous self-interpretation is on both views the last word about how consciousness represents our mental lives, since a state's being conscious consists, on these views, of one's spontaneous interpretation of oneself as being in that state. But what states consciousness represents one as being in is not the last word on what states one is actually in. Thoughts, desires, perceptions, and feelings all have characteristic causal connections with stimulus conditions and behavior and with one another. These causal connections can determine what mental states a person is in independently of what states consciousness represents that person as being in.

If a mental state's being conscious involves spontaneous self-interpretation, it is natural to speculate that such self-interpretation may be influenced by the interpretations others make of us as being in particular

mental states. The interpretations others make of us may even play a role in our coming, as very young children, to learn to apply mental concepts to ourselves.

The hypothesis that a state's being conscious is a matter of one's spontaneously interpreting oneself as being in that state fits well with the way people sometimes confabulate having thoughts and desires that they do not actually have (Nisbett and Wilson 1977, White 1988). From the point of view of the person confabulating, these cases are subjectively indistinguishable from cases of actually having the relevant conscious thoughts and desires. Consciousness represents one as having thoughts and desires that one does not actually have. Some research suggests that the same may well occur with qualitative states, such as bodily or perceptual sensations (e.g., Staats et al. 1998, Holmes and Frost 1976).

Much work in social sciences such as sociology, cultural anthropology, social psychology, and history relies on the interpretation of people as being in particular mental states. This raises a problem if the mental states one is in can diverge from the mental states one is conscious of oneself as being in. One could interpret a person as actually being in a particular mental state or simply as being conscious of being in that state. If the mental states one is in can differ from those one is conscious of oneself as being in, one interpretation might be correct and the other not. So it is methodologically important to be clear about which interpretation is in question.

D. M. Rosenthal

Consciousness, Cognitive Psychology of

The 'Hard Problem' of consciousness is how to explain a state of consciousness in terms of its neurological basis. Chalmers (1996) distinguishes between the Hard Problem and 'easy' problems that concern the function of consciousness. The Hard Problem (though not under that name) was identified by Nagel (1974) and further analyzed in Levine (1983).

There are two *prima facie* reasons for thinking that the Hard Problem has no solution.

(a) Actual failure. In fact, no one has been able to think of even a highly speculative answer.

(b) Principled failure. The materials we have available seem ill-suited to providing an answer. As Nagel (1974) says, an answer to this question would seem to require an objective account that necessarily leaves out the subjectivity of what it is trying to explain. We don't even know what would *count* as such an explanation.

1. *Perspectives on the Hard Problem*

There are many perspectives on the Hard Problem but I will mention only the four that comport with a naturalistic framework.

(a) *Phenomenal realism*, the view that consciousness is a substantial property that cannot be philosophically reduced in nonphenomenal terms. According to most contemporary phenomenal realists, consciousness plays a causal role and its nature may be found empirically as the sciences of consciousness advance. Phenomenal realism is compatible with the empirical reduction of consciousness to neurological or computational properties of the brain. (This is the perspective of this article.) This view accepts the Hard Problem but aims for an empirical solution to it. (Block 1995, Flanagan 1992, Nagel 1974, Searle 1992; McGinn 1991 argues that an empirical reduction is possible but that we can't find or understand it.)

(b) *Dualistic naturalism*. In this catch-all category, I include Chalmers' (1996) view that standard materialism is false but that there are naturalistic options to dualism such as panpsychism. Nagel (forthcoming) proposes that there is a deeper level of reality that is the naturalistic basis both of consciousness and of neuroscience.

(c) *Eliminativism*, the view that consciousness as understood above simply does not exist (Dennett 1979, Rey 1997). So there is nothing for the Hard Problem to be about.

(d) *Philosophical reductionism*. Philosophical reductionists (e.g., Dennett 1991) move closer than eliminativists to common sense by allowing that consciousness exists, but they 'deflate' this commitment—again on philosophical grounds—taking it to amount to less than meets the eye (as Dennett might put it). One prominent form of philosophical reductionism in this sense makes a conceptual reductionist claim: that consciousness can be conceptually analyzed in nonphenomenal terms. The main varieties of analyses are functional, representational, and cognitive. Many philosophical reductionists disparage *a priori* conceptual analysis, but nonetheless hold that we know on purely philosophical grounds (independently of the sciences of consciousness) that consciousness is constituted by the functional, representational, or cognitive.

Here are some examples of philosophical reductionism. Pitcher (1971) and Armstrong (1968) can be interpreted as analyzing consciousness in terms of beliefs. One type of prototypical conscious experience, as of the color blue, is a matter of an inclination (perhaps suppressed) to believe that there is a blue object in plain view. (See Jackson 1977 for a convincing refutation.) A different analysis appeals to higher order thought or higher order perception. These theorists take the concept of a conscious pain to be the concept of a pain that is accompanied by another state that is about that pain. A pain that is not so accompanied is not a conscious state (Armstrong 1968, Carruthers 1992, Lycan 1990, Rosenthal 1997 advocates a higher order thought view as an empirical identity rather than as a conceptual analysis). Another philosophical reductionist view that is compatible with the analyses in terms of beliefs concerns not the states themselves but their contents. Representationism holds that it can be established philosophically that the phenomenal character of experience is its representational content. Many representationists reject conceptual analysis, but still their accounts do not depend on details of the science of mind; if any science is involved, it is evolutionary theory (see Harman 1990, Dretske 1995, Lycan 1996, McDowell 1994, Tye 1995; Shoemaker 1994 mixes phenomenal realism with representationism in an interesting way). Conceptual functionalists say that the concept of consciousness is analyzable functionally (Lewis 1994).

According to these views, there is such a thing as consciousness, but there is no Hard Problem, that is, there are no mysteries concerning the physical basis of consciousness that differ in kind from run of the mill unsolved scientific problems about the physical/functional basis of liquidity, inheritance, or computation.

2. *How to Begin Solving the Hard Problem*

The main element in the approach I shall be suggesting to the Hard Problem is a distinction that is widely appealed to in discussions of Jackson's (1982) famous 'Mary' example. Jackson imagined a neuroscientist of the distant future who is raised in a black and white room and who knows everything scientific there is to know about color and the experience of it. But when she steps outside the room for the first time, she learns what it is like to see red. Jackson argued that since the scientific facts don't encompass the new fact that Mary learns, dualism is true.

The line of response to Jackson that I think wins the day (and which derives from Loar 1990/1997) involves appeal to the distinction between a property and a concept of that property. (See Churchland 1989, Lycan 1990, van Gulick 1993, Sturgeon 1994, Tye 1999, Perry forthcoming.)

A concept is a thought element in a way of thinking, a kind of representation. If you like, you can take concepts in my sense to be interpreted symbols in a 'language of thought.' This usage contrasts with a common philosophical usage in which a concept is something like a meaning. Concepts in my sense are individuated in part by meanings; x and y are instances of the same concept if and only if they are instances of the same representation and have the same meaning.

Someone could believe that *this color* is useful for painting pots but that red is not, even if *this color* = red. Our experiential concept of red differs from our linguistic concept of red. An experiential concept involves a phenomenal element, a phenomenal way of thinking, for example a mental image that is in some sense of red or an ability to produce such a mental image or at least an ability to recognize red—which arguably, could not be done without some phenomenal mental element.

Importantly, we can have an experiential concept *of an experience* (which we can call a phenomenal concept, phenomenal concepts being a subclass of experiential concepts) as well as an experiential concept of a color. And the very same mental image may be involved in both concepts. The difference between the phenomenal concept of the experience and the experiential concept of the color lies in the *rest* of the concept—in particular, the way the phenomenal element functions in the concept. This can be a matter of further concepts explicitly invoked in the concept—the concept of a color in one case and the concept of an experience in the other. One type of experiential concept (of a color or of an experience) involves a demonstrative plus a mental image plus a language-like representation, e.g. 'that [attention to a mental image] color' or 'that [attention to a mental image] experience' where the bracket notation is supposed to indicate the use of attention to a nondescriptive element, a mental image, in fixing the demonstrative reference. Loar (1990/1997) gives an example involving two concepts in which something like a mental image of a cramp feeling is used to pick out a muscular knot in one concept and in the other concept, the cramp experience itself. The two concepts in my notation would be 'that [attention to a mental image] cramp' and 'that [attention to a mental image] cramp experience.'

In these terms, then, Mary acquired a new concept of a property she was already acquainted with via a different concept. In the room, Mary knew about the subjective experience of red via physical concepts. After she left the room, she acquired a phenomenal concept of the same property. So Mary did not learn a new fact. She learned a new concept of an old fact. She already had a third person understanding of the fact of what it is like to see red. What she gained was a first person understanding of the very same facts. She knew already that corticothalamic oscillation of a certain frequency is what it is like to see red. What she learned is that this [attention to a mental image] is what it is like to see red. So the case provides no argument that there are facts that go beyond the physical facts.

Recall that there is a principled reason why mind–body identity seemed impossible: that a first person subjective property could not be identical to a third person objective property. But the concept–property distinction allows us to see that the subjective–objective distinction in this use of it and the first person–third person distinction are distinctions between kinds of concepts, not kinds of properties. There is no reason why a subjective concept and an objective concept cannot pick out the same property. Thus we can substitute a dualism of concepts for a dualism of properties.

3. *The Paradox of Recent Empirical Findings About Consciousness*

The most exciting line of experimental investigation of consciousness in recent years uses the phenomenon of binocular rivalry. If two different stimuli—e.g., horizontal and vertical stripes—are presented to each of one's eyes, one does not see a blend, but rather alternating horizontal and vertical stripes. Logothetis and his colleagues (Logothetis 1998) trained monkeys to pull different levers for different patterns. They then presented different patterns to the monkeys' two eyes, and observed that with monkeys, as with people, the monkeys switched back and forth between the two levers even though the sensory input remained the

same. Logothetis recorded the firings of various neurons in the monkeys' visual systems. In the lower visual areas (e.g., V1), 80 percent of the neurons did not shift with the percept. But further along the occipital-temporal pathway, 90 percent shifted with the percept. So it seems that later areas in the occipital-temporal pathway—let's call it the 'ventral stream'—are more dominantly part of the neural basis of (visual) consciousness than early areas.

However, what has also become commonplace is activation of the very same ventral stream pathways without awareness. Damage to the inferior parietal and frontal lobes have long been known to cause visual extinction in which subjects appear to lose subjective experience of certain stimuli on one side, viz., when there are stimuli on both sides. Extinction is associated with visual neglect in which subjects do not notice stimuli on one side. For example, neglect patients often do not eat the food on the left side of the plate.

Driver and Vuilleumier (2001) point out that the ventral stream is activated for extinguished stimuli (i.e., which the subject claims not to see). Rees et al. (in press) report studies of a left-sided neglect and extinction patient on face and house stimuli. Stimuli presented just on the left side are clearly seen by the patient, but when there are stimuli on both sides, the subject says he sees only the stimulus on the right. However, the 'unseen' stimuli show activation of the ventral pathway that is the same in location and temporal course (though lower in activation) as the seen stimuli. The paradox then is that our amazing success in identifying the neural correlate of visual experience in normal vision has led to the peculiar result that, in masking and neglect, that very neural correlate occurs without, apparently, subjective experience.

What is the missing ingredient, X, which, added to ventral activation, constitutes conscious experience? Kanwisher (forthcoming) and Driver and Vuilleumier (2001) offer pretty much the same proposal as to the nature of X, that the missing ingredient is binding perceptual attributes with a time and a place, a token event.

Whether or not any of these proposals are right, the search for X seems to me the most exciting current direction for consciousness research.

There is a very different approach to the nature of consciousness. Dennett (1994) postulates that consciousness is 'cerebral celebrity.' What it is for a representation to be conscious is for it to be widely available in the brain. Dehaene and Naccache (forthcoming) say consciousness is being broadcast in a global neuronal workspace.

The theory that consciousness is ventral stream activation plus e.g., neural synchrony, and the theory that consciousness is broadcasting in the global neuronal workspace, are instances of the two major approaches to consciousness in the philosophical literature: *physicalism* (though 'biologism' would be more appropriate in this context) and *functionalism*. The difference is that the functionalist says that consciousness is a role, whereas the physicalist says that consciousness is a physical or biological state that implements that role. Although functionalists are free to add restrictions, functionalism in its pure form is independent of implementation. Consciousness is defined as global accessibility, and although its human implementation depends on our biochemistry, silicon creatures without our biochemistry could implement the same computational relations. Thus functionalism and physicalism are incompatible doctrines since a nonbiological implementation of the functional organization of consciousness would be regarded as conscious by the functionalist but not by the physicalist. The big question for functionalists is: 'How do you know that it is broadcasting in the global workspace that makes a representation conscious as opposed to something about the *human biological realization* of that broadcasting?'

Many of us have had the experience of suddenly noticing a sound (say a jackhammer during an intense conversation), and at the same time realizing that the sound has been going on for some time even though one was not attending to it. If the subject did have a phenomenal state before the sound was noticed, that state was not broadcast in the global neuronal workspace until it was noticed. If this is right, there was a period of phenomenality without broadcasting. Of course, this is anecdotal evidence. But the starting point for work on consciousness is introspection and we would be foolish to ignore it.

In this section, we have seen a distinction between two concepts of consciousness, phenomenality and global accessibility. In the following section, we add a third, reflexivity.

4. *Phenomenality and Reflexivity*

Rosenthal (1997) defines reflexive consciousness as follows: S is a reflexively conscious state $\Leftrightarrow$ S is accompanied by a thought—arrived at noninferentially and nonobservationally— to the effect that one is in S. He offers this 'higher order thought' (HOT) theory as a theory of phenomenal consciousness. It is obvious that phenomenal consciousness without HOT and HOT without phenomenal consciousness are both conceptually possible. For examples, perhaps dogs and infants have phenomenally conscious pains without higher order thoughts about them. For the converse case, imagine that by biofeedback and imaging techniques of the distant future, I learn to detect the state in myself of having the Freudian unconscious thought that it would be nice to kill my father and marry my mother. I could come to know—noninferentially and nonobservationally—

that I have this Freudian thought even though the thought is not phenomenally conscious. Since there are conceptually possible counterexamples in both directions, the issue is the one discussed above of whether reflexivity and phenomenality come to the same thing in the brain.

If there are no actual counterexamples, the question arises of *why*. Is it supposed to be a basic law of nature that phenomenality and reflexivity co-occur? That would be a very adventurous claim. But if it is only a fact about us, then there must be a mechanism that explains the correlation, as the fact that both heat and electricity are carried by free electrons explains the correlation of electrical and thermal conductivity. But any mechanism breaks down under extreme conditions, as does the correlation of electrical and thermal conductivity at extremely high temperatures. So the correlation between phenomenality and reflexivity would break down too, showing that reflexivity does not yield the basic scientific nature of phenomenality.

The reader may wonder why Rosenthal includes 'noninferentially and nonobservationally' in the definition. The answer is: because one could find out that one is depressed by observing one's own behavior. This would not be conscious depression, but such a thought would be arrived at observationally and inferentially. However, this restriction is *ad hoc*, motivating the search for definition that is not *ad hoc*. Here is one: S is a reflexively conscious state $\Leftrightarrow$ S is phenomenally presented in a thought about S. This definition uses the notion of phenomenality, but this is no disadvantage unless one holds that there is no such thing apart from reflexivity itself.

We have seen three concepts of consciousness: phenomenality, reflexivity, and global accessibility. The Hard Problem arises only for phenomenality. The imaging work on consciousness engages phenomenality and accessibility. But many psychological experimental paradigms mainly engage reflexivity.

Consciousness, Neural Basis of

Consciousness is a puzzling state-dependent property of certain types of complex, adaptive systems. The best example of one type of such system is a healthy and attentive human brain. If the brain is anaesthetized, consciousness ceases. Small lesions in the brain stem and thalamus of patients can lead to a complete loss of consciousness, while destruction of circumscribed parts of the cerebral cortex of patients can eliminate very specific aspects of consciousness, such as the ability to be aware of motion or to recognize objects as faces, without a concomitant loss of vision in general. Given the similarity in brain structure and behavior, biologists commonly assume that at least some animals, in particular nonhuman primates, share certain aspects of consciousness with humans. Brain scientists, in conjunction with cognitive neuroscientists, are exploiting a number of empirical approaches that shed light on the neural basis of consciousness. Since it is not known to what extent artificial systems, such as computers and robots, can become conscious, this entry will exclude these from consideration.

1. *Some Common Neurobiological Assumptions*

By and large, neuroscientists have made a number of working assumptions that, in the fullness of time, need to be justified more fully.

(a) There is something to be explained; that is, the subjective content associated with a conscious sensation—what philosophers refer to as 'qualia'—does exist and has its physical basis in the brain. To what extent qualia and all other subjective aspects of consciousness can or cannot be explained within a reductionist framework remains highly controversial (Chalmers 1996).

(b) Consciousness is a vague term with many usages. It will, in the fullness of time, be replaced by a vocabulary that more accurately reflects the contribution of different brain processes (for a similar evolution, consider the usage of 'memory,' which has been replaced by an entire hierarchy of more specific concepts). Common to all forms of consciousness is that it feels like something (e.g., to 'see blue,' to 'experience a headache,' or to 'reflect upon a memory'); that is, it is usually about something. *Self-consciousness* is but one form of consciousness.

It is possible that all the different aspects of consciousness (smelling, pain, visual awareness, affect, self-consciousness, and so on) employ a basic common mechanism or perhaps a few such mechanisms. If so, then if one can understand the mechanism for one aspect, then one will have gone most of the way towards understanding them all.

(c) Consciousness is a property of the human brain, a highly evolved system. It therefore must have a useful *function* to perform. Crick and Koch (1998) assume that the function of the neuronal correlate of consciousness is to produce the best current interpretation of the environment—in the light of past experiences—and to make it available, for a sufficient time, to the parts of the brain which contemplate, plan, and execute voluntary motor outputs (including language). This needs to be contrasted with *on-line systems* that bypass consciousness but that can generate stereotyped behaviors (see below).

Note that in normally developed individuals, motor output is not necessary for consciousness to occur. This is demonstrated by *lock-in syndrome*, in which patients have lost (nearly) all ability to move yet are clearly conscious.

(d) At least some animal species posses some aspects of consciousness. In particular, this is assumed to be true for nonhuman primates such as the macaque monkey. Consciousness associated with sensory events in humans is likely to be related to sensory consciousness in monkeys for several reasons. First, trained monkeys show similar behavior to that of humans for many low-level perceptual tasks (e.g., detection and discrimination of visual motion or depth: Wandell 1995). Second, the gross neuroanatomies of humans and nonhuman primates are rather similar once the difference in size has been accounted for. Finally, functional magnetic resonance imaging of human cerebral cortex is confirming the existence of a functional organization in sensory cortical areas similar to that discovered by the use of single-cell electrophysiology in the monkey (Tootell et al. 1998). As a corollary, it follows that language is not necessary for consciousness to occur (although it greatly enriches human consciousness).

2. *Enabling, Modulating, and Specific Factors*

It is important to distinguish the general, *enabling* factors in the brain that are needed for any form of consciousness to occur from *modulating* ones that can up- or downregulate the level of arousal, attention, and awareness, and from the *specific* factors responsible for a particular content of consciousness.

An easy example of an enabling factor would be a proper blood supply. Inactivate the heart, and consciousness ceases within a fraction of a minute. This does not imply that the neural correlate of consciousness is in the heart (as Aristotle thought). A neuronal enabling factor for consciousness is the *intralaminar nuclei of the thalamus*. Acute bilateral loss of function in these small structures that are widely and reciprocally connected to the basal ganglia and cerebral cortex leads to immediate coma or profound disruption in arousal and consciousness (Bogen 1995).

Among the neuronal modulating factors are the various activities in nuclei in the brain stem and the midbrain, often collectively referred to as the *reticular activating system*, which control in a widespread and quite specific manner the level of noradrenaline, serotonin, and acetylcholine in the forebrain. Appropriate levels of these neurotransmitters are needed for sleep, arousal, attention, memory, and other functions critical to behavior and consciousness (Baars 1997).

Yet any particular content of consciousness is unlikely to arise from these structures, since they appear to lack the specificity necessary to mediate a sharp pain in the right molar, the percept of the deep, blue California sky, the bouquet associated with a rich Bordeaux, or a haunting musical melody. These must be caused by specific neural activity in cortex, thalamus, basal ganglia, and associated neuronal structures. The question motivating much of the current research into the neuronal basis of consciousness is the notion of the *minimal* neural activity that is *sufficient* to cause a specific conscious percept or memory (see below).

For instance, when a subject consciously perceives a face, the retinal ganglion cells whose axons make up the optic nerve that carries the visual information to the brain proper are firing in response to the visual stimulus. Yet it is unlikely that this retinal activity directly correlates with visual perception. While such activity is evidently necessary for seeing a physical stimulus in the world, retinal neurons by themselves do not give rise to consciousness.

Given the comparative ease with which the brains of animals can be probed and manipulated, it seems opportune at this point in time to concentrate on the neural basis of sensory consciousness. Because primates are highly visual animals and much is known about the neuroanatomy, psychology, and computational principles underlying visual perception, vision has proven to be the most popular model system in the brain sciences.

3. *Information Processing in the Brain that Bypasses Consciousness*

Cognitive and clinical research demonstrates that much complex information processing can occur without involving consciousness. This includes visual, auditory, and linguistic priming, implicit memory, the implicit recognition of complex sequences, automatic behaviors such as driving a car or riding a bicycle, and so on (Velmans 1991), and the dissociations found in patients with lesions in cerebral cortex (e.g., such as residual visual functions in the professed absence of any visual awareness known as *clinical blindsight* in patients with lesions in primary visual cortex: Weiskrantz 1997).

The cognitive scientist Jackendoff (1987) argues at length against the notion that consciousness and thoughts are inseparable and that introspection can reveal the contents of the mind. According to Jackendoff, what is conscious about thoughts are sensory aspects, such as visual images, sounds, or silent speech. Both the process of thought and its content are not directly accessible to consciousness. Indeed, one tradition in psychology and psychoanalysis—going back to Sigmund Freud—hypothesizes that higher-level decision making and creativity are not accessible at a conscious level, although they influence behavior.

Within the visual modality, Milner and Goodale (1995) have made a masterful case for the existence of so-called *on-line systems* that bypass consciousness. Their function is to mediate relative stereotype visuomotor behaviors, such as eye and arm movements, reaching, grasping, posture adjustments, and so on, in a very rapid, reflex-like manner. On-line systems work in egocentric coordinate systems, and lack certain types of perceptual illusions (e.g., size illusion) as well as possessing no direct access to working memory. This contrasts well with the function of consciousness alluded to above, namely to synthesize information from many different sources and use it to plan behavioral patterns over time. Milner and Goodale argue that on-line systems are associated with the *dorsal stream* of visual information in the cerebral cortex, originating in the primary visual cortex (V1) and terminating in the posterior parietal cortex.

4. *The Neuronal Correlate of Consciousness (NCC)*

The problem of consciousness can be broken down into several separate questions. Most, if not all of these, can then be subjected to scientific inquiry.

The major question that neuroscience must ultimately answer can be bluntly stated as follows: it is probable that at any moment some active neuronal processes in our head correlate with consciousness, while others do not; *what is the difference between them?* The specific processes that correlate with the current content of consciousness are referred to as the *neuronal correlate of consciousness*, or as the NCC. Whenever some information is represented in the

NCC it is represented in consciousness. The NCC is the minimal (minimal, since it is known that the entire brain is sufficient to give rise to consciousness) set of neurons, most likely distributed throughout certain cortical and subcortical areas, whose firing directly correlates with the perception of the subject at the time. Conversely, stimulating these neurons in the right manner with some yet unheard of technology should give rise to the same perception as before. Discovering the NCC and its properties will mark a major milestone in any scientific theory of consciousness.

What is the character of the NCC? Most popular has been the belief that consciousness arises as an emergent property of a very large collection of interacting neurons (for instance, Libet 1993) possibly in connection with exceeding some level of complexity (Edelman and Tononi 2000). In this view, it would be foolish to locate consciousness at the level of individual neurons. An alternative hypothesis is that there are special sets of 'consciousness' neurons distributed throughout cortex and associated systems. Such neurons represent the ultimate neuronal correlate of consciousness, in the sense that the relevant activity of an appropriate subset of them is both necessary and sufficient to give rise to an appropriate conscious experience or percept (Crick and Koch 1998). Generating the appropriate activity in these neurons, for instance by suitable electrical stimulation, would give rise to the specific percept.

Any one subtype of NCC neurons would, most likely, be characterized by a unique combination of molecular, biophysical, pharmacological, and anatomical traits. It is possible, of course, that all cortical neurons may be capable of participating in the representation of one percept or another, though not necessarily doing so for all percepts. The secret of consciousness would then be the type of activity of a temporary subset of them, consisting of all those cortical neurons which represent that particular percept at that moment. How activity of neurons across a multitude of brain areas that encode all of the different aspects associated with an object (e.g., the color of the face, its facial expression, its gender and identity, the sound issuing from its mouth) is combined into a single percept remains puzzling and is known as the *binding problem*.

What, if anything, can we infer about the location of neurons whose activity correlates with consciousness? In the case of visual consciousness, it was surmised that these neurons must have access to visual information, and project to the planning stages of the brain; that is, to premotor and frontal areas (Fuster 1997). Since no neurons in the primary visual cortex of the macaque monkey project to any area forward of the central sulcus, Crick and Koch (1998) propose that neurons in V1 do not give rise to consciousness (although V1 is necessary for most forms of vision, just as the retina is). Ongoing electrophysiological, psychophysical, and imaging research in monkeys and humans is evaluating this prediction.

While the set of neurons that can express any one particular conscious percept might constitute a relative small fraction of all neurons in any one area, many more neurons might be necessary to support the firing activity leading up to the NCC. This might resolve the apparent paradox between clinical lesioning data suggesting that small and discrete lesions in cortex can lead to very specific deficits (such as the inability to see colors or to recognize faces in the absence of other visual losses) and the functional imaging data that any one visual stimulus can activate large swaths of cortex.

Conceptually, several other questions need to be answered about the NCC. What type of activity corresponds to the NCC (it has been proposed as long ago as the early part of the twentieth century that spiking activity synchronized across a population of neurons is a necessary condition for consciousness to occur)? What causes the NCC to occur? And, finally, what effect does the NCC have on postsynaptic structures, including motor output.

5. *Experimental Approaches*

A promising experimental approach to locate the NCC is the use of *bistable percepts* in which a constant retinal stimulus gives rise to two percepts alternating in time, as in a Necker cube (Logothetis 1998). One version of this is *binocular rivalry*, in which a small image, say of a horizontal grating, is presented to the left eye and another image, say a vertical grating, is shown to the corresponding location in the right eye. In spite of the constant visual stimulus, observers 'see' the horizontal grating alternate every few seconds with the vertical one (Blake 1989). The brain does not allow for the simultaneous perception of both images.

It is possible, although difficult, to train a macaque monkey to report whether it is currently seeing the left or the right image. The distribution of the switching times and the way in which changing the contrast in one eye affects this leave little doubt that monkeys and humans experience the same basic phenomenon. In a series of elegant experiments, Logothetis and colleagues (Logothetis 1998) recorded from a variety of visual cortical areas in the awake macaque monkey while the animal performed a binocular rivalry task. In primary visual cortex, only a small fraction of cells modulate their response as a function of the percept of the monkey, while 20–40 percent of neurons in higher visual areas in cortex do so. The majority of cells increased their firing rate in response to one or the other retinal stimulus with little regard to what the animal perceived at the time. In contrast, in a high-level cortical area such as the inferior temporal (IT) cortex, almost all neurons responded only to the

perceptual dominant stimulus (in other words, a 'face' cell only fired when the animal indicated by its performance that it saw the face and not the pattern presented to the other eye). This makes it likely that the NCC involves activity in neurons in the inferior temporal lobe. Lesions in the homologue area in the human brain are known to cause very specific deficits in conscious face or object recognition. However, it is possible that specific interactions between IT cells and neurons in parts of the prefrontal cortex are necessary in order for the NCC to be generated.

Functional brain imaging in humans undergoing binocular rivalry has revealed that areas in the right prefrontal cortex are active during the perceptual switch from one percept to the other (Lumer et al. 1998).

A number of alternate experimental paradigms are being investigated using electrophysiological recordings of individual neurons in behaving animals and human patients, combined with functional brain imaging. Common to these is the manipulation of the complex and changing relationship between physical stimulus and the conscious percept. For instance, when an image is briefly flashed onto the screen and is immediately followed by presentation of a second image, the first image often remains invisible (it is said to be *masked*). Yet neurons can still respond in a selective manner to the first stimulus that is not consciously registered. Under other conditions, subjects will respond to a target although it is physically not present. The NCC in the appropriate sensory area should mirror the perceptual report under these dissociated conditions. Perceptual report can be influenced by delivering current pulses to the cerebral cortex in the absence of any physical stimulus or in the presence of an ambiguous stimulus, as explored in the context of elective surgery for epileptic patients (Penfield and Perot 1963) or in animal studies (Parker and Newsome 1998). Visual illusions constitute another rich source of experiments that can provide information concerning the neurons underlying these illusory percepts. A classical example is the *motion after effect*, in which a subject stares at a constantly moving stimulus (such as a waterfall) for a fraction of a minute or longer. Immediately after this conditioning period, a stationary stimulus will appear to move in the opposite direction. Because of the conscious experience of motion, one would expect the subject's cortical motion areas to be activated in the absence of any moving stimulus. Another approach, suitable for the establishment of a rodent model to study the NCC, relies on the differential involvement of consciousness that appears necessary to establish associative trace conditioning, but not for associative delay conditioning (Clark and Squire 1998). That is, subjects need to be aware of the temporal relationship between conditioning stimulus (CS) and unconditioned stimulus (US) if there is a delay between the end of the CS and the onset of the US, while this is not the case if the time course of the two overlap. Finally, understanding the specific actions of the different classes of anesthetic agents on cortical, thalamic, and basal ganglia neural networks will aid both the development of systems-level theories of anesthesia and the search for the NCC. Future techniques, most likely based on the molecular identification and manipulation of discrete and identifiable subpopulations of cortical and thalamic cells in appropriate animals, will greatly help in this endeavor.

Identifying the type of activity and the type of neurons that give rise to specific conscious percept in animals and humans would only be the first, albeit critical, step in understanding consciousness. One also needs to know where these cells project to, their postsynaptic action, how they develop in early childhood, what happens to them in mental diseases known to affect consciousness in patients, such as schizophrenia or autism, and so on. And, of course, a final theory of consciousness would have to explain the central mystery: why a physical system with a particular architecture gives rise to feelings and qualia (Chalmers 1995).

Conscription, Policy of

Conscription is the compulsory enlistment of people into military service. In modern democratic states, conscription is governed by a set of rules regulating eligibility, length of service, pay, and benefits. Conscription may involve universal military service, but it need not. The terms 'to conscript' and 'to draft' have become virtually synonymous.

1. Scholarship on Conscription

Conscription is one of the most important policies available to states. The very essence of the state, at least according to Max Weber, is its power to monopolize coercive power within a given territory, and this power depends on the state's control of an army, which in turn depends on the ability of government to recruit soldiers. Nonetheless, scholars concerned with developing a more adequate theory of the state have given relatively scant attention to military obligations and the institutions that enforce these obligations. Military service is demonstrably as important an aspect of the state–citizen relationship as any that exists. A government's decision to conscript and its policy implementing conscription have significant political and social implications for state building and for citizenship.

There has not, of course, been total neglect. Anthony Giddens, Michael Mann, Pierre Birnbaum, and other political sociologists have, on occasion, addressed the significance of military service and, more specifically, conscription for state building. Specialists in international relations and international political economy have certainly considered the importance of national defense and military power, but the state theorists among them have, on the whole, focused on civil vs. military domestic power, international cooperation, and trade. Military theorists and historians, including such luminaries as Thucydides, Niccolo Machiavelli, Carl von Clausewitz, and John Mahon and a host of more contemporary scholars, have discussed the political and social importance of military format as well as the role of nationalism and voluntary compliance in increasing acquiescence with conscription. However, to the extent there has been any systematic attention to the link between conscription and state building or citizenship, it has generally come from historically oriented political scientists, sociologists, and economists.

In addition to the investigations of conscription in state theory, there are two additional traditions of conscription scholarship. One focuses on contemporary policy issues: what role conscription should play in the recruitment of modern armies. The other deals with conscription data as a source of information about the population over time.

2. Conscription and State Theory

There are at least three strands to this literature. The first emphasizes the relationship between war, nation building, and state making. Here the major issues are the development of state capacity and the form of governance. The second emphasizes the relationship between conscription and citizenship. It, too, is a literature focused on the changing nature of the state, but the focus is on transformation of subjects into citizens. The third stresses the bases for and history of objection to conscription.

2.1 Nation and State Building

Otto Hintze (1994 [1906]), Samuel Finer (1975), Charles Tilly (1990), and Brian Downing (1991) capture the important role that military activity and institutions generally play in forging the infrastructure of governments. To wage war requires economic resources, including the ability to tax subjects for money and men. The way in which war is waged also has consequences for the form and power of the state. Joseph Schumpeter's (1954 [1918]) initial insight, while obvious, remains important: war permits increased government expenditure, which is sustained in peacetime, and increased government expenditure implies increased taxation. Moreover, the emergence of constitutional democracies or authoritarian regimes can be affected by the processes of extracting resources during wartime.

Conscription played a crucial role historically in the development of state capacity, particularly since the French and American revolutions. Throughout the

eighteenth century (and into the nineteenth), a single shilling pressed into the hand of a drunken man in a public house by a recruiting sergeant enlisted a soldier into the British army. In France, the dreaded *Milice royale* relied on a lottery to choose which peasants would be forced into the King's service. The army was not a popular institution, at least not for those who had to serve in its rank and file. Some joined because they liked the life, but most did so because they were coerced or needed the work or were fleeing from something worse. Those who refused did so because being in the army was inconvenient or actively repugnant. National patriotism is a relatively modern basis for service. It requires a sense of one's country as an entity that can legitimately demand contributions in the form of conscripts and taxes.

The use of coercion to compel young men to fight on behalf of a chief, a lord, or a king has long been a feature of human society. Modern conscription, however, emerged in the late eighteenth century. According to the OECD, the origin of the term conscription was in 1798 during the French Republic. At that time and place, conscription referred to a very particular process of military enrollment in which lots were drawn among the young men deemed eligible for service and which permitted those whose names were drawn to provide substitutes.

In the nineteenth century the countries of Europe and North America developed modern national states, and those in the Antipodes began the process. State building involved the creation of a military adequate to the requirements of relatively centralized government and the exigencies of international politics. The mass mobilization of the French Revolution and the Napoleonic Wars marked the beginning of the period in Europe; the American Revolution and the Civil War were critical moments for the United States. The governments of this period confronted the problems of turning feudal armies and local militias into national armies. A series of new institutions emerged to make orderly conscription possible: a census of eligible young men, rules of selection and eligibility, health examiners, and a bureaucratic apparatus capable of assigning, paying, and housing the recruits.

Historians have documented the creation of these new institutions and the problems they created for both legislators and the new bureaucrats (e.g., Chambers 1987, Schnapper 1968, Simkins 1988). Resistance to the census and to conscription was strong among those trying to avoid the reach of a centralizing state. Young men hid from the registrars, and they cut off fingers and toes to make themselves ineligible (e.g., Aron et al. 1972, Le Roy Ladurie 1979 [1973], Levi 1997). The long-term effect of the forms of conscription introduced in the nineteenth and early twentieth centuries, however, was the construction of more centralized states, whose extractive reach goes deep into the population.

Conscription can contribute to nation building as well as state building. The French army, for example, played a key role in transforming a population drawn from diverse regional and linguistic backgrounds into a single people. The British Army, on the other hand, seems to have reinforced ethnic divides in both the British Isles and its colonies. Today the armies of the United States, South Africa, and other countries with historically disenfranchized minorities are important institutions for the upward mobility of precisely those minorities once prevented from being soldiers. Investigations of other polities, including more recently developed countries, suggest reasons for variation in ethnic integration that range from the demand for troops to the differences between a professional and politicized military (e.g., Enloe 1980, Peled 1998).

2.2 Conscription and Citizenship

The institutions of conscription extend the state's social control of its people, but they can also lay the basis for the extension of citizenship. The exploration of the citizen-soldier has been the subject of considerable discussion, most notably in the work of Morris Janowitz, Samuel Stouffer, Charles Moskos, Elliot Cohen, and David Segal, but that literature has largely investigated civil–military relations and the motivations of soldiers to fight. Of more interest here is the ways in which the development of conscription interacts with the construction of the terms of citizenship.

Within the context of modern nationalism, someone who is willing to die for one's country has a claim on recognition as a full citizen of that country. Historically, conscription is often linked with demands for the franchise, social services, and other rights of citizenship. There is considerable evidence that ethnic minorities who have been exempted from conscription will become eager volunteers in order to demonstrate their loyalty and thus earn the privilege of eligibility for conscription. This may explain why so many blacks and Nisei Japanese enthusiastically signed up for United States Army during World War II, why some Druse are so eager to participate in the Israeli army, and why other notable ethnic minorities have also enlisted in their country's armies (Petersen 1989).

In France, Switzerland, several other continental European countries, and for many Israelis, citizenship, at least male citizenship, is closely tied to one's service as a conscript. There is an expectation of some form of conscription, even during peacetime. It is a rite of passage to have served in the military, and it is often a form of bonding for the cohort that drills together. The Anglo-Saxon democracies of Britain, the United States, Canada, Australia, and New Zealand have a quite different tradition. Until World War I, conscription could be imposed only during war and, moreover, only during a war of defense—although the

definition of 'war of defense' varies among these countries and among groups within these countries. Nearly all have had some extended period of conscription in the absence of major military conflagrations, but the draft remains controversial.

Conscription by democratic governments seems to succeed to the extent the policymakers design military service formats that, first, ensure relative equality of sacrifice and, second, provide a means for popular discussion and approval of the war and conscription policy. More often than not these more democratic moves are accomplished not through foresight but as revision of failed policies. With few exceptions, policymakers first introduced conscription that provided discriminatory exemptions to powerful constituents and laid nearly the whole burden of warfare on those without the franchise or other form of political clout. Such policies changed only in response to legislative conflict, political protests, and actual draft riots, such as those in New York in 1863 or in Toulouse in 1868. These acts compelled policymakers to revise their beliefs about the acceptability of permitting some part of the population to literally buy their way out of military service.

The high degree of citizen support necessary for conscription hinges on the perception of an acceptable policy bargain whose terms government actors are likely to uphold. The minimal terms of the democratic conscription bargain are that government will conscript according to some legislated and relatively equitable formula.

The history of conscription in France throughout the nineteenth and early twentieth century is one of ongoing negotiations between citizens and state officials over what makes for equitable rules governing conscription. Conscription was by lottery; a set number was chosen from the pool of eligible young men and constituted the cohort of that year. The registrars only went down the list if some of those chosen did not pass the medical examination. Throughout most of the nineteenth century, hiring a substitute was an acceptable practice. Indeed, many of those who received a 'bad' number in the lottery found substitution Pareto optimal. The unlucky recruit was generally covered by an insurance scheme his parents had bought and which provided the resources to pay the bonus or premium substitutes demanded. No one became newly eligible as a result, and young men accepted the substitution contract only if they found it sufficiently attractive—they were not compelled to serve. However, as France increasingly democratized and as the concept of equity altered in consequence, substitution was increasingly considered undemocratic and unfair.

In contrast, voluntary citizen soldiers had been the mark of the military format of the Anglo-Saxon democracies. The institution of conscription in Britain, the United States, Canada, and New Zealand during World War I represented a redesign of the democratic state and a redefinition of the obligations of citizenship. The Great War demonstrated the problems with voluntarism. It failed to produce enough enlistees or permit efficient mobilization of their labor. It led to unattractive and often inappropriate forms of moral suasion. It created bureaucratic mechanisms, such as the national registers, that may have discouraged as many volunteers as they encouraged. By publicizing the shortages in manpower, these censuses made evident the numbers who might be considered 'shirkers.' Such knowledge could make those who had enlisted as well as those who had not think twice about volunteering. If there were not to be enough men anyway, why make the sacrifice?

As states became more democratic, the relationship between conscription and citizenship changed. Conscription remained a basis for the demand for the vote and for social benefits, but it also came under more scrutiny as an obligation governments could impose, even in wartime. With increasing democratization came increasing questions of citizen approval of the wars being fought and the nature of the conscription system being imposed.

2.3 Objections to Conscription

Conscription solves manpower allocation problems during mass mobilization wars; it is a government tool for determining who fights and who works in essential industries. The institution of conscription creates as well as solves problems for democratic governments, however. There is one school of authors who object to conscription altogether as a form of unacceptable government compulsion, which abridges civil liberties and citizen choices and makes the state a Leviathan power. Others argue that conscription may be acceptable, but only during wars of defense recognized as such by the population. Finally, there are those who argue for exemptions from conscription based on conscientious objection; they make the case that individual rights here exceed the demands of universalism.

A major argument for conscription was—and is—its equity. Within democracies there develops a new standard by which to evaluate the implementation of conscription: equality of sacrifice. To the extent governments permit exemptions on nonuniversalistic grounds, they will experience an increase in refusal to consent. The pressure to offer exemptions is particularly strong during wars, such as Vietnam, that do not require total mobilization. Moreover, the fact that decisions about exemptions were made by decentralized draft boards in the United States, Britain, Australia, and elsewhere led to differential treatment of otherwise similar cases, thus confirming the sense of a discriminatory and inequitable process (e.g., Davis and Dolbeare 1968).

A related problem for democracies is the imposition of conscription without the approval of some of those it affects or despite the opposition of certain groups. There are numerous studies of resistance by particular ethnic, religious, racial, and class-based groups (see, e.g., Granatstein and Hitsman 1977, Karsten 1983, McKernan 1980). This, in the long run, is a problematic strategy for democracies, as the cases of the Irish in Britain, the francophones in Canada, the aboriginals in Australia, Canada, the United States, and South Africa, the blacks in the United States, among others, have demonstrated. Individuals who have lost or never possessed confidence that the playing field is level may be momentarily compliant due to coercion, but they are not in any sense consenting.

Principled refusal to comply with conscription dates at least from the early American militias. There are two primary grounds for refusal: religious and political. Religious objection to conscription, or what is generally called conscientious objection, requires membership of either a pacifist religion (Quakers, Mennonites) or one that denies the authority of the state over its members (Jehovah's Witnesses, certain sects of Judaism). Conscientious objection is thus most prevalent where dissenting religions thrive, as in the American colonies. Politically-based objection depends on a belief that there are reciprocal obligations between citizens and their governments and that consent can be withdrawn when the government has failed to meet its obligations. This kind of objection is most likely to arise in response to popularly contested wars, such as Algeria or Vietnam. Such factors make conscription and various forms of objection to conscription popular topics of discussion throughout the liberal democracies among politicians and the general public. There is, in addition, a significant philosophical, historical, and public policy scholarship (see, e.g. Simmons 1979, Klosko 1992, Sibley and Jacob 1962, Moskos and Chambers 1993, Levi 1997).

3. *Using Conscription Data*

For economic historians and demographers, there is an additional use for conscription. It is an important source of data. The registration and examination of conscripts provides information about the population over time as well as about the relationships between recruits and the state. It is particularly useful information for learning about height and health over history among different regions and classes (Aron et al. 1972, Floud et al. 1990, Mokyr and Grada 1996). However, it is also useful for inferring the relationship of different ethnic or religious groups to the state (Hanham 1973, Spiers 1980, Levi 1997).

What conscription data is not particularly useful for, however, is comparing the behavior of recruits across wars and countries. Most of the interesting studies are based on snapshots of a particular period in a specific place or rest very lightly on quantitative data. Despite the significant amount of data collected by armies, seldom is it collected the same way across time and or across countries or aggregated in a way useful to social scientists. Moreover, much information has been lost or remains restricted.

4. *Conscription and the Modern Army*

France epitomizes a country in which conscription and citizenship are nearly synonymous. Conscription has been part of the French political landscape since the French Revolution, except for one brief interlude. There have been significant policy shifts. Substitution and commutation were eliminated, and lengths of service and exemptions changed. In 1962, the French finally permitted conscientious objection, subsequently offering a variety of means of completing one's national service, including teaching in Africa, building *bidonville* in the South of France, and even working in a consul or bank outside of France. In the late 1990s, the greatest change of all occurred: the elimination of conscription altogether. This is largely for military reasons; the army is finding it costly to work with short-term recruits and prefers a highly trained, technologically sophisticated, and fully professional army. Belgium and The Netherlands abolished conscription prior to France, in the early 1990s, and for similar reasons. South Korea is another example from a very different continent and culture of the recent shift from a mass and conscripted army to a small and professional army.

The elimination of conscription in many contemporary states has raised a series of questions about the appropriate form of military service in democracies. One set of issues, played out largely in the pages of *Armed Forces and Society*, are the political and social implications for the civil–military relationship. Some scholars fear that increased reliance on a military elite and reduced dependence on the citizen soldier may dangerously enhance the power of the military. Others believe that the institutions of civilian government, at least in the advanced liberal democracies, will be sufficient as a countervailing power.

A related development is reflected in the all-volunteer armies of the United States and Britain. There are two issues here. The first, discussed primarily by economists and military sociologists, is the choice between conscription and volunteerism as the most efficient means for supplying manpower. Sophisticated econometric models (e.g., Ross 1994) are often developed to disentangle the costs and benefits of the different policy options. A second set of issues reflects the concern that the democracies are returning to armies unrepresentative of the population, armies composed disproportionately of the poor, the uneducated, and the minorities. There are advantages, of

course. By relying fundamentally on volunteers, more armies than the past are beginning the process of integrating women without facing issues of conscripting women, and they are enhancing the citizenship status of homosexuals as well as ethnic, religious, and racial minorities. The cost of this strategy may be high, however. Even when the army provides a means of upward advancement to such groups, participation in its ranks no longer constitutes an obligation of general citizenship and the distance between citizen and army increases.

There is no question that conscription, closely linked to citizenship in the liberal democracies during most of the nineteenth and twentieth centuries, is no longer part of the national consciousness in these countries. It is, however, a fact of life—and death—for the peoples of countries embroiled in some of the worst conflicts of the late twentieth century. The conscription of children into the armies fighting the racial and tribal conflicts in sub-Saharan Africa is a nightmare reversion to the impressment of the European past.

Conscription appears to have come nearly full circle in approximately 200 years. Modern, legitimate, and rule-bound conscription commenced with the French Republic, and it was part of the process of transforming subjects into democratic citizens. By the late twentieth century, the liberal democracies are returning to mercenary and professional armies, although severely altered from their eighteenth century forms. Countries without a tradition of democracy and without strong government institutions are using conscription solely as a tool of social control and particularistic power.

Consensus Panels: Methodology

Should you avoid electromagnetic fields produced by home appliances and overhead transmission wires, or secondhand smoke from cigars and cigarettes because they may increase your risk of cancer? These are just two recent examples of the recurrent 'menace[s] of daily life' that have been resolved by consensus panels. A consensus is a shared belief that results from a group judgment. A consensus panel is a group created for the purpose of forming or reaching a consensus. The demand for formal consensus methods has greatly increased in recent decades as the complexity of the decisions, their importance, and the amount of conflicting information involved have also increased. Four prominent, widely used consensus panel methods are described.

1. *Important Consensus Panel Characteristics*

The two most critical aspects of consensus are: (a) how widely shared is the belief, and (b) how is the panel selected? With respect to the first question, while consensus is often thought of as a belief shared by all panel members (i.e., belief unanimity), it also can connote a majority opinion or even, in practice, an average of the group's belief. The answer depends on the procedure used to reach a consensus or the source of the panel's decision.

1.1 *Source of Panel Decision*

There are two sources or ways that a consensus decision can be achieved that result in either a majority or unanimous consensus. The first, and most commonly associated with the consensus process, is that the decision is internal to the panel arising from discussion and sharing of information. In such cases an *ad hoc* panel of experts could be convened to make a unanimous recommendation. The decision to administer the swine flu vaccine to the US public resulted from such a qualitative method (Neustadt and Fineberg 1978).

Since experts with divergent beliefs often disagree, an internal consensus is often impossible. In that case, a second source of decision-making uses a number of quantitative methods to derive a majority or average opinion external to the panel or entirely independent of it. The most common of these is the Delphi method (Dalkey 1969) developed at the RAND Corporation that was actually employed in parallel with the swine flu decision (Schoenbaum et al. 1976). A more recent quantitative method known as meta-analysis (Smith and Glass 1977) or research synthesis (Cooper and Hedges 1994) is widely used to develop an average consensus of the empirical, scientific literature produced by experts.

1.2 *Panel Composition*

Consensus panels are composed of experts or nonexperts. Expert or 'blue-ribbon' panels are most commonly employed since such groups presumably not only have the requisite knowledge to reach a correct consensus, but also the credibility required to convince others of the validity of their opinion.

Since selection of experts can easily result in bias (see discussion of *ad hoc* panels, nonexperts who are neutral on the issue have commonly been convened as a jury to evaluate the existing evidence and reach a decision or recommendation. This method has been used extensively by the US National Institutes of Health (NIH) to assess the effectiveness of medical innovations (Perry and Kalberer 1980). While selection bias is not a problem for the panel's composition, it is still possible that it could affect the information being considered.

2. *Consensus Panel Methods*

The four methods in Table 1 illustrate the contemporary methods for reaching group consensus that embody the characteristics described in the previous section. Experts and nonexperts are both directly involved in internal decisions while, by using quantitative techniques, they can indirectly produce a consensus externally. Both approaches have proven useful in different circumstances, and both have strengths and weaknesses.

2.1 Ad Hoc *Panel Method*

The use of *ad hoc* panels or groups is a widely-employed organizational method for consensus decision-making. Such panels are composed of experts convened in a face-to-face meeting to make a specific decision. The method can be either unstructured or structured. In an unstructured procedure, a nonrepresentative (or nonprobability) convenience sample of experts is gathered for one session to address a single, global question such as, 'Should the swine flu vaccine be produced and distributed?' Such convenience panels are often neither representative of the range of beliefs nor independent of the agency or organization requesting the consensus decision (Neustadt and Fineberg 1978).

In a structured procedure, an effort is made to create a panel containing members representing all the views on the topic. This involves an extended search and

Table 1
Consensus panel methods

Panel composition	Source of panel decision	
	Internal	External
Expert	*Ad hoc* panel	Delphi
Non-expert	Jury	Meta-analysis

nomination process, and often open public comment sessions that include the press as well. Rather than one global issue, the decision is also broken down into a set of subsidiary questions or issues with a procedure for addressing them. Typically, subgroups are formed to address these issues. They can either be members of the panel or another group of experts who are not part of the group and thus not subject to its potential biases (e.g., groupthink, the dominance of prestigious panel members, etc.).

The swine flu decision, as reviewed at government request (Neustadt and Fineberg 1978), illustrates both the strengths and weaknesses of this method. In early 1976 four cases of swine flu were reported among US Army recruits at Fort Dix. The Center for Disease Control (CDC) convened an *ad hoc* panel to determine if a vaccine should be produced and distributed to prevent a pandemic that fall. The panel was composed of members of four Federal and State agencies plus CDC staff. A month later this same group reconvened in a joint meeting with a standing CDC advisory committee appointed and staffed by the Director. Only one of the acknowledged elder statesmen in the field of virology participated in this meeting, and he strongly believed that the country was approaching the end of an 11-year cycle when a new pandemic would occur. At the end of a day's discussion a consensus emerged that 'the possibility of a pandemic existed' and that everyone was at risk. Therefore, the panel recommended that enough vaccine be produced to inoculate the entire US population.

A similar biased consensus unanimously endorsing a swine flu vaccine program also resulted from a third panel appointed by President Ford one month later. He wanted the advice of a 'representative group' of experts, but also had to rely largely on the CDC to select them. Although some famous scientists were added, there were still notable exceptions. Most of the panelists felt that the decision had already been 'programmed.' President Ford publicly announced the Federal program later that day. A series of disasters then followed including the deaths of three high-risk elderly people in Pittsburgh early that fall shortly after being vaccinated, and soon thereafter numerous reports of vaccine-related paralysis. In December, upon the recommendation of CDC, President Ford suspended the program.

A month later an outbreak of Victoria flu erupted in a Florida nursing home. The CDC advisory panel recommended 'limited resumption of the swine flu program' so that the Victoria vaccine that was included in the bivalent doses would be available. The new US Secretary of Health, Education, and Welfare decided to convene a new, fourth 'advisory group' that was more representative and independent than the first three—two CDC and President Ford's—panels. The *ad hoc* group was to be chaired by two of the 'nation's most distinguished scientists' who were not

part of the 'flu establishment' and the meeting was open to the public and the press. The 'improvised' consensus procedure led to a recommendation to lift the ban on the bivalent vaccine for 'high-risk' groups such as the elderly. It was considered 'a great success.'

2.2 Delphi Method

One of the major problems facing *ad hoc* panels such as those considering the swine flu vaccine program was the lack of information, particularly concerning a key issue—the probability of a swine flu pandemic. Other related problems concerned the influence of dominant group members, conformity, and hidden agendas. The Delphi method (Dalkey 1969) was created to solve all of these problems.

Group process artifacts are eliminated in the Delphi Method by avoiding a face-to-face meeting. According to Dalkey (1969), one of the developers of this group judgment method, the Delphi procedure has three important 'features': (a) anonymity of the panelist, (b) multiple sessions or 'interations,' and, as noted above, (c) an external, quantitative group decision. Panelists remain anonymous since their contact is by phone or mail through the Delphi coordinator. Multiple sessions are conducted in which feedback from the previous session or 'round' is provided to the individual panelists. Typically, the information is a quantitative summary of all the panelists ratings on important questions needed to make a decision. For example, to obtain an estimate of the probability of a swine flu pandemic five experts were surveyed using a mailed questionnaire with their responses obtained by telephone (Schoenbaum et al. 1976). The process was repeated until the change in the average (in this case, the median) was less than a specified criterion (here 10 percent).

The Delphi method has a number of other benefits. It is 'rapid,' inexpensive, and can produce a relatively 'objective' estimate of 'opinion' where there is a minimal amount of information available. The swine flue decision which was investigated using this method took only four weeks, comparable to the time taken by the *ad hoc* panels. It also produced a median probability estimate for the pandemic of 0.10—a figure too low to justify a Federal program to vaccinate the entire US population.

More recently researchers at RAND (Brook et al. 1986) have developed a newer consensus method using a variant of the Delphi technique. Nine-member expert physician panels were asked to rate the 'appropriateness' of an exhaustive set of 'indications' for performing (or not performing) various procedures (e.g., carotid endarterectomy, CE) using a nine-point interval scale. Panels were selected to balance speciality, practice, and location. There were two rounds of ratings. The first, typical of the Delphi method, involved anonymous ratings using the mail to provide the panelists relevant information including literature reviews. The second, however, involved a one- or two-day, face-to-face meeting at RAND to rerate the procedures. Each physician was provided a summary distribution of all the panelists' initial ratings with their own clearly indicated. After discussion, the indications were rerated. Four quantitative methods for determining unanimity were calculated (i.e., absolute with all ratings in a three-point region indicating 'inappropriate' (1–3), 'equivocal' (4–6), or 'appropriate' (7–9); scale indicating all ratings in a consecutive three-point region; and both absolute and scale with the highest and lowest ratings removed).

2.3 Jury Method

Juries are arguably the single most common method for consensus decision making given their pervasive use in legal proceedings. While such procedures may seem beyond the scope of a discussion of formal consensus methods, that is simply not the case. Not only have juries been used to make decisions on the same issues that have been dealt with by other consensus methods (Angell 1996), but a variant of the jury method, the 'Consensus Development Program' developed by the US NIH (Perry and Kalberer 1980), has been adopted by other western nations (Lomas et al. 1988, Vang 1986).

In both cases, the juries or panels are composed of nonexpert, neutral persons who listen to an adversarial discussion or presentation by experts over a number of days before reaching a judgment or decision. For example, juries have awarded billions of dollars in damages to women who have successfully sued companies making silicon breast implants claiming that the implants have caused a variety of major diseases (e.g., cancer, arthritis, lupus, etc.). Nevertheless, a 16-member expert scientific panel of the US National Academy of Sciences concluded in a unanimous consensus that 'women with implants are no more likely than other women [without implants] to develop these systemic illnesses' (Institute of Medicine 1999).

The major difference between legal juries and those more formal methods such as the NIH Consensus Development Program is the role of experts (Angell 1996). The law has a liberal definition of expert that allows those with strong beliefs, but not equally strong credentials or evidence, to present their views to juries. Since it is often difficult for both lawyers and juries to assess the credibility of the evidence for these views, persuasion and argumentation skills generally prevail. This is not solely the case in formal consensus procedures such as the one used by NIH since 1977. The neutral panelists have both the range of disciplinary background and skills to assess the evidence, and the expert presenters or witnesses focus on the evidence, usually their own research, rather than their interpretation or opinion.

Donald Fredrickson, the former director of NIH, developed the NIH Consensus Development Program based on his experience with the successful swine flu *ad hoc* panel described (Perry and Kalberer 1980). In particular, he incorporated into this jury procedure the use of a distinguished panel chair, a series of questions, and open meetings. The panel or jury meets in open session over a two-day period at NIH, listening to presentations on the various questions, and interrogating the speakers or presenters. On the third day the panel presents its verdict—a written draft consensus statement—to the public and the press for comment, and then revises it prior to publication.

2.4 The Meta-analysis Method

Meta-analysis is the most recent consensus method. Like the Delphi method, it uses quantitative methods to aggregate or summarize expert knowledge—in this case, the scientific research literature (cf., Cooper and Hedges 1994). An average effect of some human intervention or activity (e.g., the effectiveness of CE surgery to prevent stroke or the adverse health effects of secondhand smoke) is calculated by the meta-analyst, whose role is similar to the Delphi coordinator, from all available studies—both published and unpublished—that represent the views of all experts. Consequently, it is of most value in areas where a substantial amount of conflicting scientific research has been done on a controversial issue.

A welldone meta-analysis avoids the subjectivity inherent in the other consensus methods since it relies entirely on the actual evidence developed by experts rather than their opinions or interpretations, and can be subject to replication. Moreover, it overcomes well-known human cognitive limitations in aggregating large amounts of information (Smith and Glass 1977). For example, a comparison of meta-analysis to both *ad hoc* groups and the RAND modified Delphi method has shown meta-analysis to provide a more accurate estimate than those consensus panels (Antmann et al. 1992, Wortman et al. 1988).

Such summaries or research syntheses can either stand alone, be commissioned to answer a policy question similar to the breast implant issue, or be incorporated into a group decision process. A meta-analysis to assess the impact of US public school desegregation on the academic achievement of Afro-Americans illustrates all three of these uses (Cooper 1986). As the meta-analysis was being completed, the US government convened an expert panel to examine this issue.

The six experts selected to represent the range of opinions about the benefits of school desegregation on black achievement—with two in favor, two against, and two neutral—decided to replicate the meta-analysis using only the strongest evidence. Consequently, an initial unanimous consensus was reached to include only 18 of the original 31 studies. An additional study by two members of the panel that had originally been rejected as low in quality was added. All panelists then conducted their own meta-analyses with the assistance of the original meta-analyst as well as an outside methodological consultant. However, the panelists' prior beliefs affected their choice of evidence (Cooper 1986). Despite this bias, 'the panelists achieved a high degree of correspondence … [and] agreed the effect [of desegregation] was positive' (Cooper 1986 p. 348). Nevertheless, the panel moderator/methodologist was unable to persuade the panel to agree on a written consensus statement to that effect.

3. Conclusions

The descriptions of the four consensus methods indicate that they have differing strengths and weaknesses. One important weakness that potentially affects all of them, however, is selection bias, either in the composition of the panels, the questions asked, or the evidence retrieved. While selection bias in the first three methods involving human panels has been noted above, it is also the main problem in meta-analysis. Selection or publication bias may result in the omission of unpublished studies thus overestimating the average effectiveness of an intervention. The use of open meetings is one way to reduce this bias as is careful initial planning to seek out all relevant experts and evidence. In cases where evidence is available, a combination of methods such as the jury and meta-analysis may be warranted (Wortman et al. 1988). With the rapid increase in both information and access to large computer databases, both quantitative, external consensus combined with qualitative, internal consensus may be the next step in the development of consensus methods.

Consequentialism Including Utilitarianism

Roughly speaking, consequentialism is the theory that is the way to tell whether a particular choice is the right choice for an agent to make or have made is to look at the relevant consequences of the decision: to look at the relevant effects of the decision on the world. In directing us to consequences the theory is teleological in focus; the term comes from the Greek word *telos*, meaning end or goal. It is opposed to any theory that does not make the consequences into the ultimate touchstone of rightness and wrongness in choices. The classical antonym is the deontological approach—this term comes from the Greek work *deon*, meaning obligation or duty—but there are other antonyms too, as we shall see. Where consequentialism would assess a choice by looking at its consequences, a deontological approach would assess it by looking at how the choice measured up to the obligations incumbent on the agent.

1. The Definition of Consequentialism

Nonconsequentialism comes in many forms. Deontologists hold that agents ought to discharge certain duties: they ought to tell the truth, keep their promises, be nonviolent, etc. Kantians say that agents ought to act on the categorical imperative—act only on a maxim that they could accept as a general law of behavior—or ought to treat other people always as ends. Virtue ethicists say that they ought to manifest certain virtues in their behavior. Rights theorists maintain that they ought to respect certain rights that others have against them. Contractualists assert that they ought to conform to principles that no one could reasonably object to as the bases of social life. Theorists of special obligation say that they ought to deal in a certain way with those who are bound to them, such as their children, spouses, and friends. And so on.

What is the common thread in these positions? All nonconsequentialists speak, at whatever level of abstraction, about what any or every agent ought to do or be; in that sense they are universalists. All nonconsequentialists prescribe neutral patterns of behavior or psychology or relationships: that people act on the categorical imperative, manifest certain virtues, respect the rights of their dependants, nurture their friendships, and so on. The patterns are neutral in the sense that they can be understood in the same way by everyone. And all nonconsequentialists say that the right thing for an agent to do is to instantiate the prescribed patterns—so far as they are coinstantiable—in their own behavior or psychology or relationships. In particular, they say that that is the thing to do even if instantiating a pattern in their own life means, because of the perversity of the agent's circumstances, that the pattern will be less fully realized than otherwise in the world as a whole.

Consequentialism makes a dual assertion in response to such positions (Baron et al. 1997). First, it asserts that there are certain potentially shared values by means of which possible states of affairs can be ranked, although perhaps not completely. These may be neutral patterns in human behavior or psychology or relationships, of the kind that the nonconsequentialist prescribes, or they may be neutral outcome patterns that are more detached from agency: patterns such as the maximization of human happiness or the saving of uninhabited wildernesses. And second, consequentialism maintains that the right choice for an agent to take in any decision is one of those choices, assuming there is at least one—assuming incomplete ranking is not a problem—that promote the overall realization of such values or patterns (more below on what it is to promote values).

The basic difference, then, between consequentialists and their opponents is that while each side privileges certain general patterns—treats them as values, as it is natural to say—the consequentialist side

says that the important thing is to promote the realization of those patterns in the world at large, while the opposing side says that the important thing is rather to instantiate the relevant patterns in one's own life: in one's behavior or relationships or psychology, or whatever. Consequentialists say that privileged patterns should be treated as consequences to be promoted, nonconsequentialists that they should be treated as constraints to be satisfied.

The difference between the two approaches is particularly salient for simple cases where only one pattern is taken to be relevant, and where there is no issue about the relative importance of different patterns. Consider those cases, then, where nonviolence is assumed to be the only privileged pattern—the only value—that is relevant. And consider the different ways in which that pattern may be espoused among pacifists.

The nonconsequentialist pacifist says that nonviolence is to be instantiated by agents, even if this means that there is less nonviolence overall. The consequentialist counterpart says that nonviolence is to be promoted overall, even if this means instantiating violence: say, waging the war to end all wars. In practice the two sorts of pacifist will often converge in their recommendations, as nonconsequentialist Quakers converged with Bertrand Russell in their opposition to World War I. But there is always a possibility of their coming apart, as indeed those Quakers and Russell came apart in their attitudes to World War II.

Making the distinction between consequentialism nonconsequentialism by reference to whether the agent is required to promote certain privileged patterns or rather to instantiate them—to honor them—is only one among a number of ways of making it. Another common approach is to distinguish between agent-neutral values and agent-relative ones, and to say that consequentialists advocate the promotion only of agent-neutral values, nonconsequentialists the promotion of a mixed bunch, or of agent-relative values only (Nagel 1986).

Agent-neutral values are patterns that are identified without reference to who is doing the identifying: patterns like those involved in peace being achieved, happiness maximized, a wilderness preserved, and so on. Agent-relative values are patterns that are identified by back reference to the identifying person: patterns, to take the case where I do the identifying, like *my* doing my duty, *my* conforming to the categorical imperative, *my* manifesting certain virtues, *my* looking after my children, and so on. Where consequentialists advocate the promotion of agent-neutral values, and in particular agent-neutral values of a universal cast—they do not involve benefits just to a particular person or place or whatever—nonconsequentialists can be represented as advocating the promotion of agent-relative values: the promotion by every agent of *their* doing their duty, *their* conforming to the categorical imperative, *their* manifesting certain virtues, *their* looking after their children, and so on.

2. *A Theory of the Right, Not a Theory of the Good*

To say that something is good is to hold that it has a certain value, in particular a certain positive value. To say that something is right is to hold that among certain relevant alternatives—say, among the options in a choice—it is the one to have. And so rightness and goodness may come apart. An alternative that is wrong may yet be an object of great value; it may be wrong simply because another option is an object of even greater value. An alternative that is right, on the other hand, may not be something of great value; it may be right, simply because it is the least bad option among a very poor set of alternatives. A theory of the good, a theory of value, would enable us to determine the values of different entities. A theory of the right would enable us to determine, for any set of alternatives, which alternative or subset of alternatives is the right one.

When I speak of what is good, and of what has value, I have in mind an impersonal or agen t-neutral conception of goodness and value. If I value a prospect for the increase of happiness it promises, or even for a particular effect it will have, say on planet Earth, then I value it agent-neutrally. If I value it for the benefits it will have for me or mine, or for the fact that it will keep my hands clean, or for any reason of that self-referential kind, then I value it agent-relatively. The theory of the good, or the theory of the valuable, refers to the theory of what is agent-neutrally valuable.

Does consequentialism present itself as a theory of the good or as a theory of the right, or as something involving commitments in both areas? By the account given, the theory is concerned only with the right, not with the good. It says that the right alternative in any choice is that which promotes the good, without making any commitment on the nature of the good. While it makes the right a function of the good, it says nothing in itself on the matter of what is good.

This aspect of consequentialism is often found surprising, as many people tend to identify consequentialism with utilitarianism. But utilitarianism involves a double commitment. It says that the good should be equated with happiness, whether this is understood in the sense of pleasure or preference satisfaction, and then it adds that the right alternative in any set is that which best promotes such happiness (Sen 1979). Thus when G. E. Moore (1903) rejected utilitarianism, arguing that the good was not reducible to happiness—it was a non-natural property that allowed of no such reduction—he remained a consequentialist about the right. Many contemporary consequentialists have nonutilitarian theories of the good or the valuable.

Indeed they often look like nonconsequentialists to the extent that they may think that the good encompasses reflexive patterns, such as those involved in each person keeping their promises, respecting those with whom they deal, or giving their children special attention.

Robert Nozick (1974), himself an outstanding nonconsequentialist, supports this view when he distinguishes between a nonconsequentialist theory of rights—a theory of rights, proper—and a consequentialism or utilitarianism of rights. The consequentialist theory of rights would say that it is good that certain rights are enjoyed generally, and it would imply that the right option in any choice is that which promotes the enjoyment of such rights. This right option will itself instantiate the rights-observing pattern in most imaginable cases but it will not do so in those exceptional circumstances where the best way to promote the pattern is not to instantiate it oneself: where the best way to promote rights-observance is to breach that observance in one's own case.

3. *Consequentialism, Global, and Local*

Consistently with being a theory of the right, consequentialism can be thought of as having a smaller or a larger range of application to human agents (Pettit and Smith 2000). There are sets of alternative acts that we might perform in different choices, sets of alternative decision procedures that we might follow in choosing acts, sets of alternative motives out of which we might be led to act, sets of alternative rules that we might comply with in acting, and so on. Is consequentialism a local doctrine that just tells us what the best act is in any choice, for example—or the best decision procedure, or motive, or rule, or whatever—and that then says that the best alternatives in other sets are to be defined in a derived way? If acts are privileged, the best decision procedure might be that which produces the best acts, the best rule that which is consistent with the choice of the best acts, and so on through other categories. Or should consequentialism be taken to apply globally, telling us that as the best act is that which produces the best consequences among the alternatives on offer, so the same lesson holds for items in the other sets of alternatives?

Most consequentialist positions in the literature tend to be local in character. Act-consequentialism, as it is called, tends to say that the best act is the act with the best consequences, and that the best factor in any other set of alternatives involving an agent is to be defined in some way—a number of ways are possible—by reference to how it serves the choice of best acts. Rule consequentialism gives the priority to rules in a parallel way, and motive consequentialism gives the priority to motives.

The most natural position, however, would seem to be global consequentialism (Parfit 1984). It would say that no matter what the set of alternatives under consideration, the one to be preferred is that which does best by the consequences. The same lesson will apply, of course, to that set of alternatives whose members are different sets of act–procedure–motive–rule combinations; the right combination will be that which does best by the consequences overall. The act or procedure or motive or rule selected for any context under the best combination may not be the best possible one relative to the apparent alternatives in that context. But it will be the best possible one that is available consistently with the best possible combination overall.

4. *The Role of Consequentialism*

There is a long tradition among the opponents of consequentialist doctrines, in particular the opponents of utilitarianism, of suggesting that consequentialists are committed to holding that every choice should be made in a highly calculative, actuarial mode. F. H. Bradley made the point in the last century, writing about the utilitarian approach: 'So far as my lights go, this is to make possible, to justify, and even to encourage, an incessant practical casuistry; and that, it need scarcely be added, is the death of morality' (Bradley 1876, p. 107). Consequentialists have almost always resisted this charge. Thus, Henry Sidgwick in the last century and J. J. C. Smart in this have argued forcibly that utilitarianism does not require that agents all make their decisions by explicit reference to how the options will do by the promotion of happiness (Smart and Williams 1973). The point they have wanted to make was nicely summed up early in the nineteenth century by the jurisprude, John Austin, in defending the utilitarian thinker:

> Though he approves of love because it accords with his principle, he is far from maintaining that the general good ought to be the motive of the lover. It was never contended or conceived by a sound, orthodox utilitarian, that the lover should kiss his mistress with an eye to a common weal (Austin 1954, p. 108).

As recent consequentialists hve almost all taken the view that consequentialism is a theory of the right, not a theory of the good, so they have nearly unanimously argued that it is a theory for assessing the right alternative for an agent or an agency to have adopted, not necessarily a useful theory to be applied in choosing from among alternatives. The point is usually made with respect to acts but it can also be extended to alternatives in other categories. The claim is that making one's decision by reference to which option has the best consequences may be a way of

making one's decision that does not itself have the best consequences. Suppose one is concerned with one's own pleasure, for example. It is notorious that agents who make their decisions by reference to which option will promote the most pleasure may actually enjoy less pleasure than those who make their decisions in the more spontaneous fashion, say by reference to certain rules of thumb (Railton 1984, Pettit and Brennan 1986).

This aspect of consequentialism has been described as 'the paradox of teleology' (Scanlon 1998, p. 383, n. 15). It has important implications and these need to be appreciated, if the appeal of consequentialism is to be understood. It means that the consequentialist can look with approval on agents whose mode of decision making in everyday life involves a consideration of consequences only in periodic reviews of their performance or in times of crisis. These agents may be routinely available to their family and friends; they may be reliable truth tellers and promise keepers; and they may be dependably respectful of the claims of others upon them. The consequentialist will approve of such people to the extent that they are more likely to promote the good—whatever view of the good is adopted—than actuarial, calculative types.

5. *The Positive Case for Consequentialism*

Why be a consequentialist? Surprisingly, there has been very little discussion of this question in the literature. Consequentialists tend to assume that if one is to be serious about the enterprise of moral assessment, then there is no alternative to looking at the consequences—the consequences, neutrally, or impersonally characterized—of the choices assessed. How could it be rational, they ask, to neglect any such consequences? They assume that if nonconsequentialists think otherwise, that is because of an unquestioning commitment to a theological or a commonsense viewpoint. A theological viewpoint might suggest that human agents ought to fulfill prescribed obligations and let God look after the consequences. And a commonsense viewpoint might support the attitude that the important thing in moral decision making is to look after one's own moral standing, to keep one's own hands clean, and not to worry, except perhaps in exceptional circumstances, about any bad consequences that may follow on this.

There is also a second reason why consequentialists may not have concerned themselves much with providing a defense of their position. Consequentialists are a mixed bunch, as we saw, insofar as they differ widely among themselves on the question of which substantive sorts of consequences—which valuable patterns—are the ones by reference to which choices ought to be assessed. For example, they divide into utilitarians and nonutilitarians, depending on whether or not they accept the view that it is only consequences that bear on the utility of sentient beings which matter: only consequences that affect the happiness or preference satisfaction of such beings. Being a mixed bunch, consequentialists tend each to be concerned more with arguing for their particular view of what consequences count than with arguing for the shared consequentialist credo that it is indeed consequences that matter and not the sort of thing on which deontologists and other nonconsequentialists focus.

My own belief is that those who are attracted to consequentialism are moved by a different view of justification from those who are attracted to the different forms of nonconsequentialism (Baron et al. 1997). According to consequentialism, people will be able to think of their choices as justifiable to one another only insofar as they think that there are agent-neutral values that others ought to accept and that serve to justify those choices. According to nonconsequentialist positions, people will be able to think of their choices as justifiable under a weaker condition: if they think that there are agent-relative values such that others can be made to understand why they should be moved by those values—others are moved by corresponding values in their own case—and the values justify their choices. Thus consequentialists think that justification must ultimately be based on potentially shared or identical concerns: say, with overall happiness or peace or good relations between people. But nonconsequentialists think that it can be based, even at the most ultimate level, on concerns that are isomorphic rather than identical across people: say, on the individuals' concern that they should not break their promises, whatever the impact on promise keeping more generally, or that they should further the welfare of their children, whatever the repercussions for overall child care.

6. *The Negative Case for Consequentialism*

But if consequentialists have not done much in the way of arguing for their position, what have been the issues debated between them and opponents (Scheffler 1988)? These have mainly had to do with how far consequentialism can support firm commonsense intuitions about what is morally right. Opponents typically object to consequentialism on the grounds that in one way or another it would undermine otherwise compelling moral attitudes. Rather than providing positive reason for adopting their position, consequentialists have often been content to try to deal with those objections or to try to argue that while the points made are valid, they are not as important as deontologists make them seem.

There are three sorts of objection, in particular, that consequentialists have had to confront in this ex-

change. First, that their doctrine would make many intuitively wrong choices right, many intuitively right choices wrong; second, that even where it represents many intuitively right choices as right it would provide intuitively the wrong reasons for thinking them right; and third, that it would represent as obligatory various right choices that are supererogatory, that is intuitively beyond the call of duty (Scheffler 1982, Kagan 1989). Consequentialists have often argued in this exchange that our intuitions on relevant matters need to be revised but the more general line has been to maintain that on reflection consequentialism proves less counterintuitive than its opponents maintain.

7. *The Collective Face of Consequentialism*

Suppose we had a society of utilitarians, each of whom acted in a way that utilitarians would approve. Is it possible that the collective result of their so acting might be worse than the collective result of actions that did not individually earn utilitarian approval? Is it possible, in particular, that the collective result might be worse in utilitarian terms: that it might actually lead to less human happiness or preference satisfaction than certain alternatives? Is it possible that, however satisfactory as a theory of rightness for individual agents, it is not in this sense a collectively satisfactory theory (Hodgson 1967)?

Does it matter that a theory designed for individuals is collectively self-defeating Does it matter that agents who try to do what is best by the theory, or succeed in doing what is best by the theory, generate a collective result that is worse in their own terms than it might have been (Parfit 1984)? Some are happy to say that a theory can be self-defeating in this way and yet remain a compelling theory for individuals. Others will think that this is a matter of the first importance for the assessment of a theory.

Some may be willing to concede that consequentialism can be collectively self-defeating but most deny this, on variety of grounds (Lewis 1972, Singer 1972). One well-known line is that where collective self-defeat appears to threaten, it usually transpires that one of the options before the individuals is not being taken into account: say, the option of exploring possibilities of cooperation with others, rather than acting unilaterally, or the option of seeking further information on the prospects facing the agent (Regan 1980).

The prisoner's dilemma is often taken to show that what is individually rational may not be collectively rational: each of two prisoners confesses to a crime because, whatever the other does, confessing promises a better result than refusing to confess; yet each would be better off if both refused to confess than they are by both confessing. It is worth noting that where agents have distinct ends, as they will have under nonconsequentialism, then a prisoner's dilemma is a constant threat. The distinct ends that agents have may consist in individually wanting to do their own duty, individually wanting to instantiate the categorical imperative in their own behavior, individually wanting to do the best by their own children, and so on. Such ends are potentially competitive and so it is a permanent possibility that by each pursuing their own ends as best they can, they will secure a result under which neither does as well as they might have done in their own terms. By each trying to do the best they can by their own children, for example, they may each do less well than if they pooled their resources and did their best for children as such. Whatever problems are raised for consequentialism on the collective front, it is better protected in this respect against prisoner's dilemmas, for it assigns to each agent the same end of promoting the best consequences (Parfit 1984).

8. *Some In-house Issues*

There are a number of more or less in-house questions that are debated among consequentialists. One bears on how we should identify the alternatives to be evaluated in any decision. Should an agent do A or B, we ask. A, we answer, because its consequences do better on the relevant theory of the good. But what if there is some other option, C, which the agent might have chosen instead and which would have itself been better than A? This sort of example alerts us to the fact that in the consequentialist assessment of any choice, we have to be clear about what are the relevant alternatives to bring into consideration.

The question about alternatives has not received as much attention as it deserves in the literature, but it is undoubtedly of great importance (Bergstrom 1966, Jackson and Pargetter 1986). According to one view, we should assess any action against the alternative (or disjunction of alternatives) that the agent would have taken, had the action not been performed. According to another we should assess it against the alternatives that the agent could have performed instead: against the alternatives that were, in a relevant sense, within the power of the agent. From a third-person point of view the first approach would seem to be the most pertinent, although from a first-person point of view things are not so clear.

A second in-house question has been more widely debated in consequentialist circles. This is the issue as to whether in looking at the decision an agent or agency ought to have made, we consider the actual consequences of the option chosen and the consequences that would have followed on alternatives; or whether, rather, we look at the expected consequences at the time of choice (Lewis 1969, Jackson 1991). If the answer is that we should look at expected rather than actual consequences, then the question is whether

we should look at the subjectively expected consequences—in the manner of decision theory—or whether we should look at the consequences that were in some sense objectively expected (Menzies and Oddie 1992). Suppose that a doctor prescribes a drug for a nonfatal skin condition, which has the following features: there is a 10 percent chance that it will kill the patient, an 80 percent chance that it will make no difference, and a 10 percent chance that it will cure the complaint. Imagine that the drug works and the complaint is cured. Does consequentialism take its cue from actual consequences and say that the doctor made the right choice? Or does it look to expected consequences, whether subjectively or objectively expected, and say that the doctor made the wrong choice? That is the issue here.

The third more or less in-house issue is whether consequentialism should hold that the right option is that which does best by relevant consequences—that which is optimific—or whether it is sufficient for an option to be right that it does well enough, as we might say, by the relevant consequences. Some theories of rationality are maximizing theories, requiring rational agents to maximize some function, whereas others are satisficing theories: these require rational agents just to perform satisfactorily by some relevant criterion. The question here is whether consequentialism should not take the softer, satisficing line, rather than the stern, maximizing one (Slote and Pettit 1984).

Conservation: Waterways

Waterways include natural rivers and artificial waterways which may be rivers modified for navigation. Legally the word 'river' usually includes all natural streams however small, which have a definite and permanent course. Within each drainage basin, rivers and river channels are the surface expression of the way in which water from precipitation proceeds through the hydrological cycle to oceans, seas, or lakes. In the global hydrological cycle at any one time there is just 0.03 percent of the world's freshwater, or 0.0001 percent of the world's total water, stored in rivers and waterways. The largest river in the world, the Amazon, contributes 13 percent of the total river runoff reaching the oceans annually; the 10 largest world rivers according to their discharge account for more than 26 percent of the freshwater reaching the oceans each year; and the drainage areas or watersheds of the 10 largest rivers of the world occupy 20 percent of the earth's land surface (Leopold 1994).

Rivers are dynamic components of environment because the quantity and the quality of the water alter, and the river channel itself can change position. It is partly because of this dynamic character, but also because of their resource value, that rivers have been managed deliberately by a range of direct and indirect influences so that few world rivers are now completely natural and unmodified, with more than 60 percent of the world's total river flow being regulated. Recorded river modification began as early as 5,000 years ago with the advent of irrigation in the hydraulic civilizations of the Nile and the Indus basins. Subsequently there were many small-scale modifications of rivers for drainage schemes, fish weirs, water mills, navigation, and flotability, but the major control of rivers and river systems came with the Industrial Revolution when rivers were harnessed for industrial mills, power generation, cooling water, extensive irrigation, and water supply schemes. Technological advances in the twentieth century enabled even greater modification of rivers. For example, the impact of dam construction was relatively small until 1900, moderate to 1945, but substantial after the great increase of dam building between 1945 and 1971. Whereas in 1900 there were 427 dams higher than 15 m around the world, this increased to 5,268 in 1950 and to 39,000 in 1986 (ICOLD 1988). Building continues, for example, on the Qingjiang River, a tributary of the Yangtse, a large dam is planned for completion in 2009 at the same time as the Three Gorges dam in China. For the most part, however, the era of dam building came to an end in the developed world by the late 1980s and has been succeeded by the retirement of some dams.

Dam construction and engineering modification of waterways dominating the past 2 centuries followed from a 'technological fix' vision of the environment and its resources. More recently, conservation of rivers and waterways has become dominant, as has protection of the landscape more broadly to meet the needs of the present without compromising the opportunity for future generations (Newson 1992). This shift in management approach is illustrated by five themes pertinent to conservation of waterways.

1. *Waterway Conservation*

1.1 The Need to Control the Quantity of Water in River Channels

The growth of human populations and changes in land use adjacent to rivers and waterways increases floods and flood damage from storm events. Increasingly, therefore, river management necessitates not only the modification of river channels to convey a design flow or calculated discharge of water, but consideration of a range of complementary strategies including flood control schemes, land-use zoning, and choice between big or small dams to retain flood waters according to the nature of the physical environment. Despite increased expenditure on flood control and greater understanding of the methods for flood assessment and mitigation, an increase in losses often follows flood events because of the assumption that the implemented scheme guarantees no flood damage (Smith and Ward 1998). A flood prevention scheme is designed for events of a certain magnitude and recurrence interval. Events of a larger magnitude or more frequent occurrence than the design are not uncommon. In addition, design usually considers maintenance of low flows to minimize the effects of drought upon water supply and river uses, such as fishing and recreation.

1.2 The Need to Control the Quality of River Water

Waterways initially were seen as arteries to be used for disposal of waste products of society. The magnitude of waste has grown so large, however, that successive legislation has demanded more controls, to minimize the effects of serious levels of water pollution. Particular problems arise from point sources of pollution released into a river at an identifiable location, especially from wastewater treatment systems, industrial plants, agricultural pollution, and mining operations (National Research Council 1999). The culmination of such controls, for example, has witnessed the return of salmon to the Thames and Tyne rivers in the UK. Pollution is not always an easy problem to resolve because of the way in which pollutants relate to the sediment in the river channel. In northern New Mexico, for example, plutonium released from Los Alamos Laboratory on to nearby canyon floors was attached to sedimentary particles and in subsequent decades some of the sediments and the plutonium removed to the Rio Grande river raised concerns about environment and health hazards (Graf 1994).

1.3 The Need to Manage River Channels

River channelization involves modification, usually by engineering methods, for the purposes of flood control, drainage, navigation, and prevention of erosion. Direct channelization by engineering methods including straightening and reinforcing the bed and banks, led to the modification of the majority of lowland rivers in Europe over the past 2,000 years (Brookes and Shields 1996). Extension of channelization in the United States produced unwelcome consequences so that alternative schemes of river channel management were sought, including river restoration conceived as 'working with the river rather than against it.' Many river channels are now being restored to appear as 'natural' as possible and it is not unknown for rivers

which were straightened by engineering to be 'restored' to their original meandering form. The difficulty in such restoration is to prescribe such dimensions of the restored channel as will enable the channel to contain flows likely to be very different in character from those existing before engineering channelization (Brookes and Shields 1996).

1.4 The Need to Acknowledge that River Restoration Involves More than Returning a River Channel to its Original Condition

The dynamic nature of the river channel must be considered, aided by identifying and conserving areas with special features as exemplars of typical waterways and also by educating the public about natural riverscapes. Restoration requires that river channels are managed with an awareness of the way in which they change and develop: the dynamic river must be seen against a timescale when there may have been considerable changes in palaeohydrology (Gregory et al. 1995). Consideration of what is natural is required because public perception does not always correspond with reality, especially in forested areas where woody debris is normal in river channels but public perception tends to prefer debris-free channels. Conserved areas provide an important reference designated as SSIs or sites of special scientific interest in the UK (Gregory 1997). In the US, the National Park Service (NPS) maintains high quality recreational areas and facilities, which include rivers and river access, through the 'Rivers, Trails, and Conservation Program' of the Department of the Interior. As societies move into post industrial stages, social values for rivers are changing from rivers as water resources to more complex multipurpose ecosystems or landscapes that potentially serve many objectives (Graf 1996).

1.5 The Need to Manage Rivers and Waterways Holistically Within the Drainage Basin

This need arose with the appreciation that river management in one area may have effects in other parts of the basin so that schemes of Integrated Basin Management (IBM) were devised. The modern development of water resource systems proceeded from single purpose projects through multipurpose schemes towards more integrated river basin planning. Important in progress towards more integrated planning was the development of the Tennessee Valley Authority (TVA), created as an independent federal agency from 1933 (National Research Council 1999). In order to achieve the two original primary purposes of flood control and navigation development, the Tennessee River and its tributaries were developed into one of the most controlled river systems in the world. Electric power is generated at the center of a suite of projects including navigational improvements and flood controls on the Tennessee River proper and soil erosion control, reforestation, improvement in agricultural land use, and increased and diversified industrial development elsewhere in the watershed. The TVA blazed the trail of integrated basin management. Downs et al. (1991), however, advocate distinguishing comprehensive river basin development where several components are involved, from integrated basin management where schemes interact, and from holistic management which dynamically incorporates energetics, change, and human interactions. The need to integrate consideration of ecological, as well as morphological and hydrological aspects, within a dynamic approach to river management and conservation, can be accomplished within an overall integrated approach. A new strategy for watershed management has been advocated in the US with drainage basins or watersheds as the basis for planning and management (NRC 1999).

Waterways which were once seen as elements of the environment to be conquered and tamed, are now seen as integral parts of dynamic evolving systems to be treated in a way that is sustainable and to be enjoyed and appreciated by future generations. A holistic view of rivers and waterways within the basin is the best basis for conservation, but sustainable management requires water users to make choices that cannot be made solely on the basis of scientific evidence, in part because the results of science may be ambiguous at times. In addition to scientific evidence, sustainable watershed management requires community understanding and support. Therefore, IBM depends on partnerships between governments and the public, across disciplines and international borders, and among water users with different interests and values (Heathcote 1998). Paradoxically, as greater emphasis is placed on holistic approaches, the systems managed have been increasingly fragmented by human activity, for example into reaches controlled by dams with each reach exhibiting behaviour that can be markedly different from that of nearby reaches (Graf 1996). A further consideration necessary in relation to conservation is appreciation that rivers and waterways are valued in different ways by different cultures.

Conservation: Wetlands

Wetlands is a generic name given to all types of terrain where land and water mix, and which share some of the characteristics of both. They include bogs, fens, levels, mangroves, marshes, mires, peatlands, potholes, pocosins, sloughs, swamps, river bottom lands, tidal flats, wet meadows, and wet prairies.

Wetlands cover about 7.8×10^6 km^2, or 6 percent of the world's surface, and are found in every climatic zone from the tundra mires to the tropical mangroves. They are highly fragmented and diverse, and with only a few exceptions (e.g., the Everglades, the Fenland, the Dutch polders, and major river deltas and lower valley bottoms) they rarely cover large stretches of land. Their diversity has been simplified and commonalities emphasized into the marine and estuarine wetlands of the coast, and the riverine, lacustrine, and palustrine of the interior (Cowardin et al. 1985, National Research Council 1995).

The need to conserve wetlands arises from their continuous and increasing conversion and loss. In the past, wetlands were considered wastelands, neither sound land nor good water, and therefore drained for agriculture, dredged-out for harbors or marinas, filled-in for urban or industrial purposes, or used as dumps for domestic and industrial waste. Conversion reached high proportions from c.1830 to 1960, when modern earthmoving machinery made excavation easy, steam (and later diesel and electrical) pumps lifted vast quantities of water over embankments, and the mass manufacture of clay tile drains and pipes made boggy ground firm. It is difficult to give precise figures as the process of the manipulation of hydrology is at least pre-Medieval in Europe (Darby 1983, Lambert 1985) and Asia (Ruddle 1987), and equally as ancient in the Americas (Denevan 1992). It is also difficult to define 'drained'—is it totally dry, flooded for a month, seasonally, or what? But of the estimated 1606×10^6 ha of land drained globally, 42 percent is in North America, 24 percent in Europe, 8 percent in Russia, and 20 percent in the South East Asian deltas, which leaves an infinitesimal amount of 6 percent in Africa and South America. Large as it is, however, it is still a mere fifth of the global total, the great bulk of which lies in the tundra wetlands, and to a lesser degree in the temperate coastal marshes and the tropical lowlands of the Amazon and Congo basins.

But since the early 1960s the beneficial, positive values of these productive ecosystems have been recognized increasingly. For example, their hydrological/physical functions include flood mitigation, coastal protection, recharging aquifers, and sediment trapping. Chemical functions include pollution trapping, removal of toxic residues, and waste recycling, while biological functions include biomass production and wildlife habitats. The socioeconomic consumptive benefits include food production, fuel from organic soils, fiber from hardwood forests, mangroves and reed swamps, and everywhere fish, fowl and fauna. But, perhaps above all else, it is the hard-to-quantify nonconsumptive benefits that have dominated the urge to conserve, and these include scenic, recreational, educational, aesthetic, archaeological, scientific, heritage, and historical benefits that abound in an environment where air, land, and water, and their fauna and flora, meet in an attractive and delicate way that has caught scientific and popular imagination.

Regret at the loss of game after reclamation was more than outweighed by pride in the creation of productive agricultural landscapes. Yet, paradoxically, the first concerted effort towards conservation came in the United States from the hunting lobby, aided by recreational and wildlife enthusiasts, with the active support of the Fish and Wildlife Service (FWS). Under the Migratory Birds Hunting and Conservation Act of 1934 the FWS had the right to sell 'duck stamps' which were purchased by all wildfowl hunters. Between 1934 and 1984 over $250 million was collected, the bulk being used to purchase 970,000 ha of waterfowl habitats, mostly wetland. In addition, the private duck-hunting lobby—'Ducks Unlimited' (with 600,000 members)—has raised funds ($400 million since 1937), and has purchased, created or manages over 100,000 ha of wetlands, and carried out a sustained campaign of lobbying and advertising, which

has been echoed by the Audubon Society and the Nature Conservancy Council.

After about 1960, the loss of wildfowl habitats alone was calculated to be about 121,000 ha/yr. Rising public awareness of their scenic/recreational attractions, and positive natural functions, led to public support for their conservation. Intellectual curiosity about wetlands had also been stimulated by integrated ecological studies, and research centers were established, such as the Center for Wetland Resources at the State University of Louisiana, Baton Rouge, and the Center for Wetlands at Florida University.

In addition, it was realized that the US Army Corps of Engineers (which regulated navigable rivers and coastal waters used in interstate commerce under the River and Harbor Act of 1899) was dredging annually about $300 \times 10^6 m^3$ of sediment out of coastal channels and navigable waterways and then backfilling the material in other wetlands to make land suitable for urban/residential development and marinas.

The federal Coastal Zone Management Act of 1972 allowed all states bordering the ocean and the Great Lakes to apply for federal grants for wetland preservation, provided they adopted strict land use and purchasing regulations. Coastal zone management plans were devised, which either prohibited coastal developments or allowed changes only by special permit (e.g., San Francisco Bay).

In time concern extended to the interior freshwater wetlands as toxic wastes were dumped in swamps, open space near urban areas was lost, and agriculturalists drained and infilled wildlife habitats, which incensed the powerful hunting, fishing and birdwatching lobby. But there was no legislation to control loss, although the regulation of water quality was possible.

Meanwhile in 1972, the Corps of Engineers was made responsible for regulating the discharge of dredged material under Section 404 of the Federal Water Pollution Control Act. Environmentalists argued that this implied total wetland protection, an interpretation resisted by the Corps, which argued that its responsibility did not extend to the headwaters of rivers where many wetlands were situated. Nevertheless, after legal action by environmental groups, the responsibility had to be admitted, and the Act was strengthened in 1977 (now called the Clean Water Act). From now on 'all the waters of the United States' were included, which was a legal and not a scientific concept. In addition, schemes for coastal and river alteration by the Corps could only occur after review and approved by the Environmental Protection Agency (EPA), the FWS and the National Marine Fisheries Service (NMFS), the EPA having an absolute veto over the use of any sites to be used for the dumping of dredged material.

Executive Order 11990 of 1977 required every federal agency 'to minimize the destruction, loss, or degradation of wetlands' by avoiding support of any new construction in wetlands. But coordination between agencies is poor and responsibility divided. The Corps, for example, is responsible only for those waters affected by interstate commerce, which excludes much of the coastal and nearly all inland waters. In addition, while it cannot dump dredged material in those wetlands it does control, it cannot regulate their reclamation. This explains the current massive conversion of the Mississippi River bottomlands, stimulated by the impetus of high crop prices.

It is clear too, that some federal policies, e.g., legislation dealing with agricultural tax credits, subsidies, and soil conservation has actually encouraged wetland destruction. Since 1985, however, the Food Security Act (under its 'Swampbuster' provisions), linked eligibility of farm subsidy benefits directly with what farmers did with their wetlands, preservation being rewarded and conversion being penalized. In addition, farm debts could be exchanged for conversion of land back to wetland. Increasingly, the link between the financial encouragement of agriculture and the destruction of wetlands is being realized.

Thus, although greater awareness of wetland protection is coming about, losses are still occurring. Annually, about 20,200 ha of coastal wetlands are still being converted, but over 100,000 ha in the unregulated inland wetlands, primarily for agriculture. The battle is far from won. Success will not come until the traditional approach to protection via either land use or water quality legislation is abandoned. Neither of these recognizes that it is the combination of land and water that is the unique characteristic of wetlands.

Compared to the United States, where wetlands have 'achieved divine status' (Kwong 1998), the same degree of awareness and concern about wetland loss, and hence protection, has not characterized the countries of Europe. Fragmentation of political units, the lack of a politically powerful or numerous hunting lobby, broadly 'rural' as opposed to environmental concerns, and the overwhelming dominance of food production and self-sufficiency as national goals, supported particularly by the Common Agricultural Policy of the European Union, have been the overwhelming characteristics of rural policy. Furthermore, a common awareness that centuries, if not millennia, of human manipulation have altered the European countryside and its soils, hydrology, and flora to its present state have been a corrective to any excessively sentimental notions of a 'pristine' nature.

Agricultural draining accounts for the bulk of the possible 300,000 ha lost annually, and there is now considerable awareness of the need to conserve the last remaining pieces of wetland. Most large-scale conversions, as in the Fens and Holland, are over, and it is tile draining that is nibbling away at the edges of the remaining freshwater wetlands, the filling-in of farm ponds that are perceived as redundant, and the draining of small areas of coastal salt marshes. But some coastal areas are under threat, e.g., around

Brittany and adjacent coasts that total over 500,000 ha, the Camargue and Etangs de Languedoc-Rousillon (170,000 ha) on the Mediterranean, the latter already radically altered in places by tourist development and marinas. Another unknown is the fate of the Shannon estuary in The Republic of Ireland, where large-scale industrial developments are proposed. In Ireland over 100,000 ha of peat bogs have been drained and water tables lowered prior to peat extraction, and the lowland raised bogs of Ireland and western Scotland have been severely reduced by afforestation schemes.

Actual losses are difficult to quantify because of fugitive and fragmentary sources. In total, perhaps as much as 615,135 ha were drained in France (5.2 per cent of the country) between 1970 and 1982 alone, and probably as much as 1,418,000 ha of Ireland (24.3 per cent of the country) between 1945 and 1980, of which nearly four-fifths was field drainage. In total, perhaps as much as half of the lowland fens and mires in France and the United Kingdom have been destroyed or damaged. Another measure of change is the number of species endangered or threatened. For example, 47 percent of all European bird species, all 111 of European Union breeding species of reptiles and amphibians, and 2,000 plant species are in decline.

Preservationist measures must be directed at the main culprit, agriculture and its support. In the past, CAP payments have provided generous subsidies for 'improvement' to boost production, particularly in the Less Favoured Areas which include, for example, the wetlands of western Ireland, the Islands and Highlands of Scotland, and parts of Mediterranean France and Italy. In addition support for farm improvement has been accompanied by support for prices. But since the later 1980s gross over-production, high storage costs of surpluses, adverse public opinion, and the drain that the CAP is having on the Community's finances has caused a reevaluation. Milk and food production quotas, set-aside schemes, reflooding to recreate wetlands, have all been undertaken. More significantly, the recognition of the unique fauna and flora in wetlands, and their place in the intercontinental migratory flight paths has led to their declaration as Sites of Special Scientific Interest (SSSI) in Britain, or Environmentally Sensitive Areas (ESAs) there and elsewhere throughout the EU. Birds, newts, and unusual plants are becoming the key to their preservation in a newly environmentally conscious society.

The complex infrastructure of legislation, legal precedent, scientific knowledge and active conservation groups has little counterpart in the less developed world. The need to expand food production in line with rising population have always made wetlands attractive potential farmland. In the past, at least 45,000 km^2 of the Sundarbans of the Ganges–Brahmaputra delta, and the Irrawaddy, Chao Phraya, and Mekong deltas have been transformed by millions of peasant settlers, and are only the most visible examples of a much greater process continuously at work along the entire coastline of South and Southeast Asia (Richards 1991). In more recent decades, foreign technological aid and capital inputs (especially large multi-purpose dams, barrages, canals, etc.) have often misjudged the physical capabilities and properties of wetlands. They have also ignored the traditional, indigenous, polycultural systems of agriculture–livestock–aquaculture which are sustainable, low energy-using, and frequently offer better returns than agricultural conversion. Large-scale schemes like the Kafue Gorge dam in Zambia, and the Jonglei canal across a bend in the Upper Nile, Sudan, have been highly controversial, and it is doubtful if their benefits have outweighed those of the systems they destroyed. The diseconomies of rapidly initiated and capital-intensive schemes are not confined to Western intervention. The government-sponsored transmigration schemes of Indonesia to move millions of farmers from Java to the outer islands will affect c. 200,000 km^2 of coastal wetlands. But soils are frequently nutrient-deficient, dry out too rapidly and shrink, and will not sustain the hoped-for intensive double cropping of rice. Rather, they need polycultural horticulture, planted with great sensitivity to local conditions.

Many interior wetlands are threatened in tropical Africa and South America, as are coastal tidal peats and mangroves in South and Southeast Asia. For example, in Africa there are some 224,000 km^2 of lightly used riverine flats (mostly papyrus marsh that seasonal flooding almost doubles in size) along the Nile, Niger, Zaire, and Zambesi rivers, as well as the Okavango basin. Similarly vulnerable are the floodable Gran Panatal on the upper reaches of the Rio Paraquai (c.100,000 km^2) and the flood plains of the Apure–Aranca tributaries of the Orinoco in Venezuela (c.70,000 km^2). The wetlands of the Amazon are incalculable.

Finally, the impetus to international cooperation over the conservation of wetlands has come once more through the preservation of wildfowl habitats, the one positive function that all parties can perceive, appreciate and agree upon. The Ramsar convention (1971) aims to protect Wetlands of International Importance, specifically for birds, and in 1980 the Cagliari conference widened the definition to include any endangered plant or animal species. An inventory is being compiled and maintained by the IUCN at the International Monitoring Center in Switzerland. These agreements have had some striking successes in preventing conversions in Italy, the Wadden Sea, and Pakistan, but equally they have limitations and are only as good as the compliance of the countries that sign-up to them, which currently is about only half the countries of the world.

Conservatism: Historical Aspects

1. Approaches to the Problem

An intuitive procedure for defining conservatism is to begin by listing the institutions which conservatives have sought to conserve. That will not get us very far, for conservatives have, at one time and place or another, defended a wide range of social, political, and economic institutions.

The study of conservatism has proved difficult for modern social science. Compared with the other great ideological phenomena of the last two centuries, such as liberalism, socialism, communism or fascism, the subject of conservatism is underilluminated by scholarship. One reason is because of the difficulty of arriving at meaningful generalizations about conservatism, which displays less obvious uniformity across national borders and tends to be more nationally particular than liberalism or socialism, which aspire to be universal in their reach. Moreover, since conservatism emphasizes the need for institutional and symbolic continuity with the particular past, its symbols and institutional ideals tend to be more tied to specific, usually national, contexts. For all of these reasons, studies of conservatism which go beyond one particular national context are scarce; as a result, conceptions of conservatism have tended to be parochial.

One of the earliest social scientific approaches to the issue was formulated by the Hungarian–German sociologist, Karl Mannheim, in his essay *Conservative Thought* (1927). He introduced the important distinction between traditionalism and conservatism, the former a near-universal psychological propensity to do things as they have traditionally been done, the latter an articulated set of inter-related political ideas, an ideology which arose, Mannheim thought, in response to the new and dynamic historical processes associated with the Enlightenment (see *Enlightenment*), capitalist modernization (see *Capitalism* and the bourgeois class (see *Bourgeoisie/Middle Classes, History of*. A pioneer of the sociology of knowledge, Mannheim claimed that conservative thought was linked to a worldview which could be correlated with class position, roughly that of the feudal nobility. The basic categories of each ideology, he maintained, were unconsciously determined by the experience of the world and the self-interest of the class which developed it. In the case of conservatism, it led to a focus on experience and the concrete, as opposed to universalistic, rationalistic theories of liberalism and the Enlightenment. Conservatives offered a critique of the rationalistic conceptions for reorganizing society proposed by advocates of radical reform, and focused on explaining the historical particularities of real, existing societies and the interconnectedness of their institutions.

Subsequent social scientific analysts of conservatism, even when they have not followed Mannheim's focus on class, have stressed the reactive nature of conservatism, the fact that it arises in response to a challenge (intellectual, political, or cultural) to existing institutions, on behalf of which conservative arguments are then developed. In one of the most perceptive scholarly analyses of the subject, Samuel Huntington (1957) argued that conservatism is best understood not as an inherent theory in defense of particular classes and institutions, but as a positional ideology. 'When the foundations of society are threatened, the conservative ideology reminds men of

the necessity of some institutions and desirability of the existing ones', Huntington suggested. He claimed that because 'the articulation of conservatism is a response to a specific social situation … The manifestation of conservatism at any one time and place has little connection with its manifestation at any other time and place.'

The reactive nature of conservatism is a premise of one of the finest historical studies of the subject, Klaus Epstein's *The Genesis of German Conservatism* (1966), which pays close attention to political and intellectual context and demonstrates how conservatism arose in German-speaking Europe as a response to the Enlightenment, commercial capitalism, and bourgeois liberalism. Taking the reactive approach a step further, Martin Greiffenhagen (1971), suggested that because self-conscious conservatism only arises once the institutions it values have lost their hold, conservative thought seeks not a preservation of the status quo, but uses an imaginatively transfigured conception of the past with which to criticize the present. According to Greiffenhagen, the romanticization of the past is thus an intrinsic and recurrent element of conservatism.

Two thinkers presented nonreactive conceptions of conservatism during the immediate post-war decade. In *The Conservative Mind* (1953), Russell Kirk, a US conservative man of letters, offered a conception of conservatism as based upon religion and 'belief in a transcendent order, or body of natural law, which rules society as well as conscience'—a conception which assimilated conservatism to religious orthodoxy, and was of scant use as an analytic tool. Kirk's conception was rejected by Michael Oakeshott, the most important British conservative philosopher of the era, in *On Being Conservative* (written 1956 and published in *Rationalism in Politics and Other Essays*, 1962), which presented a brilliant phenomenological description of conservatism as a disposition centered 'upon a propensity … to delight in what is present rather than what was or what may be.' Oakeshott sought to conserve a liberal and pluralist conception of society, and doubted that 'a disposition to be conservative in politics' depended on the religious and metaphysical assumptions set forth by Kirk.

2. *Definition and Characterization*

To understand conservatism as a distinctive mode of social and political thought, it is useful to distinguish it, ideal typically at least, from reaction and from orthodox. The orthodox theoretician defends existing institutions and practices because they are metaphysically true: the truth proclaimed may be based on particular revelation or on natural laws purportedly accessible to all rational men, it may be religious or secular in origin. The conservative defends existing institutions because their very existence creates a presumption that they have served some useful function, because eliminating them may lead to harmful, unintended consequences, or because the veneration which attaches to institutions that have existed over time makes them potentially usable for new purposes.

Conservatism can similarly be distinguished from reaction. The conservative seeks to conserve existing institutions, usually recognizing that the process of conservation may include the need for evolutionary reform. The reactionary, by contrast, is at odds with existing institutions, and seeks to return to some institutional status quo ante, often in a form transfigured by memory and ideology.

As misleading as the confusion between conservatism and orthodoxy is the false dichotomy of conservatism and Enlightenment. Contrary to the frequent characterization of conservatism as the enemy of the Enlightenment, it is more historically accurate to say that there were many currents within the Enlightenment, and some of them were conservative. Indeed, conservatism as a distinct mode of thought is a product of the Enlightenment. What makes social and political arguments conservative as opposed to orthodox is that the critique of liberal or progressive arguments takes place on the enlightened grounds of the search for human happiness, based on the use of reason.

3. *Characteristics of Conservative Thought*

Conservative theorists repeatedly decry the application to society and politics of a mode of thought which they characterize as overly abstract, rationalistic, and cut off from experience. Whether termed 'the abuse of reason' (by Burke 1790), 'rationalism in politics' (by Oakeshott 1962) or 'constructivism' (by Hayek), the recurrent conservative accusation against liberal and radical thought is that they are said to depend upon a systematic, deductivist, universalistic form of reasoning which fails to account for the complexity and peculiarity of the actual institutions they seek to transform.

For conservatives, the historical survival of an institution or practice—be it marriage, monarchy, or the market—creates a *prima facie* case that it has served some human need. The conservative emphasis on 'experience' is linked to the assumption that the historical survival of an institution or practice is evidence of its fitness in serving human needs. Since custom and habit are important features of human conduct, some of the usefulness of a practice comes from the fact that those engaged in it are already 'used' to it, and are apt to be discomfited by change.

Conservative thought has typically emphasized the imperfection of the individual, an imperfection at once biological, emotional and cognitive. Conservatives typically contend that human moral imperfection leads men to act badly when they act upon their uncontrolled impulses, and that they require the

restraints and constraints imposed by institutions as a limit upon subjective impulse. Conservatives, thus, are skeptical of attempts at 'liberation'. Conservatives have also stressed the cognitive element of human imperfection, insisting upon the limits of human knowledge, especially of the social and political world. They warn that society is too complex to lend itself to theoretical simplification, and that this fact must temper all plans for institutional innovation.

These assumptions explain the emphasis of conservative social and political thought upon institutions, that is, patterned social formations with their own rules, norms, rewards and sanctions. While liberals typically view with suspicion the restraints and penalties imposed upon the individual by institutions, conservatives are disposed to protect the authority and legitimacy of existing institutions because they believe human society cannot flourish without them. Unlike liberals, who favor voluntary, contractual social relations, conservatives emphasize the ongoing importance of nonvoluntary duties, obligations, and allegiances.

While there is no necessary link between conservatism and religious belief, conservatives have tended to affirm the social utility of religion. They make several arguments for the utility of religion: that it legitimates the state; that the hope of future reward offers men solace for the trials of their earthly existence and thus helps to diffuse current discontent which might disrupt the social order; and that belief in ultimate reward and punishment leads men to act morally by giving them an incentive to do so.

Conservatives typically emphasize the unanticipated negative consequences of deliberate social action. Such negative consequences, they argue, occur because reformers are unaware of the latent functions of existing practices and institutions. Reformers are insufficiently cognizant, it is said, of the contribution of the practice to the preservation or adaptation of the larger social system in which it is implicated. That contribution may be unintended by those engaged in the practice, so that its function may be unrecognized, or recognized only retrospectively, once the reform of the practice has brought about negative unintended consequences.

Together, the concepts of unanticipated negative consequences, latent functions, and functional interdependence serve as recurrent arguments against radical or wholesale reform, though not against reform as such.

Recurrent substantive themes of conservative social and political thought include:

(a) a skepticism regarding the efficacy of written constitutions, as opposed to the informal, subpolitical, and inherited norms and mores of society. For conservatives, the real 'constitution' of society lies in its historical institutions and practices, which are inculcated primarily through custom and habit;

(b) the central role of cultural manners and mores in shaping character and restraining the passions, and hence the political importance of the social institutions in which such manners and mores are conveyed;

(c) an emphasis on the family as the most important institution of socialization, and despite considerable divergence among conservatives over the proper roles of men and women within the family, the assertion that some degree of sexual division of labor is both inevitable and desirable;

(d) the legitimacy of inequality, and the need for elites, cultural, political, and economic; security of possession of property as a prime function of the political order;

(e) and the importance of the state as the ultimate guarantor of property and the rule of law, and hence the need to maintain political authority.

4. *Historical Overview*

Terms related to 'conservative' first found their way into political discourse in the title of a French weekly journal, *Le Conservateur* founded in 1818 by François-René de Chateaubriand with the aid of Louis de Bonald. 'The *Conservateur* upholds religion, the King, liberty, the Charter and respectable people (*les honnêtes gens*)', it proclaimed in its first issue. In England, the label 'Conservative Party' was first applied to the Tories by the publicist John Wilson Crocker in 1830. In Germany, the term 'conservative' came into use later in the same decade: it was first employed as an epithet against those designated as conservative, who were accused of seeking to preserve existing institutions at any price, but the term was eventually accepted by those it had been used to stigmatize. But as with many other historical developments, the phenomenon of conservatism long preceded the use of the term in political life.

The precursors of conservatism may be found in the Anglican critique of the Puritan contention that the elect or the inspired congregation, guided by their individual interpretations of the Bible, were entitled to exercise political authority. The thought of David Hume marks a watershed in the development of conservative social and political thought into a coherent, secular doctrine. Hume began by borrowing and expanding upon this critique of the politics of religious 'enthusiasm'. And he went on to criticize what he saw as its secular counterparts in the philosophically implausible and politically subversive doctrines of natural rights and of voluntary contract as the sole legitimate basis of political obligation. In 1757, Edmund Burke used similar terms to attack what he called the 'abuse of reason' among some enlightened thinkers. On the Continent, conservative social and political thought arose as a critique of the policies of enlightened absolutism. Among the foremost practitioners of this criticism was Justus Möser, himself a part of the German Enlightenment, and a

reformer of a conservative and corporatist tinge. In Holland, another Enlightenment figure, Jean de Luzac, articulated politically conservative arguments opposing the claims of 'patriots' for a more democratic constitution. The contention that conservatism arose in opposition to the Enlightenment and to the French Revolution reflects Edmund Burke's polemical characterization of the Enlightenment in his critique of the French Revolution. Though frequently reiterated, the contention is historically untenable. Conservatism arose not against the Enlightenment but within it. Much of post-1789 intellectual conservatism is continuous with the analytic strategies, if not with the tone, of pre-revolutionary conservative analysis.

It was the democratic radicalism of the French Revolution that evoked Burke's *Reflections on the Revolution in France* (1790), which became the most influential work in the history of conservative thought. Joseph de Maistre (1753–1821) and Louis Gabriel de Bonald (1754–1840) were the two leading figures in the tradition of French counter-revolutionary thought. The task with which they saw themselves confronted was rather different than the one that had motivated Burke's *Reflections*, and the nature of their conservatism varied accordingly. Burke's primary task was to conserve a British order which was substantially intact, though subject to intellectual attack. He could thus stress the historical utilitarian arguments that the existence of an institution creates a *prima facie* case that it has served some human need, and that historical continuity is intrinsically valuable because it increases the emotional hold of an institution upon its members. Similarly, Burke could underscore the importance of habit and custom. By the time de Bonald and de Maistre came to write their major works, the forces of the French Revolution had already overturned or transformed many of the key institutions of the Old Regime. The Counter-Revolutionary conservatives, therefore, were forced by circumstances to offer a rationale other than that of historical continuity, for the institutions of the old regime had been disrupted by the Revolution. De Maistre responded to the revolution by carrying to new lengths previous conservative arguments of epistemological modesty, historical particularism, and the unanticipated consequences of deliberate action.

Burke's defense of monarchy, aristocracy, and the established church stamped European conservative thought at the end of the eighteenth century and in the early decades of the nineteenth. Yet a similar critique of democratic radicalism appears, with a more republican but nevertheless recognizably conservative thrust, in the USA, first in the writings of the US Federalists, and later in the work of conservative Whig critics of Jacksonianism, such as Rufus Choate. Hume's combination of political conservatism with the championing of commerce was to remain characteristic of subsequent British and US conservatism. By contrast, the French, Catholic strains of conservatism of de Bonald and de Maistre, as well as the romantic German strains of conservatism remained less accepting of capitalist economic development than the British and US strains.

The development of conservative social and political thought after the mid-nineteenth century shows a movement from substance to function: from the defense of particular institutions to the defense of institutions in general; from the defense of the landed aristocracy to a defense of elites in general; from an emphasis on the role of the established Church to the function of culture in linking the individual to communal purposes; from monarchical authority to the authority of the state in general. In the last decades of the nineteenth century, conservatism underwent an important shift, reflecting a change in opponents and in institutional substance. The increasing dominance of industrial capitalism, the expansion of the suffrage, the rise of socialist movements and of a new brand of liberalism which was more economically redistributionist and more culturally permissive, all led to a substantial transformation of conservatism. Many of the economic institutions and policies once associated with European liberalism (see *Liberalism*) now became that which conservatives sought to conserve. This new brand of conservatism was pioneered in late nineteenth century Britain, and is reflected in the works of James Fitzjames Stephen and W. H. Mallock and by the US theorist, William Graham Sumner.

The rhetoric by means of which institutions were defended also changed. It placed less emphasis on the veneration of tradition as such, while seeking to increase the emotional hold of existing institutions by showing that they were in accord with the needs of historical development. In England and the USA, the language of common law and of inherited tradition was increasingly abandoned in favor of the language of science. The justification of the social utility of landed elites was replaced by a more general defense of the need for elites in the realms of economics and politics, while the defense of the established Church was transformed into a defense of cultural elites. In Germany, too, the substance of conservatism was transformed, from a defense of aristocracy, a social order based on fixed estates, and paternalist monarchism, toward an emphasis on the functions of the state as such, a transformation exemplified in the work of the twentieth century German theorist, Carl Schmitt.

One recurrent strand of thought which is related to conservatism, yet politically and analytically distinct from it, is radical conservatism, a strand particularly powerful in inter-war Europe, where its adherents often came to favor fascist regimes (see *National Socialism and Fascism*). Radical conservatives share some of the concerns of more conventional conservatism, such as the need for institutional authority and continuity with the past. But they maintain that the processes characteristic of modernity have

destroyed the valuable legacy of the past for the present, so that a restoration of the purported virtues of the past demands radical or revolutionary action. Hence the credo of one radical conservative, Moeller van den Bruck, that 'Conservative means creating things that are worth conserving.' Radical conservatism shares with conservatism an emphasis on the role of institutions in providing restraint and direction to the individual, but seeks to create new institutions which will exert a far stronger hold on the individual than do existing ones, which because of their relative tolerance are perceived by radical conservatives as 'decayed.'

After the defeat and discrediting of fascism, conservatism in the latter half of the twentieth century was defined not only by its opposition to communism, but by antipathy to the spread of the welfare state and attempts to bring about economic redistribution, and by skepticism regarding the solution of social problems through massive governmental action.

The study of conservative movements and conservative ideology provide an ongoing challenge to social scientists. For they must provide analyses of a phenomenon which is dynamic and changes over time, which varies between nations and often between regions within nations, and which often appears in combination with a variety of other trends (religious, nationalist) and under a variety of nomenclatures. These difficulties—together with the political predilections of the majority of social scientists, who tend to be antipathetic to conservatism—have led to a gap between the historical significance of conservatism and the extent of its exploration by scholars. This is lamentable, for not only have more-or-less conservative parties dominated western European and US politics for substantial portions of the last two centuries, but conservative thinkers have played a leading role in the development of modern thought.

Conservatism: Theory and Contemporary Political Ideology

1. Definition

An initial problem that arises in attempting to define conservatism is whether it is a theory or simply an attitude towards change. Most dictionary definitions incline toward the attitudinal definition, describing conservatism as a preference for existing institutions, and opposition to change. With this definition the content of conservatism will vary depending on whatever is the current institutional and ideological status quo. Yet the writers, parties, and movements that have described themselves as conservative share a number of common values and doctrines, which typically include theories of human nature, history, society, and politics.

The term 'conservatism' was first used in England after the 1833 Reform Act when the Tory Party, which had roots going back to the late seventeenth century, renamed itself the Conservative Party. The central doctrines of conservatism were expressed before the word was invented, most notably in Edmund Burke's

Reflections on the Revolution in France (1790), where we can find most of the central doctrines of conservatism, developed in response to the liberal and radical thinking of the French revolutionaries. In opposition to their demand for liberty, Burke stressed the values of order, tradition, and gradual change. Against the revolutionaries' call for equality, Burke stressed society's need for hierarchy, deference, class differentials, and a special position for the church and the nobility. In opposition to the radical individualism of the French, he insisted on the importance of community, tradition, and history. He criticized the antiinstitutional rationalism of the revolutionaries by stressing the importance of social institutions that have stood the test of time, and the weakness and fallibility of individual reason. Against their centralizing statism, he lauded the 'little platoons' of localism as defenders of liberty, and contrary to their anticlericalism, he praised the elevating effect of inherited religious beliefs.

In developing these ideas Burke was able to draw on the Western tradition, classical ideas of natural law, Christian views of hierarchy and man's inherited inclination to evil, as well as medieval practices of localism and organic corporate groups. Although himself an adherent of the Whig Party, his ideas were influential not only on the thinking of the British Conservative Party, but on conservative parties and movements elsewhere in Europe, and later in the United States. As originally expressed, their emphasis on order over freedom, hierarchy over equality, religion over anticlericalism, localism over centralism, and community over the individual stood in marked contrast to the liberal doctrines that they criticized.

2. *European Conservatism*

In the political struggles of nineteenth and twentieth centuries, European conservative parties drew on the conservative tradition to defend the interests of property, the upper classes, the military, and the church, and appealed to nationalist and patriotic feelings in support of their programs. Their efforts were not restricted to the defense of class and privilege. In 1867, hoping to secure lower class support for 'tory democracy,' Benjamin Disraeli, the Conservative Prime Minister in England, extended the suffrage. Otto von Bismarck initiated a program of social insurance in Germany to counteract socialist appeals; and Pope Leo XIII in his 1891 encyclical, *Rerum Novarum*, defended the living wage for the worker, and promoted the organization of trade unions (preferably under church auspices) while denouncing the extremes of liberalism and socialism. Less laudably, conservative parties in Germany, Austria, and elsewhere, in the twentieth century, sometimes allied themselves with or supported extreme rightists and even fascists and Nazis, seeing them as a bulwark against Communism. Hitler, for example, was able to come to power legally because of the votes of German conservatives.

The conservative impulse continues to be important in European politics. Since the 1833 Reform Act the British Conservative Party has been in power much longer than any other party. On the continent Christian Democratic centrist parties often work together with conservative groupings, linked by their commitment to religion, and to a 'social market economy.' Twentieth-century conservatives, despite earlier hostility to market forces, have increasingly embraced free enterprise economics. They have been critical of European economic and political integration on nationalist grounds. Nationalist resistance to foreign immigration also accounts for some of the support for conservative parties and movements.

3. *Conservatism in America*

In *The Liberal Tradition in America*, published in 1955, Louis Hartz argued that with the exception of a few Southerners, notably John C. Calhoun, Americans were all Lockean liberals, and that European-style conservatism was absent from the American political scene (Hartz 1955). Ironically at the very time that his book was published, a genuine and self-conscious conservative movement had begun to emerge on the American scene. Russell Kirk had published *The Conservative Mind* (Kirk 1953) arguing that Burke rather than Locke should be the model for America. At the University of Chicago, the German émigré political theorist, Leo Strauss, published *Natural Right and History* (Strauss 1953), which attacked Locke as a proto-Hobbesian and denigrated the natural-rights tradition in favor of classical models of politics, especially that of Plato. Another émigré, Erich Voegelin, appeared on the cover of *Time* magazine after he published *The New Science of Politics*—in which he associated communism, liberalism, and revolutionism with a Christian heresy, gnosticism, that attempted to establish heaven on earth (Voegelin 1952). Whittaker Chambers, who had accused Alger Hiss of spying for the Soviet Union, also linked Communism and liberal utopianism in his book, *Witness* (Chambers 1952). In 1955 William Buckley, the *enfant terrible* who had earlier published *God and Man at Yale*, an attack on the dominance of secular and leftist views at his *alma mater*, founded *The National Review* as a journal to promote conservative political and economic thought. Combining militant anti-Communism, the defense of traditional values, and the promotion of free enterprise economics, it became the principal organ of the conservative movement in America.

Together these publications formed the intellectual basis of the conservative movement in mid-twentieth-century America. As in the case of William Buckley, their conservatism was also linked to free-enterprise

economics, as defended in the writings of two University of Chicago economists, Friedrich Hayek and Milton Friedman. In *The Road to Serfdom* (Hayek 1944) and later works, Hayek argued that the growth of government threatened liberty and stifled the economy, while Friedman's 1955 lectures, published as *Capitalism and Freedom* (Friedman 1962) developed similar themes, as well as making innovative proposals to increase competition and privatize government functions, many of which were adopted in later decades. Their arguments were based on classical economic liberalism, but in the American context the two economists were viewed as conservative since they defended the existing capitalist system. In addition, their common hostility to Communism linked them to the social and political conservatives in the newly burgeoning movement.

The conservative movement became a major factor in national politics with the presidential candidacy of Barry Goldwater in 1964. After Goldwater's defeat, Ronald Reagan became the movement's leader. Promising to revitalize national defense against the Soviet Union, restore moral values, and downsize the welfare state and reduce the scope of the federal government, he led the conservative wing of the Republican party to victory in the presidential election of 1980. In the late 1970s, the conservative movement received support from a new group, the Neo-Conservatives, former liberal intellectuals who criticized what they perceived to be liberal weakness in the face of the Communist threat, and rejected the excesses of the New Left counterculture that had emerged in the 1960s (Kristol 1983). They provided key policy makers to the Reagan administration in the areas of defense and education, while the free market economists directed economic policy, cutting taxes and welfare programs.

4. *The Religious Right*

Conservatism in America had often been an elite phenomenon, but the Religious Right gave it a broader populist base. Building on the religious opposition to the Supreme Court decisions outlawing school prayer and recognizing a constitutional right to abortion, conservative churchmen, mostly but not exclusively evangelical Protestants, organized the Moral Majority, and later the Christian Coalition, to reverse what they saw as a liberal tendency to secularism and toleration of immorality. They also shared with other conservatives opposition to the Soviet Union, and a belief in free market economics. In the 1990s, they opposed the gay rights movements, and the increasing toleration of homosexuality in America. They became an important pressure group within the Republican Party, effectively vetoing candidates for national office who favored abortion, and pressing for the appointment of Supreme Court justices who were sympathetic to their views.

5. *Tensions within Conservatism*

American conservatism contains within it many different currents. Ronald Reagan and the Soviet threat could hold its various strands together, but with the end of the Cold War there were increasing tensions among them, in particular as to whether social and moral issues, or downsizing government and encouraging free markets, should be given priority in public policy. Concern about moral decline, a frequent conservative theme (Bennett 1993) and issues such as abortion, gay rights, and public prayer became the subject of *Culture Wars* (Hunter 1991) from local school districts to the Supreme Court.

The members of the Supreme Court, most of them appointed by Republican presidents, became deeply divided along conservative–liberal lines, both as to theories of constitutional interpretation—'original position' vs. 'the living constitution,' federal-state relations—and as to the rights of the individual against those of society. Decisions by a 5–4 majority were frequent, and the question of the ideological sympathies of future Supreme Court appointees was an issue in the 2000 presidential campaign.

6. *The Future of Conservatism*

A line in a Gilbert and Sullivan operetta asserts that 'every little boy and girl alive, is either a liberal or a conservative.' It seems that conservatism, in the sense of a reluctance to make rapid and wholesale change, is related to a continuing need in the human psyche. It also expresses a general set of preferences about politics and society that undergirds the ideology and program of many political parties and movements. While there may be a broad ideological consensus on the values of democracy and market economics, there will continue to be debate about the relation of the individual to society, the respective demands of freedom and order, the extent to which equality is necessary or desirable, the proper allocation of roles to state and non-state actors, and the need for mediating institutions and local self-government. As long as this is the case, a future role for conservativism as a theory and ideology seems assured.

Figure 1
Lijphart's typology of democratic regimes (reproduced with permission of Yale University Press from Lijphart A 1977 *Democracy in Plural Societies: A Comparative Explanation*, p. 106, Fig. 2)

Consociationalism

The term 'consociational' dates back at least to 1603, when the German scholar and statesman Althusius used it to denote a polity consisting of an association of several societies. In modern political science, 'Consociational democracy means government by elite cartel to turn a democracy with a fragmented political culture into a stable democracy' (Lijphart 1969, p. 216). Although this situation has been labeled in a variety of ways ('Politics of Accommodation,' 'Power-sharing,' '*Pacificatie-democratie*' (in Dutch), '*Proporzdemokratie*' or '*Konkordanzdemokratie*' (in German)), consociational democracy (or consociationalism) is the term that is most widely used. Consociationalism is used empirically to explain stable democracy in deeply divided societies, and normatively to prescribe a solution to societies where democracy is at risk because of social segmentation. In this article these two uses are examined in turn, before discussing some of the criticisms passed on the theory.

1. *The Consociational Explanation*

Deep social cleavages, whether they are based on ideology, religion, class, language, or ethnicity, generally are regarded as unfavorable conditions for stable democracy (see *Cleavages: Political*). The risk is limited when cleavages are crosscutting (e.g., when members of a particular ethnic group belong to different social classes), because this is supposed to generate cross pressures which have a moderating effect on social conflicts (see *Cross-pressures: Political*). The risk is greatest when social cleavages coincide and reinforce each other (e.g., when all members of a particular ethnic group belong to one social class, and all members of another ethnic group to another). However, there are democracies that maintain political stability despite coinciding cleavages. In the late 1960s and early 1970s case studies of several such countries revealed a common pattern: social conflict was not moderated by crosscutting cleavages at the mass level, but by cooperation between the social segments at the elite level (e.g., Lehmbruch 1974, Lijphart 1975, Steiner 1974).

By looking at both the mass level and the elite level, a fourfold typology of democratic regimes was developed, as shown in Fig. 1. The situation of a homogeneous society and competing elites is most conducive to stable democracy. The United States and the United Kingdom serve as examples of such 'centripetal democracy.' One might argue that the combination of social homogeneity and elite cooperation guarantees stability even more, but the lack of democratic choice in such a 'depoliticized democracy' is likely to lead to antisystem opposition. The situation that is most dangerous for stable democracy is where society is divided deeply and the leaders of the social segments compete. Classic examples of this 'centrifugal democracy' are Weimar Germany and the French Fourth Republic. Consociational democracy represents the situation in which deep social divisions are prevented from destabilizing democracy by elite cooperation.

The list of countries that are claimed to be or to have been consociational democracies gradually has expanded and now includes Austria (1945–66), Belgium (from 1918), Canada (1840–67), Colombia (1958–74), Cyprus (1960 and 1963), Czechoslovakia (1989–1993), India (1947 to the late 1960s), Lebanon (1943–75 and after 1989), Luxembourg, Malaysia (1955–1969 and since 1971), The Netherlands (1917–67), and Switzerland (since 1943), with contemporary Canada and Israel being classified as semiconsociational. The

European Union has also been described as consociational. As can be seen from the dates, consociationalism has disappeared in many cases, either because it failed (often because of international interference: Lebanon, Cyprus) or because it was so successful in accommodating the social cleavages that it rendered itself superfluous (e.g., in Austria and the Netherlands). Because of the latter cases, consociationalism is sometimes seen as a transitional phase.

Generalizing from such case studies, the theory of consociational democracy has been developed (e.g., Nordlinger 1972, Lijphart 1977). Lijphart's contribution has been so influential that consociationalism often is equated with his work. He distinguishes four characteristics, each of which should be present for a country to be classified as consociational: (a) government by grand coalition (i.e., including representatives of all social segments); (b) segmental autonomy (federal arrangements in case of geographical concentration of subcultures (see *Federalism*), or subcultural autonomy with regard to schools, etc; (c) proportionality in the electoral system (see *Proportional Representation*), but also with regard to civil service appointments, distribution of public funds for schools, etc; and (d) minority veto (sometimes in the form of qualified majority requirements for certain types of legislation).

In a later offshoot of consociationalism, Lijphart elaborated a distinction between majoritarian democracy, which is characterized by 10 institutional features that concentrate power in the hands of the majority, and consensus democracy, which is characterized by an identical number of features that make decision-making as inclusive of all relevant parties or groups as possible (Lijphart 1999). Although the characteristics of consociational democracy are primarily behavioral whereas the characteristics of consensus democracy are largely institutional, and although consociationalism is also defined by the existence of deep social cleavages, both concepts clearly overlap and many consociational democracies are also classified as consensus democracies.

2. *The Consociational Prescription*

Consociational engineering is recommended as the only viable option for deeply divided countries that seek to achieve or maintain stable democracy. The two cases in which this advice appears to have been influential are Northern Ireland and South Africa (for the recommendations in South Africa, see Lijphart 1985). The 1998 Good Friday Agreement in Northern Ireland, which was endorsed by referendums in Northern Ireland and in the Irish Republic, contains several clearly consociational characteristics (dual premiership, a proportional electoral system (STV), requirements for 'parallel consent' in the legislature, etc.). In South Africa, the transition from apartheid (see *Apartheid*) was facilitated by a consociational interim constitution (including a government of national unity and an electoral system of proportional representation), but in the constitution of 1996 few consociational elements remain.

The prescriptive use of consociationalism has sparked a debate on the conditions that are favorable and unfavorable to the successful adoption of a consociational solution. First, it is more likely that elites refrain from intersegmental competition if they perceive the benefits of competition to be outweighed by its costs. This is the case when no social segment has a majority or can entertain any hope of achieving a majority. However, even if one segment has a (near) majority, its leaders may still prefer to share power with the minority if that minority has inflicted casualties or economic damage on the majority or can credibly threaten to do so, or if the minority's support is indispensable to face an external threat (cf. Nordlinger 1972, pp. 42–53). Second, it is more likely that a consociational solution succeeds when followers agree with their leaders' choice of intersegmental cooperation, or when the elites are relatively immune from intrasegmental competition. The latter is the case when elites control the mass media, or when dense networks of subcultural organizations or patron-client networks make it difficult for competitors to challenge the incumbent elites (cf. Nordlinger 1972, pp. 78–87).

Some other factors that are mentioned as favorable to the emergence of consociationalism are less self-evident (social segments of equal size, a small country, geographical concentration of segments, etc.; cf. Lijphart 1985, pp. 119–28). An important remaining question is whether some social cleavages are more amenable to elite accommodation than others. In view of consociationalism's potential for existing deeply divided countries, the question whether ethnic cleavages constitute a favorable or an unfavorable condition is of particular relevance (e.g., Barry 1975, pp. 502–3).

3. *Critiques of Consociationalism*

The central tenet of consociationalism (i.e., that political stability need not be safeguarded by cross-cutting cleavages at the mass level, but can also be maintained by intersegmental elite cooperation) has gone relatively unchallenged. In addition to controversy over favorable and unfavorable factors, most of the criticisms that have been passed on consociationalism are directed at the classification of some countries as consociational democracies, and at the way in which key concepts have been defined and operationalized, in particular by Lijphart (e.g., Barry 1975, Halpern 1986, Lustick 1997. For Lijphart's

reaction to most criticisms raised until then, see Lijphart 1985, pp. 83–117).

The country whose consociational credentials have been called into question most is Switzerland (e.g., Barry 1975). The debate centers on the question whether Swiss society is deeply divided, as religious and class cleavages cross-cut linguistic divisions, and as the linguistic segments had very few ambitions that brought them into conflict with one another.

Such controversies, it is argued, arise from the vagueness and elasticity with which many of the key concepts of consociationalism such as segmentation are defined (e.g., Halpern 1986). For example, one of consociationalism's four characteristics, grand coalition, includes not only all-party governments (as in Switzerland), but also oversized coalitions, all-party advisory commissions, joining forces in a catch-all party (e.g., India's Congress Party), or 'diachronic coalitions' in which power rotates, as in Colombia between 1958 and 1974. These different mechanisms can still be seen as functional equivalents that all facilitate elite cooperation, however. A more important problem is that elites are unlikely to cooperate all the time, on all issues, and in all arenas. Even in consociational democracies, elites tend to compete in elections, for example. Any classification of elite behavior as adversarial or coalescent therefore must rest on an often-impressionistic aggregation of elite behavior across issues and arenas.

Finally, the democratic quality of consociationalism is sometimes impugned because of the predominance of elites and the absence of opposition. From the perspective of democracy as a device to keep elites accountable and responsive to the masses, this is a pertinent criticism. However, in the deeply divided societies for which consociationalism offers a solution, the most salient distinction is not between elites and masses, but between social segments of a more or less ascriptive nature. In that situation democracy may be better served with a relative emphasis on inclusiveness, and in that respect consociational democracy (and consensus democracy) outperforms adversarial or majoritarian democracy.

Constituent Structure: Syntactic

Although we perceive sentences in natural languages such as English, Chinese, Hopi, etc., as mere sequences of words, as in the division of Example (1) into six words, much if not all of language that is of interest involves structure that goes beyond the segmentation of the speech-stream into words. The grouping of words into phrases is called constituent structure.

(1) Old men and women visited Martha.

Constituent structure can be shown to determine the meanings of sentences, for example. Every theory of meaning requires that the account of meaning obeys Frege's Principle of Compositionality (Frege 1952), which states that the meaning of a complex expression is determined by its parts. In this connection, it is noteworthy that the sentence in (1) above is ambiguous, the ambiguity turning on the question of whether the women are old or not. In other words, the sequence *old men and women* has two interpretations, which can be represented with two different structures for the sequence. The two structures can be represented as follows:

(2) Old (men and women) visited Martha.

(3) (Old men) and women visited Martha.

In short, the ambiguity in (1) hinges on whether (a) the conjunction *and* is joining two nouns, the unity of which is modified by the adjective *old*, or (b) the conjunction *and* is joining a noun with an adjective-

plus-noun sequence. The example shows that one cannot specify the meaning of a sentence such as (1) by simply stringing the meanings of the words together. In this sense, natural languages such as English have a great deal in common with most systems of formal logic, which interpret sentences of logic by means of parentheses, which group the 'words' of the logical expression (Allwood et al. 1977). An example shows this for prepositional calculus, the simplest logical language. Beginning logic students are asked to determine the truth of the following expression, simplified here, reflecting different groupings of the logical words:

(4) Not (p or q) is equivalent to (Not p) or q.

Where p and q reflect simple propositions, which can be either true or false.

If two expressions are logically equivalent, they always have the same truth value. To determine whether or not (4) is true, therefore, one must assign p and q all possible combinations of truth values (both true, both false, p true and q false, or p false and q true), and given the semantic rules for *or* and *not*, one sees whether in all four cases, *Not (p or q)* has the same truth value as *(Not p) or q*.

The two sentences do not have the same truth value consistently, indicating that the parentheses, which reflect the grouping of elements, affect the meaning. Natural languages are similar to logical languages, in the sense that the meanings of sentences in both types of language depend on groupings of words—in short, constituent structure. There is a question, however, of whether or not constituent structure in natural language is represented in the same way that it is represented in logic. In logic, when complex sentences are constructed, as in (4), they are constructed in a series of steps, so that *Not (p or q)* is built by first disjoining p and q, and then negating the result. The rules of formation are called the syntactic rules, and hence syntax, in both logic and in natural language, is just the principles of sentence formation, as opposed to semantics, which interprets the results of the syntax. In logic, each syntactic rule is followed by a semantic rule. Hence, when the expression *p or q* is formed, *p or q* is interpreted. When *p or q* as a unit is combined with *Not*, the meaning of *Not* combines with the meaning of *p or q* to determine the meaning of the whole expression *Not (p or q)*. Given that each syntactic rule is followed by a semantic rule, it is unnecessary to actually represent the grouping by means of parentheses in a structure. The process of formation, known as a derivation, is what actually determines the meaning. The parenthesis is simply a way of describing the derivation of this sequence.

An open question, therefore, is whether constituent structure in natural language needs to be represented in an actual structure, or whether the process of forming sentences is enough to determine meanings of sentences. Most linguists assume that constituent structure must be represented by positing structures

for sentences known as phrase-markers, which are usually given as tree diagrams or labeled bracketings. The two tree-diagrams for (1), corresponding to both structures, are given Fig. 1, and they are equivalent to the labeled bracketings in Fig. 2.

A word of explanation is in order. NP stands for n(oun) p(hrase), VP for v(erb) p(hrase), and S for sentence. The diagrams in (7) and (8) are called phrase-markers, which are representations of the structures of sentences.

One piece of evidence for the words of the sentence being grouped has been based on meaning. However, there is evidence from a variety of sources for constituent structure. The approach to linguistics developed in the United States since roughly the 1930s (Bloomfield 1933), known as structuralism, has concentrated on the development of rigorous procedures for isolating and classifying the units of language, such

as grammatical categories. The method for classifying words into grammatical categories is based not on meaning but on distribution. A grammatical category (known from traditional grammar as a part of speech) is defined thus:

(5) A grammatical category is a class of elements whose members are mutually substitutable (i.e., interchangeable without loss of acceptability of the result) in a sufficiently wide range of environments.

So the class of, for instance, nouns is the class of elements that can appear in the environments in which nouns can appear, so that, for instance, *books*, *tables*, *chairs*, *sincerity*, *truth*, etc., can appear in enough of the same slots in a sentence to the exclusion of other words such as *from*, *at*, *and*, and *laugh* to justify putting them into a group, and calling this group nouns. (See *Word Classes and Parts of Speech*.)

The definition of grammatical category given in (5), however, which partitions the set of single words into classes, also defines sequences of words into members of the same grammatical class as single words. To illustrate, consider the underlined spaces in (6):

(6) (a) ____might interest me.
(b) I talked about____.
(c) He likes____.

Just as one can substitute the class of nouns that were exemplified above for one another, so one can substitute, for example *big books*, *the books*, *the big books*, *the big books about Nixon* for the word *books* in all of the environments in (8), as well as many others, leading us to conclude, from the definition of grammatical category given in (7), that the italicized sequences in this paragraph are all members of the same grammatical class as the simple noun *books*. We nevertheless must distinguish between simple members of a grammatical category, such as nouns, and the more developed phrasal instances of these grammatical categories. Hence, we use the term 'noun phrase' for the latter, and the simple term 'noun' for the former.

The same considerations that were illustrated above for noun phrases lead us to establish the other phrasal categories, such as verb phrases, adjective phrases, and prepositional phrases. There are a variety of processes that operate in grammar, which can move or delete linguistic elements. An example of movement is given in (7), and an example of deletion is given in (8):

(7) (a) Though he may laugh, it won't matter.
(b) Laugh though he may, it won't matter.

(8) (a) John laughed, and Bill laughed as well.
(b) John laughed, and Bill did____as well.

The (b) versions of (9) and (10) exemplify the movement and deletion of *laugh*. However, sequences of words can undergo these processes:

(9) (a) Though she may finish her homework, it won't matter.
(b) Finish her homework though she may, it won't matter.

(10) (a) John finished his homework, and Bill finished his homework as well.
(b) John finished his homework, and Bill did____as well.

The sequences of elements that undergo such grammatical processes are those sequences we would want to posit as constituents, so the movement process that is exemplified in (11b) is said to move verb phrases, and the deletion process at work in (12b) deletes verb phrases. For a variety of reasons, one would say that a verb phrase is being moved and deleted in (9b) and (10b), respectively, but the verb phrase is one that consists of a simple verb.

There is also evidence from the study of sentence processing in psycholinguistics for constituent structure. In one experimental paradigm (Fodor and Bever 1965), complex sentences (i.e., sentences with various types of subordinate clauses) are recorded, and clicks are superimposed on the recorded sentences by splicing a tape containing the click into a complex sentence. The location of the click was varied with respect to its location in the sentence, occurring from one syllable away from a clause boundary to a number of syllables away. For example, in sentence (11), the click would occur at various points away from the bolded clause boundary:

(11) John told Susan **that** Sally was hungry.

Experimental subjects always reported the click at the clause boundary, regardless of the click's objective location. These results indicate a salience of a structural point within the sentence as a whole.

While there is thus a great deal of evidence for constituent structure for languages such as English, there is less evidence from other languages, such as Warlpiri, which exhibit free word order (Hale 1983). Such languages are usually informally termed 'free word order' languages, but the term does not denote a totally unified class of languages. Japanese (Saito 1985) and Hindi (Mahajan 1990), for example, allow relatively free word order phrases within simple sentences, but require that phrases occur together. Hence, one finds subjects, objects, and indirect objects occurring in any order relative to one another, but subjects must stay together, as must objects, indirect objects, and indeed any phrasal units. Warlpiri, on the other hand, shows much less cohesion, so that the various parts of what are considered for instance, noun phrases, can be separated from one another by material from outside the noun phrase. The cohesion of noun phrases in Japanese and Hindi provides evidence for constituent structure in these languages, and evidence exists that Japanese has a verb phrase, regardless of the free word order among major constituents (Saito and Hoji 1983). The word-order variation in Japanese and Hindi has been analyzed by Saito and Mahajan, respectively, as arising from movement of the noun phrases from a fixed basic position. It is much more difficult to make this type of analysis for the truly free word order languages such

as Warlpiri. Baker (1995, 2000) has some suggestions. Languages with free word order of this sort have extensive case-marking, which would express the grammatical relations of the various noun phrases, so that the case-markers on what would be in English the parts of the noun phrase would signal the semantic units of Warlpiri sentences without making them constituents in the actual syntax.

Putting aside the question of the best treatment of truly free word order languages, we have seen that although a language is usually described as a set of strings (i.e., sequences of words) that is generated by a grammar, the strings are structured into constituents. Chomsky (1957) introduced the distinction between the weak generative capacity of a grammar, which is the set of strings that the grammar generates, and the strong generative capacity of the grammar, which is the set of structures that the grammar generates.

It is paradoxical that we only directly perceive the strings of a language, because most, if not all, of what is interesting about a language is defined in terms of strong generative capacity. We have seen that meaning is determined by structure, a hierarchical notion given by the constituent structure, rather than by linear order of words. Most grammatical operations have been shown crucially to implicate constituent structure, such as movement and deletion operations, as we have seen. Given that constituent structure is not directly perceptible, unlike linear order, it poses severe learnability problems, as pointed out by Pinker (1984), and is usually taken to be innate. This leads to a predicted universality of constituent structure, and this assumption has been used in recent years in work on comparative grammar, such as Pollock's work on French vs. English verb movement (Pollock 1989). Here Pollock studies the placement of adverbs with respect to verbs in both languages, assumes that the adverb is generated in the same structural position in both languages, and attributes the different positions of the verbs with respect to the adverbs to the scope of a verb-movement rule that applies much more generally in French than in English. Pollock shows that the differences between French and English verbs with respect to their linear order vis-à-vis adverbs correlates with other differences between French and English verbs, suggesting that verbs in the two languages differ in their structural positions.

It is also worthwhile to consider an alternative description of English which does not posit constituent structure, a model described in Chomsky (1957) as a finite-state grammar, based on the work of Shannon and Weaver (1963) on information theory. This model views a grammar, in generating a sentence, as a machine which enters successive states when constructing a sentence, and each word that is added to the sentence as it is created puts the grammar into a different state. Each word can be described in terms of its possible continuations, and the machine starts in state S0. A finite state description of, for example, sentence (1) would be as shown in Fig. 3.

Figure 3
Finite-state grammar representation of (1)

The basic idea of a finite-state grammar is that there are a finite number of states because there is a limit on the number of words in a possible sentence. There does not seem to be, in fact, a limit on the length of a sentence in English or any other language that is due to grammar. For example, it is possible for a sequence of adjectives to occur before a noun in English, as in (12):

(12) Tall, beautiful, intelligent, rich, affable people.

Because there is no bound on the number of adjectives that can occur before a noun, an English sentence can be of any length whatever. Finite-state grammars can account for this obstacle to finiteness by allowing certain word-classes to loop back upon themselves. However, while finite-state grammars can account for iteration of words, they cannot account for iteration of phrases, as in (13), as Chomsky (1957) points out:

(13) John thinks that Fred knows that Mary believes that Max pretended that Joe was hungry.

In this case, the potentially infinite length is due to the containment of a sentence, a phrasal unit, within another sentence.

Chomsky's critique of finite-state grammars appeared shortly after an analogous critique occurred in psychology, in which Karl Lashley (1951) criticized associationism, which viewed behavior as being describable in terms of contiguous responses, so that, for example, going to the refrigerator to get a sandwich would be described, in associationist terms, as putting one step toward the refrigerator door, putting out one's hand, opening it, grasping the refrigerator door handle, pulling it toward one, etc. Lashley noted that such a view did not take into account the notion of an over-arching plan. Lashley was arguing that thought required constituent structure, and the finite-state grammar could be viewed as the linguistic implementation of associationism.

Constitutional Courts

Constitutional Courts (CCs) are specialized courts with jurisdiction over constitutional matters.

In constitutionalist systems (constitutionalism) the constitution is considered to be the highest law with normatively binding force for political actors including the lawmaker. While one may detect antecedents in antiquity and in English common law the modern history of the 'higher law' nature of the constitution starts with the constitutions of the American colonies and the American and French revolutions. On a theoretical level, it is the distinction between *pouvoir constituant* and *pouvoir constitué* (Siéyès) that establishes the constitution's binding force over the lawmaker. In more recent constitutional theory the idea of the constitution as guaranty of the basic consensus and the protection of the democratic process and human rights against parliamentary majorities have become more important arguments. Today, most constitutionalist democracies use courts to guarantee the binding force of the constitution. While many countries follow the example invented by Marshall in *Marbury v. Madison* and give this function to the ordinary courts, others (and their number is increasing) use specialized CCs.

1. Constitutional Courts in Historical and Comparative Perspective

1.1 Democracy without Judicial Review

Judicial control of the political system is not a necessary feature of a democratic society. In systems with 'flexible constitutions' like the UK and NZ the constitution is at the disposal of the lawmaker. But even in countries with 'rigid' constitutions that are not at the disposal of simple majorities, the binding force can be conceptualized as a sanctionless imperative for the lawmaker. This was, for example, the case in France until the constitution of the fifth Republic introduced a (moderate) form of constitutional control. In other constitutionalist democratic systems judicial review is expressly excluded (NL, Switzerland on the federal level until 1999), still others know only an organized self-control of the lawmaker during the lawmaking process (Finland). However, the prominent examples of constitutionalist democracies without any form of judicial control are disappearing rapidly: with the constitutional reform of 1999 Switzerland has given its Supreme Court constitutional functions, Finland is considering a similar step and even the bulwark of parliamentarianism, Great Britain, has introduced a (very modest) form of judicial control of Parliament with the 1998 Human Rights Act. Increasingly, some form of judicial control of the political system has become a defining element of modern democracies.

1.2 Constitutional Control as Function of Ordinary Courts: The 'American' or 'Diffuse' Model

The introduction of judicial control by the US Supreme Court in *Marbury v. Madison* (1803) is not based on a constitutional authorization but rather on a logical conclusion drawn from the higher law status of the constitution. This power is, therefore, shared by all courts; there are no special procedures or remedies in constitutional matters; and decisions have no *erga-omnes*-effect. This system (called 'diffuse' in comparative constitutional law) has been adopted widely in legal systems whose constitutions are silent on judicial review, for example, common law countries and Scandinavia. Even though this system is regularly called the 'American' system, the US Supreme Court is in many ways an atypical case: it concentrates (through the *certiorari* system) on cases with constitutional implications, its judges are selected with their constitutional role in mind, and the *stare decisis* rule gives its judgments a *quasi-erga-omnes*-effect. In a socio-

logical sense it acts very much like specialized CCs and is, therefore, included in many comparative works on 'Constitutional Courts' without being one in a technical sense. This is atypical for the 'diffuse' system because for ordinary courts (including supreme courts) in such systems (e.g., in Scandinavia) constitutional questions are only a minor part of their function and judicial review is rarely exercized. Outside the US only a few Supreme Courts of this type (perhaps most notably the Indian Supreme Court) have assumed an active constitutional role.

1.3 Constitutional Courts: The 'Austrian' or 'Concentrated' Model

In contrast to the American model, CCs are the result of conscious constitutional design. Their history starts in 1920 with the Austrian Constitution based on a draft by Kelsen. The power to find laws unconstitutional was reserved to a special constitutional organ (therefore, this system is called 'concentrated'). In its original version only federal and state governments could appeal to the Court. It is no coincidence that CCs were invented by Kelsen. They are, on the one hand, a logical correlate to a hierarchical view of the legal system. On the other hand, Kelsen's pure theory of law tries to shield law against politics and, therefore, Kelsen was an opponent of the American model. The monopolization of constitutional control by a specialized court which could only be mobilized by a limited number of state organs for a constitution that did not contain a bill of rights was as much a barrier to the development of generalized judicial review as the institutionalization of constitutional control. Here again the name-giving case of the 'Austrian Model' is not representative: the vast majority of CCs created later were given much broader powers in constitutional systems with extensive substantive provisions. From a beginning with a much more restricted role than in the American system, today most CCs are more active political players than most courts in diffuse systems. The rise of CCs began after WW II: CCs were important elements in the democratic reconstruction of Germany and Italy. Their model was influential in the third wave of democratization, beginning with Spain and Portugal followed by the transformation in East Europe in which CCs played an important role. Constitutional reforms in other parts of the world similarly introduced CCs (South Korea, Thailand). South Africa gave its CC the unique function of certifying compliance of the new constitution with the principles agreed to in the peaceful abolition of Apartheid. In addition, other countries without a tradition of judicial review introduced CCs in constitutional reforms (*Cour de Arbitrage* in Belgium 1980). France created a restrictive form of preventive judicial control through a *Conseil Constitutionnel* in 1958. It is no coincidence that the rise of the CC-model is closely connected with situations of constitutional transition. In this situation there is a conflict between values and interests protected by old law and the legitimacy of the new constitutional order. In this situation a CC has obvious advantages over the American model because the ordinary judiciary will often be compromized by its involvement in the old order. While it is extremely difficult to transform legal cultures completely just by introducing a new constitution, a specialized court composed specifically for this task and with an institutional commitment to the new constitution can play a decisive role in bringing the inherited legal culture in conformity with the new model.

1.4 Mixed Systems

Some countries have left constitutional cases to the ordinary courts but have recognized the special nature of constitutional litigation by concentrating it in a Supreme Court or special chambers, by creating special constitutional remedies and by decreeing the *erga-omnes*-effects of judicial review. Examples can be found especially in Latin America (because of the competing influences of civil law inheritance and north-American constitutionalism) but also in Europe (Ireland, Estonia, Switzerland after the reform of 1999).

1.5 International Constitutional Jurisprudence

Since the end of WW II judicial control of the political system has gained an international dimension. With a decisive innovative approach the European Convention for Human Rights allowed individuals to sue their governments for violation of human rights in an international forum (a model later followed by the American and recently the African human rights systems). For countries without a bill of rights the ECHR-Organs served as a kind of substitute CC (and the desire to create a local forum to precede international proceedings has influenced the move towards judicial review, e.g., in GB).

With the European Communities, for the first time, an international organization created mandatory and binding court control over community organs and member states. The main function of the European Court of Justice is to safeguard the uniform application of European Law, but it also can be considered a CC of the European Union.

2. Organization and Powers of Constitutional Courts: An Overview

There is a broad range of different solutions for the organization of constitutional control through CCs.

2.1 Composition

In general, the rules for the selection of judges tend to address more openly their political function than those of ordinary courts. They try to square the circle between providing for judicial independence and democratic legitimacy. A majoritarian solution (election by the majority of the day) creates the least theoretical problems for democratic legitimacy but endangers the control function. Attempts to reconcile the two aims include the election with super-majorities (Germany) leading *de facto* to equal appointment rights between government and opposition; the distribution of nominating rights among different constitutional organs (Austria, France); and the inclusion of professional bodies in the nominating process (Italy). As the political element is stronger, appointment to CCs tends not to simply consist of advancement in the judicial hierarchy. Law professors and former politicians are especially highly represented. A relatively strong political influence on the appointment process is counterbalanced regularly by strong guarantees for judicial independence. Appointment or election is either for life or long-term.

2.2 Jurisdiction

In contrast to the 'American' system in which the constitutional question can only be raised incidentally during a case, in a CC system the constitution and constitutional court acts circumscribe the jurisdiction of the Court. There is a broad range of models from very restrictive to very broad opening of constitutional control.

The power of abstract judicial review as a means of objective control outside concrete cases on application from privileged applicants (state organs, entities of federal systems, quorums of members of parliament) is perhaps the one most typical for CCs (and most distinctive compared to the diffuse system). In its most restrictive, purely preventive form, the French *Conseil Constitutionnel* must be engaged to in the short interval between parliamentary vote and promulgation, thus reconciling constitutional control with the maxim *la loi est la loi*. Much more common is repressive abstract review after the law has come into force.

Concrete judicial review allows other courts to refer constitutional questions raised in their proceedings to the CC which holds the monopoly in finding laws unconstitutional.

Access to the CC is most open where it can be mobilized by individuals (constitutional complaint, *amparo*) in case of violations of human rights (usually only after exhaustion of other remedies).

In addition, CCs adjudicate disputes between state organs, the components of federal systems, have quasi-penal functions (impeachment, prohibition of parties) and supervise the election process.

3. Constitutional Courts and Political System

In political theory the role of CCs remains controversial. Their power to overrule the decisions of elected representatives of the people is difficult to reconcile with the theoretical premises of majoritarian democracy. In countries with a CC the debate tends to be less heated than in systems where judicial review has been invented by judges because the constitution makes express provision for jurisdiction. With the extension of judicial control in the last decades, rigorous opposition against it in the name of democracy has declined. Despite the theoretical merits of the majoritarian argument against judicial control over parliament, practical experience has shown it to be a workable reconciliation of majority rule with safeguards against the dangers of majority rule. The international human rights discourse has provided additional legitimacy to control over elected governments exercised in the name of a higher legal order. There remains, however, a permanent tension between the power of CCs to interfere in the political process and the tenets of democracy. But the debate has shifted from the merits of judicial control in the abstract to its proper boundaries. In jurisprudence this discussion is led in the framework of concepts like 'judicial restraint' and 'political questions' while in social science perspective the political role of CCs and their impact are studied. For this debate one of the oldest contributions, Justice Stone's footnote 4 in *Carolene Products* (304 US 144 [1938]), is still a valuable guide: the protection of the democratic process itself and that of 'insular' minorities not able to protect themselves in this process is easier to justify than the enforcement of competing value judgments.

4. The Sociology of Constitutional Courts

CCs (and constitutionally activist Supreme Courts) hold a special place in sociology of law. Their distinguishing feature is almost banal: they are very small. Different from other sociolegal court studies, with CCs one is not dealing with a social group but individually known actors. CCs apply a body of law that typically is more open textured and politically more controversial than normal law. This contrasts with other courts both facilitates and impedes their sociological analysis. On the one hand, CCs offer case-studies of the relationship between law and politics that make the relationship between judicial values and decisions impressively obvious. Therefore, sociology of law treatises often use constitutional jurisprudence to illustrate this relationship. On the other hand, they are so distinct from other courts that the application of sociolegal findings about judicial behavior to them is difficult, and generalizations from constitutional cases to other courts are dangerous.

4.1 Actors

Because of the political role of CCs the politics of elections and appointments is an interesting subject of research that is in this case more directed to concrete selection processes than to generalized study of recruitment patterns. While there are correlations between known judicial background (including party politics, religion, status) and decision there is no simple one-to-one relationship. The guaranteed independence (cf. 3a *supra*) of CC judges has often resulted in disappointment on part of selecting politicians. This can be explained with the self-image of judges and the institutional interests of CCs. For their impact in a political system CCs rely heavily on their perception as neutral arbiters and they would lose legitimacy if they appeared to be mere instruments of their selectors. The high prestige CCs enjoy in many systems (especially compared with politicians) very much depends on this aura of independence.

4.2 Mobilization

One of the major differences between courts and elected policy makers is the fact that courts are reactive, not active participants in the public arena. While this fact is often used as an argument by defenders of judicial review against majoritarians it appears to be of limited significance as a barrier for judicial involvement in politics. In systems with very restricted access to the court like in Kelsen's original model or the French *Conseil Constitutionnel* where only few institutional actors can mobilize the court, it holds true. But access to most CCs tends to be much broader (3b *supra*) and the different avenues combine to bring most politically controversial matters before the courts. When the German *Bundesverfassungsgericht* accepts less than 2 percent of the ca. 5000 complaints received annually one may assume that the court does not so much react but rather selects actively those issues it wants to address. In addition, CCs are inventive in finding ways to involve themselves in politically sensitive subjects without regard to restrictions under procedural rules. In a related development the more active courts do not restrict themselves to decide the case before the court but use *obiter dicta* to make long exhortations on future political action, thus departing from the judge's role of reactively deciding on the past for the politician's role of actively influencing the future.

4.3 Decision-making

Similarly, the binding force of law cited (especially by lawyers) as a restriction of judicial power is less important for CCs than for other courts. Judicial decision-making always has a political dimension but it is subject to constraints intended to promote a specific juridical rationality and to hinder idiosyncratic decision making by judges. These constraints appear to be less effective with CCs. Their decisions are less strictly programmed by law. While some constitutional law provisions (organizational norms, e.g., on elections) can be very specific, those texts that are relevant today in most constitutional proceedings—fundamental rights or constitutional principles—are very open textured (and traditionally in constitutional jurispurdence have been expanded further, rather than narrowed). CCs have to balance broadly worded rights against similarly broadly worded infringement-clauses and find the solution regularly by balancing private rights and public interest against each other under extremely open concepts like the principle of proportionality which give widest possible room of interpretation.

CCs have transcended the classical boundaries of judicial politics in another way. In principle, courts are different from political actors because they are restricted to yes/no decisions (lawful/unlawful) over the past which is a powerful incentive for judicial restraint (e.g., if a CC had only the alternative of either declaring a tax law void and risking public bankruptcy or accepting the law as constitutional). CCs have found ways around this problem. For example, they refrain from declaring laws void but order the lawmaker to change them in a given time. Or, they use the interpretation of laws or *obiter dicta* to enforce political compromises between proponents and opponents of a law under scrutiny. Such flexible forms of judicial decision free the court from the stark yes/no alternative and broaden its potential to actively involve itself in policy-making by influencing future policies, building coalitions, and instigating political compromises. A promising strategy for measuring judicial activism appears, therefore, to be the study to what extent CCs have given up the ideal-typical judicial style of decision making for a political one.

B.-O. Bryde

Constitutionalism

Constitutionalism must be distinguished from three somewhat related terms, a constitution, a constitutional text, and constitutionism. Every country, James T. Shotwell was fond of saying, has a constitution, most countries have a constitutional text, but very few have constitutionalism. And, we might add, almost all public officials claim to practice constitutionism.

Narrowly defined, a nation's constitution refers to its arrangement of public offices and powers as well as individual and group rights. More broadly, as Aristotle came to use the word, it signifies a way of political life, what modern theorists are apt to call a 'constitutional order,' which can vary from that of Mao's China and Stalin's Soviet Union, on the one hand, to the more benign systems of Australia, Canada, the Federal Republic of Germany, and the USA.

A constitutional text identifies the document (or set of documents) that supposedly spell out the nation's basic political principles, institutional arrangements, modes of selecting public officials, and the rights and duties of private citizens. The contents of these documents vary widely, as does their authority. At one extreme would be Stalin's constitutional text, a pious fig leaf; at the other extreme are the constitutional scripts of countries such as France, Ireland, Norway, and the USA, whose terms public officials usually try to follow.

The awkward neologism constitutionism refers to adherence to the terms of the constitutional text or those of the broader constitutional order. Because the basic values of both a constitutional order and of a constitutional text can range from those of totalitarianism to a loose libertarian political system, officials of most governments, even Chile's, under Agosto Pinochet, can often pretend to be practicing what they consider constitutionalism, while in fact they are only following constitutionism, that is, being true to the constitutional order.

The concept constitutionalism, however, differs from constitutionism in demanding more than adherence to any given constitutional text or order. Constitutionalism is a normative political theory that endorses a special kind of constitutional order, one that counts among its practical tenets that every exercise of governmental power, whether representing the will of a single leader, an elite, or an overwhelming majority of citizens, is subject to important substantive limitations. In short, constitutionalism contends that the central value of any society must be human dignity. It follows that there are some things that government cannot do, no matter how faithfully it follows procedures specified by a constitutional text and a larger constitutional order, or even if its actions perfectly mirror the deliberate judgment of a charismatic fuehrer, benevolent junta, or the majority of voters. Obviously, this normative theory is incompatible with most forms of authoritarian government. Moreover, it co-exists uneasily with its usual partner, representative democracy.

Constitutionalism is closely related to the concept of limited government. Indeed, constitutionalism can be viewed as one among a variety of species of that much older genus (Gordon 1999). There are many possible ways of restricting political power, countervailing force being among the more obvious. Because the people of Israel had a deserved reputation for waging war, the Roman Empire tried to avoid open conflict by according Jews certain special civil rights, exempting them from requirements to worship pagan gods and to pay taxes to maintain local shrines, and also according them the privilege of sending money to the Temple at Jerusalem. Theology may provide another check. Anyone reading Homer must be struck by the irascible Olympians' jealous responses to human hubris. Later in Western history, the prophets tried to impose restraints on the kings of Israel, as did the Catholic Church on European monarchs through the middle ages. Custom may provide an additional limitation, recognized in a ruler's promise to do justice to his subjects even as his father did justice to their fathers in return for his subjects' pledges of fealty.

The possibility of armed conflict may give a practical impetus to the acceptability of certain ideas, and custom and theology are typically major ingredients of a political culture. But again, their collective relationship to the norms of constitutionalism depends on the substance of the customs, theology, and political culture. Certainly, neither the frequently malevolent behavior ascribed to Homer's gods nor the murder

and rapine celebrated in 'heroes' like Achilles and Odysseus would support the ideals of constitutionalism. For them, human beings were typically mere things to be exploited and discarded. On the other hand, the foundations of modern constitutionalism rest on the theological claim of Judaism and Christianity that all men and women are made to the image and likeness of an all-loving God—a basis that does not prevent people of other (or no) religions from availing themselves of constitutionalism's benefit of controlling government.

What we know as constitutionalism also grew out of the efforts of Western Europeans to curb absolute power by creating political institutions that could express customs and moral codes. Thus, one can look on constitutionalism as a political theory made operative through the institutionalization of certain norms into the political system. And, although its medieval and early modern roots are visible, efforts to restrict government began much earlier in Western history. Without doubt, the citizens of ancient Athens did not have a concept of universal human dignity as rich as that of people living in modern constitutional democracies; still, their constitutional order did not accept government as unlimited in authority. Athens had in place institutions that could check even the Assembly, a legislative body in which every citizen had a right to speak and vote on any proposed public policy. Among these institutions was a version of judicial review: a citizen could challenge the constitutionality of any decree the Assembly had approved by filing a claim that would be heard by a jury, ranging in size from 500 to 1500, randomly selected from those citizens who were willing to sit. In that forum, the issue of the decree's congruence with the polity's constitution could be further debated, decided, and voided if deemed to violate the constitutional order (Hansen 1991).

In the modern world, the open processes of representative democracy are often hailed as the most effective protector of individual rights against government. 'The mass of the people,' Thomas Jefferson wrote John Taylor in 1816, 'are the safest depositary of their own rights.' The reasoning is that, if allowed access to a free press, to speak freely among themselves, to organize for political purposes, and to vote in honest elections, citizens will zealously guard that deposit. Democratic theories thus stress that a political system should choose its principal decision makers through open political processes and, in turn, those decision makers should follow similarly open processes in making public policies and then standing for periodic re-election. Democratic theorists preach that, because the reach of governmental power and individual rights are contestable, the legitimacy of governmental action is better resolved through elected representatives responsible to the people than by an elite's judging a policy's congruence with its understanding of the polity's underlying norms. The voters can affirm or reverse constitutional interpretation at the next election.

Constitutionalism shares concerns about process as well as many of the substantive values democratic theorists endorse. Constitutionalists, however, are more pessimistic about human nature; they are constantly concerned, even obsessed, with the human penchant to act selfishly and abuse power. They fear that even the 'mass of the people' are sufficiently clever to oppress others without hurting their own rights. As James Madison wrote to Jefferson:

> In our Governments the real power lies in the majority of the Community, and the invasion of private rights is chiefly to be apprehended, not from acts of Government contrary to the sense of its constituents, but from acts in which Government is the mere instrument of the major number of its constituents (Meyers 1973, p. 206).

The fundamental dispute between constitutionalist and democratic theorists centers on how best to protect rights against government. For democrats, the right to political participation is the fundamental right because is it 'protective of all other rights.' Constitutionalists respect the right to political participation but are more apt to view 'the right to be let alone' as more fundamental. They tend to view democratic political processes as 'at best regulated rivalry … Political power rapidly accumulates and becomes unequal; making use of the coercive apparatus of the state and its law, those who gain the advantage can often assure themselves of a favored position.' Private funding of political campaigns aggravates these problems (Rawls 1971, p. 226).

Constitutionalism, therefore, demands 'a system of regularized restraints [beyond free elections] upon those who exercise political power' (Friedrich 1964, p. 17). A constitutional text with a bill of rights and judicial review are the most visible but not the sole constitutionalist restraints. Many constitutionalists, like most democratic theorists, also emphasize the importance of political culture. As James Madison told the First Congress when he introduced the Bill of Rights.

> It may be thought that all paper barriers against the power of the community are too weak to be worthy of attention … [Y]et, as they have a tendency to impress some degree of respect for them, to establish the public opinion in their favor, and rouse the attention of the whole community, it may be one means to control the majority from those acts to which they might otherwise be inclined (*Annals of Congress*, I, 440f, 1789).

Separate institutions competing for power (Jones 1990) and federalism are also typical constitutionalist weapons. Democrats are likely to speak of the 'sovereignty of the people,' while constitutionalists tend to regard the very concept of sovereignty as a dangerously fuzzy concept. They prefer a political

system in which power is so dispersed that the supreme law making power, if it exists at all, will be only found in the midst (and mist) of jealous interactions among popular and elitist institutions.

No nation has fully adopted constitutionalism any more than any nation has fully embraced democracy. Indeed, with its distrust of human nature and insistence on the primacy of individual rights, pure constitutionalism might make governance in the modern world impossible. So, too, unmodified democracy might soon commit suicide by allowing today's majority to restrict the minority's political rights and tomorrow's new majority, in turn, to restrict tomorrow's minority (though it had been part of yesterday's majority) until finally only a small junta or single dictator were governing. The most common arrangement in the modern world is becoming constitutional democracy, a marriage between representative democracy with its notion that the people should rule through their freely chosen representatives, and constitutionalism, with its norm that if the people govern, they should not govern too much. Like most marriages this one constantly endures tension and often experiences conflict, even turmoil.

Constitutionalism, Comparative

1. Introduction

The idea and practice of comparative constitutionalism is a new field propelled by the political and technological changes of the late twentieth century (Jackson and Tushnet 1999), yet it is rooted in antiquity, in the methodology of Aristotle and his students at the Lyceum. While not a well established area of academic study (ACLS, 1990) comparative constitutionalism exists both as a normative and legal practice as well as a form of comparative political and legal analysis.

Comparative constitutionalism is now widely practiced by both constitution-makers and constitutional interpreters. Comparative constitutionalism became prominent in the late twentieth century, expanding exponentially in practice with the wave of constitution-making that accompanied the end of the Cold War. While comparative constitutionalist practices are initially applied in the process of constitution making, in which participants seek to apply models and experiences from other contexts, it is perpetuated in the debates over the meaning of each new constitutional provision from the moment of its adoption. This practice is institutionalized in the jurisprudence of many constitutional and supreme courts who through their decisions effectively engage in a transnational comparative constitutional discourse on constitutional meanings and functions.

Academically, a single definition of comparative constitutionalism is even more difficult to formulate. In philosophy, political science, and law, comparative constitutionalism is used both normatively to evaluate constitutional provisions, and empirically to describe, contrast, and reflect upon the consequences of the different rights and institutional provisions of constitutions around the globe. As a normative exercise, the survey and comparison of constitutions remains close to the original Aristotelean method of comparing different constitutional provisions and institutions in order to define a better form of government. This approach has been supplemented with historical accounts which explore the development of constitutionalism through time (Pennington 1993) and across national borders (van Caenegem 1995) A normative emphasis is also prevalent in a range of

studies that focus on some of the foundational questions underlying the adoption and implementation of constitutions: the relationship between constitutionalism and democracy (Elster and Slagstad 1988; Habermas 1996); the origin of the notion of fundamental rights and the role of civil society (Mamdani 1991); and even the idea of a diversity of forms of constitutionalism that might be achieved through demands for cultural recognition in a post-colonial age (Tully 1995). While increasingly of an interdisciplinary nature and central to the idea of constitutionalism, these studies tend either to focus on the conceptual and theoretical issues or to adopt a country by country approach rather than a comparative perspective (Gordon 1999, Pennock and Chapman 1979).

However, with the emergence of globalization as both an empirical phenomena and as an object of study (see *Globalization: Legal Aspects*), the debate on constitutionalism has taken a comparative turn (Singh 1989). Comparative constitutionalism in this latter sense has two distinct foci: on the one hand there is a focus on comparing the different institutions that are employed to secure democratic forms of government (Sartori 1994), or their role in shaping particular social issues such as identity and diversity (Rosenfeld 1994, Habermas 1998). On the other hand there is an emerging focus on constitutional borrowing, adaptation, and hybridization (Badi 2000, Klug 2000).

The dispersal of sovereignty, which is inherent in the process of globalization, provides further difficulties for the definition of constitutionalism, as may be witnessed in the debate over citizenship and democracy in the European Union, or in the ideas of shared sovereignty which have been introduced into the debate over the future of Jerusalem. The post-twentieth century emphasis on the negotiated settlement of disputes over governance and power, whether at an international or local level, provides fertile ground for debating constitutional alternatives. Here, comparative constitutionalism becomes a pragmatic alternative to continuing conflict.

2. *The Global Context*

Alarm over the Americanization of the world became a central theme for many critics of globalism in the 1990s. At the same time, many lawyers participated in and celebrated the new emphasis on the 'rule of law,' presuming the global adoption of law and legal processes as a precondition for successful transitions from authoritarian regimes and command economies into a new world order. The adoption of bills of rights and the empowerment of courts, which characterized many of these political transitions, led many to believe these developments indeed reflected the embrace of American values in the post-Cold War era. Bruce Ackerman heralded the emergence of a 'world constitutionalism,' arguing that the 'enlightenment faith in written constitutions is sweeping the world' (Ackerman 1997). Another prominent United States constitutional scholar, Cass Sunstein, argued that the 'right kind of constitution could play an important role in fueling economic development and democratic reform; indeed, under current conditions, it may be indispensable to them' (Sunstein 1993).

With the widespread adoption of constitutional forms genetically tied to the innovations of the American revolution, it is not surprising that both advocates and detractors of the American experience assume the United States to be the hegemonic model. However, American lawyers and scholars who participated in a billion-dollar program in the 1990s to promote the rule of law around the world found themselves in competition with alternative constitutional models. Although the bulk of activity in this 'rule of law' movement focused on judicial and legislative reform designed to promote market economies, it is important to recognize that a central product of this dual process of political transformation and rule of law advocacy was fundamental constitutional reform in half the world—in approximately 104 of the 188 members of the United Nations. Of these, a staggering 78 percent, or approximately 81 countries, adopted completely new constitutions.

Given a common belief in the United States Constitution as a 'source of inspiration and ideas … studied and appraised by scholars, invoked by publicists, adopted or adapted by revolutionaries, nation builders and statesmen' (Henkin 1989), many of those who joined the multitude of legal expeditions to assist in constitution making in Eastern Europe, Africa, and elsewhere were surprised to find themselves confronted with alternative constitutional models. As exporters, advocates of the American model found that instead of enjoying an unassailable status, they faced open competition from advocates of the German, Canadian, Indian, or other constitutional experiences. Given that these alternative constitutional experiences are to a large extent themselves based on the American model of constitutionalism, it seems counterintuitive to regard the dominant model, the American experience, simply as one of a number of alternative models. Yet this is the case, and may be explained by the emergence of comparative constitutionalism. Constitution-makers, interpreters, and litigants actively compared their own conditions and experiences with the current and historical experiences of other countries, in order to advocate one or another constitutional solution, whether a particular constitutional institution, the specific form of a constitutional clause, or the meaning of particular constitutional language. These practices became increasingly common through the 1990s as states around the globe engaged in one of the most profound processes of constitutional and political

reconstruction ever. It is this context that has framed the new intellectual interest in comparative constitutionalism.

3. Constitutions, Constitutionalism, and the Politics of Comparison

Comparative constitutionalism has shifted its emphasis from being a philosophical debate over the nature and form of good government to a more legal focus on the application and meaning of particular constitutional structures and rights, as well as on the role of the judiciary in the project of limited government (Sajo 1999). While the question of judicial review, and particularly the debate over the relationship between constitutionalism and democracy, dominated much of the academic discourse in the twentieth century, the changing social and political context has brought greater attention to the interaction of constitutional ideas and institutions across different legal systems and national boundaries (Schedler et al. 1999, Hanafin and Williams 1999, Teubner 1997). This new trend is beginning to define a new field of comparative constitutionalism in theory and practice.

Comparative constitutionalism originated in western thought with Aristotle. In the *Nicomachean Ethics* (Aristotle 1996) he made a case for the comparative study of constitutions, arguing that by studying the 'constitutions we have collected … we shall perhaps be more likely to see which constitution is best, and how each must be ordered, and what laws and customs it must use' (Aristotle 1181b, 13–22). Although only the *Constitution of Athens* (Aristotle 1996) remains from this early venture, the product of this analytical exercise is presented by Aristotle in *The Politics* (Aristotle 1996) and remains a principle source for the study of comparative government, which still largely aims to construct a normative definition of institutional and political practices that are necessary in order to secure the good life.

The Aristotlean notion of constitutionalism, combining both a distinctive political order and the idea of a political regime in general is, according to Carl Friedrich, the source of the 'modern idea of a constitution as the organization of a government, its offices, and the relation of the offices' (Friedrich 1968a). For Friedrich, however, this understanding, which recognizes all forms of government as exhibiting one or other form of constitutionalism, was inadequate, for it incorporated dictatorial forms of governance within the idea of constitutionalism. Instead, Friedrich (1968b), along with McIlwain (1947) and Wormuth (1949), emphasized the relationship between constitutionalism and individual liberty. For them, the essence of constitutionalism is not the organization of power but rather the idea of limited power. From the idea of restraints on power to the separation and division of power, the focus among Anglo-American theorists through the middle decades of the twentieth century was on the guarantee of individual liberty which they took to be the product of various means of limiting state power (Pound 1957).

Writing first in the shadow of Nazi Germany, then in the aftermath of World War II, and during the Cold War, Friedrich shifted the focus away from the comparative perspective inherent in the Aristotlean approach by posing the question: what is the political function of the constitution? From this starting point, Friedrich identified the protection of the individual member of the political community as the primary object of constitutional government, thus redefining constitutionalism as a 'modern phenomena' whose central concern is the practice and theory of limited government (Friedrich 1968b). This focus empowered western theorists to reject constitutional forms, particularly the 'symbolic' state socialist constitutions that failed to limit state power, as aberrations of the constitutionalist tradition. Thus constitutionalism was once again given a normative form, but at the cost of limiting the concept only to those constitutional arrangements that successfully limited and controlled state power.

The failure of post-colonial constitutions in Africa and other parts of the Third World, despite the inclusion of clauses formally limiting, separating, and controlling state power, produced an alternative, 'socio-legal' approach to constitutionalism. Legal academics and political scientists argued that it was important to understand the economic and social context that determined the effective constitution of power in these newly independent states (Ghai 1991). Taken further, this analysis seeks to demonstrate how the underlying colonial and neocolonial conditions of social organization, particularly the dual legal system and lack of land tenure security, restrict the capacity of civil society in Africa (Mamdani 1996, Shivji 1998). Without changes in these conditions, it is argued, the notion of legal rights against the state and restraints on state power are ephemeral. Despite this disillusionment with formal constitutions and constitutionalism, struggles for democracy and interethnic strife in many developing countries has fueled a continual search for understanding the place constitutionalism may play in the reconstruction of post-colonial states. Yash Ghai has sought constitutional solutions to problems of ethnic strife, both in his practice as a constitutional advisor and in his academic work (Ghai 2000). He has also applied this socio-legal perspective to analyzing the role of constitutional formulations produced to define the relationship between the central government in China and a reintegrated Hong Kong (Ghai 1997).

With the protection of the individual as its central goal, and the restraint of political power as its essential feature, the study of constitutionalism lost steam in the Anglo-American world. It split in two distinct directions, one legal, the other political. On

the one hand, an interest in judicial review became the central concern of legal constitutionalists. Here the idea of comparative constitutionalism became, and remains so to some extent, equated with comparative constitutional law (Capelletti and Cohen 1979). In this context the comparative approach either focuses on the specific problem of judicial review, engaging in a comparison of the process of judicial review, exercised by courts around the world (Cappeletti 1989), or compares the case law of different jurisdictions in order to explore different means of the constitutional resolution of particular issues from the protection of property rights (Allen 2000) to abortion and hate speech (Jackson and Tushnet 1999). On the other hand, the fiscal crisis of the state and political conservatism in the late 1970s and 1980s led to a direct political attack on the role of the state in society. Despite challenges of cultural imperialism by those advocating an 'Asian model' of autocratic paternalism, or by those who argued that 'constitutionalism is largely a cultural phenomena and not simply the product of properly designed institutions and structures of government' (Franklin and Baun 1995), it was the emphasis upon the need to restrict state power that created an intellectual and political environment in which the constitutional protection of individual rights and the institution of judicial review became the dominant features of a post-Cold War international political culture.

The emphasis on the legal form of constitutionalism, and on judicial review in particular, shifted the focus onto the role of the judiciary, encouraging both a practical emphasis on judicial reform as well as in interest in the global expansion of judicial power (Tate and Vallinder 1995). However, at the same time, the failure and even collapse of governments in Africa and the Asian economic crisis in the 1990s brought a renewed focus on the question of power and the need for effective governance. This focus raised the question of how the constitutional allocation of power should in fact empower the state to achieve a level of social coordination necessary for individual security and freedom.

4. *The Problem of Governance and the Role of Comparative Constitutionalism*

If constitutionalism is, historically, the struggle to regulate political competition, then it is unsurprising to discover that different constitutional options in fact reflect continuing ideological and political alternatives. The politics of constitution making (Elster 1995) is thus festooned with the claims of competing political advocates who project their ideological perspectives and political goals into constitutionalist forms (Klug 2000). While the post-World War II response to the violation of human rights produced a movement that could insist on the recognition and promotion of human rights through both international and domestic fora, the re-emergence of a nineteenth century liberalism, in the guise of a 1980s neoliberalism, had profound implications for the politics of constitution-making in the post-Cold War era. In this context, Friedrich von Hayek's conception of politics as threatening a liberal order that is simultaneously complex and delicate (Hayek 1960) provided a central argument for those who sought to shrink the state. Although democratic theorists and constitutional scholars had long highlighted the anti-democratic implications of constitutional review, the neoliberal project emphasized the 'rule of law'—requiring an independent judiciary with powers of judicial review—and demanded a constitutionalization of many other institutions and areas of governance as a means to limit the destabilizing impact of politics.

Despite the gains made by neoliberalism at the end of the Cold War, the politics of constitution making remained eclectic. Although the vast majority of states undergoing reconstruction through processes of constitutional change in this period seemed to accept the liberal paradigm of individual human rights and multiparty democracy, this did not preclude the simultaneous inclusion of a range of alternative constitutional elements, including socioeconomic and cultural rights, which reflect alternative traditions (see *Civil Liberties and Human Rights*). Significantly, the dominant liberal democratic tradition itself contains different trends, sometimes complementary, sometimes contradictory, advanced by different social forces and reflecting a plurality of interests. Of these, the two trends that had the most direct impact on processes of post-Cold War state reconstruction emphasized liberty and equality. While there is a significant overlap in liberalism's ideological commitment to liberty and equality, emphasis on one or the other provides a range of alternatives within the liberal democratic tradition. These extend from classic nineteenth-century liberalism, with its emphasis on individual freedom and property rights, to the claims of the democratic collectivity inherent in the social democratic liberalism of the post-World War II era. While both aspects of this tradition emphasize electoral democracy and the protection of individual rights, they also contain contradictions with important consequences for the shape and role of the state.

While the struggle for equality, whether aimed at economic or racial inequalities, elicited the power of the state to address entrenched private power, the struggle for individual freedom has eschewed the state, often characterizing governmental power as the very source of oppression. These different responses to the state have obvious consequences for the structure of government, the most dramatic being the emphasis on the need to downsize or limit the role and capacity of the state. Combined with a reaction against the commanding role held by the state in socialist societies

and strengthened by the fiscal crisis of the state in western democracies, this tendency significantly influenced the international political culture that framed the post-Cold War process of state reconstruction. By contrast, the classic elements of a social democratic state, including the state's social welfare orientation and regulatory role in the relationship between capital and labor, including the creation of corporatist institutions which gave organized labor an important voice in social organization, fell into political and ideological disrepute and began to be dismantled.

In this context, comparative constitutionalism provides an opportunity to rethink many of the longstanding assumptions about traditional constitutional forms so as to understand their role in the construction and maintenance of different constitutional orders. There are three sets of values that frame traditional notions of constitutionalism: (a) federalism, or the spatial division of power, (b) the separation of powers between different branches of government, (c) the notion of constitutional rights. Each of these address different aspects of the 'problem' of power—its allocation, application and restriction—within the nation state. While these constitutional values, with their diverse historical origins, have become increasingly 'universalized,' their application in increasingly varied historical, cultural, and political contexts has produced a diversity of approaches and understandings which provide a diverse 'global text' for political actors, constitution makers, constitutional interpreters, and litigants.

5. *The Practice and Theory of Comparative Constitutionalism*

As a field of empirical academic research and legal practice, comparative constitutionalism suffers many of the methodological challenges that have encumbered the fields of comparative law and politics. Apart from the more obvious difficulties of language and the different legal traditions which plague the comparative law project, each country's historical, social, political, and economic contexts require attention in studying the origins and meanings of particular constitutional forms. More recently, the increasing comparative jurisprudence of constitutional and supreme courts in a number of countries has broadened the scope of comparative constitutional law, and has raised questions about the theory and practice of constitutionalism in the context of a globalizing world. On the one hand, there is a growing attempt to formulate constitutional theories to throw light on the 'increasingly cosmopolitan character of constitutional interpretation' (Choudhry 1999). On the other hand, there is a call for Anglo-American lawyers to recognize the need for a broader legal theory of the state or civil-law type *Staatslehre* (Dyzenhaus 1998) as an essential step towards the formulation of an adequate theory of the relationship between law and political power. It is this relationship that is at the heart of the idea of constitutionalism and the object of research and practice in the growing field of comparative constitutionalism.

Constraint Satisfaction Models

A designer creates something by a particular time, under a specified cost, making use of only certain materials. Problems like this can often be solved by progressive satisfaction of specified constraints. Virtually any problem can be stated in terms of constraints, and solutions are essentially problem states that satisfy constraints. Additional complications may arise when some constraints are more important than others or when there is no perfect solution in which all constraints can be completely satisfied. This article stresses that solution of such problems can be modeled in a natural way with constraint-satisfaction neural networks.

1. *A Neural Constraint-satisfaction Algorithm*

Each unit in a constraint-satisfaction neural network can represent a hypothesis that is interpreted as true when the unit is active and false when the unit is inactive. Connection weights between the units can represent implicational constraints between the hypotheses. These connections are typically exhaustive, bidirectional, and symmetrical. There can also be external input to a unit, reflecting external evidence, and a bias input, reflecting *a priori* tendencies. The relative importance of these various constraints is implemented by the sizes of weight, input, and bias values. Goodness is the degree to which the network satisfies all the constraints.

In a generic constraint-satisfaction algorithm, the goodness contributed by a particular unit i is defined as

$$goodness_i = \sum_j w_{ij} a_i a_j + bias_i a_i + input_i a_i \qquad (1)$$

where a_i is the activation of receiving-unit i, a_j is the activation of sending-unit j, w_{ij} is the weight between them, $bias_i$ is the bias of unit i, and $input_i$ is the external input to unit i. Goodness increases when units connected by positive weights achieve similar activations and units connected by negative weights achieve dissimilar activations, and as unit activations come to resemble their biases and their external inputs. Goodness over the entire network is defined as the sum of

individual goodness values across all receiving-units i in the network

$$goodness_o = \sum_{ij} w_{ij} a_i a_j + \sum_i bias_i a_i + \sum_i input_i a_i \quad (2)$$

Such functions go by different names in different fields: Lyapunov functions in dynamic systems, Hamiltonian functions in statistical mechanics, cost functions in optimization theory, and fitness functions in evolutionary biology (Hertz et al. 1991).

Unit activations are updated so that overall goodness increases or eventually stays the same. The update rules employ net input to a unit i, defined as

$$net_i = int\left(\sum_j w_{ij} a_j + bias_i\right) + ext(input_i) \quad (3)$$

where *int* and *ext* modulate the relative influence of internal and external factors, respectively. With a positive net input, the activation of a unit i is computed as

$$a_i(t+1) = a_i(t) + net_i(ceiling - a_i(t)) \quad (4)$$

where $t+1$ indexes the updated activation, t indexes the previous activation, and *ceiling* is the highest activation that units can achieve. Equation (4) specifies that, before being added to the previous activation, net input is scaled by distance to the ceiling, thus preventing unit activations from rising above the ceiling. With a negative net input, unit activation is updated by

$$a_i(t+1) = a_i(t) + net_i(a_i(t) - floor) \quad (5)$$

where *floor* is the lowest activation value. Here, activations are kept from falling through the floor by scaling net input by distance from the floor before adding net input to the previous activation. Thus, goodness increases because positive net inputs drive unit activations toward the ceiling while negative net inputs drive them toward the floor. Overall goodness in the network continues to increase until units reach their extreme values or net inputs fall to 0. Such states are called stable (or fixed-point) attractors, and a network reaching such a state is said to have settled into a solution, although the solution may only be a local maximum of goodness.

The dynamics of network behavior can be conceptualized within a multidimensional space in which the activation of each unit is represented as a particular direction. Each point in this space, an activation vector, represents a possible state of the network. Besides converging on fixed-point attractors, constraint-satisfaction networks, depending on their weights and inputs, can also settle into limit cycles (characterized by periodic motion of the activation vector) or strange attractors (characterized by chaotic movement of the activation vector) (Hertz et al. 1991).

2. Algorithmic Variations

There are many possible variations on this basic algorithm. Activation values can be continuous or binary. Activation updates can be synchronous or asynchronous, deterministic or stochastic, and can minimize energy or maximize goodness. Energy is basically the negative of goodness. A fixed-point attractor is a low energy point within a basin of attraction, and any input pattern within a particular basin is transformed into the attractor state for that basin. Constraint-satisfaction networks are sometimes called *Hopfield* networks after the person who developed the first energy functions for them (Hopfield 1984).

A variety of different nonlinear activation functions can implement updates, e.g., sigmoid or hyperbolic-tangent functions. Initial activations can start at 0 or be preset to other values. Unit biases, inputs, decay, self-connections, and internal and external modulators are optional. Connections can be symmetric or asymmetric.

The search for a global goodness maximum can be facilitated by simulated annealing, a process of gradually lowering the temperature (or gain) of the activation update function in order to move networks with stochastic, binary units out of local maximums (Hinton and Sejnowski 1986). Such networks are called Boltzmann machines because the probabilities of the states are characterized by the Boltzmann distribution in statistical mechanics.

Connections can be determined by conventional learning algorithms, such as the Hebb rule or the delta rule (Hertz et al. 1991), or be set by a programmer, perhaps on the basis of psychological principles. Finally, activation updating can be incorporated into multi-layered feed-forward networks that learn with back-propagation of error, in a technique called recurrent back-propagation (Hertz et al. 1991). This allows for the inclusion of hidden units, enabling the learning of nonlinear patterns. Boltzmann machines can also use hidden units, to the same advantage.

3. Symbolic Constraint Satisfaction

In Artificial Intelligence (AI), problem solving typically is viewed as search through a problem space, where a particular state of the problem can be transformed into another particular state by applying some operator. Such searches may generate solutions in the form of paths through the search space. When a search reaches a dead end without a solution, the problem solver backtracks to a more promising state to continue the search. Constraints can limit the size and complexity of search by eliminating parts of the search space, in some cases eliminating the need for backtracking (Kumar 1992). Symbolic constraint-directed search has been applied to a wide range of

AI problems including planning, scheduling, design, reasoning, belief maintenance, map coloring, and machine vision.

Although many interesting algorithms, heuristics, and issues have arisen from this research on symbolic constraint satisfaction, it has not generated any notable models of human performance, perhaps because symbolic methods for search and constraint propagation have psychologically unrealistic working-memory requirements. Also, symbolic methods do not cope naturally with constraints that conflict with each other or vary in importance.

4. *Neural Constraint-satisfaction Models*

A large number and variety of psychological phenomena have been simulated with constraint-satisfaction neural networks. Content-addressable memories are stored as fixed-point attractors, retrievable from cues containing part of the memory content (Hopfield 1984). Values for particular slots in schemas are completed in a way that satisfies constraints imposed by external and internal information (Rumelhart et al. 1986). Analogies are mapped on to new problems by satisfying constraints imposed by similarity, structure, and purpose (Holyoak and Thagard 1989). Favored explanations are those that maximize coherence among hypotheses and evidence (Thagard 1989). Decisions and plans maximize coherence among goals, subgoals, and actions (Thagard and Millgram 1995). Forming impressions of people is a matter of reconciling information about their behavior and characteristics and the stereotypes of the perceiver (Kunda and Thagard 1996). Attitudes change in a way that increases consistency across attitudes and beliefs (Spellman et al. 1993). Cognitive dissonance is reduced as constraints imposed by attitudes, beliefs, and their implications are employed to increase consonance (Shultz and Lepper 1996). Objects are recognized by matching visual scene information with model features in a consistent way (Chen and Lin 1994). An input string of letters is transformed within a recurrent feed-forward network into an attractor representing a pronunciation of the corresponding word (Plaut et al. 1996). Damaging the units or connections of recurrent feed-forward networks alters the basins of attraction, simulating a variety of neuropsychological deficits such as dyslexia and prosopagnosia (Plaut 1995).

5. *Future Trends in Constraint-satisfaction Research*

Current activities can be extrapolated to predict some near-future trends in research with constraint-satisfaction models. First, it is likely that constraint-satisfaction models will be extended to other psychological phenomena. These might include cognitive balance theory, belief maintenance and perseverance, problem solving, and additional neuropsychological deficits.

For both new and current domains, it can be expected that constraint-satisfaction models will be run, not only to cover existing psychological phenomena, but increasingly to predict new phenomena that could guide empirical research.

Efforts might continue to expand the limited memory capacity of current constraint-satisfaction networks. The number of patterns that *Hopfield* networks can store and accurately retrieve is only 13.8 percent of their number of units (Hertz et al. 1991).

Neural network modelers might use some of the heuristics discovered in symbolic constraint-satisfaction research to enhance the power of neural models to cover the guessing and backtracking required on more difficult problems.

Finally, the neurophysiology of constraint satisfaction could be more fully explored to the mutual benefit of both modeling and brain research. Evidence has been found for attractors in the olfactory system of rabbits and cats (Freeman 1991) and in monkey visual cortex (Miyashita 1988). Brain imaging of humans suggests that the anterior cingulate cortex is involved in the monitoring of cognitive conflict and interference, and this can be modeled by neural network energy (Botvinick et al. 1998).

Constructivism/Constructionism: Methodology

What makes a particular research method 'constructivist' or 'social constructionist' in orientation? In a sense, the answer lies less in the method or technique itself than in the philosophy with which the technique is used. For example, an interview can be conducted to count the number of positive self-statements in the interviewee's verbal output, or to classify him or her according to some extant diagnostic system. However different these aims might be from one another, both could be considered to express traditional research goals associated with applying or creating universally 'true' or valid categories for human experience. In contrast, other interviews might be conducted to tease out a network of personal meanings unique to a particular respondent, to reveal his or her shifting reliance upon different narratives over the course of therapy, or to raise questions about the apparent coherence of a particular line of political discourse. Such interview methods might well be constructivist, as they focus on distinctive patterns or processes of constructing (or deconstructing) meanings in a given personal or social context, without the presumption of universality that attends traditional knowledge claims in psychological science.

More specifically, a research method might be classified as constructivist or social constructionist to the extent that it (a) elucidates 'local' as opposed to 'universal' meanings and practices, (b) focuses upon provisional rather than 'essential' patterns of meaning construction, (c) considers knowledge to be the production of social and personal processes of meaning-making, and (d) is more concerned with the viability or pragmatic utility of its application than with its validity *per se*. This emphasis on local, provisional, and pragmatic assessment of (inter)personal meanings can be illustrated by a closer consideration of three core techniques associated with a constructivist or social constructionist approach, each of which encompasses many different variations. These include repertory grid technique, analysis of narrative processes in spoken or written 'text,' and discourse analysis.

1. Repertory Grid Technique

Developed within personal construct theory, the repertory grid technique represents a widely used method for studying personal and interpersonal systems of meaning. Because of their flexibility, repertory grids (or *repgrids*) have been used in literally thousands of studies of a broad variety of topics, ranging from children's understandings of physical science principles and consumer preferences to formal structures of self-reflection within cognitive science and the mutual validation of belief systems between friends. However, their most consistent area of application has probably been in the clinical domain, where grids have been used to assess the meaning systems of clients in psychotherapy, and how these change over the course of treatment. The 'reptest' was initially designed by George Kelly, the author of personal construct psychology, as a means of assessing the content and structure of an individual's repertory of role constructs—the unique system of interconnected meanings that define his or her perceived relationships to others.

In its simplest form, the reptest requires the respondent to compare and contrast successive sets of three significant people (e.g., my mother, my father, and myself), and formulate some important way in which two of the figures are alike, and different from the third. For example, if prompted with the above triad, a person might respond, 'Well, my father and I are very self-reliant, whereas my mother is very dependent on others.' This basic dimension, *self-reliant vs. dependent*, would then be considered one of the significant themes or constructs that the person uses to organize, interpret, and approach the social world, and to define his or her role in it. By presenting

the respondent with a large number of triads of varying 'elements' (e.g., a previous romantic partner, best friend, a disliked person, one's ideal self), the reptest elicits a broad sampling of the personal constructs that constitute the person's outlook on life and perceived alternatives. These constructs can then be interpreted impressionistically, used as the basis for further interviewing of the respondent, or coded using any of a number of reliable systems of content analysis, conducted either manually or using available computer programs.

Although the analysis of construct content is often revealing, most contemporary users prefer to extend the method beyond the simple elicitation of constructs by prompting the respondent subsequently to rate or rank each of the elements (e.g., people) on the resulting construct dimensions. For example, a respondent might generate a set of 15 constructs, on which 10 important elements (e.g., my mother, father, self, partner) could be rated, yielding a matrix of 150 specific ratings that would then be amenable to a wide range of analyses. Although the repgrid was originally devised as an interview-based or paper-and-pencil measure, most contemporary users rely on any of a number of computer programs for their elicitation and analysis, such as the popular *WebGrid III* program available via the Internet.

Although analysis of the grid can focus on simple element ratings (e.g., observing that the respondent views herself as *self-reliant*, *hard-working*, *emotionally controlled*, etc. on a sample of her personal constructs), it is typically more helpful to conduct a comprehensive analysis of the grid to discern larger patterns. This might involve correlating and factor analyzing the matrix of ratings to see at a glance which constructs 'go together' for the respondent (e.g., *self-reliance* is associated with being *psychologically healthy*, whereas *dependence* implies *weakness*), or to learn what people are most and least alike in the respondent's view. These linkages among constructs often suggest why people remain 'stuck' in symptomatic patterns, as when a client resists reconstruing himself as *happy* instead of *depressed*, because the former is associated with being *superficial* as opposed to *deep*. Similarly, patterns of identification among elements in a grid can be clinically informative, with some of these (e.g., degree of correlation between actual self and ideal self) providing useful indices of progress in psychotherapy.

At the most general level, grids can be useful for identifying how 'tightly' or 'loosely' a given person's meaning system is organized, as revealed, for example, by the average degree of correlation among the constructs that comprise it. Like most constructivist methods, repgrids focus on personal or local (e.g., family) systems of meaning, with no assumption that these generalize to other people. Moreover, repgrids measure construct systems at a particular moment in time, demonstrating meaningful sensitivity to variation across education and psychotherapy, rather than presuming to reflect invariant psychological essences. Finally, most users of repertory grids consider the ultimate hallmark of their value to be the degree to which they prompt relevant insights for the respondents who complete them, although some investigators have also demonstrated their validity and reliability in more conventional terms. Assessment methods having some affinity to the grid technique include the *laddering technique*, which elicits the higher-order value implications of the respondent's constructs of behaviors and social roles, and the *self-confrontation method*, which evaluates an individual's sense of agency and communion with others through an analysis of important life events. A common feature of these methods is their focus on *personal structure*, viewing meaning in systemic terms that can be depicted visually to enhance its comprehension and discussion by research participants.

2. *Narrative Analysis*

Narrative psychology considers thinking processes to be guided by the structures and elements of which stories are composed. Instead of viewing logic as the guiding force behind information processing and meaning making, narrative psychologists view people as organizing life events into plot structures and creating themes that give them significance. This model of organization can be classified as constructivist due to the agentic, creative processes involved in the formation of narratives.

Individuals create stories to help them comprehend and communicate their experiences and interactions in the world. Narratives are generated through the use of language, common scripts, and symbols derived from different cultures and traditions, and therefore are necessarily context dependent. Stories produced are seen as reflecting truths unique to their individual authors and contexts and as rooted within distinctive lived histories.

The narrative perspective has become popular only over the last 20 years, but has grown rapidly into a movement in psychology, partly due to its broad relevance across cognitive, developmental, and clinical areas of research. In the cognitive domain, investigators have demonstrated that people inherently organize ambiguous experiences using story schemas, and have studied the way that narrative formation structures memory as well as perception of events. Developmental researchers have traced the emergence of children's story-telling competencies, and their progressive shift toward accounting for the perspective of listener vs. narrator. In the domain of psychotherapy, researchers have developed methods for mapping the topical and thematic shifts that characterize client accounts of their experience, relating these to good and poor outcome. The *Narrative Process*

Coding and System illustrates the use of constructivist methods to identify and characterize narratives from transcribed psychotherapy sessions.

First, an investigator using the system segments the session dialogue into topic units that are identified through shifts in protagonists and themes. For instance, a client may begin a session discussing a conflict she is having with a colleague and then shift to examining a marital issue. The identification of topic segments can allow researchers to consider how themes are maintained or changed through discussion and how the interpersonal psychotherapeutic process can act to facilitate narrative development. Second, the researcher codes these topic segments into one of three narrative processes. External narrative sequences are dominated by event description. The recounting of the steps entailed in registering for university would be an example of this narrative sequence type. Internal narrative sequences focus upon emotional and experiential states. For instance, a portrayal of the different feelings present on the first day of classes would exemplify this narrative process. Finally, reflexive narrative sequences entail analysis and interpretation of events and internal reactions in order to understand their significance. An exploration of the meaning of attaining a higher education would be classified as reflexive. Within different psychotherapy orientations, research has suggested specific patterns of narrative process associated with positive outcome. For instance, a shift between internal and reflexive exploration has been associated with successful humanistic psychotherapy.

Like other methods, whether or not the narrative process coding system is 'constructivist' depends on the epistemic intent that guides its use. For example, the system can be used within an objective, experimental model of science to compare the distribution of narrative sequences within different transcripts. Within such a model, results can be tabulated and statistical arguments for generalization of findings can be developed that aspire toward more universal implications. Although useful in some respects, such an application departs from the emphasis on individuality that characterizes most constructivist research. Alternately, this narrative tool can be used in a discovery-oriented framework, and themes identified that represent local, provisional truths. For instance, dominant narrative themes could be identified within the discourse of women with eating disorders on the topics of food and body image, and these themes could be explored in relation to the lives of these individual women and their social contexts.

Other narrative coding methods include the identification of *core conflictual relationship themes* implicit in client accounts of problems with other people, and the coding of interviews to establish the degree to which the narrator experiences him or herself as an *origin* or *pawn* in connection with important events. In each case, the epistemic framework within which findings are presented and interpreted will dictate whether or not a method is being used in a constructivist spirit.

3. *Discourse Analysis*

Whereas constructivist methods tend to focus on the meaning-making efforts of individuals, families, and small groups, social constructionist methods shift attention to the broader systems of 'languaging' that characterize public speech, disciplinary discourse, or cultural contexts. Even when applied to individual language users, such methods tend to have a critical thrust, such as when careful 'deconstructive listening' is used to bring to light the hidden assumptions that constrain a speaker's view of what positions are permissible for self or others. Social constructionist methods are in this sense more radical than constructivist methods, attempting to uproot oppressive and marginalizing forms of thinking and speaking that have dehumanizing consequences.

An example of social constructionist methods is provided by *discourse analysis*, the critical evaluation of social 'texts' to reveal their concealed constraints and contradictions. For example, analyses of published debates in the South African parliament in the early 1980s have elucidated the shared assumptions about the superiority of whites held by both liberal and conservative MPs. Likewise, feminist discourse of the 1970s has been 'deconstructed' to expose the ways in which 'butch/femme' lesbians were marginalized to support a politic that advocated lesbian androgyny. Interestingly, discourse analysts have been especially active in undermining traditional assumptions in psychology, such as the largely unexamined convictions that people ideally function as rational 'selves' and that psychotherapy involves a move toward greater 'reality contact.' As a method, discourse analysis appears to be more an art than a science, borrowing from deconstructive and critical literary theory in order to understand and resist 'dominant narratives' that limit the terms of debate or the permissible range of human variation that is considered 'normal.' It is therefore sometimes used by psychotherapists concerned with helping clients free themselves from the oppressive narratives of their lives, and recover a sense of themselves as the authors of their experience. Related social constructionist methods include the *analysis of rhetoric*, the tropes or moves used to advance a persuasive argument, and *textual analysis*, which reveals the way in which authors skillfully position themselves and others within the moral discourse of an account, so as to present themselves to best advantage.

In summary, constructivist and social constructionist methods in psychology are multifaceted in form and diverse in application, but tend to express a shared commitment to revealing the structure of personal and

collective meanings and the processes by which they are constructed. Given their convergence with postmodern trends in the human sciences, it is likely that their influence will continue to grow in the future.

Constructivism in Cognitive Psychology

Constructivist thinking and reasoning have played a major role in psychology for several years; for example, in William James' 'pragmatic method' as well as in Barlett's 'construction of remembering.' In modern cognitive psychology constructivist principles and concepts are the basic elements of research, especially in the fields of learning, language and memory. Rumelhart (1980) analyses cognition as an interpretation process controlled by cognitive schemes. Johnson et al. (1999) examines the construction of mental models for 'extensional reasoning' of 'naive individuals.' Constructivist principles and concepts are also relevant for scientific knowledge because 'knowledge of all kinds, including scientific knowledge, is a construction of the human mind' (Scarr 1985, p. 499). The concept that all knowledge and thinking is a result of construction is certainly the core assumption of all versions of scientific constructivism.

1. What does Constructivism Mean?

Constructivist approaches refer to an epistemological position in which knowledge is regarded as constructed. These approaches concentrate on the analysis of single processes or functions. Constructivist approaches present themselves through a remarkable spectrum in psychology. Therefore, our understanding of constructivism as a unifying principle is questionable. Instead we prefer to distinguish varieties of constructivist reasoning in psychology (and philosophy), which share at least the first two of the following characteristics: they analyse the ability of individuals to act and to demonstrate self-control, partly with the consequence of taking distal variables like genetic variation into special consideration (Scarr 1985, p. 510). They are based on the assumption that knowledge is the result of constructive processes; and the consequence of this for the analysis of person-situation-interaction is that these are constructed on the basis of experiences, i.e., the same context is seen and applied differently.

Finally, interventions and instructions will be viewed here in relation to individually-constructed experiences and their applicability and fit. These three characteristics are core features of constructivist reasoning. The following representation of constructivist perspectives in psychology refers to the consideration of these features and not only to the fact that the author calls himself a constructivist. This manner of thinking is legitimate because on the one hand there are numerous authors who do not call themselves constructivists but are closely associated with this perspective. On the other hand, there are considerable differences between various constructivist approaches, especially between radical constructivism and social constructivism as well as between constructivist approaches to learning and knowledge acquisition.

Radical constructivism—which views realism in science as inadequate and assumes an informational closeness of cognitive systems (Maturana & Varela 1987)—plays a subsidiary role in psychology, even though it is postulated as the prototype of constructivist perspectives. Radical constructivists like Maturana or Varela always question the possibility of objectivity and truth because only information which is viable and serves to support the system is, according to them, processed. Truth, objectivity and knowledge are thus constructed. Radical constructivism focuses on epistemology and studies the relationship between knowledge and the world, rejecting realism and any form of ontology.

A second version of constructivism is named 'constructionism' or 'social constructionism'. This version

follows the tradition of the social psychology of Cooley and Mead. It analyses the processes 'in which the individuals describe and explain the world in which they live or how they see it' (Gergen 1985, p. 3f). Social constructionism, in contrast to radical constructivism, focuses on the acting and thinking individual and describes the construction of knowledge as the result of social interaction in contexts which form the foundation of shared knowledge. This view has proven itself remarkably fruitful for numerous psychological fields, for example, in the analysis of cognitive development or the development of prejudice and self-impression.

A third version of constructivism is engaged in exploring the correlation of learning and instruction, especially in the area of mathematic knowledge (Cobb et al. 1997, Resnick 1994). Knowledge acquisition is discussed here in close connection with situated learning and related instructional approaches. In this review, only the two last-presented versions of constructivism will be discussed, due to the fact that these have been the most influential in cognitive psychology. First of all, approaches which define themselves as constructivist will be presented. Second, studies will be discussed which contain the core features of constructivist reasoning. Constructivism emphasizes the active experience-based knowledge construction and its embedding in social contexts. From this point of view intervention and instruction are chosen with regard to their individual fit. In this article cognitive tools which are typical for constructivistic approaches will be discussed first: conceptual metaphors, cognitive schemes, and subjective theories. In the second part they will be described in different psychological application areas. Therein the potential of constructivistic approaches for the research on text comprehension and the development of domain-specific knowledge can be shown. Moreover a better understanding of the relationship between construction and instruction can be gained.

2. *Principles for the Construction of Knowledge*

'The business of cognitive science is to give empirically grounded explanations of the phenomena of mind, in the broadest sense of that term' (Fernandez-Duque and Johnson 1999). Thus the goal of cognitive psychological studies is the pursuit of principles and concepts which describe and explain the construction of knowledge. Piaget compares a child's development of intelligence to the development of scientific theories. Bruner (1990) suggests the use of concepts which are useful to the analysis of narrative structures for the analysis of mind. Personal constructs (Kelly 1955), cognitive schemes (Rumelhart 1980), metaphors (Ortony 1980), folk theories of mind and behavior (Bruner 1990, Lillard 1998) and theory-theories (Gopnik & Wellman 1994) have proved important for the construction of everyday knowledge and scientific knowledge. Through these concepts, active experience-based processes of knowledge construction, rooted in different contexts, are analyzed.

Kelly points out in his personal construct theory in 1955 that individuals basically behave like scientists: they too develop theories about their environment and use personal constructs of prediction and interpretation to control their environment. Kelly postulates these predictions by forming and using personal constructs as active psychological processes which lead to different choices. Individuals cannot always change their environment, but they can always construct it differently. Kelly (1970) described this as constructive alternativism. Psychological research is especially useful to facilitate effective psychotherapy. Personal constructs represent the experiences of individuals and form the precondition for active, sometimes alternative construction of knowledge. Rumelhart uses the concept of cognitive schemes in a constructivist manner to analyse knowledge representation and how that representation facilitates the use of knowledge in particular ways (Rumelhart 1980, p. 34). Cognitive schemes are understood as data structures. They are active computational devices which represent meaning and procedural knowledge. Following Barlett with his 'gist story,' Rumelhart describes the effects as interpretation and as a reconstruction of the original interpretation. Rumelhart later (1999) uses the concept of metaphor in a more complex way, as a theoretical model by employing the computer of the computer as a model of mind. Such metaphors of mind (Ortony 1980) are currently used for describing different research approaches, i.e., attention and metaphors for learning.

Fernandez-Duque and Johnson (1999, p. 84) understand the conceptual metaphor 'as conceptual mapping of entities, properties, relations and structures from a domain of one kind (the source domain) onto a domain of a different kind (the target domain).' They understand it as a tool for the construction of scientific theories. Here you can also find typical arguments for constructivist approaches, even though the researchers do not regard themselves as constructivists. Fernandez-Duque and Johnson show 'that a highly constrained set of conceptual metaphors is constitutive and definitive of the theoretical perspectives taken toward attention and toward the search programs based on these theories' (Fernandez-Duque and Johnson 1999, p. 84). Conceptual metaphors like the ones described above not only structure folk models but also 'our most sophisticated scientific theories.' Fernandez-Duque and Johnson show this by using metaphors such as the filter metaphor, the spotlight metaphor, the spotlight-in-the-brain metaphor and the attention-as-vision metaphor. These metaphors guide research questions and influence the search for data and its interpretation.

Metaphorical reasoning is clearly central to the construction of ordinary and scientific knowledge, for mathematic as well as for cognitive psychology (Moreno & Mayer 1999). Ortony (1980) as well as Sternberg (1990) emphasize the function of metaphors in the creation of new knowledge and promote viewing incidents in a new light, because 'without an understanding of the metaphors that generate or at least guide various theories' (Sternberg 1990 18), psychological theories of intelligence can not adequately be related to each other. Mayer (1992) describes the theoretical development of learning as a development of three metaphors; the metaphor of response acquisition, knowledge acquisition and knowledge construction.

The construction of new knowledge by cognitive schemes and metaphors can as well be found in approaches in which knowledge construction in everyday life is basically viewed as equivalent to the development of scientific knowledge. This equivalence of folk psychology and scientific psychology (Bruner 1990) means that new knowledge is constructed as meaningful knowledge and that narrative formats are regarded as key tools for the construction of meaning. In his representation of the theory of mind, Bruner emphasizes the assumption that ordinary knowledge is equivalent to theoretical knowledge and is generated domain-specific and in the range of cognitive development. Children develop concrete theories of everyday psychology or about mathematics, which they constantly change.

Those naive theories, as well as metaphors and cognitive schemes, encompass different but related coherent concepts which are used as tools for the construction of knowledge. Thus these concepts are 'building blocks of cognition' (Rumelhart 1980), which describe and explain the phenomena of mind (Fernandez-Duque & Johnson 1999). The views related to these concepts describe remarkably closely the core features of constructivism, specified at the beginning of this article.

3. *Fields of Application for Constructivist Approaches in Psychology*

In the following part, some of the most important fields of application for constructivist approaches in psychology will be analyzed. These include remembering and knowledge representation, language and text comprehension, learning and instruction, and cognitive development as well as social cognition, social biases and social stigmata. Cognitive processes are still the most important aspects of research using constructivist approaches. In developmental and social psychology a considerable amount of social constructivist research can be found which expand on the theories of Piaget, Vygotsky, and Mead (Berger and Luckmann 1966).

In 1932 Bartlett stated that remembering 'is an imaginative reconstruction, or construction, built out of the relation of our attitude towards a whole active mass of organised past reactions or experience' (Bartlett 1932, p. 213). Bartlett used the concept of cognitive schemes but did not think it as important as Rumelhart did (1980). Remembering is, according to Bartlett, less the recall of knowledge memorized in cognitive schemes and more of a transactional process which zigzags between the perception of past and new experiences and which leads to revised construction of knowing and acting. Psychologists arguing in a constructivist way often refer to Bartlett, however, they come to very different assumptions about the functional meaning of cognitive schemes and their evaluation of 'stored schema view' (Clancey 1997).

Clancey (1997) regards the 'stored schema view' as inadequate and undynamic. Thomas (1999, p. 224) argues in a similar way, claiming 'it is not the schema but the activity it supports that carries intentionality and embodies our perceptual and imaginal awareness'. In contrast to activity-oriented approaches, the mental model theory states that 'what we perceive depends on both what is in the world and what is in our heads—on what evolution has wired in our nervous system and what we know as a result of experience. The limits of our models are the limits of our world' (Johnson-Laird 1989, p. 471). Johnson-Laird et al. (1999) understand mental models as cognitive representations of relevant situations, which have a structure and content. At present these types of moderate constructivist approaches represent the mainstream of cognitive psychology. This is also demonstrated by the fact that the situated approaches have problems with certain phenomenon, especially with the phenomenon which Landauer and Dumais (1997) call 'Plato's problem' or 'the poverty of the stimulus,' i.e., 'how people acquire as much knowledge as they do on the basis of as little information as they get.'

This problem is the basis of Chomsky's nativist-constructivist theory of language (Chomsky 1991). Chomsky emphasized the creative aspect of language, because a person always hears for the first time the combination of sentences which another speaker verbalizes. Thus Chomsky and his school propose 'a language acquisition device, an innate mechanism which prepares linguistic competences like a language instinct.' The theories for text comprehension emphasize both language production and the active construction of knowledge. Kintsch and his associates (1988) developed a theoretical model of text comprehension which discriminates between a text basis, i.e., the relations deduced from semantics, and a situational model. They have also evaluated the model in various studies.

Deep understanding is not possible until a situational is constructed, which integrates a textual basis and the reader's knowledge. To this end Kintsch (1988) presented a theoretical approach which he

calls 'construction-integration model.' In the above-described sense, this model of text comprehension is a constructivist model which describes in detail knowledge-construction and the activation of knowledge. In addition, there are studies which consider the third core feature of constructivist reasoning, which involves instruction in the ideal proportion of individually-constructed experiences and their individual usability and fit. McNamara et al. (1996) showed that 'high-knowledge readers could be stimulated by difficult, less coherent texts to active processing.' Studies like the one described above show that language reception and text comprehension for the purpose of generating situational models can be adequately supported by constructivist instruction. It is at this point that constructivist-oriented theories of learning and instruction begin. These theories analyse which learning environment supports the construction of knowledge without affecting active processing. These approaches, which view themselves as constructivist, are subsumed under the notation 'situated learning.' The particular characteristics of situated learning are:

(a) learning is an active and constructive process (the situational perspective shares this assumption with the cognitive perspective);

(b) the process focuses on the sharing of distributed knowledge in social groups;

(c) learning is analyzed in the framework of learning environments and described as an adaptation to the constraints and opportunities of the context;

(d) such adjustments are based on the participation of the members of the learning group. Their participation is at first characterized as peripheral and then as central as experience is gained.

Analyses of situated learning prefer to focus on the analysis of effective learning environments and their characteristics. Some of these characteristics have been realized in the following approaches: 'cognitive apprenticeship' (Collins et al. 1989), 'collaborative learning culture' (Brown 1997) and 'authentic learning' (Bruner 1990).

The theory of situated learning is first of all constructed as a theory of instruction and of the mode of operation of learning environments. This theory shares with the cognitive view the assumption that learning is a constructive and knowledge-based process. A further basic assumption is that the use of new media for the development of constructivist learning environments is taken into consideration (Moreno & Mayer 1999).

The development of learning and knowledge acquisition is another subject of constructivist-oriented approaches in long-term studies. This is particularly important for the constructivist theory of mind (Schwanenflugel et al. 1998), which is generated by children for different knowledge domains: about nature (physics, biology) or about memory, comprehension and the intentionality of interpersonal relationships (psychology).The theory of mind is at its core a constructivist approach, which is based on the following assumptions:

(a) knowledge is organized in a similar manner to theory and refers to a core set of beliefs;

(b) the theory of mind is relatively coherent, uses constructs and serves as a basis for predictions and explanations for the behavior of other persons;

(c) the theory of mind is at least partly innate or innately predisposed;

(d) Parts of the theory of mind clearly underlie cultural variations, for example the fundamental ideas of what causes action (Lillard 1998).

Theories of mind are often equated by researchers to scientific theories and conceptual change as a change of paradigm in the sense of Thomas Kuhn. Such analogies can be found in Piaget, Kelly, Bruner and representatives of the theory-theory. Equating the theory of naïve actors and scientific theories is highly problematic if questions of validity, falsification or operationalization are regarded. This position also underestimates the efficacy of social biases (for details see Nickerson 1999) and how they are analyzed by the research of social judgement.

The effect of social cognition in the construction of individual reality has a long tradition, especially in social psychology. For Gergen, a basic assumption for social construction is that 'the terms in which the world is understood are social artifacts, products of historically situated interchanges among people' (Gergen (1985, p. 4). These artifacts are of various types. They range from quality attribution to implicit personality theories to social processes of stigmatizing. One of the most robust findings of individual perception research is the 'lay dispositionism' (Choi et al. 1999). It is upon this finding that typical judgement failures like the correspondence bias, i.e., the belief that behavior of other persons can be explained by personality traits or other internal attributes, are based. Modern social judgment research shows clearly the manner in which individuals construct their knowledge about other persons. This research also demonstrates how individuals impute their own knowledge to others (Nickerson 1999) and retain conflicting attitudes which coexist in the different evaluations of the same attitude object. Wilson et al. (2000) convincingly describe in their model of dual attitudes how old, stored attitudes interact in different ways with new constructed attitudes and thus remain stable while affecting behavior.

Stereotype correspondence biases, dual attitudes and implicit personality theories are, like the above-mentioned metaphors and cognitive schemes, important tools for the construction of the individual reality. This construction is faulty and these errors are subject to revision in the framework of 'bargaining processes' in cooperative groups, especially 'if anchor and adjustment heuristics are used' (Nickerson 1999). These constructions of reality become problematic if they lead to social stigma. Stigmatizing is commonly

understood as a process by which the members of a group mark a stigmatized individual as a consequence of the internalized judgments (Crocker et al. 1998). Research on the construction of coherent knowledge about one's own personality by judgments of others, stereotypes and lay dispositionism (Choi et al. 1999) show remarkably clearly how moderate constructivist psychological approaches give rise to empirically-based explanations of the phenomena of mind (Fernandez-Duque and Johnson 1999).

4. Conclusion

There are considerable differences within this research domain, especially with regard to the meaning of cognitive representation and the question of the extent to which plans control actions. The question regarding the degree to which individual action is influenced by universal principles is also contentious. For Chomsky and his school, language acquisition is controlled by a powerful innate mechanism. Resnick (1994) speaks in this regard of 'biological constraints and prepared schemes and skeletal and hardwired structures which influence learning by protomathematic dispositions.' In contrast, Scarr emphasizes the importance of 'genetic variation and genotype-environment effects for the development of intelligence' (Scarr 1985). In addition, ideas can be found regarding the effect of the social stereotype and the blindness of individuals due to correspondence bias and lay dispositionism (Choi et al. 1999). Bargh's pessimism becomes apparent when he speaks about a cognitive monster—an enormous amount of once-constructed stereotypes, which are resistant to change and once activated, produce automatic stereotypes (Bargh 1999).

These two poles characterize the wide range of constructivist thinking in psychology and show once again the importance of constructivist-oriented instructional support. By the promotion of instruction—which offers room for the construction of knowledge, self-control, self-organization and shared knowledge in collaborative groups—the gulf between nativism and the cognitive monster can be bridged. This is the position of a moderate constructivism, which is particularly accepted by modern psychology in connection with multimedia. This position bears little relation to the radical constructivism and its refusal to recognize reality and objectivity.

On the other hand, the moderate constructivism, which we represent, opens new doors to understanding the phenomenon of mind. The moderate constructivism emphasizes processes like knowledge acquisition, the individual activity potential and the importance of reality construction without claiming the equivalence of naive and scientific knowledge.

Constructivist Psychotherapies

As a philosophical position that emphasizes both personal and social processes of meaning-making, constructivism has influenced several contemporary traditions of psychotherapy. For this reason it is more accurate to consider constructivism as a general approach to understanding people, conceptualizing psychological distress, and fostering human change than to view it as a distinctive 'school' of psychotherapy associated with a particular theorist, preferred method, or specific set of problems requiring treatment. Thus, constructivism is best viewed as a 'metatheory' that encompasses many late twentieth century developments in clinical theories as diverse as psychoanalysis, existential-humanistic psychotherapy, cognitive-behavioral therapy, and family systems approaches. In addition, a number of novel psychotherapies have been devised along avowedly constructivist lines, from personal construct theory, which was formally set forth in the 1950s, to narrative therapy approaches that have become prominent only in the last 10 to 15 years. Appreciating the contributions of these diverse models therefore requires a consideration of their core philosophic similarities and the range of concepts and strategies that shape their expression at the level of clinical practice.

1. *Constructivist Philosophy*

If there is a unifying theme that links constructivist forms of psychotherapy, it is at the level of their epistemology, or theory of knowledge. Although most constructivists acknowledge that a 'real world' exists outside of human consciousness or language, they are much more interested in the nuances in people's construction of the world than they are in evaluating the extent to which such constructions are 'true' in representing a presumably external reality. This emphasis on the active, form-giving nature of the mind dates back at least to the Italian rhetorician and historian Giambattista Vico (1688–1744), who traced the development of thought to the attempt to understand the world by projecting upon it human motives, myths, fables, and eventually linguistic abstractions. The German philosopher Immanuel Kant (1724–1804) likewise emphasized the transformative character of the mind, which necessarily imposes spatial, temporal, and causal order on the phenomena of experience. From these philosophers, constructivists borrowed a model of knowledge as an active structuring of experience, rather than a passive or receptive assimilation of a 'noumenal' reality of 'things in themselves,' uncontaminated by human knowing.

At the threshold to the twentieth century, these themes were elaborated by the German analytic philosopher, Hans Vaihinger (1852–1933), whose Philosophy of 'As If' asserted that people develop 'workable fictions' (e.g., of mathematical infinity or God) to order and transcend the hard data of experience, and establish distinctively human goals. A similar emphasis on the distinction between our linguistic 'map' of experience and the 'territory' of the

world was made by the Polish intellectual Alfred Korzybski (1879–1950), whose system of general semantics focused on the role of the speaker in assigning meanings to events. From these thinkers, constructivists drew the implication that human beings operate on the basis of symbolic or linguistic constructs that help them navigate in the world without contacting it in any simple, direct way. Moreover, they suggested that such constructions are viable to the extent that they help us live our lives meaningfully and find validation in the shared understandings of others in our families, communities, and societies. 'Postmodern' thinkers who follow in this constructivist vein further stress the extent to which we live in a world constituted by multiple social 'realities,' no one of which can claim to be 'objectively' true across persons, cultures, or historical epochs. Instead, the constructions on the basis of which we live are at best provisional ways of organizing our 'selves' and our activities, which could under other circumstances be constituted quite differently.

2. *Constructivist Psychotherapies*

The first person to develop a thoroughgoing theory of psychotherapy along constructivist lines was the American clinical psychologist, George Kelly. Working in the relative isolation of rural Kansas in the 1930s and 1940s, Kelly confronted the overwhelming psychological needs of farming communities that had been devastated by the twin crises of the Dust Bowl and the Great Depression. This prompted Kelly to design efficient psychotherapeutic procedures in which clients were coached to enact fictional identities in their daily lives for a fixed period of time (usually only 2 or 3 weeks). Working from a 'self-characterization' written by the client, the therapist and a consulting team first drafted an 'enactment sketch' of an imaginary person whose way of construing life differed from, but did not necessarily contradict, the client's own. The client and therapist then practiced this novel role in a series of therapeutic enactments with the therapist playing various acquaintances, authority figures, and family members, while the client simultaneously generalized the role to the actual relationships in his or her life. At the end of this period, the role was consciously set aside, and the therapist and client discussed the extent to which the client's sense of self and social world were permeable and provisional constructions that might be lived out quite differently if viewed in alternative ways. Kelly's 'fixed role therapy' was therefore the first form of brief therapy, and it foreshadowed the use of dramatic and narrative strategies of change incorporated in many contemporary constructivist therapies. Eventually, Kelly drafted a comprehensive psychology of personal constructs that placed these procedures in a rigorous theoretical context, and suggested diagnostic, therapeutic, and research methods targeting the unique meaning systems that individuals devised to structure and anticipate the themes of their lives. Interest in Kelly's work remains strong throughout North America, Europe, and Australasia, with contemporary personal construct theorists challenging, broadening, and applying his initial theory to a range of current problems and disorders.

A second tradition of constructivist therapy began to gain momentum in the late 1970s as an outgrowth of cognitive and cognitive-behavioral therapies emphasizing the role of the person's interpretations of events in a range of disorders. Michael Mahoney, an American pioneer in the cognitive trend, began to critique its reliance on rationalistic epistemologies that presumed that emotional adjustment was a straightforward matter of making one's cognitions realistic and in line with an observable world. In particular, Mahoney, along with colleagues such as the Italian theorist Vittorio Guidano, began to turn attention to the 'core ordering processes' by which persons construct and maintain a sense of self in a social field. This gave rise to more developmental forms of constructivist psychotherapy, which focused on the periodic perturbation of an individual's conscious identity through confrontation with difficult or traumatic live events. At a strategic level, these therapies involve a variety of procedures for enhancing clients' self awareness and helping them reconstruct an emotionally coherent sense of their identities across time. Significantly, this emphasis on identity construction redirected attention to the often tacit, intuititive, and non-conscious processes by which people organize their experience of self and others, extending the more common focus of cognitive-behavioraltherapies on people's conscious 'inner dialogue' or 'automatic thoughts.' By the 1990s, a focus on cognitive-emotional schemes of self-and-relationships had begun to augment more traditional cognitive therapies, and even initially rationalistic approaches such as the American psychologist DonaldMeichenbaum's cognitive-behavioral modification began to be revised along constructivist lines (see *Cognitive Therapy*).

As the more relativistic philosophy of constructivism became widespread, it began to permeate even long-standing traditions of psychotherapy, such as psychoanalysis. One harbinger of this trend was the American analyst Donald Spence who argued that analysis could not unearth the historical truth of the patient's life, but only constitute a procedure for disclosing its narrative truth in the eyes of its author—the client. In keeping with the psychoanalytic tradition, however, constructivist analysts still tend to emphasize the usefulness of accessing and reviewing emotionally significant memories of one's early life, but view these less as veridical 'insights' than as inventions subject to the demand for narrative

'smoothing.' One interesting recent expression of this approach is the depth-oriented brief therapy developed by the American psychologists Bruce Ecker and Laurel Hulley, which uses a procedure of radical questioning to reveal the hidden implications of the client's pro-symptom and anti-symptom positions. Like other contemporary constructivist approaches, this integrative model of therapy relies more heavily on experiential exploration of the client's meanings (e.g., using visualization exercises) than on the interpretive stance preferred by classical psychoanalysts.

Another long-standing tradition to be influenced by a constructivist position is humanistic-existential psychotherapy, whose emphases on human choice, agency, and phenomenology or the study of experience converged with core themes in personal construct theory and related forms of constructivist theory. One outgrowth of this convergence is the self-confrontation method devised by the Dutch personality theorist Hubert Hermans which uses open-ended questions to elicit those 'valuations,' or important units of meaning that a person uses to structure a sense of her or his past, present, and future. The client then rates critical life experiences on a standard list of affect terms, which yields measures expressing the degree of self-enhancement, union with others, negative emotions, and positivity associated with each, providing a basis for self-reflection or a method for mapping therapeutic changes in meanings over time. A second example of the infusion of constructivist themes into humanistic therapy is the dialectical approach of the Canadian psychologist, Leslie Greenberg, which emphasizes the role of personal experience and internal conflict in the creation of subjective meaning (see *Experiential Psychotherapy*). For example, therapy might attempt to synthesize two strongly-felt and mutually contradictory internal experiences, such as self-contempt and the self-prizing. This could involve helping the client vividly experience both stances through the use of a 'two chair' technique, in which the client successively speaks from each position and fosters their integration into a new structure (e.g., self-acceptance). In keeping with constructivist themes, the 'selfhood processes' that are the focus of theseapproaches are viewed as continually evolving andprovisional, rather than a static 'essence' to be simply discovered or actualized.

Finally, family systems therapies have been revolutionized by a social constructionist perspective, adopting a non-authoritarian view of therapy as conversation whose goal is to alter what the American psychotherapists Harlene Anderson and Harry Goolishian termed the 'problem determined system.' In such approaches, the therapist functions less as an expert dispensing answers, than as a conversation manager who promotes the sort of exchanges among family members that 'dissolve' old problems by 'languaging' about them in a new way. Other family therapists have adopted the constructivist metaphor of lives as stories, and have devised novel means of helping clients free themselves from the 'dominant narratives' that originate in particular families and cultures, and that keep them from feeling like the authors of their own lives. For therapists such as Michael White in Australia and David Epston in New Zealand, externalizing the problem by reconstruing it as something separate from the client's 'self' provides a useful first step toward recognizing its destructive impact on clients and the relationships in which they are engaged. Therapy can then turn toward recognizing and validating those exceptional moments when a person begins to resist the dominant narrative, and rewrite his or her life story along more hopeful lines. A common theme in these systemically informed variants of constructivism is their emphasis on the resourcefulness of individuals, families, and communities in resolving problems in living. Accordingly, clinical work is cast as a search for solutions, rather than a diagnosis of dysfunction.

3. *Critical Perspectives*

Despite the creative contributions of constructivism to contemporary clinical practice, challenges to this perspective have been raised by realists who question what they view at its 'anything goes' relativism. From the vantage point of these critics, the constructivist emphasis on multiple realities risks undermining conventional understandings of 'truth' as well as 'objective' procedures of research into therapy process and outcome. However, constructivists have responded that a respect for the ways in which various people and cultures construe life differently accords well with the diversity and multiculturalism of contemporary life, and actually provides a psychological basis for twenty-first century ethics. Likewise, constructivists have noted that, their criticism of naïve realism notwithstanding, psychologists working within this tradition have carried out literally thousands of empirical studies, on topics as diverse as the structure of personal meaning systems and the intricacies of change in the process of psychotherapy. Significantly, these efforts have often required the development of new tools for revealing individual and conversational meaning-making, such as the role construct repertory grids devised by personal construct theorists, and the narrative process coding schemes validated by constructivist psychotherapy researchers. Thus, it seems unlikely that constructivism will erode the disciplined study of psychological phenomena in an uncritical attempt to embrace all knowledge claims as equally valid.

Tensions also arise within the constructivist camp, particularly between theorists who champion the individual's role in meaning-making, and those who emphasize the extent to which meanings reside in systems of culture and language that precede any given individual. Indeed, the debates engendered by the

latter social constructionist position are likely to continue, as they tend to undermine the straightforward depiction of the self-as-agent endorsed by constructivists with more humanistic leanings. This same emphasis on the social and discursive construction of reality, however, has sensitized constructivism to issues of familial, ethnic, and cultural meanings, thereby enhancing its relevance and inclusiveness. Ultimately, the challenges faced by constructivist theories and therapies can be viewed as the predictable 'growing pains' encountered by any significant new perspective that promises to help shape the future, as well as the present, of psychotherapy.

Consumer Culture

The term consumer culture refers to the culture of the consumer society. It suggests that the representations (signs and images) and values of contemporary societies revolve around consumption: the purchase and enjoyment of goods for the construction of lifestyles. Advertising is important here in supplying a whole repertoire of images and representations of the good life that have become associated with particular commodities and brands. Consumer culture is driven by a modernist dynamic to expanding the range of goods and meanings on offer through the search for novelty, technological innovation, and the exotic. Many of the activities of everyday life are dominated by the consumption of goods and experiences in a variety of sites such as malls, city centers, department stores, theme parks, tourist resorts, heritage centers which offer a range of simulations, spectacular spaces, and sign play. These 'dream worlds' lead to the aestheticization of everyday life with the promise of new experiences, the loosening of emotional controls, and the exploration of desire. At the same time, consumer culture also provides resources for lifestyle construction and the promise of self-improvement and renewal: for reworking the body, identity, and relationships. Resources for repositioning the self within a consumer world in which the constant supply of new material goods, signs, and images make the task of classification, of 'reading the signs,' and locating people and things within stable status hierarchies, all the more difficult and compelling.

1. History of the Term

Production and consumption are often seen as fundamentals of social life. All societies produce some forms of material goods that are exchanged and consumed. Yet the identification, theorization, and naming of specific activities as production, exchange, or consumption is of relatively recent origin and takes its impetus from the emergence of the discipline of economics since the eighteenth century. Historically, the weight of interest has been upon production and exchange, revolving around questions of delineating the general forms and 'laws' seen as governing economic activities. From this perspective, consumption remains relatively unproblematic: people are seen as having 'natural' or infinitely expanding needs and desires for new and better goods. The object of all production is assumed to be consumption, yet why and how people consume, what they do with the consumer goods, given the premise of rational economic action, has only been of peripheral interest, as for example in allegedly marginal situations where people refuse to consume, or purchase and consume 'irrationally.' The sociological critique of economics which

developed in the late nineteenth and early twentieth centuries, focused on the limits of rational action as the sole mode for explaining social life. Durkheim, Weber, Marx, Simmel, Pareto, Parsons, and Veblen analyzed the social and cultural parameters within which economic action was embedded and in various ways began to raise questions of consumption.

For many intellectuals and academics the topic of consumption remained intertwined with discussions of mass culture. The logic of capitalist mass production was seen as leading to a proliferation of standardized consumer goods, in which the aim of marketing was to generate uniformity of taste. Hence culture became produced by industrialized techniques and became a commodity like any other. The culture industries sought to manipulate and control consumption, which became associated with passivity and massification leading to the elimination of individuality and creativity. With the post-World War II society development of a fully-fledged consumer society, especially in the United States, Japan, and parts of Europe, the analyses and critiques of consumption gathered momentum. In the late 1950s and 1960s a number of works came into prominence which sought to diagnose and challenge the logic of the 'affluent society' with its perceived manipulative advertising, status seeking soulless conformism, and suppression of alternative definitions of the good life (Packard 1958, Galbraith 1961, Marcuse 1964).

The term consumer culture itself seems to have originated in the 1970s and gained impetus from the work of Ewen (1976) and Bell (1976) who added historical and analytical depth to these more polemical critiques. Yet the term had little impact on the majority of scholars at the time. In the field of sociology, the sub-fields of the economy, industry, class, and power had long dominated the center of the field. The general tendency in sociology was to operate with a reductive and epiphenomenal view of culture. Yet from the late 1970s onwards the study of culture, everyday life, gender, emotions, leisure, and consumption that had long been marginalized and confined to the periphery, now became seen as legitimate areas of study and began to move towards the center of the field. A key influence here in the 1980s was postmodernism which problematised the role of culture in social life with its focus on the instability and mixing of codes, the overproduction of sign and images, along with the effacement of the boundary between art and everyday life. For some critics postmodernism became seen as the 'cultural logic' of the consumer society, reinforcing the link between image saturation, consumption, and postmodern fragmentation (Jameson 1984, Baudrillard 1993).

Yet for others, the negative evaluation of consumer culture became more problematic. This was especially the case for those writing from within cultural studies, anthropology, and women's studies, who sought to contest taste hierarchies which denigrated popular culture, and allegedly wasteful and mundane activities such as watching television soap operas or shopping. There was also an interest in examining the roots of modern consumption by historians and sociologists, who refused to see the consumer society as an unproblematic outgrowth of industrialization, rather for some a consumer revolution was seen to precede the revolution in production. The origins of consumer culture were traced back to eighteenth-century England (McKendrick et al. 1982), sixteenth-century Elizabethan England (McCracken 1988), and even linked to the rise of a romantic ethic (Campbell 1987). Questions about the particularity of Western consumer culture and the rise of consumer cultures in the big cities of Song and Ming Dynasty China and Tokagawa Japan have also begun to be raised (Myoshi and Harutoonian 1989), along with a greater sense of the longstanding historical centrality of East Asia in an interconnected global economy (Gunder Frank 1998).

In the 1990s the investigation of consumer culture became a part of the legitimate study of culture, as the importance of consumption in providing resources for identity construction and forms of sociability, both mainstream and oppositional, became acknowledged. In response to this more nuanced sense of the role of consumption, a spate of publications, textbooks, edited collections, monographs, and journal articles occurred, along with the founding of specialist journals on consumption. The term began to circulate more widely, gaining legitimacy and currency in the media through the efforts of cultural intermediaries who used the term in exhibitions, museums, and popular culture. Consumer culture has increasingly become a part of everyday language.

2. *Material Goods, Cultural Classification, and the Body*

A central feature of consumer culture is the proliferation of material goods. While people in all societies use material goods, their production, exchange, and circulation are usually limited and surrounded by strong rules and rituals. There have been many instances of sumptuary laws that restrict the consumption of goods, such as the wearing of certain types of clothes (e.g., in the European Middle Ages silks, velvet, lace, bright colors were forbidden to peasants and other groups at the lower end of the social spectrum). The development of a culture around consumption is premised upon the removal of restrictions to access for goods, and the assumption that the capacity to pay the price in the market is the sole arbiter of use. In addition, it is based upon the assumption that the volume and significance of goods in circulation steadily increase, that mass produced goods become readily available and used in everyday

practices to play a central role in the construction of narratives and identities. A key feature here is novelty: new goods are constantly being produced and sought after; something that increases the amount of information in circulation that is necessary to make sense of new goods and integrate them into lifestyles. Hence advertising and background discussions aimed at helping to educate consumers into new tastes, take place within mass media such as newspapers, magazines, television, and radio programs.

The consumer society and its culture are often criticized for materialism: that people thirst after new goods to the neglect of the spiritual side of life. Yet it can be argued that the proliferation of goods has not been driven by a relentless empty materialism or greed, but has as much to do with cultural meaning systems. It is the relational matrix of the set of goods that is important, the ways in which goods are used not only to mark status divisions, but also to delineate the boundaries of social relationships and cement in-groups against out-groups. In effect goods can act as both doors and bridges to exclude or build relations with others. This suggests that consumer goods can be seen as resources for classifying the social world in which the logic of signs and cultural categories are used to create or reinforce social distinctions between groups. It also pointed to the process of investment in acquiring the skill to manipulate, read, and display the taxonomies of goods, dress, and demeanor: an approach which has its basis in anthropology (Douglas and Isherwood 1980, Bourdieu 1984).

Yet it can be argued that the classification system of consumer culture is inherently unstable, it has all sorts of gaps and ambiguities when compared to the relative closure of the primitive classifications described by Durkheim and Mauss, or the classical systems of science as described by Foucault. Here we can point to both the quest for innovation and novelty driven by the dynamics of the fashion system and the impact of new technologies that constantly disturb taxonomies. If goods have been seen from the point of view of economics as possessing both a use value (in terms of the purpose or need they fulfill) and an exchange value (monetary value), the progressive development of consumer culture complicates the picture. Advertising, it can be argued, attaches a further meaning to the commodity, a secondary 'ersatz-use-value' or 'sign-value,' which can occlude the original use (Adorno, Baudrillard). The replacement of use value by sign value implies that the meaning of goods becomes unstable, given the vast repertoire of themes and imagery (romance, exotica, beauty, adventure, the good life, excitement, fulfillment, solidarity, etc) which advertisers can draw upon.

There has been a general shift within the history of advertising away from direct description of the qualities of the product, to the use of more indirect associational imagery, in which meaning becomes elided and goods become associated with vague, but potent notions of lifestyle. The instabilities of the imagery associated with goods and the expansion of the media through which imagery can be created and recreated (especially with television, and the newer electronic forms such as the Internet) are seen by some as leading to an overproduction of signs and images. Such 'culturally saturated societies,' are often characterized as typically postmodern, with their fluid, depthless culture in which meaning refuses to stabilize or cohere (Baudrillard 1993, Jameson 1984). The oft-quoted archetypal example here of postmodern sign play is MTV (music television), with its endless series of pop videos in which images constantly change and flow into one another before the viewer can recover them into a coherent narrative.

Yet postmodern sign play constitutes just one end of the continuum of consumer culture activities. At the other end are highly formalized and ritualized consumption practices, in which every act and body movement, such as in eating, drinking, dancing, is heavily coded and carries weighty significance for the participants. The elaborately coded consumption of court societies would be a good example here. The latter example also helps us see that while consumption can entail watching the media in private, a good deal of consumption is more directly social; it involves others, people who come together in social practices in which there are varying demands for reciprocity. Consumer culture offers a large repertoire of resources for the construction and renewal of identities and presentation of the self as people move between public and private settings. Hence consumer culture promotes a world in which spatial and social mobility feature strongly: individuals are invited to imagine themselves operating in different settings, with different people and trying out different experiences. In an anonymous urban world, appearances become more important, and the possibility of 'passing,' of masking, reworking appearance, becomes both possible and acceptable. The values of personality, the development of charm, fascination, attractiveness become preferred to the more traditional virtues of character: integrity, duty, hard work, and thrift. Consumer culture through magazines, newspapers, and self-help books offers a mass of literature on self-improvement: how to reform the self, the body, sex life, and relationships. Here the body becomes more important as its 'seen and seeing' quality becomes central to the construction of what is heralded as an essentially embodied self. In the consumer culture view of the world the connection between body image and self image is presented as a crucial one, with the positive benefits of 'look good, feel good' body maintenance health and fitness routines extolled. The body then is a key resource for identity building (Featherstone 1982).

At the same time we should not underestimate the ways in which individuality and conformism are both presented as necessary, something that requires a complex integrative structure to achieve the right

balance for each situation. Consumer goods can be used as resources to cement collective relationships and renew the social order: wearing the right clothes and demeanor for each occasion, executing the correct performance, having appropriate accessories and material objects to hand which stamp the person as part of a status group. In Japan, arguably one of the most highly developed consumer societies, these aspects are very important, with consumer culture goods used to reinforce stable and lasting relationships (Clammer 1997). Department stores in Japan are big promoters of gift giving and provide elaborate services to help choose, package, and deliver the appropriate gift to cement relationships at work, in the family, between friends, and for a whole range of intermediaries and service providers. Consumer culture then, needs to be understood in its different social contexts, and we cannot assume that everything that occurs within Western modernity is immediately exportable around the world. Self-cultivation, reflexivity, and life projects, which are associated with consumer culture in the West, cannot be assumed to develop readily everywhere, and the instabilities and transgressive sign play associated with the 'dream worlds' of consumption cannot be assumed to be always as threatening to identities and the social order.

3. *Spaces of Consumption, Shopping, and Gender*

A key aspect of consumer culture has been the development of new spaces for consumption, shopping, and entertainment: the arcades, city centers, and department stores which originated in the nineteenth century and the wider range of sites such as cinemas, cafés, resorts, leisure, and theme parks and malls that developed in the twentieth century. These were sites for purchasing goods and experiences, for looking at goods, for seeing and being seen, for enjoying the swirl of the crowd and the reading and misreading of the rich fabric of urban life with its vivid color advertisements, street decorations, and neon signs. They were relatively safe spaces that enabled women to venture out into public in greater numbers. The influential writings of Benjamin (1999) and Simmel (1997) provide a view of the experience of modernity as an essentially urban one, in which the crowds, movement, shocks, provided a bombardment of the senses with new impressions. The sensitivity to the heightened visual quality of modern life is captured in the *flâneur*, the stroller, who first appeared in the new consumer spaces of the nineteenth century to take in the fleeting fragmentary impressions of the crowds, the street, the buildings, and minutiae of the urban landscape.

If advertising was important in educating consumers into new tastes and desires, the department stores which appeared in Europe, the United States, and Japan in the second half of the nineteenth century and the early decades of the twentieth century, can be seen as playing an equally important role in the formation of consumer culture. Unlike traditional shops, the department store was a space in which it was possible to walk around and examine goods on display. A key feature here was the opulence of the setting; department stores were designed spaces that sought to house the expanding range of cheap mass-produced consumer goods in novel ways. They were built on a massive scale with impressive architecture, layout, and decor as new public-private spaces that invited the consumer to stroll around, to stop and look, to take in the latest goods framed in exotic and luxurious display settings. They helped to expand the time frame of shopping so that it could become a pleasurable activity in itself, whether it be the actual purchase of goods or the activity of 'window shopping,' 'just looking,' and experiencing the 'Hollywood set' quality of the displays. In addition, stores saw themselves as artistic and entertainment places where people could witness performances and spectacles, such as ballet, concerts, art exhibitions, and fashion shows. They also advertised themselves as communal centers, places where women could meet, engage in sociability, and even spend the whole day. It is no accident that department stores were referred to as 'dream worlds,' 'fantasy palaces,' and 'cathedrals of consumption' through their capacity to dominate the urban landscape and generate and legitimate a new consumer gaze and set of pleasures (Nava 1997, Williams 1982).

With the emergence of city centers as sites of consumption in the late nineteenth and early decades of the twentieth centuries, women were able to move more freely in the new public and public-private spaces. Department stores and other shopping, entertainment, and expanding service sector sites such as cinemas, restaurants, hotels, cafés, also provided new opportunities for women's employment. These were all places where emotional labor and presentational skills were important, and where women had to learn how to look and be looked at. Places of encounters with customers and members of the public, and of the viewing of the latest fashions and spectacular displays, provided new forms of knowledge and embodied competencies which could foster confidence and independence and generate a sense of an adventurous more exciting life. This formed the basis for a new definition of gender incorporating both a greater sense of self-control and expressivity. Something, which reached a peak in the 1920s with the flapper, the hedonistic young woman who had bobbed hair, wore a short skirt, and hyperactively danced to the jazz beat, which started to circulate around the world through the efforts of the nascent Hollywood film industry with movies such as Clara Bow's *It!* Consumer culture started to globalize: in Japan for example the department store became a central institution and along with the cinema, helped to provide stimulus for the emergence of a new form of femininity, the *moga* girl,

the modern girl who incorporated some of the elements of the flapper (Silverberg 1991)

The popularity of cinema going in the early decades of the twentieth century was important, as the majority of movie audiences were women. Like the department store the cinema was a legitimate place where women could come together in public relatively free from the surveillance of men. Like the department store it was a site that nurtured dreams and desires. It was also a powerful vehicle for fostering identification with others across gender, class, age, and ethnic lines along with the simulation of emotions. Something which has given rise to the view that the cinema helped educate women into new forms of public life which can be seen as having positive social implications. In effect the cinema led to the development of a cinematic public sphere, a key element in the formation of a women's public sphere (Hansen 1991). Here a sense of public responsibility for the other could be seen as not merely developing through the alleged rational argumentation of the (male) public sphere, but through emotional identifications and aesthetic experiences.

This positive view of the ways in which consumer culture spaces offering greater freedom and self-expression for women squares uneasily with accounts of consumption and mass culture as forms of deception, offering seductive and intoxicating pleasures. In accounts, such as those of the Frankfurt School, the fear was that mass culture and consumer culture amounted to forms of regression, with the dangers of loss of emotional control and the dissolution of the ego and social boundaries, and even the loss of civilized codes and sexual abandon (Huyssen 1986). This perspective misses the ways in which the decontrol of the emotions can take place in controlled ways, in which the swings between rigid rational control, and dangerous unbounded emotions are managed in subtler, playful, and less threatening ways. At the same time it can be argued that this capacity for emotional decontrol developed in men too, with men increasingly asked to cultivate their appearance and engage in bodily maintenance. In the second half of the twentieth century with the expansion of consumer culture, we have the emergence of new masculine ideals, the celebrities of leisure, sport, and the media who cultivate 'personality' (Featherstone 1995).

Shopping offers an interesting impure hybrid form: it mixes purposiveness, pleasure, and play. It is also often seen as offering the short-term pleasures of the purchase and conspicuous consumption, the vulgar tasteless pleasures of the new rich, in which high price is taken as the only guide to the real value of goods. Something which can be contrasted to the elaborately coded taste hierarchies and finely graded distinctions of the connoisseur or collector, who works hard to place the object in a context and assess its immanent value. Yet this perspective misses the ways in which particular forms of shopping can involve discrimination and careful judgment of taste. When people shop for clothes, for example, it can often entail the use of elaborately coded knowledge of the fashion system and the latest styles. Here the pleasures of knowledge, of manipulating the classification system come together with the pleasures of the body, with knowledge of one's own bodily form and what suits it. A different form of pleasure from flicking through a mail order catalogue or surfing through the Internet's 'click and purchase' shopping sites. Going out to shop puts the emphasis upon performance and enactment. Crucial here is the capacity for movement in spaces, for the sensual (especially visual) pleasures of physical movement, of handling and touching the goods. In the postwar era, malls and shopping centers have become important consumer sites through their capacity to offer secure, comfortable spaces for shopping, entertainment and sociability (see *Entertainment*). While recently there has been some decline in the popularity of malls in the United States and a shift back to city centers, with the expansion of gated communities and globalization of divided, more dangerous cities, malls have expanded in many parts of the world. They have become important secure public-private spaces largely for the new middle classes, and particularly for women, to engage and experiment with consumer culture lifestyles and new forms of sociability.

4. Aestheticization Processes and the Cultural Intermediaries

Consumer culture can be seen as offering and legitimating a wide range of aesthetic experiences and bodily pleasures, something that has become designed into goods and consumer spaces by the growing ranks of cultural intermediaries. Yet this involves a highly differentiated set of practices with the rhythms of the day, the week, the year pulling different spaces of consumption into view. Buying a birthday present or gifts on holiday takes different types of judgment about price, taste, and aesthetics than the weekly supermarket visit or the purchase of a utility such as a washing machine. Consumer spaces include the warehouse form of hypermarket such as Wal-Mart, a de-aestheticized environment with minimal decoration and display setting, where cheapness and 'value-for money,' are everything. On the other hand, they also include sites in which every effort is made to give goods or a brand a quasi-sacred significance, as for example we find in the Nike Museum in Chicago, where trainers are displayed like art objects.

It is possible to envisage a continuum here, ranging from sites in which standardization of infrastructure and product are to the fore, where people are processed in and out rapidly, to sites where the consumer is invited to linger and have an experience, where consumption involves consuming the setting, the excitement, and aesthetic pleasures of discovery of

novelty. At the standardized end we have McDonald's and Wal-Mart, the phenomenon of the chain or brand that offers the simplification of complex consumer choices through its alleged reliability and value for money (see *Fast Food Enterprises*). Near this end are the 'no place' spaces of airports, chain hotels, and resorts, which also seek to offer the insecure customer, who has no time or inclination to browse or experiment, predictability and reliability.

At the other end we have the experiential sites that offer the ambience of 'amazing spaces;' sites where every effort is made to disguise standardization and uniformity and cultivate the exotic and the new. Here the pleasure can be both in the participation in the experience, or in anticipation through learning processes (browsing guidebooks, planning, imaginative constructions, and dreaming). Opening up exotic worlds through foreign travel and exploring art, counter-cultural, and bohemian experimental lifestyles can involve not just excitement, but also the risk of identities and relationships. Yet, consumer culture seeks to market the risk and adventure too, both directly, through the 'ultimate experience' of high risk sports, such as paying large sums of money to be guided to the top of Mt. Everest by companies such as Mountain Madness or Adventure Consultants, and indirectly in all sorts of more controlled simulations such as 'white knuckle rides.'

The provision of various blends of excitement and novelty along with standardization and the familiar is found in many consumer culture sites: ranging from theme parks, resorts, hotels, bars, restaurants, shops, malls, to museums and heritage sites. Consumer culture's capacity to offer 'dream worlds,' reaches a new high point with theme parks such as Disneyland, where 'imagineers' have been able to produce hyper-real full-scale simulations of fairy tales, novels, and historical settings in which visitors are invited to 'step inside the dream,' and enjoy the movie set quality and full sensory immersion of another world. The retro bar, restaurant, shop, and even mall can work off this logic of seeking to construct spaces which provide a unique simulated experience. They work parasitically off the theme park, heritage park, and movie set design skills in constructing or reconstructing another world. They draw on content from a wide range of sources: from sacred tourist and historical sites, to the vulgarity of Las Vegas strip's popular culture, to the vitality and creativity of bohemias and urban subcultural spaces. The logic here is more one of seeking to provide mass customization than mass consumption. The capacity built into the infrastructural building technologies and the media image technologies is increasingly one that permits not only standardization and reproduction, but also reformatting and re-creation. Today's digital technologies can easily and rapidly spin out variations of codes, not just to provide the multimedia aspect of the experience; digitalization also becomes an integral element of the overall design process as architectural design itself increasingly works through virtual and simulated forms.

Consumer culture can be seen to work in a dual way through representations and sites. It draws on a wide range of representations to construct a culture around material goods, weaving a range of imagery and sign play to make commodities more enticing and exciting (advertising in its various forms being the key here) and provides a whole range of publicity material to educate consumers into enjoying new tastes. It also requires specific spaces to sell, display, and house goods and experiences (hypermarkets, department stores, malls, theme parks, resorts, etc.). Yet many of the sites become enriched with representations, with attention given to the décor and the setting to the extent that the act of purchase becomes an experience or that what one purchases or seeks out is an experience. If consumer culture has helped to swell the ranks of service sector occupations, then within this group design and associated cultural intermediaries have become increasingly salient. These groups, which include those members of the new middle classes working in the media, fashion, design, advertising, marketing, and the culture industries, are those who design the consumer culture representations, the informational aspect of consumer goods, and the experiential dimension of consumer sites.

These new cultural intermediaries have been referred to as 'para-intellectuals' given their admiration for artists and intellectuals and their constant search for knowledge of new and different lifestyles, sensations, and cultures (Bourdieu 1984, Featherstone 1991b). Their predisposition to explore the full range of global cultures, to seek out new styles, or recycle traditions, and search for the exotic through travel makes them have dispositions that could be labeled postmodern, through their aesthetic interest in playing with signs and cultures. Like artists and intellectuals they have an interest in travel and experimental bohemian lifestyles, to provide the stimulus for new ideas and themes to work into consumer culture imagery. Here, the city as the home of both the bohemian and the *flâneur* is seen as an important repository or database, in providing some of the dangerous and exciting places and personae with which to generate new cultures and lifestyles. The new cultural intermediaries have been in part responsible for the 'democratization of bohemia,' for feeding transgressive bohemian themes and images of the sexualized or fantasy city back into everyday consumer culture (Pels and Crebas 1987, Wilson 1998).

5. *Globalization and the Limits of Consumer Culture*

It can be argued, that since the 1960s, the pace of the globalization of consumer culture has increased (Featherstone 1995). This has been particularly evi-

dent since the 1980s with the lowering of tariffs through GATT and the WTO, state deregulation, and the extension of the market. The collapse of the Soviet bloc furthered the extension of market capitalism. Now the consumer culture, however unevenly it has occurred within particular societies, has become the main provider of images of the good life. Globalization has also meant the rise of the information order, with spatially dispersed more elaborate production and consumption networks coordinated through the use of electronic communication. Consumer brands and imagery have become globalized, yet the vast majority of humanity, who cannot gain access to the loop, can only experience consumer culture on this level of images and dreams.

Yet what if the excluded were to become included? Would this mean that we run into the limits of the consumer society? Some argue that we have already reached the limit, that it is not merely resource depletion, but global warming and the disturbance of the planetary ecological balance that are occurring. If global 'bads' are seen to accompany the spread of global goods, then it is the unintended consequences of unregulated consumption, the accumulation of risks through the drive for increased technological innovation and scientific progress, which have become evident. The consumer society, then, is also a risk society and increasingly we are becoming conscious of the global scope of risk chains and networks. At the same time there would also seem to be the beginnings of the emergence of a global public sphere, where concerns about the pace of change, the exploitation of natural resources, the dangers of the biotechnological revolution, are starting to trouble some groups. Something akin to global public opinion is in the process of formation, as we saw in 1999 in Europe and the United States with the reaction against genetically modified food. The Internet with its speed, cheapness, and scope is becoming important here in providing consumers with the means for developing associations, networks, and campaigns that can raise questions about the need for more responsible forms of consumption.

Yet consumer culture is a long way from becoming a conserver culture. The dynamic of consumer culture is still one in which the search for new sensations and change dominate. Increased global flows of culture and the mobility of images through the media and information technology are accompanied by increased mobility of people, whether in pursuit of work or tourism. The demand for greater speed through information and transportation technologies has serious resource implications, along with new unintended risks and integral accidents. Serial and multiple lives in which people seek to experience intensified more exciting sensations of short duration, fit well with consumer culture. This seems to have been one of the unintended legacies of artists, intellectuals, and bohemians, however much the content of their work seeks to provide an urgent critique of consumer culture. Cultural modernism and postmodernism betray their origins in Western modernity and have yet to work through the dynamic of global post-humanism and a planetary humanism, in which the responsibility is to think the limits of 'the new,' the limits of mobility, movement, and the consumer. If there is something beyond the modern, then it implies thinking through new forms of consumption and developing a different relation to the object world of nature and technology.

Consumer Economics

1. Introduction

Consumer economics is concerned with the allocation of the scarce means of the consumer over a variety of different commodities and services. These goods and services may be material as well as immaterial. What matters is that they are not available to the consumer for free. They carry a price. What also matters is that they are desirable, that is, that the consumer is willing to pay a price for them. As a rational being, the consumer will select that set of goods and services that pleases him or her most among the ones he or she can afford.

Two basic ingredients are involved in this selection: limited means and consumer preferences. The first one, limitation of the budget, expresses the fundamental scarcity that is the *raison d'être* of modern microeconomics. The second one, the ordering of the available alternatives according to preferences, reflects the role played by personal attitudes, biological needs, social aspirations, cultural trends and so on in determining how the scarce resources are being allocated. In the marketing approach to consumer decision making the emphasis is mostly on what shapes preferences. In the theory of consumption and saving, the focus is on the lifetime wealth constraint and to a lesser degree on the explanation of (time) preference. On the level of generality used here both ingredients will be discussed in an even-handed way.

Neither the budget nor the preferences are fixed or necessarily exogenous to the economic system. In the present context, however, the budget or total available means will be taken as given for the consumer, while also the preferences are not an object of choice for her or him.

Consumer theory is about individual behavior. Empirical data frequently refer to an aggregate of consumers, for example, a nation. Without some additional assumptions the theoretical results do not carry over to such an aggregate and the empirical relevance of the theory is minimal. The additional assumptions imply the existence of the *representative consumer*, who can be treated as if he or she were the individual consumer of the theory.

Empirical applications are abundant. Davenant (1699) is the earliest known example. It explains the price of corn as a function of the amount harvested. For a long time empirical work and theory were virtually unrelated. It was only just before World War II that the applications were first based on theory. Still, one usually focused attention on the demand for a single good. In more recent times attention has also been directed at the explanation of demand for all goods simultaneously, for which there is an explicit theory that offers the appropriate framework.

2. The Budget

The total means available, the *budget*, are used to pay for the quantities of the various goods and services, goods for short, that the consumer wants to acquire. It is assumed that the number of different goods is finite and fixed. The set of quantities is called a *bundle*. The budget is then the total amount to be paid for a bundle. Theory assumes the budget to be given for the consumer. Not quite correctly, 'income' is frequently used as a synonym for total means.

The *price* is the amount of money to be paid for a unit of a particular good. The prices are assumed to be positive, with negative and zero prices not admitted. Quantities are most of the time taken to be positive as well. The framework can be extended to also cover negative demands: 'bads,' or the supply of home-produced goods, for example. Here the focus is on positive demands. With positive prices and positive demands the budget must be positive.

Theory assumes that the goods are fully divisible. This is a realistic assumption in the case of fluids like gasoline, but not empirically valid for many types of household durables. Theoretically, one can replace the durables themselves by the services these render, which are continuously divisible, but empirically the stream of services is not directly observable. It has been

attempted to reformulate consumer theory in terms of integer quantities. This development has not entered the mainstream of consumer analysis.

Most of the time the quantities are taken to be the objects of choice and the prices given for the consumer, at least in the short run. There are cases where the quantities are fixed and the prices are endogenous. The Davenant study just mentioned is an example where the prices are being explained and the harvests of corn being fixed. This reversal of causality is specifically of relevance for nonstorable agricultural produce. If for all goods the quantities are the variables explained one speaks of *regular* demands. The case of endogenous prices is one of *inverse* demands. When for some goods the quantities are endogenous and for other goods the prices are endogenous, one speaks of *mixed* demands. Although inverse and mixed demands are easily handled by the theory, the mainstream is concerned with regular demands.

3. *Preferences*

According to the basic postulate of consumer theory, the consumer selects that bundle among the available alternatives that gives the most satisfaction. Assumptions are made that guarantee the existence of a complete, reflexive, and transitive *preference order* defined on the set of bundles. The requirement of completeness, that is, the ability to order all possible alternatives, is somewhat stronger than needed. It is enough if the consumer is able to order the bundles in the neighborhood of the set of bundles that fit in the budget. The assumptions of reflexivity and transitivity are of a logical nature.

The assumptions about the preference order do not exclude the possibility that bundles occupy the same rank in that order. All bundles with the same order form an *indifference class*. In the case of the choice between only two goods the graphical representation of the indifference class is the *indifference curve*. The set of all indifference classes is named the indifference map. Theory specifies a continuity postulate for this map. This amounts to the property that a drop in the quantity of one good of a bundle can always be compensated for by a change in the quantities of one or more other goods to stay within the same indifference class. This assumption rules out *lexicographic preferences*, where the preference for one good absolutely dominates the desire for other goods.

The preference order is equipped with two further properties. One is that of *desirability*. More of any good is preferred, keeping the quantities of the other goods the same. There is no satiation. Moreover, it excludes the existence of intersecting indifference classes. It also implies that the budget is always used fully. The other property is that of *convexity of preferences*: a linear convex combination of two bundles is preferred to the least preferred one of the two bundles themselves. This property is of special importance to guarantee a unique solution to the consumer's choice problem.

4. *Utility*

Under the assumptions made about the preference order there exists what is known as the *utility function*. It assigns a (real) value, utility, to bundles in such a way that for any pair of bundles the one that is preferred to the other obtains a higher value. In the case that the consumer is indifferent between the two bundles they obtain the same value.

Given the desirability property of preferences the utility function is *monotonously increasing* in the quantities of the goods. Convexity of preferences implies that the utility of a convex combination of two bundles obtains more utility than the one with the least utility. It is known as the property of *quasiconcavity*.

The name 'utility function' is slightly misleading. It is a preference indicator. Utility is not 'produced' by a bundle. The utility function associates with a bundle a certain value that reflects the rank of its indifference class. There is also no uniqueness of the index. Adding to all rank values the same value yields another utility function that corresponds with the same preference order as the original one. In more general terms: given a particular utility function for a preference order any order preserving or monotone increasing transformation of it will yield an equally valid utility function. As far as consumer demand is concerned only *ordinal* properties of a utility function matter. *Cardinal* properties that are not invariant under order preserving transformations have no effect on choice behavior.

In fact, consumer theory does not need a utility function at all. However, a utility function appears to be a convenient tool for describing the consumer's choice. No damage is done using a particular utility function, as long as it correctly reflects the preference order.

A related concept is that of *marginal utility*. Mathematically, it is simply the first derivative of the utility function with respect to the quantity of a certain good. It represents the increment in utility for an infinitesimal increase in that quantity. In view of the desirability of preferences it is always positive.

5. *Demands*

Taking the case of exogenous prices, the consumer selects that bundle among the bundles that can be acquired with the given budget that he or she prefers most. Under the assumption made for the preference order the selected bundle is unique. It can be written as a set of functions, one for each good, of the budget and of the set of prices. As the selected bundle fits in the budget also the demand functions will fit in it. This is

the *adding-up* property of demand. The composition of the bundles that satisfy the budget will remain the same if all prices and the budget change by the same positive factor. This then also holds for the set of demand functions. These are *homogeneous* of degree zero in the budget and the prices.

One of the implications of the assumptions made is that for two bundles in the same indifference class the amount demanded of a certain good is less if its price is higher. This is the *Law of Demand*. Note that it concerns bundles belonging to the same indifference class. It is the most important qualitative result of consumer theory. The more general version stating that demand for a good is a negative function of its price is not true with the same degree of theoretical validity. This law was put forward for the first time by Davenant (1699).

Observe that the adding-up, homogeneity, and negativity conditions have been formulated without the use of the concept of utility. For the derivation of further properties of demand functions the utility function proves to be convenient.

6. Consumer Equilibrium

With the utility function as a tool the consumer's choice problem can be described as maximizing utility with respect to the quantities of the various goods under the condition that the bundle chosen fits in the budget. The first-order condition for this constrained optimum is the proportionality of the respective marginal utilities with their prices. This result is known as the *Second Law of Gossen*. It characterizes the consumer's equilibrium. It implies that for all goods the marginal utilities divided by the prices are the same.

One interpretation of this outcome is that an extra unit of currency is allocated over the various goods in such a way that it yields the same increase in utility per unit of currency for all goods. The marginal utility of a unit of money spent on each good is the same.

The marginal utilities are cardinal concepts, but their ratio is ordinal. There is a tendency to work with this ratio that is known as the *marginal rate of substitution*. In equilibrium the marginal rate of substitution between two goods is then equal to the price ratio of these goods.

Proportionality of marginal utilities and prices is not only the equilibrium condition in the case that the quantities are endogenous and the prices exogenous, but also when the prices and quantities reverse roles in this respect. In fact, this condition also holds when for some goods the prices are exogenous and the quantities endogenous, while for other goods the opposite is true.

Under the usual assumptions made, the equilibrium conditions can be solved for a unique set of values for the endogenous variables given the values for the exogenous variables and the shape of the utility function. In the case of endogenous goods the solution can be expressed as a set of demand functions in terms of total means available and the prices. These demand functions have a number of interesting properties, which play a role in empirical analysis.

7. Properties of Demand Functions

Under rather general conditions the demand functions are differentiable with respect to income or total means and prices. The derivatives satisfy certain conditions. Frequently one expresses those conditions in terms of *elasticities*, defined as the proportional change in demand as a consequence of a (small) proportional change in means (*income elasticities*) or in prices (*price elasticities*), respectively. The elasticities can be easily derived from the derivatives of the demand functions. Note that neither derivatives nor elasticities are necessarily constants according to the theory. The choice of constant coefficients is a matter of empirical expedience. Income elasticities can be negative. In this case, an increase in income reduces demand for the good. This usually happens if there exists a similar product that is much more attractive. If the income elasticities are negative one speaks of *inferior* goods. Goods with positive elasticities are *superior* or *normal* goods. Income elasticities can be larger than one. Then as income increases, the budget share, being the share of expenditure on the good in question in total expenditure, will increase. A good with such a property is named a *luxury*. A *necessity* is a good with an income elasticity less than unity.

In Sect. 5 some properties were mentioned. The adding-up property reflects that the demands exhaust the budget. The *Engel* adding-up condition states that the sum of the income elasticities multiplied by the respective budget shares adds up to one. The *Cournot* adding-up condition refers to the price elasticities. The sum of the price elasticities for the prices of the various goods with respect to the price of one good, say good i, multiplied by the budget shares, equals minus the budget share of the ith good. These properties imply that if one knows all but one of, say, the income elasticities, one can reconstruct the remaining one as a residual.

The homogeneity condition entails that the sum of the income and price elasticities equals zero. The same proportional increase in income and all prices will have no effect on the quantity demanded. Thus, knowing all but one of those elasticities enables one to find the remaining one.

The price effects can be split up in a part that represents the move from one indifference class to the other and in a part that reflects substitutions within an indifference class. The first effect can be neutralized by an adequate change in means, such that one stays in the original indifference class. It is named the *income effect of price changes*. The other part of the effect of a price change is known as the *substitution effect of price changes* or as the *compensated effect of price changes*.

The income effect of price changes can be combined with the effect of an income change to form the effect of a *real income* change. This represents the move from one indifference class to the other.

The substitution effects can be collected to form a matrix, the *Slutsky* matrix. On its diagonal one finds the substitution effect on the demand for a good by its own price. On the basis of the assumptions made it should be negative, see Sect. 5. For superior goods the income effect of the own price change is also negative. Then the two effects work in the same, negative, direction. This cannot be generalized. If the good is an inferior commodity, the income effect will be positive and may, in absolute value, be larger than the substitution effect. The total own price effect is then positive. Such a good is known as a *Giffen good*. No empirical cases are on record, but they cannot be ruled out on theoretical grounds. For practical purposes the total own price effect may be taken to be negative.

A further property of the Slutsky matrix is its symmetry, first stated by Slutsky (1915). It is a mathematical property of great empirical consequence, but with hardly any intuitive appeal. The empirical importance can be illustrated for the case that there are 20 goods in the budget. The number of Slutsky cross-price effects is then 20*20–20 = 380. The property that these are pairwise equal reduces the empirical problem by 190 fewer coefficients to estimate separately.

The elements of the Slutsky matrix contain a considerable amount of information about the preferences of the consumer. Two instances of this will be taken up in the following sections.

8. *Complementarity, Substitution, and Independence*

Preferences are specifically of interest when they refer to interactions between goods. If two goods reinforce their desirability, one speaks of *complementary* goods. Examples are wine and cheese. Two goods are *substitutes* if one can replace the other to a certain degree; beef and pork, for instance. In the case of *independence* there is no specific relation between the two goods. How are these fundamental relations between goods reflected in empirical demand behavior?

The early marginalists started off from the marginal utility of a good. If it goes up if one has more of another good, the two are complements. If it goes down, the pair are substitutes. Unfortunately, this rather straightforward definition is not an ordinal one. Depending on the type of utility indicator corresponding to the same preference order, two goods may be complements rather than substitutes. The original meaning of the terms 'complements' and 'substitutes' clearly refers to the preference order and not to a particular representation of it.

It has been attempted to associate complementarity and substitution with the sign of the marginal rate of substitution, an ordinal concept. This definition is remote from intuition and the consequence for the signs of the compensated price elasticities are not easy to trace. Hicks (1939) cut that Gordian knot by using the sign of the elements of the Slutsky matrix. A negative sign means complementarity and a positive one substitution. However, there are problems with this definition. One of these is that positive off-diagonal elements of the Slutsky matrix tend to be larger or more numerous than negative elements, reflecting the tightness of the budget, which, as such, has nothing to do with preferences. The approach of Allais (1943) appears to meet most of the difficulties, but is not that simple to apply.

In the early days of empirical application of full-sized demand systems the assumption of complete independence was used frequently. Under this assumption there exists a utility function that is additive in (functions of) the various goods. The best known example is the Samuelson–Klein–Rubin utility function. It is a weighted sum of the logarithms of the quantities of the goods as far as they exceed some minimum value. The implied demand functions are correspondingly also more simple than in the case of real preference interaction between goods. The impact of price changes other than that of the own price takes the form of a change in a price index where the identity of the other price change does not matter. A consequence of complete independence is the limited number of coefficients to estimate. Given the paucity of data, typical for the early years of empirical demand analysis, a small number of unknown parameters was an attractive feature, even if the underlying assumption was not quite realistic.

9. *Separability of Preferences*

Terms like 'wine' and 'cheese' actually refer to conglomerates of different types of wine and different types of cheese. If the preferences for the various types of wine are independent of the amounts of the diverse cheeses consumed, one speaks of *separability* of preferences. This does not mean that the total amount spent on wines as a group does not depend on the total amount of cheese consumed. For the preference interaction between wines and cheeses the wine nature of the wines and the cheese nature of the cheeses dominate the relation and the specific brands do not matter. As a consequence the consumer's behavior can be modeled as a stepwise procedure. First, the consumer decides on the total amounts of wine and cheese he or she wants to consume. Next, given those amounts and the prices, he or she determines how much of each type of wine and of each type of cheese he or she will purchase. For the first level the consumer needs to know total available (real) income and all the prices. However, those prices can be represented by a price

index for each group. The consequence is that the impact of a change in the price of, say, Gouda cheese on the demand for, say, a high-class Burgundy wine is only by way of the effect of a change in the price index of cheese. The origin of the price change does not need to be identified.

It is a simple matter to extend this framework to more than two levels. For example, one can think of a hierarchy of the type: total consumption, food, meat, beef, with beef taken as the elementary good.

For the full set of demand relations separability means a rather simple constraint on the Slutsky coefficients for interactions between goods belonging to different groups.

Separability is very convenient for empirical work. One can estimate the first level model separately from the lower level models and in this way control the dimensionality of the estimation problem. In fact, the data usually are only available in already aggregated form. The assumption of separability justifies working with those aggregates as if they were elementary goods.

A special case of separability is *strong separability*. There the aggregates have no special type of interaction like that of substitution or complementarity discussed in the previous section. They are all independent vis-à-vis each other. The Slutsky matrix then becomes even more constrained than for the case of ordinary or weak separability.

Under separability the utility function can be written as a function of a set of subutility functions, one for each group. Under strong separability the preference order can be represented by a utility function that is additive in those subutility functions.

10. Indirect Utility and Expenditure Functions

The utility function is a function of the quantities of the various goods. One can replace these quantities by the *optimal* quantities, the demand functions. One obtains the *indirect utility function*, an expression in terms of total means and all prices. It indicates the maximum attainable utility for the given total means and these prices. Its derivatives are the marginal utility of total means and the marginal utilities of the various prices. The former shows how much utility can be increased if total means are slightly increased. The marginal utility of a price is the reduction in utility when the price goes up. These properties of the indirect utility function are based on those of the demand functions. Another property is its homogeneity of degree zero in means and prices. Otherwise said: an increase of means and prices by the same factor leaves utility unchanged.

The indirect utility function is a cardinal concept like the original utility function. The properties just mentioned, together with a curvature assumption, are ordinal, however. The *Identity of Roy* can be used to derive the demand functions from a well-specified indirect utility function. To obtain the demand function for good i one simply takes the negative of the ratio of the marginal utility of the price of good i and that of total means. It is a convenient way to arrive at a proper functionally specified set of demand functions. The alternative to deriving the demand functions as the optimal values for the direct utility function under the budget turns out to be practical only for very simple functional specifications of that function. The Roy identity can be seen as a convenient short cut.

A concept similar to the indirect utility function is the *expenditure function*, also known as *cost function*. It yields the minimum outlay or means to obtain for a given set of prices a given level of utility. It can be obtained from the indirect utility function by fixing the level of utility and solving for the means. It has, *mutatis mutandis*, similar properties to the indirect utility function. It reacts positively to both an increase in the level of utility to be reached and to price increases. It also has to satisfy a certain curvature condition. Corresponding to the identity of Roy there is *Shephard's lemma*. By differentiating the expenditure function with respect to the price of good i, keeping utility constant, one obtains the optimal demands as a function of the prices and the level of utility.

To distinguish these demand functions from the ones that are expressed in prices and *means*, they are named *Hicksian* demand functions. The former ones are then the *Marshallian* demand functions. One can shift easily from the Hicksian to the Marshallian demand functions by replacing the level of utility by the expenditure function. Likewise, one may change from the Marshallian demand functions to the Hicksian ones by substituting the total means variable by the expenditure function. For empirical purposes the Hicksian demand functions are not so useful because one would need a value for the utility level, which would be rather arbitrary. However, starting from a well-specified expenditure function one can derive the Hicksian demand functions in which one replaces the utility level by the indirect utility obtained from the expenditure function.

From a theoretical point of view, the Hicksian demand functions are of considerable interest. Their price derivatives represent the effect of price changes with utility kept constant. They are precisely the Slutsky coefficients introduced in Sect. 7. The Slutsky matrix turns out to be the matrix of second-order price derivatives of the expenditure function.

Another interesting feature of the expenditure function itself is its role in the derivation of the *constant utility price index*. Consider the case of a consumer who is in equilibrium. The expenditure function gives the minimal amount of expenditure to reach a given level of utility with the current prices. Take another set of prices but keep utility constant. The expenditure function will now show the minimum outlay required to reach the original utility level with the new prices.

The ratio of the latter and former amounts can be seen as a price index. It indicates the factor by which one has to multiply the total means to keep the same level of welfare. The factor could be more or less than one. In the case of a general price increase it will be larger than one. The practical use of the constant utility price index meets with the difficulty of specification of the expenditure function. However, its theoretical appeal cannot be questioned.

11. Empirical Validity

Do data on consumer behavior reflect the properties that theory postulates? In the case of *demand functions for a single good* the properties of interest are the negativity in the response to a change in the own price for the good in question and the homogeneity condition, implying no response to an equiproportional change in income (budget) and the prices. Usually negativity does not create serious problems and the demand equations in estimated form readily display this property.

Statistical tests tend to be less lenient for the homogeneity condition. This is somewhat puzzling because of the plausibility of this property, which is sometimes interpreted as the absence of a monetary veil. Homogeneity justifies the proposition that allocation of means is based on relative prices rather than on absolute ones, which is a central issue in microeconomics. Many reasons have been advanced to explain away this dilemma such as inappropriate data, specification errors (absence of explicit dynamics, for instance), and the use of incorrect test statistics. Correction of some of these shortcomings appears to have achieved some success.

In the case of *systems of demand equations* explaining demand for a set of goods simultaneously, negativity does also not create a serious validity problem, but homogeneity is less easily accepted. Additional properties of empirical interest here are Slutsky symmetry and separability. Symmetry appears to agree with the data. This may be more a matter of the wide confidence intervals of the estimates of the estimated Slutsky coefficients than of the truth of the symmetry hypothesis itself. Separability of preferences has such attractive properties for applied work that it is frequently used in spite of its demonstrated lack of empirical validity.

Also in consumer analysis, theory and application are being handled in a balanced way, reflecting doubts about both theory and facts and about the procedures to reconcile them.

Consumer Psychology

Consumer behavior refers to the acquisition, consumption, and disposal of time and offerings (goods, services, and ideas) by decision-making units (individuals, dyads, and larger groups). Consumer behavior is pervasive and universal involving, as it does, choices made during the waking moments of virtually all human beings in all societies and cultures. In addition to overt observable behaviors (e.g., making a purchase, wearing a shirt, engaging in word-of-mouth communications regarding products), consumer behavior also includes the covert psychological states and processes (e.g., motives, learning, attitudes, decision making, past experience) that underlie and influence the overt behaviors. Last, while consumer behavior involves trying, rebuying, and increasing some behaviors, it also includes the cessation or lessening of some of those same behaviors (e.g., smoking, unsafe sex, eating fatty foods).

Though also referring to the covert psychological processes, when used to describe a scholarly endeavor, consumer psychology refers to using distinctively psychological concepts and methods to understand consumer behavior. These days, scholars who employ clearly psychological concepts and methods to study consumer behavior are more likely to do so from venues other than departments of psychology.

1. The Complexity of Consumer Behavior

Consumer behavior includes often-overlooked layers of complexity. Offerings may be acquired in ways other than via purchasing, including via renting, borrowing, trading, finding, stealing, as a gift, and so forth. Similarly, consumption—which occurs over time periods of varying duration (from the almost instantaneous munching and swallowing of a potato

chip, through the wearing of a shirt for several years, to buying and living in a home for decades)—generally involves distinct facets, including using, maintaining (e.g., cleaning a suit), storing, and retrieving, all or some of which may be repeated over time. Once consumption ends, one may be faced with disposing of the item (or its container). One can decide to throw it away, convert it to serve some other purpose, trade or exchange it for something else, sell it, give it away, and so forth. Consumer behavior also reflects cyclical and contingent qualities. Having purchased, consumed, and disposed of a tube of toothpaste, we acquire a replacement and repeat the cycle. Car insurance and gasoline are generally acquired contingent upon having acquired a car.

Time is finite; how we choose to spend it has tremendous implications for virtually all other aspects of our lives. In some respects, one can actually buy and trade time, e.g., paying someone to mow our lawn and free our time for something else.

Offerings come in many forms and are not limited to products and services provided by commercial or for-profit entities. Offerings also include political candidates, television programs, newspaper articles, leisure time activities, different articles within the same newspaper, and so forth.

Engaging in consumer behavior involves several roles, including behaving as the decision maker, purchaser, and/or user. Often, these roles are confined to a single individual, as when one person chooses, purchaser, and then consumes a soft drink. Alternatively, they may involve two or more individuals (e.g., wife decides, husband purchases, child uses).

Last, consumer behaviors occur not in a vacuum, but in the context of everyday life where they tend to be influenced by numerous external factors, including cultural, social, political, environmental (e.g., not shopping during a snow storm) and physical (e.g., not wanting to stoop for a product on a low shelf) considerations.

2. *Why Study Consumer Behavior?*

As understanding consumer behavior is often the key to business success, many who study consumer behavior come from disciplines (e.g., economics, marketing, advertising, retailing) that support business activities. But why do psychologists find it worthy of study? Discussed in greater detail elsewhere (Jacoby 1975, pp. 981–5), a few of the reasons are as follows.

Consumer behavior is a domain providing innumerable opportunities for important, socially meaningful research. Learning how to influence the underprivileged in the USA and elsewhere to adopt and increase consumption of products and services good for them and to cease consumer behaviors that are less appropriate or even harmful is one example. Studying why there is so high a rate of noncompliance with physician prescription dosage instructions and studying how to reduce this rate is another.

Attempting to understand consumer behavior forces one to consider a broader array of factors than is typical in much psychological research. This occasionally leads to seeing relationships that might not have been noted had one not been compelled to approach the subject using a broader (or at least different) perspective. Consumer theory and research thus have the potential to contribute to the development and extension of psychology itself. As an example of a conceptual contribution, consider a richer, more dynamic way of conceptualizing stimulus–organism–response (Jacoby 2002). As an example of an empirical contribution, consider the development of process methods that enable psychologists to better test dynamic theories regarding how information acquisition leads to the development of, and molecular changes in, higher order cognitive processes (Jacoby et al. 2002).

Consumer research provides numerous opportunities for working with dependent variables that, from the perspective of our test subjects, are meaningful and consequential. Further, because of the universal and pervasive nature of consumer behavior, this arena provides excellent opportunities for examining the validity and limits of psychological theory.

3. *Evolution of the Scholarly Approach to Studying Consumer Behavior*

The origins of scholarly work on consumer behavior may be attributed to the economists of the eighteenth and nineteenth centuries (e.g., Adam Smith, Jeremy Bentham, Alfred Marshall). These economists held that a person's desire for goods and services generally exceeded the person's ability to pay. Therefore, buying decisions were theorized to result from a process during which a value was assigned to each desired offering based upon the person's 'rational' assessment of that offering's ability to satisfy his or her needs and desires. This want satisfying ability was termed 'utility' and it was held that consumers would seek to maximize utility. According to these economists, the price of the offering was the key element in the maximizing utility equation. Raising an offering's price was predicted to lower its sales; lowering its price would increase sales. Though seemingly commonsensical, this proposition suggests that, given changes in price, consumers respond like billiard balls, buying when prices are lowered and refraining when prices rise. Little (perhaps nothing) else matters.

In terms of the stimulus–organism–response (S–O–R) model familiar to psychologists, it can be seen that the 'economic man' conception is severely limited, suggesting as it does a relatively empty organism whose behavior is determined by economic stimuli and little else. According to the classic S–O–R

formulation, external stimuli (e.g., price changes) first need to be perceived, understood, evaluated, and integrated with other psychological phenomena (e.g., past experience, current needs, attitudes, and expectations, etc.) before having impact, if any, on the individual's behavior. Thus, while one can see various reasons why a price decrease would lead to increased purchase (as predicted by economic theory), one can also see various reasons why it would have either no effect (e.g., the price change does not represent a 'just noticeable difference'; the consumer would purchase the same amount of the items regardless), or the reverse effect (e.g., sales decrease because the consumer interprets the price decrease as reflecting a decrease in quality, or because the consumer views the item as no longer having the desired snob appeal, etc.). To best understand and predict consumer behavior, we would have to know something about the consumer's motives, *a priori* expectations, how the incoming information is perceived and interpreted, and so forth—namely, the factors traditionally studied by psychologists and then some. (Parenthetically, when this is done, it is often found that other factors are more important than price. Examination of contemporary consumer behavior texts reveals that most devote fewer than a half dozen or so pages to price considerations.)

Responding to limitations in the 'economic man' model, both theorists and practitioners began adding variables to the stimulus and especially organism portions of the S–O–R model. During the 1930s through the 1960s, a number of European émigrés trained in Freudian psychoanalysis, collectively known as 'motivational researchers' (e.g., Dichter 1960), became influential among the business community. Other psychological constructs (including attitude and personality) also were introduced during this period. By the mid-1960s, the emerging models (developed not by psychologists, but by professors of marketing) reflected primarily psychological and/or sociological factors (e.g., Andreasen 1965, Engel et al. 1968, Howard and Sheth 1969). Engel et al.'s, book now in its seventh printing, was the most influential introductory text for perhaps 15 years and remains popular. The 1960s also represented the time when an increasing number of psychologists with a scholarly bent began studying consumer behavior. Reflecting evolution, a number of today's leading texts (Hoyer and Maclnnis 1997, Peter and Olson 1999, Solomon 1999) are authored or co-authored by PhD psychologists (Hoyer, Olson, Solomon).

Around 1970, two developments did much to shape the emerging field. First came the formation of the Association for Consumer Research (ACR), today considered to be the principal scholarly organization in the field. Starting with a few hundred members in 1969–70, ACR's membership consists of researchers from a wide variety of disciplines and now numbers nearly 2,000, including several hundred psychologists. Though its members focus on different issues (e.g., marketing researchers tend to be more interested in understanding purchase decisions, communication researchers more interested in interpersonal or mass media communication, home and family economists more interested in postpurchase issues, etc.), their shared frame of reference is that, influenced by elements in a complex environment, consumers are information-processing, problem solving, decision-making, choice-making beings. Its annual series, *Advances in Consumer Research*, best illustrates the diversity of the field.

The second major development was the introduction of the *Journal of Consumer Research*, the first journal devoted specifically to consumer research. Prior to the early 1970s, scholarly work on consumer behavior appeared sporadically in journals spanning many disciplines. Work having a behavioral science (including psychological) perspective tended to appear in the *Journal of Applied Psychology* and, to a lesser extent, in the *Journal of Marketing* and *Journal of Marketing Research*. While these journals continue to publish some of the better consumer research, their principal focuses lie elsewhere. A collaborative venture by a number of national societies, the first issue of the *Journal of Consumer Research* appeared in 1974 and quickly became the field's flagship journal. Using the first 15 years of JCR publications, Hoffman and Holbrook (1993) provide an interesting perspective on the intellectual structure of the field. A 1991 *JCR* article by Cote et al. (1991) employ a citation analysis to assess the influence of the journal across the behavioral sciences. As a field of inquiry, consumer research is now interdisciplinary and intersector, being conducted by researchers operating from within academia, government, industry, and public not-for-profit groups.

4. *The Introduction of Psychology to Studying Consumer Behavior*

Interest by psychologists in consumer behavior and the factors that influence such behavior extends one hundred years. In 1900, H. Gale published work on the position of an advertisement on the printed page in 'The University of Minnesota Studies on Psychology.' Walter Dill Scott (whose dissertation on attention and persuasion was with Wundt), introduced the concepts of needs and motives in his 1903 book, *The Theory of Advertising*. Scott's 1908 book, *The Psychology of Advertising in Theory and Practice*, emphasized psychology by placing the word in its title. However, except for occasional articles in the *Journal of Applied Psychology*, psychologists devoted little scholarly attention to consumer behavior during the first half of the twentieth century. When studied at all, consumer behavior was often viewed as convenient for testing more fundamental psychological propositions. For

example, when the USA was experiencing shortages in traditional cuts of beef during World War II, Kurt Lewin's classic studies on public versus private commitment assisted both government and industry in making internal meats (e.g., brain, liver, kidney) more palatable to the US consumer. With the exception of Katona (1951, 1960), who was essentially a voice in the wilderness, few psychologists studied consumer behavior for its intrinsic interest. Situated in industry, most members of APA's Division of Consumer Psychology had an applied orientation and were interested in research that assisted business.

This emphasis began changing in the mid-1960s. The first chapter on consumer psychology appeared in *Annual Review of Psychology* (Twedt 1965). The second appeared (Perloff 1968) three years later, as did a chapter in the *International Encyclopedia of the Social Sciences* (Krugman 1968). In addition to the traditional focus on the consumer *qua* purchaser (i.e., as the object of business interests), these contributors focused greater attention on the consumer *qua* consumer. This emphasis became entrenched during the decade that followed (Jacoby 1975, 1976), gaining even greater strength in the intervening quarter century (Jacoby et al. 1998). By the early 1980s, the dominant focus of APA's Division of Consumer Psychology (which had been renamed The Society for Consumer Psychology) had shifted to studying the consumer *qua* consumer. In 1992, it began publishing the *Journal of Consumer Psychology*.

Concurrent with increasing numbers of psychologists finding that consumer behavior merited their scholarly attention, scholars in other disciplines eagerly embraced psychological theory and methods for their own consumer behavior research, with many advising their doctoral students to minor in psychology (particularly social, cognitive, or measurement psychology). Cross-fertilization was enhanced as increasing numbers of newly minted PhDs in social, cognitive, and experimental psychology assumed faculty positions in departments of marketing and other disciplines where they studied consumer behavior. A number subsequently became highly regarded scholars and leaders in the field. Adding to this trend, prominent psychologists began participating in Society for Consumer Psychology and Association for Consumer Research conferences, occasionally publishing articles in consumer behavior journals; examples include William McGuire (1976), Robert Zajonc (Zajonc and Markus 1982), and Daniel Kahneman (Ratner et al. 1999).

5. *Current Content and Focii of Consumer Psychological Research*

A psychologist reading today's introductory texts would feel right at home. Even those not (co-) authored by psychologists most often devote chapters to familiar subjects, including motives, attention, perception, categorization and comprehending, learning, memory, attitudes, persuasion, and decision-making. Large portions of other chapters are devoted to personality, values, cognitive dissonance, the self, affect, and symbolic considerations. Much of the remaining content tends to be sociocultural in nature, with chapters typically covering cultural and cross-cultural influences, subcultures, social class, reference and other group (e.g., age, gender, race, religion) influences, and family and household considerations.

Though consumer researchers study a wide variety of psychological phenomena and topics, some have dominated. Attitude theory has enjoyed sustained popularity for more than three decades. During the early 1970s, hardly an issue of the *Journal of Consumer Research*, *Journal of Marketing*, or *Journal of Marketing Research* appeared without at least one (and often more than one) article making heavy use of Fishbein's seminal work (cf. Fishbein and Ajzen 1975). Since the late 1980s, attention has shifted to more contemporary attitude theories (Chaiken 1980).

In the early 1970s, research on various aspects of cognitive processes (including judgment and decision-making) surfaced, quickly providing what currently remains the dominant intellectual focus in the field. Summaries of this work, as well as work on other topics, may be found in *The Handbook of Consumer Behavior* (Robertson and Kassarjian 1991). More recently, mood, affect, and the nature of the consumption experience also have captured substantial researcher attention. It is expected that all these emphases will continue to remain strong.

Another thrust has been increasing attention devoted to how consumer research may be used to develop, evaluate, and influence public policy affecting consumer well-being. While research of this sort sometimes appears in the journals noted above, much is now published in the *Journal of Public Policy and Marketing*, a journal established for this purpose in around 1980.

The field has experienced shifts in research methodology. Early nonpsychological research placed great reliance on surveys. As psychological factors assumed greater prominence in the field's models, experimentation became and remains the dominant methodological approach. Since the 1990s there has been a gradual acceptance of qualitative research methods of various sorts—ethnographic, interpretivistic, introspective, etc.). Approximately 15 to 20 percent of the currently published work utilizes such methods, and this trend is expected to continue.

6. *Emerging Focii in Consumer Research*

In addition to the emphases mentioned above, other anticipated trends include the following. First, though we do not expect many to forsake reliance on static

verbal report methods, it is expected that consumer researchers will gradually display greater use of qualitative and quantitative methods that capture the dynamic nature of the behavior and underlying psychological processes. Second, while some work has always focused on socially important issues and improving social welfare, we expect to see an increase in such research. Third, we expect consumer researchers to be drawn into applying their expertise in a number of other realms. Such a trend has been emerging in the legal arena, where consumer psychologists are called on to study phenomena such as deceptive advertising, trademark confusion, and product misuse/liability. The Internet and e-business represent another realm where considerable consumer research can safely be predicted.

Last, as noted, the Association for Consumer Research is widely acknowledged to be the central organization for consumer researchers of any stripe. Unlike the Society for Consumer Psychology, which subscribes to the American Psychological Association's Code of Ethics, the governance of ACR has resisted efforts to develop and implement any such code. This is regrettable, especially given the tremendous opportunities that consumer researchers, as researchers and consultants, have for affecting all consumers. Accordingly, one would hope and expect ACR's neglect to change, preferably sooner rather than later.

Consumption, Environmentally Significant

1. Introduction

The nineteenth and twentieth centuries have seen an unprecedented surge in the number of people on the planet and a corresponding boom in the construction of buildings, roads, machines, and other artifacts. Both outcomes relied on technologies that mastered nature by controlling disease and facilitating access to material resources. This intensification of human activities has left its mark on the air, soil, water, and all

living systems. Some effects are minor or at least reversible, but others result in dramatic, long-lasting changes that may be demonstrably undesirable. There are widespread concerns today that, on balance, human activities are degrading the environment substantially.

Two familiar categories of activities are at the root of the problem: production and consumption. In the modern world, more and more of people's time and energy is spent producing goods and services to earn a living and then using this income to purchase an unprecedented quantity and variety of items for consumption. These are the principal activities involving human use of fuels, materials, water, and soil and therefore the basis for environmental disruption. For this reason, production and consumption are the obvious targets for changes in behavior.

Production and consumption cannot be called to a halt, but they can be carried out differently. Which changes, and how much change, are desirable are not questions that can be answered in a definitive way. Bold ideas are needed to break the cycle of more people, more production, more damage. The social and natural sciences can provide guidance for trying out these ideas in what is essentially a social experiment on a global scale. Contemporary information technologies make possible an unprecedented quality of public access to information and participation in debate.

Many efforts to reduce systematically harm to the environment focus on creating technological options for production activities (see *Industrial Ecology* and *Industrial Metabolism*). Another active area of investigation produces policy advice for public and private-sector executives. The focus of attention on consumption is relatively recent. It holds the promise of technological and policy opportunities, such as more fuel-efficient cars or tax breaks for better insulated homes. However, in addition, it also opens up the new prospect, which is far less developed, of systematically exploring lifestyle options for the direct benefit of household decision-makers. Thus the following questions can be posed. Which environmental changes are most problematic? How is consumption related to environmental change? Can people change their lifestyles and consumption patterns? The final section describes how social scientists can enhance the prospects for changes in consumption.

2. *Which Environmental Changes are Most Problematic?*

The environment consists of air, water, soil, minerals, microorganisms, animals, and plants—all bound by the great cycles and overlapping systems of which they are part. Changes to the environment, whether due to human activities or not, exhibit an unlimited variety. For example, 'water pollution' may involve contamination by a variety of wastes, each with different properties (see *Water Pollution: Marine*; *Water Pollution: Terrestrial and Groundwater*). The concentration of a particular waste material (as measured in g m^{-3} of water) depends on the amount discharged and the condition of the water—for example, whether it is still or moving. Another variable is whether other foreign materials are also present in the water and in what quantities. Polluted water could be confined to a remote location, or it could be heavily utilized for industrial purposes, irrigation, or even household use. Furthermore, different individuals will react differently even upon similar exposure to the same pathogen or toxic material.

Thus a specific act (like discharging a volume of chlorine from a paper mill into a river) will under different circumstances be associated with a variety of changes to the environment, and these changes may have either benign or ill consequences. The interactions of several different activities are common and compound the unpredictability. We would like to rank-order environmental problems according to a single, unambiguous criterion and resolve them one after the next starting with the most serious, but this is not a realistic expectation (see *Human–Environment Relationship: Indicators*). Consider the set of problems that are candidates for the most threatening to life on earth, such as climate change, the contamination of fresh water, or the ubiquity of toxic materials. Like the broom of the sorcerer's apprentice, each one subdivides into a large number of component problems, most associated with the confluence of multiple activities.

The only approach to preventing environmental damage that can hope to match the enormity of the challenge is the wholesale change of habits so as to eliminate many problems in one fell swoop. This would require a limited number of powerful solution concepts, each of which is capable of governing innumerable individual changes. Recent thinking about how to reduce the environmental impact of production activities provides examples of such concepts. Industrial Ecology promotes the transformation of industrial systems by copying a few basic principles that are characteristic of ecological systems. One is to close production loops, reclaiming wastes of one process for productive reuse in others, instead of discarding them as useless. Design for the Environment includes environmental criteria in the design process for industrial products, alongside the conventional criteria of performance, cost, and esthetics. Finally, Life-Cycle Analysis describes the environmental impact of a product from the extraction of materials for its fabrication to its disposal. Based on such studies, many analysts have concluded that producers should take responsibility for products over their full life cycle. Such solution concepts are working their way into the language and customs of corporate

cultures. Some firms make changes only when they are cost saving in the short-term or required by law. With the passage of time, however, and for a variety of reasons, others are seizing the initiative to reduce the environmental impact of their production activities. In this article a parallel path toward greater citizen initiative is described.

3. *How is Consumption Related to Environmental Changes?*

There are systematic differences in the environmental pressures associated with lifestyles of poverty and of affluence. In this article the concern is mainly with the consumption patterns typical of the industrialized countries because they serve as models for aspirations and emulation around the globe.

Purchased goods and services satisfy not only basic needs but also the desire for mobility, novelty, physical comfort, and luxury. The use of consumer items entails environmental degradation beyond that associated with production. The automobile provides the most important illustration. It is responsible for noise, traffic congestion, urban sprawl, and disposal problems in addition to the emission of a variety of pollutants that enter the atmosphere and get swept into soils and water supplies. Food consumption likewise presents major challenges quite distinct from the formidable ones associated with agriculture. What people choose to eat has major implications for land use, and packaging for foods (as well as for other household items) ends up after a short service life in landfills. The disposal of half-used containers of household chemicals or pharmaceuticals is also a serious problem. In recent years there have been systematic efforts to quantify the different ways households use energy, materials, and water and the various kinds of garbage that people discard (see, for example, Dillman et al. 1983, Schipper 1996, Wernick 1996, Rathje et al. 1992).

One of the most striking differences between production and consumption activities is the enormous amount of time, effort, and money that have gone into developing technological alternatives in the production environment and studying the implications of choosing different options. One reason for this amount of scrutiny is that a new plant may cost hundreds of millions of dollars and serve for many decades. Households, by contrast, are offered mainly commonsense advice in popular books or by interested parties (for example, through mailers that accompany utility bills). There are important opportunities, which should be exploited, such as better insulation and more energy-efficient appliances. Perhaps the best example is the real prospect for substantially more fuel-efficient cars. However, increasing numbers of researchers are convinced on the basis of their analyses (e.g., Duchin and Lange 1994) that these technological changes cannot offset (and through lowering costs may even stimulate) the growth in demand.

More fundamental changes in consumer behavior, especially regarding mobility (linked to cars and, increasingly, air travel) and material goods, are possible, but they are difficult to achieve for two reasons. First, consumer behavior reflects underlying lifestyle decisions that are intimately tied up with the sense of personal identity. Individual consumer purchases are part of a pattern, and large changes cannot be made one element at a time. For example, if a household decided to give up its cars, it might be necessary to change jobs or to move from a house to an apartment near public transportation or nearer to work. Second is that lifestyle changes are strongly constrained externally, notably by policy decisions like zoning and tax legislation or investment in highways rather than public transportation infrastructure. Some countries have experimented with nationwide incentives for eliminating unnecessary packaging and reusing or recycling the rest (Germany; see Fishbein 1994) or with extensive and convenient public transportation systems intended to displace car travel (The Netherlands). These are efforts of historic significance, but their success is inconclusive. To realize the potential of such initiatives, people need to examine their own households' lifestyle decisions, not just their consumption choices, in a context of well-articulated alternatives, in the same way that firms have begun to actively consider organizational and technological alternatives aimed at reducing their environmental impact. If households come to favor new alternatives, their choices can be expected to influence legislation and public investment priorities.

4. *Can People Change their Lifestyles and Consumption Patterns?*

Starting in childhood, people experience relationships with family, friends, neighbors, bullies, shopkeepers, thieves, police, librarians, and teachers. They develop values and opinions, acquire habits, hobbies, and skills. Later they may engage in paid work, all sorts of unpaid work, and political and community activity, choose where they will live and with whom, establish a household, and possibly have children of their own. They may frequent fast food restaurants, forego meat, prefer bowling or opera, drive tens of thousands of miles a year, etc. All of their attitudes and activities, constrained as they are by such things as legislation and public infrastructure, jointly comprise their lifestyle. The pattern of consumption, with its direct implications for the environment, is one expression of lifestyle choices. If lifestyle does not change, changes in consumption, in particular as they affect the environment, are likely to be slow and incremental. Many people today suspect that changes in lifestyle could bring about decisively better outcomes.

All people have the same basic material needs for food, clothing, shelter, and fuel and are daily exposed to common cultural messages. Even in a modern society that strives for individual self-realization and is relatively tolerant of unconventional living arrangements, only a limited number of distinctive lifestyle patterns emerge. We can define a household's lifestyle in terms of how it carries out the activities that satisfy its members' needs and desires. A taxonomy for describing these activities is proposed by Duchin (1998):

(a) Food
(b) Care of old and young
(c) Healthcare
(d) Personal care
(e) Education
(f) Household administration
(g) Clothing (garments and cleaning)
(h) Recreation and entertainment
(i) Vacations
(j) Housing (systems and maintenance)
(k) Household appliances and furnishings
(l) Household cleaning
(m) Transportation
(n) Home work for pay
(o) Home work for community
(p) Work outside home
(q) Idleness.

Market researchers in the US have provided a uniquely holistic view of American household lifestyles, laying the groundwork for a systematic approach to the questions that interest us. Based on the statistical analysis of a large database compiled from diverse sources, they concluded that the lifestyles of the approximately 100 million American households could be described in terms of only a few dozen categories. They gave these categories colorful names such as Furs and Station Wagons (described as 'new money in metropolitan bedroom suburbs'), Gray Power ('upper middle-class retirement communities'), Single City Blues ('downscale, urban singles districts'), and Public Assistance ('America's inner-city ghettos') (Weiss 2000). Today, consumer-marketing strategies use these categories routinely to target client households that are likely to purchase particular products. Households with similar consumption patterns tend to have similar impact on the environment.

Households with distinct lifestyles have different prospects for changing their lifestyle scripts. Individuals move from one category of household to another at turning points in the life cycle, for example upon graduation from high-school or university or at retirement. The challenge is for people to consider a new set of lifestyle scripts, especially at these critical junctures when change is more easily achieved.

It is an open question as to whether people will be engaged by this challenge rather than mainly responding to initiatives taken by corporate executives and politicians. There is a wide range of views about the extent to which individuals act in their personal self-interest or take a wider set of concerns into account (for an overview see Friedman 1996). People behave differently with their loved ones and with strangers and are generally less selfish in family settings than in business decisions. They often trade off immediate gratification for longer-term considerations and are willing to make sacrifices for the benefit of others—not only intimates or acquaintances but anonymous others or society at large. In fact, some people will go out of their way to save a river or risk their lives to prevent an accident. Can a critical mass of people be expected to travel less or eat less meat voluntarily in pursuit of a better quality of life, or for the good of the planet?

The standard economic proposition is that self-interested behavior is 'rational' behavior and that people act 'altruistically' only in exceptional circumstances. According to this view, the only way to influence firms or individuals to act differently—for example, to use less energy or generate less waste—is by the coercion of regulations or, better still, by affecting the money bottom line through subsidies and other positive incentives, or through charges and taxes. But is it true that this is the most effective way to prod households, like profit-making firms, to act in the public good?

Psychologists, anthropologists, and sociologists view the personal decision process to be a complex balance among considerations that frequently overrule individual self-interest. They provide reason to believe that appeals to the full set of motivations and behaviors—accompanied by an analysis of bold options—can encourage lifestyle decisions that reduce pressures on the environment. While different cultural settings call forth different patterns of motivation and behavior, Fiske argues persuasively that they can all be covered by a four-category taxonomy that includes communal sharing, authority ranking, and equality matching, as well as the kinds of behavior associated with what he calls market pricing (Fiske 1991).

When there are not powerful motivations to act otherwise, people often try to do the best they can for themselves, and 'rational choice' is a compelling explanation for many everyday decisions. But large numbers of people are passionate in their concern about the environmental dangers they perceive and ready to take initiative to transform the situation. This is what it means to say that there is an environmental movement (Stern et al. 1999). Nonetheless, consumption behavior has changed relatively little compared to attitudes about the environment. Arguably the most important obstacle is the difficulty of imagining new scripts and removing the obstacles to actually living them. What is needed are a detailed and sustained dialogue about lifestyle options, demonstration projects designed and implemented with the collaboration of a variety of experts, and the celebration of pioneers in all walks of life. How can such an unprecedented dialogue and experiment be initiated?

5. What Can Social Scientists Contribute?

This article has argued that environmental problems are too numerous and varied to yield to policies designed to deal with them one by one. Taxes and subsidies act only indirectly and slowly. A direct focus on a few powerful solution concepts can, in principle, resolve many problems at once. A great deal of research by engineers and applied physical scientists is already aimed at radical technological innovations in production (and consumption) and demonstration projects to illustrate their feasibility. Now it is time to turn to lifestyles and consumption.

Social scientists are interested in how different kinds of households carry out the full range of everyday activities. They can provide a coherent and systematic description of types of households and household lifestyles as a basis for understanding how we now live. The development of this structure makes it possible to use quantitative methods to analyze the implications of adopting new lifestyle scripts, ones that capture the public imagination. The objective of the analysis is to see how much difference it would make if particular new scripts were adopted. Feedback from analysis can sustain a more realistic public dialogue than one based only on anecdote and advocacy.

This is the age not only of the environment but also of the Internet, with its capability for sharing information and networking of both physically proximate communities and virtual ones with members around the globe. This medium might provide a powerful way to launch and maintain relevant public dialogue about individual and community decisions. If facts, figures, demonstration projects, and analysis inform this dialog, the combined effort of experts and citizens could actually make a difference. In fact, universities—and social science scholars in particular—might profitably reinvent their disciplines in the process.

Consumption, History of

The history of consumption, though a distinct field of historical research and writing only since the 1980s, has recently emerged as an especially vigorous area of inquiry. Stimulated by the visibility and power of the consumer economy in contemporary societies, scholars have redoubled their interest in investigating its past—to locate its beginnings, trace its growth, and assess its historical effects. In principle, then, to write a history of consumption is to shed light on all of those practices, institutions, identities, and meanings attached to the merchandising, acts of purchase, and final use of goods. Earlier traditions of social history addressed some of these concerns. The Annales School stands out for its abiding interest in material culture, especially in the early modern world (Braudel 1977, Roche 2000).

British social historians too, in the course of debating working class standards of living and moral economy during the industrial revolution, were clearly concerned with consumer habits, as were historians of France when writing about the subsistence crises

and bread riots of the old regime and Revolution. Increasingly, subjects such as leisure-time use, once considered separately, are now grouped along with the study of tourism, cinemagoing, television viewing, and other types of spectatorship and reception, reading included, as properly belonging to the history of consumer cultures, especially insofar as they are produced under capitalist exchange relations. The coherence of the field derives, thus, not from any single topic, but rather from the large and complex role that consumer practices are now interpreted as playing in forming collective identities, social movements, and individual subjectivity.

1. Approaches and Concepts

Because there is no general theory for why people consume, and the determinants of consumer practice are recognized as ranging from the economic calculations involved in obtaining commodities to the psychological satisfactions derived from their possession, the methodologies deployed to study the history of consumption are decidedly eclectic. Social history is still the dominant approach. But because of the complex nature of the subject matter and the fact that the timing of the study of consumer cultures coincided with the rising fashion for cross-disciplinary and multicultural studies, histories of consumption draw on an unusually wide range of disciplinary influences. These range from economics, marketing research, anthropology, and sociology to cultural and cinema studies and art and design history.

Evidence of past consumer behaviors is provided by sources as diverse as industrial archeology to recover the shards of past material life; probate records to discover the legacies and bequests of the dead, thereby to estimate the value they put on goods; business records to reveal merchandising strategies; and advertising copy, both to disclose the imagination of taste brokers and to reveal the embedding of 'social tableaux' in the popular imagination. Topics such as leisure-time use, which were once treated as specialized subject areas, are now grouped along with tourism, cinema-going , television-viewing, and other types of spectatorship and reception, reading included, as properly belonging to the history of consumer cultures, especially insofar as they are produced under capitalist exchange relations. The coherence of the field derives, thus, not from any single topic or debate, but rather from the belated discovery of the large and complex role that consumer practices play in forming collective identities, demands for social entitlement, and individual subjectivity.

The subfield's rapid establishment evidences a convergence of pressures. One stimulus came from social historians critical of neoclassical economists who, by treating consumer choices as ahistorical, reducible to demand curves based on the price and availability of goods, ignored the symbolic and social value of commodities. Social historians were also critical of the previous generation of historical scholars who, by focusing on social relations around production, failed to capture the significance of consumer practices to class, politics, ideology, and values.

Another stimulus arises from the so-called postmodern or postscarcity sensibility of the late twentieth-century West. The generally high living standards, the rapid shift from manufacturing to service-oriented industries, and the densely symbolic consumer cultures of late twentieth century capitalism seem to have profoundly altered conceptions of individual and social identity such as to pose a double question. One is whether the postmodern epoch has not engendered an entirely new relationship with material life, so much are modern cultures in the thrall of material abundance to the exclusion of nonmarket values; the other is whether the ambivalence about goods so deeply rooted in Western culture did not previously inhibit study of the power of things to shape social life (Featherstone 1991).

At first, the failure of socialist-type planned economies, which construed themselves as the only fundamental alternative to free-market, individualist consumer capitalism, reinforced a post-Cold War Consensus that consumer freedom was an unalloyed social good, engendering a celebratory attitude toward consumer abundance. As time passes, however, the globalizing trends that go under the names 'Americanization,' 'Coca-colonization,' or 'McDonaldization' has generated worries that the rapid-fire spread of Western-style consumer habits will not just destroy indigenous ways of life suited to local resources and customs, widening the gap between rich and poor nations, but also ruin the global environment.

Finally, feminist historiography has opened up whole new vistas on consumer practices by highlighting the gendered division of labor around domestic goods, provisioning, and shopping, the bridges between market-driven consumption models and household decision making, and the timeworn tropes associating the female figure with the fickleness of changing styles of culture and consumption (de Grazia and Furlough 1996).

The self-made, often empirical, character of the new field belies the influence long exercised by political economy and historical sociology on ways of thinking about consumption. Adam Smith's famous dictum from the *Wealth of Nations* (1776) that it is innate for people to 'treaty, barter, and purchase' (Bk. 1, Chap. 2) is often cited to legitimate Western models of acquisitive individualism, as are his remarks that 'Consumption is the sole end and purpose of all production … The maxim is so perfectly self-evident that it would be absurd to attempt to prove it' (Bk. 4, Chap. 8). Karl Marx's distinction in *Capital* Vol. 1

(1867) between use-value and exchange value is still influential among critics of capitalist consumerism, used to differentiate between so-called real and false needs, the latter fostered by bourgeois stratagems to fuel 'false consciousness.'

The 'fetishism of commodities,' meaning the process by which exploited human labor is embodied in goods to give the appearance that they circulate the market under their power, their value thereby derived from relations of exchange rather than the alienated labor that originally went into their creation, is still an important reference point for historians critical of the commodification of culture and other goods. The Marxist tradition is also referred too for having emphasized production as determining of class identities to the neglect of relations around consumption.

Non-Marxist German historical sociology also stands as an important reference point. Max Weber is often cited for his paradoxical argument that capitalist accumulation was spurred by an Puritan asceticism. Seventeenth century Dutch indulgence in their 'embarrassment of riches' belies Weber's argument (Schama 1987). Consumerism, a recent critic of Weber argued, is central to the modern Western world outlook, but its origins lie not in capitalist relations of exchange or the Protestant religious ethic so much as in the eighteenth century romantic structure of feeling, combined of alternations of 'anticipatory pleasure and consumatory disappointment,' (Campbell 1987) Weber's more lasting contribution is to recognize the signal importance of socially differentiated consumer practices, based on *de facto* elite monopolies over certain goods, to reinforcing social status and power.

This intuition is most fully developed in the French sociologist Pierre Bourdieu's notion of 'cultural capital' and the ways in which late twentieth century elites manage it to establish class 'distinctions.' Maurice Halbwachs too, writing early in the century (1912, 1933), made the important point on the basis of on cross-national comparisons of lower-class standards of living that different notions of lifestyle, based on class identities, might be more important to shaping consumption practices than differences of income. The influence of his contemporary, the anthropologist Marcel Mauss, is still notable for his distinction between commodity exchanges under capitalist systems and the 'gift economies' based on reciprocity of non capitalist or precapitalist exchange systems. No historian of consumer culture can forego familiarity with the US sociologist Thorstein Veblen's *Theory of the Leisure Class* ([1899] 1953).

A mordant critic of the turn-of-the century US elites, he excoriated them for renouncing the craft spirit to revel in 'conspicuous consumption.' Rivals for place and power in an ever more fluid social structure, they engaged in 'pecuniary emulation,' generating the phenomenon, reproduced down the social ladder of what later would colloquially be called 'keeping up with the Joneses.' Veblen's contemporary, the German historical sociologist Werner Sombart, is equally interesting for hypothesizing that different types of exchange relationship (moving from feudalism to the 'high capitalism' of his epoch) yielded very different overall outlooks toward wants and needs (Sombart [1913, 1967]). He was the first to argue, on the basis of his study of the US working class in *Why is there no Socialism in America?* (1904) at the beginning of the twentieth century, that an abundance of goods, consumed within a more or less democratic framework, could significantly condition political ideologies.

2. *Periodization*

Like historians of industrialization, historians of consumption struggle over the timing of the moment of birth of a mass consumption society. Some argue the breakthrough was as early as the sixteenth century, fruit of the circulation of images related to the printing press and the cultural exchange around the Mediterranean world and with Northern Europe (Muckerji 1983). Others argue that the eighteenth century was when the collective mentality of the medieval world based on scarcity, austerity, and self denial, evolved into what the philosopher Charles A. Taylor calls the 'culture of ordinary life.'

Historians of the early nineteenth century forcefully place the first consumer revolution within the context of the vast shifts in terms of trade that saw Europe's emergence as the center of the first global world economy. That even the habits of urban lower classes and perhaps even rural cottagers changed in this period is debated. Optimists argue that the demand side was as important as the supply side in the industrial revolution, and modern manufactures such as Wedgewood porcelain ware benefited not just from aristocratic and bourgeois patronage, but also from the custom of a broad band of people capable of purchasing 'populuxe goods' (McKendrick and Fairchild 1993). That workers in the British Empire early acquired new tastes for sugar, tea, and rum, and rural cottage workers were willing to exploit themselves harder to enter the market to purchase exotic wares, is now well-demonstrated. Still, both the British and American colonial experience show that emergent consumer culture was not an unalloyed progress.

Sugar, as it sweetened tastes, also toughened the bonds of empire. The boom in demand was an incentive to expanding slave systems in the colonies; sugar and tea were also stimulants that eased the pangs of early industrial manufacturing's appalling work rhythms (Mintz 1993). American Colonial records show that householders traded off declining health standards for an improved sense of psychological well-being; tea drinking and smart tea sets

spread while nutrition declined (Shammas 1993). What seems sure is that as material life changed dramatically in the course of the first and second industrial revolution, the gap between the conditions of living of a goods-rich bourgeoisie and a goods-poor working class and peasantry was hugely enhanced. This divergence of conditions would only begin to diminish from the first third of the twentieth century.

To speak of the first mass consumer society, one has to turn to the USA around the beginning of the twentieth century. There, the 'consumer revolution' was favored by a peculiar combination of vast economic resources, quasidemocratic outlooks, and the rapidly expanding needs of a huge, mobile, urbanized emigrant population. Workers were decently enough paid, class stratifications around consumption enough diminished, and markets highly protected to encourage large units of manufacturing and retailing to orient themselves to standardized low cost per unit production for a mass market. Cheap, abundant food and ample housing reduced the family budget share devoted to nutrition and shelter (which summed together in Western Europe still consumed as much as 75 percent of the working class family budget through the 1950s). This freed monies for other goods. By the late 1920s, as many as three-fifths of the US people were 'consumers,' with all due attention to huge differences of income. The Ford Model T (1908) was the paradigmatic good, and US production and domestic consumption of automobiles outstripped the whole world's combined down to the 1950s.

Not surprisingly, the USA pioneered the invention of practices and institutions related to mass consumption (though not the department store, which was the fruit of the nineteenth century bourgeoisie and highly developed in Western European large cities as well as Japan). Chain-store retailing started as early as the 1840s. The cash register began to be widely marketed from 1884. Retail credit had become widespread by the 1920s. Scientific advertising campaigns drawn up by complete advertising agencies dated from before World War I. Mass marketing using survey research and public opinion polling dated from the 1920s. The first government-sponsored national census on distribution occurred in 1929, compared to the British (1951) and the French (1965). Supermarkets flourished from the early 1930s.

Government aggressively promoted exports not just of consumer goods but also images and institutions of the consumer-centered US way of life, the belief that there was no real freedom without consumer abundance becoming a key tenet of US anticommunist foreign policy by the early 1940s. More and more, entitlement as citizens was couched as a right to a decent standard of living, to be achieved not through economic leveling or by government provision, but through free markets and higher incomes. Cold War 'consensus history' attributed the USA's purported superiority as a 'people of plenty' to the relatively harmonious 'communities of consumption' by contrast with Europe's class divisiveness. Recent historical studies are invaluable to weigh the formation of and cracks in this consensus. Whereas studies of the 'brokers' of the new circuits of consumer culture, including advertising and department store managers, etc, put the emphasis on the blunting of class consciousness (Leach 1993), studies of immigrant and working-class culture show that the language of commodities could be effectively used as civic dialog to refashion demands for social justice as demands for entitlement to a high standard of living (Cohen 1990).

Western Europeans would not achieve similar changes in standards of living until the 1960s, in the wake of the destruction of the most rigid aspects of the bourgeois class order of prewar Europe, reconstruction under the hegemony of US consumer models, the growing confidence of entrepreneurs in the face of widening and deepening markets, the pressure of labor movements on behalf of higher wages, not least government belief in Keynesian growth politics that spurred demand by supplementing low wages with generous welfare state protections.

If there is still no one historical account of the great transformation of the twentieth century which turned postwar Western Europe into a relatively affluent society, recent studies nonetheless pick up on several singular features. One is the sharp class stratifications carried over from the aristocratic into bourgeois regimes of consumption (Roche 2000, Auslander 1996). Another is the centrality of the world of small shopkeepers well into the twentieth century. Before the so-called 'Auto-Fridge Revolution' of the 1950s, there was the commodified leisure and spectatorship of the interwar period. Entry into the world of mass consumption was an arduous struggle even in the early 1950s. Evidence that affluence dimmed working class consciousness is at best ambiguous, as Goldthorpe showed in his famous study of early 1960s British auto worker (*The Affluent Worker*) although it certainly undercut earlier subcultures.

The study of the history of consumer practices in Eastern Europe picked up only in the wake of the collapse of Soviet-type planned economies. The story of the appalling scarcities of the Stalinist years in the former USSR is now well documented. However, to measure postwar, especially post-1950s, developments strictly by Western European and especially US standards misreads the extent of social provision, the pressure from ideologically competing models, the very different point of departure of development, and the paradoxes of finally delivering significant quantities of consumer durables in the 1960s and 1970s just as Western Europe passed to a postscarcity economy. More generally, new research promises to weigh the importance not just of the political regime but of deeply culturally determined ideas of market exchange in shaping wider notions of consumer culture (Merkel 1999).

3. Consumption Regimes Outside the West

The history of consumption in non-Western countries moves in two directions. One is to show the influence of Western consumer culture, the other to show the relative autonomy of developments by delving deeper into national and regional legacies.

The first instinct of writers on non-Western consumer culture was to emphasize the imperialistic nature of Western consumption habits. Aggressive corporate capitalism, most notably US-based media and communications corporations, not only sought uncontested economic power, using force to sustain it, but also fostered a hypertrophic consumer culture so out of proportion to local economic developments that it was capable of snuffing out indigenous cultures. Western consumer culture thereby perpetuated if not aggravated, semicolonial dependency. Closer study, critical of the Eurocentric presuppositions of 'cultural imperialism,' highlights the complexity of the interaction between international commodity flows and indigenous material life.

Subaltern studies posit the essential autonomy of postcolonial subjects; ethnographic studies dissect the multiplicity of interpretative responses to the imported consumer mores; anthropological studies probe the creative uses of material culture as a 'dialog around development.' None would dispute that the major direction of cultural flows is currently from the West, notably from the USA in the form of US 'infotainment' industries. However, studies focusing on practically all of the world's regions make a strong case for seeing significant variation in local vernaculars, notably in the cinema and popular music. Major differences turn on how much freedom local cultures have to refashion, 'creolize,' or hybridize material and cultural commodities (Smart 1999).

As historical research on consumption widens geographically, more and more emphasis will be put on the relative autonomy of developments, the evolution of sensibilities about material goods different from in the West, the factors that explain the disposition to or resistance against using Western goods (Bayly 1986, Hamilton and Chi-Kong Lai 1989). If the measure is not the quantity of goods and durability of structures but the quality of life that provided for physical well-being but used resources economically, the Japanese compared favorably with the British in the nineteenth century (Hanley 1997). Japan clearly had a distinctive trajectory of development. Urban markets and print culture flourished as early as the Tokugawa period in spite of sumptuary laws (ended only in 1868) that prescripted behaviors on everything from the size and location of residence to style of headgear and footwear. The emergence of mass consumption before World War II was disjoined from democratization. The males of the modern middle-salaried class were notably new goods oriented, out of eagerness to show off their capacity to master Western-type technologies and thereby legitimate their place in the social hierarchy.

4. New Agendas

The history of consumer movements stands as an important chapter of the history of consumption. Consumer cooperatives have a venerable history, starting from 1844, when the impoverished spinners of Rochdale in the north of England formed associations to secure their food supply against speculators and the exploitative practices of company stores. From the late nineteenth century, often in connection with the socialist movement, cooperativism spread globally, sometimes to fall victim to political repression, sometimes to succeed so well as to become practically indistinguishable from capitalist enterprises except in its democratic membership statutes and payout of dividends. Movements on behalf of consumer protections were pioneered in the USA as early as the Progressive era.

The goals were to regulate against corporate malfeasance, regulate against consumer fraud, promote truth in labeling laws, and to protect domestic manufacturing and labor unions with Buy National campaigns. Public interest campaigners, most famously the American Ralph Nader, overturned the age-old rule of *caveat emptor* through campaigns and law suits to hold manufacturers liable for consumer safety. Aside from studying actual movements of protest or reform, historians of consumer cultures constantly engage with the vexed question as to whether mass consumption, like the 'bread and circuses' in Roman times or the provisioning boards of absolutist monarchies, has blinded subaltern classes to their exploitation or whether goods, services, and occasions of consumption cannot equally be used, like other social activities, to create communities of opposition, facilitate communication (and thereby to provide alternative perspectives on prevailing power arrangements), and propose new standards of living that, implicitly at least, challenge the existing distribution and styles of wealth and power.

If one is to find fault with this vital field, it is that its rapid growth had caused it to reflect too little on its own genealogy and on the issues that spurred its development. If, initially, the field referred largely to the contemporary period, it now embraces Greco–Roman antiquity as well as postcolonial Central America, the superabundant material culture of the West, and the economies of scarcity of Africa and Southeast Asia. What then, if any, are the shared concerns? One certainly is methodological, common to social history generally, namely to overcome the bias toward the object-laden as opposed to the objectless in the reconstruction of the past. Another concern is to consider the symbolic charge of goods in tandem with the inequalities and asymmetries of power that to a greater or lesser degree are common to

all societies. Historically, people have always used goods to think about their society. Ultimately, the historian's charge is to discover, classify, and compare the extraordinarily different range of ways this has occurred.

Consumption, Sociology of

The sociological study of consumption is as old as sociology itself. Its empirical roots lie in the early development of statistical methods. In the middle of the nineteenth century, information about household budgets in different parts of Europe began to be collected with the purpose of determining the subsistence minimum. These studies concentrated on the consumption of food. This is how the statistical regularity named after its inventor Engel was established. It showed that a rise in income correlates with a decline in the share of food consumption of all household expenses. This seems to hold true even today (Ilmonen and Pantzar 1986).

Although household budget research had theoretically interesting results, it had a pretheoretical character. Theory was introduced into sociological research by Marx (1976). According to him, a commodity had both a use value and an exchange value. He further argued that in a market economy the latter began to dominate at the same time as the production relations between people turned into commodity relations. Marx called this phenomenon commodity fetishism. His views had an important effect on the sociology of consumption in the 1900s.

For Marx, consumption was subordinate to production. This idea was common in his time. A human being was understood primarily as a producer—as a *homo faber*—and the concept of consumer had not yet been invented. Its invention has been attributed to Condillac. However, his concept of *consommateur* is ambiguous, as it also refers to eating. Perhaps Condillac, like Engel, saw eating as a basic form of consumption. More importantly, however, he conceived the consumer as an abstract entity that satisfied its needs with objects produced for the market.

1. The Classic Stage of Sociology: The First Wave of the Sociology of Consumption

It was only in the classical period of sociology that consumption began to be analyzed as a distinct sphere of action. This period witnessed the first wave of the sociology of consumption. Several of the major sociologists of the time (e.g., Sombart, Weber, Tarde) analyzed consumption as part of the birth of capital-

ism and the modern way of life, paying special attention to fashion and the consumption of luxury goods. From the viewpoint of the sociology of consumption, the most important of them was Simmel (1930), whose *magnum opus* dealt with money as the mediator between consumption and various qualitative relations. He also analyzed the significance of consumption as a manifestation of city life and noted how central a mechanism fashion was in the modern world.

Simmel approached fashion from the perspective of social class. The upper strata rejected the prevailing fashion when it began to trickle downwards in the social hierarchy. It is Veblen (1926), however, who is regarded as the main formulator of this 'trickle down' theory. He called the way the upper class strived to distinguish itself from other classes 'conspicuous consumption.' Its central characteristic is the acquisition of expensive luxury goods with the aim of improving one's social standing. As the consumption of these goods becomes increasingly common first in the middle class and later in the working class, the upper class has constantly to struggle to show its standing by means of consumption. This is the driving force of consumption. Mills (1976) later emphasized its importance when he wrote about the 'status panic' of the middle class.

2. *The Second Wave of the Sociology of Consumption*

The second wave of the sociology of consumption spanned the interwar period and the period immediately following the World War II. Mauss (1925), better known as an anthropologist, was developing a general theory of exchange and gift giving. According to him, the latter is not as selfless an activity as might appear at first glance. The person giving a gift is, in practice, expecting a return present, even though they may deny this. Mauss' observations were to have a far-reaching influence on the sociology of consumption.

Another line of European sociology that touches upon consumption is connected with the critical theory of the Frankfurt school. On the one hand, Benjamin (1972) continued Simmel's work in describing city life. He focused on shopping alleys and popular culture as manifestations of modern life. He also studied fashion, but as an indicator of time rather than class. Blumer (1969) continued to develop this theme in the US. On the other hand, Adorno and Horkheimer (1979) criticized the spreading of commodity fetishism through popular culture. They did not restrict their criticism to consumption, though. They used it to show how capitalist society comes to an impasse when it subordinates use value to exchange value. This theme was developed further in both the German sociological tradition, including Haug's (1971) critique of commodity aesthetics, and in the American sociological tradition that dealt with the artificial aging of products and the manipulation of consumers. This approach has long roots. It reaches back to Adam Smith's critique of 'vanity consumption' and extends to the twenty-first century in the persistent criticism of marketing and consumerism.

In another American research tradition consumption is conceptualized more broadly. Consumers are not considered mere victims of the 'captains of markets' but are seen as actively expressing their values and goals through consumption. Lazarsfeld (1982), for example, pointed out that market communication is not etched in consumers' minds as on an empty board; instead, its message progresses in two stages through opinion leaders to people at large. Even then its reception depends on existing tastes and preferences. This realization led to another: that consumption provides excellent material for the analysis of social change. Riesman (1969), among others, used all sorts of consumption data to describe the moral change in American society. He argued that there remained only one and at the same time the most modern personality type: the 'other-directed' personality, for which consumption had become a central dimension in life.

3. *The Differentiation of the Sociology of Consumption into a Sphere of Its Own: The Third Stage of the Sociology of Consumption*

The third stage of sociological consumption research and, at the same time, the formation of the subdiscipline of the sociology of consumption occurred at the end of the 1970s. While previous sociological analyses were characterized by a great deal of moralizing about consumption, consumption now came to be seen as a meaningful social activity that offers a valuable perspective on society.

The new phase was ushered in by Bourdieu, who had also come to be known as an anthropologist. He ended up describing, by means of consumption, the maintenance of the class structure of French society in a way that resembles Simmel's and Veblen's view of status commodities trickling down in the social hierarchy. However, whereas Veblen stresses that consumption becomes an important means of making social distinctions in a situation in which differences are disappearing, Bourdieu (1979) argues that distinctions are embodied in specific habituses and internalized in consumption choices. He is, of course, not the only one who sees consumption as a means of maintaining class barriers and social distinctions. Concurrently with his research, similar studies were being carried out in the Anglo-Saxon world. These studies showed that consumption reflects important social divisions and temporal categories. This research tradition (e.g., Sahlins 1976) departs from Bourdieu's approach in that it leans primarily on the Durkheimian

legacy. Consumption is seen within it as mirroring not only all sorts of social distinctions (class, age, gender, etc.), but also social time and qualities of its social context (feast or everyday life, dining in or out, etc.).

In the 1980s and early 1990s we saw the sociology of consumption characterized by at least four research orientations. First there was the approach, connected with the postmodern turn and influenced by Simmel and Benjamin, which focused on the meanings of consumption. In line with Baudrillard's theorizing (1988), it argued in the poststructuralist spirit that consumption is not a language. Clothing, food, etc., do not constitute a language-like sign system open to a uniform reading by all members of the same culture. Rather, consumption forms mere systems of classification that become increasingly important as the significance of consumption increases. Attention is thus focused on the role of consumption in the formation of social identities and on the embodiment of consumption. When seen as a crucial building block of identity, consumption has been regarded as an important expression of *Zeitgeist*. This perspective has been easily adaptable when defending the idea of a postmodern turn.

Then there is the empirically oriented approach centered on food. It analyzes a theme made topical by globalization and by the changing basis of social order: the stability and change of consumption patterns. The concrete objects of research include the symbolic dimension of foodstuffs, the national and cultural aspects of meals, the gender-, age-, and class-related forms of eating, eating habits, the 'problem' of omnivorousness and eating disorders, eating out, and preparing meals at home, and the fate of the family meal. Sociologists of food have found that food choices are surprisingly stable despite the improved availability of all kinds of foodstuffs. They have also proved that the direction of change is not only from centers to peripheries ('Macdonaldization') and that the flow of luxury goods is not only from top to bottom in the social hierarchy: in many cases a dish originally favored by the common people has become popular among upper classes too (like pizza and traditional Chinese meals).

A third research orientation is rooted in the Durkheimian and Maussian tradition dealing with the circulation of commodities. It elaborates on the central features of the institution of gift-giving, focusing on the ways in which an object, *qua* present, loses the status of commodity, as it is bad taste in Western societies to give presents that are merely commodities with an exchange value. Wrapping the present up in an ornamental package signifies the loss of the commodity status. It is also thought that a gift must be 'special.' For it to be experienced as valuable, it must reflect the personality of its giver.

This research tradition has also examined hobbies and exceptional consumption patterns, especially collection. It has been found that any product or object can become a collectible, thereby losing its commodity status and gaining a new meaning in relation to the already existing or imaginary parts of a collection. When a collection is seen as 'complete,' it can be commodified and sold on the market.

The fourth line of research in the sociology of consumption deals with the questions: What are the aesthetic and other characteristics that make commodities appealing to us? These reflections have resulted in the rejection of various theories of basic needs and pre-established need hierarchies. Needs are, by contrast, seen as mediated by the cultural filter and as historically changing forces that are as much the outcome as the starting point of our activity. In addition, this research orientation addresses the way in which unsatisfied needs give rise to ultimately unsatisfiable desires and how this process contributes to the creation of the consumer society. In this context Campbell (1987) has pointed out how modernization has refined the quantity-oriented hedonism based on the Protestant ethic into quality-oriented hedonism. Contrary to Weber's view, the romantic 'spirit' propitious to self-realization and consumption too has played an important part in this process of refinement.

4. *Trends in the Sociology of Consumption*

The meaning–centricity of the sociology of consumption began to be criticized as too cognitivist at the end of the 1990s. This cognitive paradigm is committed to the ideas of agency and reflexivity, neglecting the fact that only part of consumption can be reduced to them. Furthermore, it reduces the entire sphere of consumption to meanings. The focus has been on the external meanings of commodities, usually provided by researchers themselves. From these models researchers have deduced the meanings consumers must have intended to convey to others. Although the subjective dimension of consumption (its personal significance) has been studied, the emphasis has still been on its cognitive aspects at the expense of its experiential side. Finally, only 'public,' or 'visible,' consumption has managed to kindle the interest of cognitively oriented sociologists.

Attempts have therefore been made to broaden the perspective of the sociology of consumption. Of course, the meanings attached to consumption and their connections with the spatiotemporal and social structures of everyday life and identity formation will continue to be analyzed. It is, after all, impossible to imagine consumption without meanings. The central mechanisms of consumption and their connection with social order are also likely to continue to receive attention. Nevertheless, there is evidence to suggest that the sociology of consumption is fragmenting into several approaches.

First, it is evident that researchers are more and more interested in the experiential dimension of

consumption and thereby in the emotional bond in the commodity–person relationship. This opens up a new perspective on the consumption-driven process in which individual and collective identities are constructed historically, more or less on the basis of personal emotional sensation.

Second, the nonreflexive aspects of consumption, or consumption routines, are a new focus of research, which addresses the spatial and temporal arrangements of everyday consumption: the gendering of consumption routines (cleaning, cooking, etc.) and their variation with age, ethnic background, and religion. Routines, however, are constantly shaken by change. The accelerating social change, the increasing health awareness, and risks produced by gene technology and product forgery make consumers reflect on their routines and sometimes change them. This has thrown a challenge to sociologists, forcing them to pay attention to people's ways of dealing with consumption risks. The latter theme has brought the concept of trust to the center of the sociology of consumption too, paving the way for the analysis of trust as a means of routinizing consumption. This research orientation is formulating a theoretically interesting tension between reflexive and nonreflexive action in general.

A third research focus attracting increasing interest is the change in the spatiotemporal experience triggered by the new supergoods—products of information technology that have become part of everyday life. This change not only destroys old forms of sociality and practices connected with them (such as shopping); it is also creating new kind of virtual sociality independent of space and time. How this is constituted and reflected back on information technology is a new challenge for sociology.

The fourth rising line of research in the sociology of consumption is connected with the end results of consumption: wastes, waste management, and the recycling of used products. Both are now billion dollar industries, and research on consumer society is being complemented with research on 'rubbish society.' It opens up an interesting perspective on not only waste treatment routines but also on consumers' opportunities of commodifying their wastes and selling them on waste markets.

The sociologists of consumption do not lack objects of research. Moreover, it should be pointed out that consumption not only reflects social practices but has a dynamic of its own as well. It seems to be a self-sustaining phenomenon. For instance, the idea of a petrol-powered car implies petrol stations. These, again, imply filling up the tank, and so on. This autonomy of consumption, which Simmel noted at the beginning of the twentieth century, is drawing more and more attention, founded on the realization that present consumption choices not only guide future production decisions but also shape our common future in general.

Contemporary History

1. Appearance of the Term and the Activity

Contemporary history (*Zeitgeschichte*, *Histoire contemporaine* or *Histoire du Temps Présent*, *sovremennaia istoriia*, *storia contemporanea*, etc.) has recently become a designation for a branch of historical research and writing that emerged in the period after 1945. This period signifies the history of events leading up to, and including, World War II and the period

since. The term, however, is far older. The 'idealist' philosopher of history, Benedetto Croce (Croce 1917) claimed that all history must be contemporary history. By this he meant that since the historian's mind always mediated any reflection on the past, history must reflect the mentality of the historian: his (there was no her considered) political concerns, social position, etc. Contemporary history thus seems to occupy an unstable niche between the safely past and the historian's present. During the early days of 'professional' historians, i.e., university-trained, the term appeared largely in titles by amateurs; the professionals tending to dismiss it as an impossible and 'unscientific' enterprise.

Those critical of the field reproach it with its lack of perspective and its paucity of sources, above all since most nationally preserved archives are closed for a customary 30 years or more. Critics also complain that there is no dividing line between contemporary history and mere political partisanship or 'journalism'—a term usually meant to suggest that an account must be ephemeral and partial. These critiques will be considered at the end of this article. Recall, however, that one of the very greatest of ancient historians, Thucydides, insisted that explaining and narrating the great civil war still engulfing the Hellenic world as he wrote, was a valid historical exercise.

Contemporary history has, in fact been a historiographical enterprise as venerable as any other. The great French medievalist Marc Bloch also denied a radical break between past and present. Contemporary history is contrasted with the history of a relatively remote past. (Bloch, 1949, p. 89, Noiriel, 1999, pp. 7–28). Those who distrust contemporary history suggest that 'the past is another country,' by which it is meant that the ways of thinking and acting, the principles for collective association, the bonds of loyalty and governance, are different enough from our own, such that the historian must work his way into them through hermeneutic dealing with sources. But this remoteness is no less true for many societies in the world of the twenty-first century. Nor can the remote past be totally strange; otherwise there would be no way of arriving at statements of motivation or descriptions of behavior. No history can presuppose radical alterity.

The time period included in 'contemporary history' has never been rigidly defined in any national usage. Contemporary history usually signifies a contrast with 'modern history,' a term that most Western historians now apply to the entire period since the French Revolution, although before 'contemporary history,' came into usage, 'modern history' was sometimes extended to the entire epoch since the close of the Middle Ages. In 1775, the German historian J. G. Büsch distinguished modern from medieval and ancient history, and within modern history, an epoch even more recent. After the French Revolution, some historians, including Ranke, labeled post-revolutionary history as the 'newest' or more recent history within the newer history dating from 1492. Not only Leopold von Ranke, but also many of the major German historians of the nineteenth century devoted lectures to the most recent events, whether the revolution of 1848 or the founding of the German Empire in 1871. Defending the study of contemporary history in 1886, Emile Bourgeois contrasted its application by scholars and teachers to events after 1789 with the popular notion of the history 'of our own generation.' The latter, he proposed, faced pitfalls, but what he preferred, following the Germans, to call 'modern history' since 1789, could be studied as a science. (Bourgeois 1886 pp. 12–4) In today's contexts the term has become a synonym for twentieth-century history or Western history since 1914 and the outbreak of World War I. The *Journal of Contemporary History*, founded by Walter Laqueur and George Mosse in 1966, has taken the twentieth century as its purview and its first issue focused on the rise of fascism. In other contexts, it remains the history of the ideological conflicts that led to the rise of fascism and Nazism, the Second World War and afterward. In the Soviet Union the Bolshevik or 'October' Revolution formed an ideologically defined boundary. Still other historians, above all in the North American context, apply it to post-World War II events, i.e., to the period since 1945. Outside Europe and the Americas it can refer to the period of national independence since the end of colonial rule.

Sometimes contemporary history is construed as comprising the era from which historical participants are still alive. Modern, as well as ancient historians have considered the availability of live witnesses to be essential: Thucydides cited the questioning of witnesses as one of the scientific sources of his researches. *The Institut de l'Histoire du Temps Présent*, reorganized in 1980, defined the presence of witnesses as a crucial criterion for its investigative mission. But if the starting point is not fixed, the end point is. Common to all definitions of contemporary history is the idea that it must extend, whether as events or as the account of those events, until the present day. It is designed to explain current social, political, or cultural development. While 'post-modern' has become a general term in cultural studies, post-contemporary remains oxymoronic, although in fact some German advocates of '*Zeitgeschichte*' argued that the post-1945 period constituted a 'newer' rather than an older contemporary history.

2. *What Qualities Define Contemporary History?*

Beyond the criterion of recentness or actuality, is there any distinguishing characteristic to contemporary history? Does it have any real specificity on non-temporal grounds? Contemporary history is history that is usually deemed to provide an explanatory or

interpretive background for events still being contested or whose ramifications are still affecting current political or social development. But non-contemporary history also performs this function. The history of African-American slavery would not be described as contemporary history even though that institution still casts a long and powerful shadow over current American politics. All major developments permanently structure today's alternatives and all history presupposes such an enduring influence. Most historians seek to defend the 'relevance' of their inquiry—sometimes by claiming analogies with the past, sometimes by claiming a real, even if remote, impact of past events on the present. Such a claim alone cannot distinguish contemporary history. Nonetheless, contemporary history often has an impact—and is intended to have an impact—on current political outcomes. Contemporary history comprises narratives and explanations that lead to policy decisions, electoral contests, and sometimes to political trials. It is a history with consequences. This does not mean that contemporary history is less capable of escaping partisan judgements than history of the remote past. Historians of all eras bring to bear their values and political temperaments. They cannot shed these although they can and should achieve self-insight into the way their psychological make-up conditions their interpretation. In this respect the contemporary historian can muster an equal degree of self-insight. Certainly his or her history can prove as encompassing and detached as the history of more remote eras. Still, contemporary history bears an intimate relationship to the choices facing the society in which the historian is rooted. Such choices often seem particularly urgent because they are the legacy, not only of long trends and development, but also of episodes of recent conflict, and sometimes violence.

Thus, while the particular beginning point of contemporary history can be subject to debate, it is usually and logically taken to be a significant 'rupture' or caesura in the recent past. (This suggests that contemporary history, now so often defined as history since 1945, may within a few decades be interpreted as history since 1989. The first issue of the Italian journal *Contemporanea* cited the events of the late 1980s and 1990s as constituting 'a turning point in world history, imposed with the force of a periodizing caesura.' (p. 3)) Such ruptures, often accompanied by radical change and intense political or international conflict, require explanations and narratives designed to account for the sudden transition of institutions or regimes. Even where a new regime decides to forswear any judgmental effort about the past, the transition itself, the process by which a seemingly stable set of institutions, gave way to another, requires intellectual mastery.

Not surprisingly, it was in France, where the Third Republic remained a contested regime until World War I, that the political stakes of contemporary history most starkly emerged. For conservatives, the French defeat at the hands of Prussia in 1870 demonstrated the Revolution of 1789 had undermined national cohesion. Hippolyte Taine's *Origines de la France Contemporaine* (1875–1893) explained the debility of French society as a legacy of the Revolution; the *Société d' Histoire Contemporaine* (1890) remained under Catholic conservative influence. But the Left did not simply cede contemporary history to the Right; Emile Bourgeois (1886) excoriated Taine's indictment, anticipated all the later criticisms of post-1989 history, but claimed the enterprise was no less valid than 'doing a writing' of the history of earlier epochs. The Republicans in power created a Chair in Modern and Contemporary History in 1884 and ensconced in the University, the historians of the Left founded the *Revue d'Histoire Moderne et Contemporaine* (1890). Pro-Republic historians fought for control of the official history texts taught in schools, among them Ernest Lavisse's 10-volume *Histoire de la France contemporaine de la Révolution à 1919* (Noiriel 1998, p. 14).

Contemporary history has thus often originated as an effort to determine responsibilities, often for disastrous outcomes (either on the part of those acting for the old order or for the new holders of power). Institutions established to research contemporary history have had the assignment of examining the origins and responsibility for recent human-rights abuses. If such painful episodes as dictatorship or state-sponsored terror, revolutionary upheaval or war and sometimes the collaboration of citizens with an occupying power had not taken place, contemporary history might be a less compelling enterprise. Sponsorship of contemporary history often involves a society's self-examination—despite the reticence on the part of those wishing to avoid confronting their own complicity—after political catastrophe, whether humiliating defeat in war or domestic recourse to terror or authoritarianism.

Such a self-reckoning encounters resistance among historians as well as from former power holders. Nominally designating the field as a special branch of history allows some of this reticence to be overcome, whether political or academic. In Germany and France, the respective terms '*Zeitgeschichte*' and '*Histoire du Temps Présent*,' were adopted in part to differentiate their fields of study from history that had been academically credentialled. In the German case, early postwar researchers into the National Socialist period confronted a widespread resistance among professional colleagues to study the Third Reich. The alleged reasons given were the closeness of the period and the passions it aroused—in fact, many scholars, of course, had been highly supportive of the regime. Still, *émigré* scholars, new political leaders, and an emerging generation of historians understood that the Nazi period could not be bracketed off on the grounds of being too close to study.

In fact, the proximity of the Third Reich led some historians to argue, not that one must be more distant, but that rather only those who had experienced the temptations of National Socialism might understand how complicated the moral as well as historical issues were in order to really understand its history. Outsiders and those who came later would allegedly lack the capacity for '*Verstehen*' or empathetic immersion into the events that German Historismus had always prescribed. As the author of a major discussion of postwar German and Japanese historiography writes (Conrad 1999, p. 217): 'objectification without the mediating role of empathy (*Einfühlung*), according to this view, had to produce a distorted image: the Germans would appear merely as a distant object and no longer the legitimate subject of history.'

3. *Institutes, Progress, and Controversies*

In 1950, the German Federal and state governments financed the Munich-based Institute for the History of the National Socialist Era, renamed simply the *Institut für Zeitgeschichte* in 1952. It became the leading research institute into National Socialism, engaged some of the most promising researchers, and since 1953 has issued the indispensable '*Vierteljahrshefte für Zeitgeschichte*,' devoted to publishing documents as well as narrative and interpretative studies, and a series of book-length monographs. The Institute and its quarterly represented recognition that the Nazi era formed part of German history but presented particular historiographical challenges. The concept of '*Zeitgeschichte*' or 'contemporary history' legitimized opening up scholarly research on this painful, indeed often shameful, past, but simultaneously recognized some theoretical distance from more distant and settled subjects. From its reappearance in 1949 to 1960, the traditional *Historische Zeitschrift* only published one substantive article on the NS period. Even the leading Third Reich researcher Hans Buchheim, argued that the NS period was not appropriate for doctoral research although courses were offered—often by visiting or returning *émigrés* such as Hans Rosenberg—at the university level. The topics usually involved the factors undermining Weimar, the foreign and military policy of the Third Reich, and the unsuccessful Twentieth of July plot. The publication of Karl Dieter Bracher's magisterial *Dissolution of the Weimar Republic* (1955) finally presented the success of the Third Reich within the long-term structures of German history; nonetheless, the author was trained as a political scientist; he understood his task less burdened by the inhibitions of the historical profession. Bracher's work duly arrayed structural, ideological, and contingent factors. Still, to envisage Nazism as a consequence of the long-term continuities of modern German history—that is, its institutional and social structures and not just supposedly general leanings toward authoritarianism—remained the agenda of subsequent historians. For the researchers of the 1960s, the buffer of 'contemporary history' became less essential: Nazism represented only the latest and most extreme recourse of old and new elites who resorted throughout the modern period to national expansion and authoritarian measures. And only by the decades of the 1970s and 1980s did historians seek to probe the 'mentalities' of ordinary Germans under the regime, to measure the acquiescence or enthusiasm for the regime and for its anti-Semitic program. The *Institut für Zeitgeschichte* carried out some of its most original work within the so-called Bavarian project organized by director Martin Broszat, which was an effort to explore the categories of enthusiasm, acceptance, and '*Resistenz*' (or small-scale noncompliance) in the Third Reich.

This research program, for all the insights it generated, revealed that the conceptual difficulties raised by the Nazi experience still lingered as special challenges for *Zeitgeschichte*. Whether in scholarly works such as those of Ian Kershaw or popular depiction of the Nazi era in the German television series *Heimat*—and contemporary history is increasingly presented by the visual media—Nazi rule still appeared to impinge as a force from outside society. It did not really penetrate the local community. Widespread acts of '*Resistenz*' suggested a society that endeavored to maintain its autonomy from politics. Contemporary history had begun as an effort to account for the highly disturbing victory of the National Socialists; three decades later, it focused on the limits of totalitarianism. Nonetheless, the most recent studies of denunciation and police activity (Fitzpatrick and Gellately 1997) have again placed the accent on the self-policing of society rather than its resistance.

In France the *Comite d'histoire de la Second Guerre Mondiale* was transformed by the initiative of Rene Rémond and other historians into the *Institut pour l'Histoire du Temps Présent*, which in the 1980s and 1990s became the leading foyer for research on contemporary France. Its debut marked a new willingness to focus on the Vichy period, which had been subject to euphemism and obscurity. Perhaps because it was early taken in hand by a younger generation of researchers—a development that occurred only later in the trajectory of the *Institut für Zeitgeschichte*—its conceptual categories for dealing with traumatic history were less evasive. It has had a remarkable series of *colloques* in which actors and historians have met together to consider such subjects as labor under Vichy or the early efforts at postwar economic and social transformation. Such countervailing and critical interaction would probably not have been possible in Germany; where in effect younger historians gradually had to press for deeper investigations. Still, French research was also subject to equivalent resistance to full disclosure and confrontation.

Postcommunist societies have devoted major academic resources to assimilating the historical legacy of the long decades of communist rule. In East Germany popular revelations about Stasi collaboration, the debates about trying functionaries of the former GDR, and the insistence of the civic movements of 1989, have all encouraged serious historical examination of the former regime. The collapse of the GDR brought a rare opportunity to do contemporary history since the documentary sources of the regime were put at the disposal of researchers within a few years of its collapse. Aside from numerous memoirs and popular accounts, a major center for carrying on this research has been the *Zentrum für Zeitgeschichtliche Forschung* in Potsdam (originally *Schwerpunkt Zeitgeschichtliche Forschung*), an institute that incorporated researchers from the former Academy of Sciences of the GDR and was entrusted with the mission of studying the GDR as a regime. While its personnel and approach were severely contested at first by dissidents, who felt that it was quasi-apologetic, the ZZF has now brought out significant edited monographs on culture and society in the former GDR as well as more traditional accounts of international relations and politics.

War origins and responsibilities have traditionally been a major source for contemporary historical research ever since Thucydides, although the investigations are not always thought of as 'contemporary history' as such. World War I led to rival publications of diplomatic documents and then narrative accounts of the international relations that led to the conflict. These were often partial, but based upon recently opened—if often very incomplete—archival sources, but the history that emerged was not conceived of as a particular or tentative branch of history. US historiographical revision, somewhat analogous to the difficult reassessments in Germany and France, also marked the late 1950s and 1960s. 'Revisionist' historians (the term 'revisionist' has had successive applications over time) aroused harsh denunciations when they suggested that Americans, not Soviets were largely responsible for the Cold War, whether because of the personality of Truman or the 'needs' of American capitalism for world-wide markets. A particularly bitter controversy arose over the use of the atomic bomb, which Gar Alperowitz suggested was designed to intimidate the Soviets, not end a war with Japan that had shortly to yield victory in any case (Maier 1970).

The emergence of the 'new' historians in Israel prior to 1990 should also be understood as part of this worldwide wave of reconsidering taboo subjects, pre-eminently the fate of the Arab population living in the area of Palestine that would become the Jewish state. The traditional accounts of the 1947–48 founding of the country overwhelmingly alleged that the Palestinians had fled from their homes in the Jewish regions on instructions from Arab leaders who promised that they would be resettled after Israel was defeated. The 'New Historians' have instead blamed Israeli leadership for aggressive action against Arab civilians in an effort to uproot as many as possible.

In Japan, debate over the origins of the Pacific War was often lively in university milieus, but more inhibited in schools and public forums. An initial postwar willingness to question Japanese policies was not followed to the same degree as in Germany and Japan has often been depicted as a victim of the war, a view reinforced by the atom bombing of Hiroshima and Nagasaki. Nonetheless, among professional historians and increasingly in the wider public, more self-critical accounts have been emerging. The Nanjing massacre has brought sustained historical debate, in which the Japanese profession revealed itself as unready to reconsider the dissident view of the war.

Thus while 'contemporary history' is a term that denotes no more than particular chronological criteria, recent output suggests that its implicit subject matter has been the opening up of the earlier 'shameful' experiences of a society, at least those within the memory of living participants. Thus the whole question and to what extent citizens cooperated remains morally and analytically troubling. Until the end of the 1960s, historians and political analysts tended to emphasize the power of the totalitarian regime—its capacity for violence, atomization, conquest, and subjugation of an autonomous society. Thereafter, analytical histories argued for the limits of totalitarian rule and the persistence of 'niches' where individuals could conduct a normal private life whether under National Socialism or Communism. By the 1990s contemporary historians were tending to examine not the immunity of society from dictatorship but rather the self-policing of society. The legacies of 1945 and 1989 in Europe have made Nazism, Fascist, collaborationist, and Communist regimes—the problem of 'totalitarianism'—perhaps the leading theme for contemporary historians, as the dismantling of South African Apartheid and military dictatorships in Latin America has done elsewhere. Contemporary history has wrestled with the issue of how to describe the nature of acquiescence, enthusiasm, and dissent under totalitarianism. Research has come to center on the relationship between civil society (that category rediscovered for scholarship by 1989) with political authority (Fitzpatrick and Gellately 1997).

4. *Contemporary History as 'Collective Memory'*

Given its highly charged political content, research into contemporary history has surged into new forums, which produce not a historical narrative as traditionally understood, but important efforts to reconstruct and critically evaluate the national past. Distinctive since around 1980 has been the wide recourse to official bodies to investigate—and to

acknowledge publicly—the human-rights abuses of authoritarian regimes that have been dismantled. The work of the South African Truth and Reconciliation Commission can be construed as an investigation into contemporary history (the case is less persuasive for commissions that took their evidence in secret). Its objective was not primarily to establish a historical narrative but to hear testimony from victims and acknowledge the violence done to those testifying. By being established with the right to confer amnesty, the TRC encouraged perpetrators to describe their role in enforcing the Apartheid regime.

Truth commissions or other committees of inquiry can, but need not, produce traditional historical accounts. The TRC, for example, elicited many partial narratives of personal experience and explanations of why and how both perpetrators and victims behaved. The findings presented are not usually cross-examined or subject to critique of sources and methods. A contemporary history of Apartheid, for example, would require an effort at synthesis and contextualization within an overarching temporal account that fully revealed. For instance, such structural and background issues as sources of investment and labor, migration of whites and blacks, long-term ideological formation, and the Anglo-Boer clash. In short, the whole relevant history of the society before and during Apartheid. It would sacrifice immediacy for more encompassing perspective (Truth vs. Justice 2000; Rotberg and Thompson 2000). Nonetheless, this sort of public hearing has increasingly served, in effect, as the first approach to a historical account of the previous regime.

The motivation behind such efforts remains more admittedly political than most academic historians would feel comfortable acknowledging. Former victims and dissenters urge exposure of the past as a moral and political as well as historical acquisition. The East German Citizens Movement (*Bürgerbewegung*) pressed for a large-scale German parliamentary inquiry, the Enquete-Commission, into the functioning of the East German regime that produced volumes of testimony and analytical essays. In this respect much of the impetus for contemporary history, as the history of a military experience or dictatorship, emerges not just from professional historians but from advocacy groups.

Such efforts represent an effort not just to advance historical research, but to establish versions of what the French sociologist Maurice Halbwachs called 'collective memory,' the construction of a group's version of the past (and not just a retrieval of events gone by). As an activity, contemporary history thus involves, along with traditional research and official boards of inquiry, many volunteer efforts to memorialize historical sites and record interviews for local history (the 'history-workshop' movement; see especially *History Workshop Journal*). The themes can be work and family experience, the impact of major events, such as war or political programs on local life. History is also increasingly presented in a museological context. Museum curators or those charged with exhibitions have pressed agendas of historical reassessment, often to encounter opposition and charges of distorting the past. The 1995 'Enola Gay' exhibit at the Aerospace Museum that was to focus on the American bombing of Hiroshima seemed critical enough of American policy to incite veterans groups and their Congressional supporters to demand closing the exhibit, which, in fact, was substantially modified. The Wehrmacht exhibit produced by the Hamburg Institute, which featured a travelling set of photographs of German army atrocities on the Eastern Front, likewise provoked criticism and reaction (Thiele 1997). Whether or not contested, such exhibits and museums play a powerful role in historical education—perhaps preeminent now is the US Holocaust Museum, which has become one of the most frequently visited Washington sites.

Finally, it is important to note that the prolific debates over museums, likewise over the concepts for memorials, have themselves become one of the major topics for contemporary history. The so-called history of memory or more precisely the history of 'collective memory' has developed apace along with contemporary history. (See the journal, *History and Memory*.) It is its most self-reflective branch, and thus appeals to the intensely self-reflective trend of postmodernist culture, historical and otherwise. Obviously each of these themes opens up not just a political but a social history of power.

5. *Methodology and Objections*

Advocates of contemporary history have sometimes suggested that it has a distinctive methodology. But in fact it must rely on the evaluation of sources that historians learn for all periods. As with the history of earlier eras, the historian must learn to compensate for the absence of some sources and to treat those available with caution. The contemporary historian can use economic data, interviews, public-opinion surveys, the media, and available sources. Other recently developed historical approaches designed for other periods—'everyday history (*Alltagsgeschichte*),' cliometric history, 'microhistory' and anthropology, can be exploited for the contemporary period as well as earlier periods.

Still, contemporary history does present particular problems: the contradiction between closeness and objectivity. How often do historians who lecture on the recent past not encounter the questioner who states, 'I was there, I know … !' The witness will usually complain that the contemporary historian does not really have the story right. But precisely because he or she was there, the witness has experienced only one level of the story. He or she cannot usually rise above

personal experience, often one that has left deep psychological scars; to attain the perspective needed for a general history. This is not a question of intent or even of mere distortions left by imperfect memory. The problem of one-sided history does not lie with the reliability of the witness or lack thereof, but with the failure to balance a story. The historian can decide that every witness or victim has, in fact, left an accurate memoir, and still have concern about the marshalling of these accounts as the major source. Those historians of Stalinist purges and the Gulag who stress their enormous human toll have given a higher value to memoirs and autobiography of 'victims' than so-called revisionists who have contested the high number of victims and feel that victims' memoirs have colored the objectivity needed about the period (Getty and Manning 1993). The issue is not the reliability of the sources or the accuracy of memory, but of contextualizing the memoirs. The German historians who documented the expulsion of Germans from East Central Europe in 1945 took special care to test the reports of Soviet brutality and rape for accuracy. But that was hardly the point: what made these reports problematic was the fact that the authors showed no equivalent concern for the victims on the other side and thereby could hardly furnish a satisfactory account of causality (Aly 1997, Conrad 1999). Contemporary history can be afflicted with a misplaced and misleading stress on the reliability of witnesses at the expense of contexualization.

Nonetheless, most critics reproach the field its paucity of traditional sources, above all since most nationally preserved archives remain closed for a customary 30 years or more. This is often true, but it is also true to an even greater extent for periods in the remoter past. The mass of printed documentation, of statistical inquiries, of public opinion and media reports, of possible interviews, and now telephone and other records is in fact overwhelming. True, written minutes and archives will reveal debates within governmental agencies that may not be fully disclosed to the contemporary history. The quality of history that can be written once these become available will be more informed. But this cannot disqualify contemporary history from counting as respectable scholarship.

Critics also complain that there is no dividing line between contemporary history and mere political partisanship or journalism—a term usually meant to suggest that an account must be ephemeral and partial. But of course the issue is what sort of journalism. Historians journalistic reporting and analysis use as source material in its own right. There are historians whose narration of the past remains as superficial, as keyed to headlines without any probing of deeper explanations, as the most superficial newspaper report. And there are journalists who endeavor to uncover and integrate in a written text models of explanation as deep and persuasive as what historians propose. The valid distinction is not between history and journalism, but a history or journalism that is content with day-to-day reporting—a disclosure of events—and a history or journalism that seeks to probe and place immediate events into a framework of long-term analysis.

Contemporary history, it is charged, cannot transcend the ideological passions of the day and is thus less 'objective' than history of earlier times. Any reflection, however, on the history of major events will show that while consensus does finally build around some attributions of responsibility, many deep interpretative divisions persist or are renewed. There is no transcendent view of whether the Gracchi were social reformers or mere demagogues; whether revolutionary violence was a response to real enemies or a pure paranoia; whether the problem of American slavery might have been resolved without civil war; whether Germany was particularly responsible for the outbreak of World War I; and whether the Americans do or do not bear some of the responsibility for the Cold War. Political divisions are fundamental to human societies and there can be no more value-free a resolution of the issues involved for historians than there was for contemporary actors. But this does not mean that historians are condemned to partisanship. Whether dealing with events of the moment or those long since over, researchers can follow certain safeguards. They can report the evidence that might contradict their chosen narrative interpretation or current political preference, and they can seek to include the reasoning of adversaries within an overall historical account such that it becomes multi-voiced.

It is true that contemporary history is likely to be superseded. But this is true of all historical treatments including those of antiquity—each will be rewritten as the interests and preoccupations of a current generation of scholars change. All history is subject to revision: revision in questions, revision in methods, and revision in perspectives.

Contemporary history enjoys no less sanctity. Granted, the contemporary historian must remain particularly aware that the questions that motivate him or her may be dictated by current controversies and thus soon superseded. The contemporary historian should self-consciously seek to anticipate, say, frameworks that successive generations might pose and not just the agenda of the moment. Some anticipation of the future, at least as a spectrum of possible issues and inquiry, as well as contextualization in terms of the remote past, remains necessary for the staying power of contemporary history. Thucydides understood that. Thucydides abides.

Content Analysis

Content analysis is a class of techniques for mapping symbolic data into a data matrix suitable for statistical analysis. When the term is used, one refers to the content analysis of cultural artifacts (e.g., books, architectural styles, discourse on prime-time television, etc.). That is, one refers to a mapping of non-numeric artifacts into a matrix of statistically manipulable symbols. Thus, content analysis involves measurement, not 'analysis' in the usual sense of the word. Whereas one might perform a content analysis of campaign slogans, one uses the data generated in such a content analysis to analyze (i.e., not 'content' analyze) the slogans' effects on public opinion. Texts and transcripts have been by far the most common objects of content analysis. For this reason, the focus of this article will be on the content analysis of texts (i.e., on *quantitative text analysis*). (For discussions of qualitative text analysis techniques, see *Linguistic Turn and Discourse Analysis in History*; *Event History Analysis: Applications*; *Ethnography*; *Qualitative Methods, History of*).

1. Classical Content Analysis

The first large-scale applications of content analysis came with the Second World War and US government commissioned propaganda analyses performed by Lasswell, Berelson, George, and other content analysis pioneers. During the first decade of the postwar era, a classical approach to content analysis emerged that involved the generation of data matrices of a particular type. These matrices typically exhibit a row for each sampled text block and a column for each theme (or meaning category) that may or may not have occurred in each block. Cells in the matrix are counts of the number of times the theme associated with its column occurred in the text block associated with its row. Thus, classical content analysis typically produces matrices of word- or phrase-counts, albeit sometimes ones embellished with value and salience weights (cf. Pool 1955, Stone et al. 1966, Holsti 1969, Smith 1992).

During a conference held in 1955 at the University of Illinois' Monticellos Allerton House many of these text-analysis pioneers gathered to develop solutions to the methodological problems of the day. Pool (1959) is the scholarly legacy of this conference. The most influential, if not the largest faction among the participants, was a group of Harvard researchers who made extensive use of what they called 'contingency analysis.' After generating a matrix of theme occurrences, these researchers would compute a matrix of associations between pairs of themes. Contingency analysis then proceeded as the researcher developed (usually *post hoc*) explanations of why some themes co-occurred (i.e., were positively associated) and why others were disassociated (i.e., were negatively associated).

In a casual but extremely insightful remark at the conference, Osgood (1959) noted, 'As a matter of fact, we may define a method of content analysis as allowing for "instrumental" analysis if it taps message evidence that is beyond the voluntary control of the source and hence yields valid inferences despite the strategies of the source.' And later, regarding contingency analysis, 'The final stage, in which the analyst interprets the contingency structure is entirely subjective, of course.'

In other words, classical content analysts treat words as symptomatic instruments from which the researcher can diagnose the source's possibly unconscious or unacknowledged characteristics.

2. Representational vs. Instrumental Interpretation

Shapiro (1997) has extended Osgood's meaning of 'instrumental analysis' by differentiating it from 'representational analysis' in which the researcher attempts 'to classify, tag, or retrieve the intended meanings of the authors.' At issue in this distinction is whether it is the source's or the researcher's perspective that is used to interpret the texts under analysis. When a researcher understands texts representationally, they are used to identify their sources' intended meanings. When a researcher understands texts instrumentally, they are interpreted in terms of the researcher's theory. Thus, Namenwirth exemplifies the latter approach in his argument that the sources of his texts 'are unfamiliar with many fundamental properties of their own culture and prove unable to specify its structural rules … To recover culture's properties and rules, we cannot ask culture's participants to answer these questions. Instead, we must rely on outsiders as investigators and use their methods, however unreliable these may prove to be' (Namenwirth and Weber 1987). Accordingly, instrumental text analysis methods are used to identify individual and societal characteristics about which society's members may be unaware; representational methods are used to characterize texts in ways that their sources intended them to be understood.

Osgood and Shapiro's representational/instrumental distinction helps direct attention to the import that researchers' analytic frameworks have for their findings. For example, consider a small subpopulation of male novelists who only write books with elderly female heroines. In seeking to understand their choices of leading characters, the researcher with a representational orientation might scour the novelists' prefaces, possibly discovering references there to a need for elderly female heroines as a corrective to an overuse of young male heros in contemporary literature. In contrast, a researcher with an instrumental, Freudian orientation, would likely find the choice of matronly heroines to be symptomatic of Oedipus complexes among the novelists. Note that in the former case the novelists' own meanings are assigned to their writings, whereas in the latter case the researcher's (Freudian) perspective is applied.

Methodological challenges related to representational text analysis are those associated with the researcher's ability to sympathetically understand the sources of his texts (see *Ethnography*; *Qualitative Methods, History of*). In both representational and instrumental text analyses the researcher is responsible for developing an explicit method for systematically applying the sources' or researcher's perspectives in interpreting the texts under analysis.

3. Data Matrices Produced in Content Analyses of Texts

Independent of whether it is representational or instrumental, a content analysis always involves the production of a data matrix. That is, it requires that words be mapped into a two-dimensional matrix representation suitable for statistical analysis. This (i.e., content analysis's 'data matrix requirement') greatly simplifies the task of delineating the domain of possible questions that quantitative text analyses are able to address. In particular, it allows this domain to be defined according to the various ways in which the columns (or variables) and rows (or units of analysis) of this data matrix can be defined. The balance of this article is devoted to further developing this observation, and consequently to helping the text analyst identify the most appropriate text analysis technique(s) for the research question at hand.

3.1 Variables

During the 1970s to the 1990s semantic and network text analysis methods have added to classical content analysis' word/phrase counts, other types of variables for the statistical analysis of linguistic data. Whereas in a thematic text analysis (of which classical content analysis is an instance) one examines occurrences of themes, in a semantic text analysis the examination is of sentences (or clauses) in which themes are interrelated. Moreover, in a network text analysis the examination is of themes' and/or sentences' locations within networks of interrelated themes. The three are not mutually exclusive, but may be combined in the same analysis.

The type of data matrix generated in a thematic text analysis has already been described in the first paragraph of Sect. 1. In brief, it is a matrix having one row for each randomly sampled block of text, and one column for each theme (or concept) that may occur in these text blocks. Cells in the data matrix indicate the number of occurrences of a particular theme within a specific block of text. As computer power has grown, and key-word-in-context searches have become easier, researchers have developed text analysis software with which *ad hoc* dictionaries (i.e., sets of theme categories) can be constructed interactively (Popping 1997). When the themes in these dictionaries are constructed to reflect the meanings intended by the texts' sources, consequent analyses are 'representational thematic text analyses.' When dictionaries' themes are constructed to reflect the researcher's perspective for interpreting the texts, consequent analyses are 'in-

Table 1
A data matrix from a semantic text analysis

ID-number	Subject	Action	Object
1	10	34	53
2	8	21	78
3	13	34	61
4	10	35	61
5	16	29	44

strumental thematic text analyses' (also known as classical content analyses). In all cases it is essentially a matrix of word-counts that forms the basis for a thematic analysis of texts.

Analyses of word-counts yield inferences about the predominance of themes in texts. For example, Namenwirth and Weber's (1987) cultural indicators research reports shifts in the prevalence of various political and economic themes over time. Yet note that if, e.g., certain types of 'political protest' are found to occur in texts in which one also finds mentions of 'economic inflation' one is unable (on the basis of a data matrix of word-counts) to determine if the protests are *mentioned in the texts as* being the cause or the effect of inflation. This is because information on semantic relations among themes such as 'political protest' and 'economic inflation' is not afforded by aggregated word-count data.

Relations among themes are encoded in a semantic text analysis, however. In a semantic text analysis the researcher begins by constructing a template (a semantic grammar). Themes from sampled texts are then mapped as syntactic components within this template. For example, Markoff et al. (1974) have developed a two-place semantic grammar for 'grievances' that contains one syntactic component for the object of the grievance (i.e., what is being grieved about) and another for the action that should be taken toward this grievance. The reader is referred to Franzosi (1990) and Roberts (1997) for more detailed descriptions of the application of semantic grammars in text analysis.

Table 1 illustrates a data matrix that might have been generated in a semantic text analysis. Note that the cells in the data matrix do not contain indicators of theme occurrences, but contain discrete codes for the themes themselves. The column in which a specific theme's code appears indicates the theme's syntactic role within the researcher's semantic grammar. In generating Table 1, blocks of text were encoded as sequences of subject–action–object triplets. Inferences from such a data matrix might be made within randomly sampled newspaper accounts of labor disputes, by comparing the odds that representatives of management vs. labor initiate collective bargaining. Within transcribed speech from a sample of minutes of prime-time television content, inferences might be drawn regarding the odds that blacks vs. whites refer to themselves as targets of aggression. More generally,

Figure 1
A network of causal relations among themes.

and in contrast to thematic text analysis, semantic text analyses yield information on how themes are related according to an *a priori* specified semantic grammar.

Writings on semantic text analysis methods date back to Gottschalk's instrumental analyses in the 1950s on psychological states and traits (e.g., Gottschalk and Kaplan 1958). Gottschalk has since developed highly automated, parser-based text-encoding software for measuring (according to his perspective on states that are reflected in how people relate words) such psychological states as hostility, depression, and hope (Gottschalk and Bechtel 1989). The Kansas Events Data System (KEDS) is another special-purpose, parser-based program that can be used either instrumentally (in conjunction with the standard World Events Interaction Survey (WEIS) coding scheme) or representationally (based on user input content categories gleaned from one's data) in analyzing event data from news reports (Gerner et al. 1994). Most other uses of semantic text analysis are representational, however. For examples, see Franzosi's (1997) research on labor disputes, Roberts's (1989) on ideology shifts, and Shapiro and Markoff's (1998) work on public opinion in eighteenth century France.

Network text analysis originated with the observation that once one has a series of encoded statements, one can proceed to combine these statements into a network. Moreover, once text blocks are rendered as networks of interrelated themes, variables can be generated to measure the 'positions' of themes and theme-relations within the networks. For example, let us imagine that we construct a network of themes in which all linkages indicate causal relations. Assigning the names theme-A and theme-B to any pair of themes in the network, one could develop a measure of 'the causal-salience of theme-A on theme-B' as the proportion of all sequences of causal linkages that are ones in which theme-A is the cause and theme-B is the effect.

For example, the simple three-theme network in Fig. 1 contains four sequences of causal linkages, namely $A \rightarrow B$, $A \rightarrow C$, $C \rightarrow B$, and $A \rightarrow C \rightarrow B$.

Table 2
A data matrix from a network text analysis

ID-number	Causal salience measures					
	A on B	A on C	C on B	B on A	C on A	B on C
1	.50	.25	.25	.00	.00	.00
2	.25	.00	.50	.00	.25	.00
3	.00	.00	.25	.25	.50	.00
4	.00	.00	.00	.50	.25	.25
5	.00	.25	.00	.50	.00	.25
.	.	.	.	.	.	.
.	.	.	.	.	.	.
.	.	.	.	.	.	.

Accordingly, the 'causal salience' of theme-A on theme-B equals 0.5, which is the proportion of the four sequences in which A is the cause and B is the effect. Note how calculation of this measure draws on more than isolated semantically-linked themes in a corresponding block of text. It incorporates information on all themes and links within the text-block's network representation.

Thus, a data matrix such as that in Table 2 might be generated from a sample of networks that contained variables measuring the causal-salience of each pair of the texts' themes. Network text analysts have developed many other measures of network characteristics. A theme's 'conductivity' is one example, referring to the number of linkages that the theme provides between pairs of other themes (Carley 1997). Another is of theme linkages that are logically implied, but not explicitly stated, in each block of text (Kleinnijenhuis et al. 1997). In addition to pioneering work in this area by Osgood et al. (1956), nearly all quantitative network text analysis research has been conducted either by Carley or by a group of Dutch researchers in Amsterdam (Carley 1986, van Cuilenburg 1986, 1988, Carley and Palmquist 1992). All of these researchers do representational network text analysis. The dawn of instrumental network text analysis awaits a social scientist who both develops a network representation of language (analogous to a semantic grammar) and uses an interpretive perspective in developing rules for 'filling in' the network's arcs and nodes given various combinations of sentences in text blocks.

3.2 Units of Analysis

The discussion thus far has yielded a 2×3 taxonomy of quantitative text analysis methods. These methods are distinguished on the first dimension according to whether the source's or the researcher's perspective is the basis for interpreting texts, and on the second dimension according to whether they use variables that reflect occurrences of themes, themes in semantic roles, or network-positions of themes or theme-relations. Let us now proceed to specify the types of units of analysis that are possible in a content analysis of texts.

In the earliest stages of every quantitative text analysis, the researcher is confronted with a 'mountain of words' (a text-population) about which statistical inferences are to be drawn. On the one hand, this text population may be an initially undifferentiated mass (e.g., a sample of minutes of speech on US prime-time television could be drawn at random from the undifferentiated 'mountain of words' that were uttered during a year's time). On the other hand, the text population may consist of clusters of sentences such as newspaper editorials, transcripts of interviews, diary entries, and so on. In either case, a representative sample can only be drawn once the text population has been divided into distinct text-blocks, each of which is then assigned a unique number and sampled at random.

Yet the text population should not be mindlessly divided, even if it appears to the researcher as already a collection of discrete text-blocks such as editorials, interviews, or diary entries. This is because the statistical inferences that the researcher may legitimately draw from texts depend fundamentally on the units into which the text population is divided initially.

Imagine a researcher, who wishes to analyze prime-time television data according to performers' mental models (or conceptual frameworks). In such a case, the researcher would begin by dividing the text population into blocks associated with each *performer*. On the other hand, if the researcher wished to analyze the narratives (or story lines) depicted on prime-time television programs, the researcher would begin by dividing the text population into blocks associated with each *program*. Yet performers may appear in more than one program, and programs will involve many performers. As a result, the researcher's inferences will differ, depending on this initial division of the text population.

In short, the researcher who wishes to ask a substantive question of a population of texts must not only consider the thematic, semantic, and network variables required to address the question, but also the units of analysis yielded when this population is divided into text-blocks.

Thus far two types of units of analysis have been mentioned that might be yielded when a text population is divided; namely the conceptual framework of the text's source (e.g., the television performer's mental model), and the message that the text conveys (e.g., the program's story line). But of course, there are others.

Consider Lasswell's (1948) oft-cited depiction of communications research as the study of 'Who says what, in which channel, to whom, and with what effect?' In his article-long answer to this question, Lasswell argued that communications' effects can be largely understood as functions of their source, message, channel, and audience. Moreover, these four

aspects of communication are the most common *contextual variables* used in analyses of texts and transcripts:

(a) characteristics of source (gender, affiliation, biases, etc.),

(b) characteristics of message (local vs. domestic news, descriptive vs. evaluative orientation, etc.),

(c) characteristics of channel (radio vs. TV news, public vs. commercial network, written vs. spoken medium, etc.), and

(d) characteristics of audience (sociocultural and/or historical setting within which text appeared).

Thus, other than source- and message-identifications, the researcher may also identify text-blocks according to their channel and/or intended audience.

However, comparisons among texts' sources, messages, channels, and audiences are only possible if each text-block under analysis can be clearly identified according to its type of source, message, channel, and/or audience. The key in selecting a unit of analysis is not to assume that one's population of text is comprised *a priori* of clearly distinguishable text-blocks. On the contrary, it is the researcher's responsibility to divide this population into blocks—blocks that can be uniquely identified according to the contextual variables required for addressing the research question at hand.

4. *What Questions Can Content Analyses Answer About Text Populations?*

Content analyses of texts yield data matrices with text-related variables and, almost surely, contextual variables. Text-related variables in the matrix may measure occurrences of themes, theme-relations within a semantic grammar, and/or network-positions of themes and theme-relations. Contextual variables may indicate the source, message, channel, and/or audience uniquely associated with each text-block under analysis. Accordingly, content analyses of texts afford answers to questions about 'what themes occur,' 'what semantic relations exist among the occurring themes,' and 'what network positions are occupied by such themes or theme relations' among texts with particular types of source, message, channel, or audience. Within these limits, the decision of which question to ask is, of course, where the researcher's own imagination takes hold.

Content Validity

Validation is a process of disciplined inquiry. In the social sciences, it entails the systematic assembly of logical and empirical evidence to support the intended use of the test scores. Content validation is the process of obtaining such evidence in the form of expert judges' evaluation of test content in relation to a defined domain of knowledge or universe of behavior. Suppose an examinee takes a test of foreign language proficiency, and must translate sentences and identify the meaning of vocabulary words. The test user wants to draw inference from performance on the test items at hand to a broader universe of behavior represented by these tasks. Practical constraints of testing time, examinee fatigue, examinee motivation, and cost of item development limit the number of items on the test. Thus these items and response formats must represent a hypothetical pool of tasks that could have been presented covering the same content. Validity arguments for this inference hinge largely on whether a clear domain of language proficiency was defined, and how adequately this domain was sampled by the exercises.

Using expert judges to review the domain description and evaluate specific features of the items in relation to this domain, as well as collecting and summarizing their judgments, is known as content validation. Content validation evidence is useful in (a) assessment of educational achievement; (b) assessment of job knowledge or skills by employers; and (c) professional certification and licensure testing. It may also play a role in establishing construct validity of instruments for assessing affective traits.

1. *History and Terminology*

Attempts to define content validity were prominent in the measurement literature in the mid-twentieth century (Ebel 1956, Gulliksen 1950, Lennon 1956). From 1950s–1980s measurement experts (e.g., Cronbach 1971) identified three distinct approaches to validation: (a) content validation; (b) criterion-related validation, both predictive and concurrent; and (c) construct validation. Throughout this period, however, a few theorists continued to challenge whether content judgment studies fit within the definition of validation (e.g., Fitzpatrick 1983, Messick 1975), but this view was not dominant.

Originally, content validation was applied primarily in educational achievement testing. Clearly, the usefulness of test scores as indicators of student learning depended upon the linkage between items presented on the test and the body of knowledge which the items sampled. The 1970s witnessed a growing trend for personnel psychologists to employ content validation to justify use of test results in personnel selection and advancement decisions, despite some notable reservations (Ebel 1977, Fitzpatrick 1983, Guion 1977). This application grew in inverse proportion to waning confidence in the adequacy and legal defensibility of other validation procedures for many jobs and employment settings. Licensing and certification testing also relied on content validation throughout this period (Shimburg 1982).

Approaching the twenty-first century, a more unitary view of validity prevailed (Messick 1989). One theme of this perspective is that proficiency in an academic subject or job performance domain should be viewed as a construct. Although not new, the idea gained mainstream acceptance. From this viewpoint, all validation efforts are designed to provide evidence of construct validity, but there are multiple aspects to the process of construct validation (and multiple types of evidence). Content is consistently the first aspect and involves determination of the construct relevance, representativeness, and technical quality of the test using expert judgment (Messick 1995).

Other terms are associated with content validity, but not synonymous. 'Face validity' is the extent to which items appear relevant to a trait in the eyes of laymen or examinees who are not necessarily experts in the subject tested (Mosier 1947). 'Instructional validity' and 'curricular validity' were spawned in the mid-1970s during landmark litigation over the use of high-school competency examinations in Florida (see Yalow and Popham 1983). Curricular validity refers to congruence between item content on an achievement and curricular objectives and textual materials. Instructional validity refers to congruence between item content and instruction from teachers.

2. *Design of a Content Judgment Study*

Content judgment studies typically are undertaken by test developers as part of their initial validation effort for a new test of knowledge or proficiency. Test users may also conduct local content validation prior to the

decision to adopt an existing, published test. These studies may require replication over time to demonstrate that changes in curricula or job requirements have not undermined the meaning of the test scores. A content judgment study involves systematic collection of observations. Steps in the process may include:

(a) Specifying the questions to be addressed.
(b) Defining the domain of interest.
(c) Identifying the features of the exercises to be examined in the judgment process.
(d) Developing a structured framework for the review process.
(e) Selecting qualified experts for that domain.
(f) Instructing the experts in the review process.
(g) Collecting and summarizing the data.

2.1 Domain Definition

With achievement tests, domain definition typically is extracted from instructional objectives commonly used by those who teach the subjects; review of curricular materials and published textbooks also may play a central role in domain definition. Interviews or surveys of instructors have also been used in this process (see Yalow and Popham 1983). Test specifications (blueprints), used by test developers to maintain the desired proportional coverage of various content areas and cognitive performance levels, may also be used in domain definition. In personnel or licensure testing, domains, or required or prerequisite knowledge may be defined through a detailed job description provided by experts, or a job analysis based on detailed observations of individuals performing the job (Kane 1997); however, in licensure testing the domain is restricted typically to skills and knowledge that are essential to public safety (Smith and Hambleton 1990). A 'critical incidents' technique may also be employed to capture important knowledge or skills that spell the difference between successful and failing job performance. Thorough domain definition also includes the format(s) in which individuals may be expected to display their knowledge: i.e., it covers both a stimulus and response domain (Guion 1977).

2.2 The Judgment Process

The judgment process focuses upon at least three features of the test items: (a) relevance of item content to the domain; (b) balance of coverage or the extent to which the collection of items adequately sample the content domain; and (c) technical quality of the items, response formats and scoring procedures (Messick 1989, 1995).

Relevance of item content is assessed by evaluating the importance of the knowledge or skills required to answer the test item in relation to successful performance in the domain. Judges may be asked to rate frequency and criticality of the skill or knowledge tapped by the exercise. When the domain is complex, the study may involve having a sample of experts (a) evaluate the appropriateness of the objectives or list of behaviors that comprise the domain; and (b) match exercises to those objectives.

Representativeness (balance of coverage) is ascertained by having the judges review the entire test to identify areas of the domain that may be over- or under-represented. It is possible for all items on a test to be relevant when reviewed individually, but yet for the coverage of the domain to be disproportionately limited to only a few objectives or skills. A mathematics test, for example, might stress computational skills, but place little emphasis on problem-solving, even though both skills are stressed in the curriculum. The proportions of items matched to each objective or job behavior are examined to assess appropriateness of coverage. The format for examinee response to exercises may also be considered in evaluating representativeness. In judging technical quality of exercises, experts attend to features of the question, response format, scoring rubrics or keys, and administration and scoring instructions that might interfere with examinees' ability to display their knowledge of the correct response.

2.3 Selecting and Training Judges

Judges' qualifications and the overall representative nature of the panel of judges in terms of demographic characteristics and educational/professional backgrounds are important issues in the design of a credible content validation study. The instructions given to the judges and training they receive before undertaking their review should also be planned and documented. Finally, in large-scale content validations, level of agreement across the panel is useful information.

3. Analyzing Data from Content Judgment Studies

Thorough content validation studies yield substantial amounts of data. Each item should have a record containing multiple judges' ratings for each feature of the item that was reviewed. Marshalling these data for analyses to summarize results at the individual item level and for the total test requires forethought. At the simplest level, indices such as percentage of items classified to objectives may be computed and reported. Judges' mean ratings for each item and over the test as a whole on frequency or criticality may be computed. More sophisticated treatments of data from content validation studies also have been suggested. Crocker et al. (1987) described various quantitative indices used in content judgment studies, including measures of (a) overall fit between test and curriculum; (b)

degree of fit for individual items to content domain; (c) fit between test specifications and examinee performance; and (d) error estimation in judges' ratings. In addition, new technical approaches to analyzing job analysis data are emerging (e.g., Kane 1997, Šireci and Geisinger 1995).

3.1 Evolving Standards for Content Validation

Standards for evaluating test development and use have been articulated since the 1950s by a series of joint committees of the American Association of Educational Research (AERA), the American Psychological Association (APA), and the National Council on Measurement in Education (NCME). These standards have received global recognition. In the first published committee report, each recommendation was labeled as ESSENTIAL, VERY DESIRABLE, or DESIRABLE (APA 1954, p. 20). The primary recommendation for content validation was:

> If a test performance is to be interpreted as a sample of performance in some university of situations, the manual should indicate clearly what universe is represented and how adequate the sampling is. ESSENTIAL.

Additional recommendations included that the descriptions be provided for sources of items, criteria for inclusion or exclusion of items, and method of sampling items from the domain. A decade later, the *Standards* (APA 1966) specified that content validity information should include:

1. The universe that the test items represented (ESSENTIAL).
2. The adequacy of the procedure for selecting a sample of items from the universe (ESSENTIAL).
3. The dates of publication of any textbooks from which items topics were selected (ESSENTIAL).
4. The professional qualifications of the expert judges (VERY DESIRABLE).
5. The directions that they received (VERY DESIRABLE).
6. The extent of agreement among judges (DESIRABLE).
7. Any classification or taxonomy used in item selection (DESIRABLE).

The next edition of the joint standards (APA 1974) generally upheld the previous standards for content validity but recognized increasing applications of content validation in personnel selection:

> When a test is represented as having content validity for a job or class of jobs, the evidence of validity should include a complete description of job duties including relative frequency, importance, and skill level of such duties. ESSENTIAL. (p. 46)

In 1985, the joint *Standards* downplayed the notion of 'content validity' as a separate test quality; but recognized the uniqueness of its form of evidence (AERA et al. 1985). In addition, these standards covered domain definition and content validation for licensure testing. The final edition published in the twentieth century (AERA et al. 1999) includes two standards for validity evidence from content judgment studies. First,

> When the validation rests in part on the appropriateness of test content, the procedures followed in specifying and generating test content should be described and justified in reference to the construct the test is intended to measure or the domain it is intended to represent. If the definition of the content sampled incorporates criteria such as importance, frequency, or criticality, these criteria should be clearly explained and justified. (p. 18)

Second,

> When a validation rests in part on the opinions or decision of expert judges, observers, or raters, procedures for selecting such experts and for eliciting judgments or ratings should be fully described. The qualifications, and experience, of the judges should be presented. The description of the procedures should include any training and instructions provided, should indicate whether participants reached their decisions independently, and should report the level of agreement reached. If participants interacted with one another or exchanged information, the procedures through which they may have influenced one another should be set forth. (p. 19)

Shifts in wording and focus of criteria for evaluating content judgment studies reflect trends in the measurement community's view of validity *per se*. Yet, given advances in the theory, quantitative models, and technology of modern psychometrics, it is remarkable that the underlying logic, methods, and criteria for content judgment studies have survived with so little change. Evidently the concept possesses enduring utility for a broad range of test developers and test users.

Contextual Studies: Methodology

Within the social sciences, 'context' refers to the physical, social, cultural, and temporal environment in which behavior occurs. As a term, context is used rather loosely, and can refer to an interpersonal relationship (e.g., children's emotional expression in the *context* of the parent–child relationship), a social group (e.g., interpersonal conflict in the *context* of a peer group), a physical setting (e.g., sex role behavior in the *context* of the classroom), a locale (e.g., crime in the *context* of neighborhood poverty), or a broad expression of time or culture (e.g., the role of religion in the *context* of twentieth century America). The study of context in the social sciences, once the province of disciplines such as sociology and anthropology, has now become an accepted focus of inquiry within perspectives that formerly had been concerned exclusively with the study of individuals in controlled, laboratory settings, such as psychology. This article examines the ways in which context is taken into account in contemporary social science research.

1. Historical Underpinnings

The contemporary study of context has its origins in a number of different disciplines, not only sociology and anthropology, but also *ethology* (the study of animal behavior in natural habitats), *ecology* (the study of biological organisms and their environment), and urban geography (the study of the development and functioning of neighborhoods in cities). All of these disciplines emphasize the fact that any human or animal behavior cannot be understood outside of the setting in which it occurs. In this sense, the organism and context are seen as inextricably linked.

Psychology, as a discipline, was slow to embrace a contextual point of view. Although numerous writers had attempted to move the field in this direction—most notably, Kurt Lewin (1951)—the study of psychology was dominated for much of the twentieth century by experimental scientists, who studied human behavior in the laboratory. Context was seen as a nuisance variable—something that got in the way of pure science—and the goal of experimental research was to study behavior under conditions that permitted the investigator to control any variable that was seen as extraneous to the research focus. If one wanted to study, for example, how individuals make decisions, the researcher would need to control the setting in which the decision-making took place, so that each subject in the study could be observed under identical circumstances. The simplest way to do this was to perform research in a laboratory, where each and every element of the context could be controlled.

The benefit of controlled laboratory research is that it permits the scientist to isolate pure behavioral phenomena, uncontaminated by the outside environment. But this benefit must be weighed against the fact that phenomena observed under controlled experimental conditions may not be the same as phenomena observed in their natural context. The way in which individuals make decisions in a psychology laboratory, for instance, may not resemble the way they

make decisions at home, at work, or in a store. Just as ethologists would not want to generalize observations of caged animals to the behavior of that same species in the wild, social scientists must be careful about generalizing findings derived from controlled experiments to human behavior outside the laboratory. This is not to question the importance of laboratory-based research but, rather, to note that the laboratory is itself a context, and that features of this context, like any other context, necessarily influence the behavior that occurs within it.

During the 1970s, concerns about ecological validity—the extent to which an observed phenomenon in a research investigation is a valid reflection of that phenomenon as it occurs in natural contexts—were voiced by numerous investigators working in a variety of areas. In the study of intelligence, for example, scholars raised questions about whether standardized intelligence tests adequately captured intelligent behavior as it occurs in the real world. Several researchers found that individuals who performed poorly on standardized tests of mathematics frequently demonstrated the ability to use very sophisticated mathematical reasoning when observed during day-to-day situations, such as shopping. Similarly, scholars of social behavior discovered that individuals' behavior was considerably influenced by the context in which it took place, and that conclusions drawn from studies of behavior in one context (e.g., observations of young children at home) could not always be extended to other settings (e.g., observations of these same youngsters in the preschool classroom). Ecological psychologists drew attention to the fact that individual behavior was profoundly shaped by the structure of the physical environment in which people lived. Several classic studies of schools indicated, for example, that students' behavior in small schools was markedly different from students' behavior in large schools (Barker and Gump 1964).

In the late 1970s, psychologist Urie Bronfenbrenner drew widespread attention to the role of context in human development and behavior by noting that the scientific literature on child development was based almost entirely on the study of children interacting with strangers in strange situations for the briefest amounts of time. How, Bronfenbrenner wondered, could social scientists hope to contribute to the solution of social problems if they insisted on studying human behavior in a contextual vacuum? Although his comments were aimed at students of child development, they applied equally well to other disciplines. In his book, *The Ecology of Human Development*, Bronfenbrenner (1979) called on the field to think in more sophisticated fashion about the settings in which development took place, and he outlined a model of context that researchers could use to guide their thinking and empirical investigation. This work, and the thinking it would subsequently inspire, led to the development of the ecological perspective on human development, a perspective that grew more and more influential over the next several decades (Bronfenbrenner and Crouter 1983).

2. *The Ecological Perspective*

Within the ecological perspective, the context is construed as a series of nested environments, with each level of contextual influence embedded within a larger level, not unlike a set of Russian dolls. At the innermost, or most proximal level of contextual influence, are the immediate settings in which individuals spend time—the family, the friendship group, the classroom, the workplace, the laboratory, and so forth. Most studies of the role of context in shaping human behavior and development are studies of single contexts examined in isolation from one another (e.g., the impact of the family context on child development, the impact of teaching practices on student achievement).

The ecological perspective provides a conceptual framework within which to investigate more complex interactions between persons and environments, however. Three notions are especially important in this regard. First, proximal settings are seen as connected to each other, because events that take place in one setting often have ramifications for individual behavior and development in another. Socialization in the family context influences how adolescents behave in the peer group, peer influence processes affect how adolescents behave in the classroom, experiences in the classroom affect students' performance in extracurricular settings, and so on. Within the ecological perspective, therefore, an important focus of inquiry is on the ways in which, and the extent to which, different settings are linked, and the impact of these links on individual behavior.

Second, within the ecological perspective, these proximal settings are seen as contained within broader institutional and community contexts that shape the structure of settings and influence what takes place within them (Duncan and Raudenbush 1998, Jencks and Mayer 1990). Families and friendship networks reside within neighborhoods, for example, and qualities of neighborhoods influence how families and friendship networks function. Parents interact with their children differently in poor neighborhoods than they do in more affluent ones, for example, and, as a consequence, child development may vary across neighborhood contexts. Similarly, schools exist within communities, and characteristics of communities—urban vs. rural, tightly knit vs. impersonal—necessarily influence the ways in which schools are organized and operate. Within the ecological perspective, therefore, one needs to examine relations among nested contexts as well as between individuals and settings.

Finally, proximal settings and the broader environments that contain them are located within particular historical, social, economic, political, geographical, and cultural contexts—'macro-systems'—that influence the nature, structure, function, organization, and influence of all levels of the environment. Schools in Japan function differently than those in Canada, and differences between Japanese and Canadian schools have implications for the ways that teachers and students interact with each other, which in turn have implications for understanding student achievement in each context. A city's neighborhoods today may bear little resemblance to these very same neighborhoods 50 years ago, and the ways in which neighborhoods have changed over historical time may have important implications for understanding transformations in family life and parent-child relationships. Important social and economic events—wars, economic depressions, natural disasters—shape proximal and distal settings in important ways that have ramifications for individuals' behavior and development. Within the ecological perspective, researchers are interested in the influence of macro-systems on the settings located within them, and, consequently, in the rippling effects of these influences on individual behavior and development.

3. *Methodological Challenges in Contextual Research*

As more and more social scientists began to incorporate an increasingly sophisticated model of context into their research designs, it became clear that the scientific study of context presented a number of new and formidable methodological challenges. The discussion shifted from *whether* one needed to study context (the consensus was that one did) to how best to do so. Among the most important of these concerns involved deciding upon the most appropriate way to assess context, developing models of the transactional nature of contextual influence, and disentangling the effects of hierarchically organized, or nested, environments.

3.1 *Objective vs. Subject Assessment of Context*

One of the longstanding debates in the study of context concerned the relative merits of objective vs. subjective assessments of the environment. Objective assessments attempt to separate the measurement of context from the assessment of the individuals whose behavior is the target of investigation. A researcher interested in the influence of the parent–child relationship on child development might conduct impartial observations of family interaction in the home and draw his or her own conclusions about the relationship on the basis of what was observed. Similarly, a student of neighborhood stress and its impact on mental health might draw upon official statistics on crime, poverty, unemployment, and housing density and look at these in relation to residents' mental health problems.

Subjective assessments of context, in contrast, rely on the research participants' perceptions of their environment. These perceptions can be assessed by asking individuals to complete questionnaires or by interviewing them about the settings in which they live. Thus, a researcher interested in parent–child relationships might interview parents about their socialization practices or ask children to complete questionnaires about their parents' behavior. Similarly, someone interested in neighborhood stress and mental health might collect information from neighborhood residents on their perceptions of the community's dangerousness, economic health, or housing quality and examine the links between these perceptions and one or more indices of mental health.

These different approaches to the assessment of context have particular strengths and weaknesses. The advantage of using objective assessments inheres in the fact that the assessment of context is not contaminated by the characteristics of the individuals whose behavior is being studied. Suppose, for instance, a researcher interested in neighborhood stress and mental health gathered information about each by interviewing a sample of residents and found that depression was more prevalent in dangerous areas. Because depressed individuals may describe their neighborhoods in more negative terms than nondepressed individuals, however, it would be difficult to know whether the observed link between dangerousness and depression was genuine or merely an artifact of biased reporting. If, however, the relationship between dangerousness and depression were confirmed in a study using official crime statistics, one would have more confidence in the validity of the finding.

The advantage of using subjective assessments of context is that such assessments capture the context as it is experienced by the participant. Some social scientists argue that it is the subjectively experienced context, and not the objective context, that has the most profound impact on behavior and development. Individuals' perceptions of their neighborhood as safe vs. dangerous, for example, may well influence how they behave far more than the actual level of crime as measured by official statistics. As the sociologist W. I. Thomas wrote early in the twentieth century, if individuals 'perceive situations as real, they are real in their consequences' (Thomas and Thomas 1928). Of course, one problem that arises when researchers rely on subjective assessments of context concerns the reconciliation of different subjects' perceptions of the same context. In family research, for example, it is common to find that different family members characterize their family context in different ways.

Ultimately, the most thorough assessment of context is one that employs multiple sources of infor-

mation and uses multiple methods of assessment. By combining information from objective and subjective sources, from multiple vantage points, and gained through observational, self-report, and archival data, researchers are often able to provide richer and more accurate characterizations of a setting than are achieved through one approach alone.

3.2 The Transactional Nature of Contextual Influence

A second methodological challenge involves capturing the transactional nature of contextual influence. Although researchers often claim to be studying the influence of context on the individual, in reality the situation is far more complicated than this, in at least three important ways. First, individuals are not the passive recipients of contextual influence, but are active agents who shape the contexts in which they live. At the same time, contexts are not static entities, but settings that change and develop over time. Thus, while children are no doubt influenced by their family environment, family environments are themselves influenced by the children who inhabit them. Similarly, friendship groups both affect, and are affected by, their members. Finding ways to model the reciprocal and dynamic relations between individuals and their environments has been an especially difficult challenge for researchers.

Second, it is often difficult to separate the effects of contextual selection from those of contextual influence (Jencks and Mayer 1990). In laboratory experiments individuals can be randomly assigned by the researcher to different groups and then compared to see whether group membership affects individual behavior. Outside the laboratory, however, people often pick the contexts in which they spend time. Consider, for example, the often reported finding that delinquent teenagers often are members of peer groups composed of other delinquent adolescents. Is this because delinquent peers influence their friends to engage in antisocial behavior, or is it due, instead, to the propensity of delinquent individuals to choose to affiliate with others who share similar attitudes and values? Obviously, it is not possible to answer this question without randomly assigning individuals to different peer groups (not a feasible option in most research) or observing individuals and contexts over time. Similar problems exist in attempts to document the influence of neighborhoods on their residents. Because individuals have some control over where they live, it is difficult to disentangle the effects that neighborhoods have on individuals from the factors that lead some people to select particular neighborhoods in which to settle.

Third, different individuals are often affected by the same contextual factors in very different ways, making it extremely difficult to generalize about the effects of various contextual factors on individual behavior and development. A highly active and impulsive child may fare poorly in a relatively unstructured classroom, whereas this same context may be perfectly suitable for a more passive, more placid youngster. Similarly, an employee who is self-reliant and self-directed may thrive in a work environment that permits a great deal of autonomy, but this same work environment may prove problematic for an employee who needs a great deal of guidance and supervision. The recognition that contextual influence varies as a function of differences between individuals has stimulated a good deal of interest in the study of 'person-environment fit'—the extent to which a given context meshes well with the individual's personal characteristics.

3.3 Hierarchical Nature of Contextual Influence

The third methodological challenge concerns the hierarchical and interactive nature of contextual influence. The recognition that individuals are affected by multiple contexts simultaneously has necessitated the development of more sophisticated conceptual and statistical models in order to best describe the complicated ways through which individuals are influenced by the contexts in which they live (Duncan and Raudenbush 1998). Some contexts, for example, affect individuals directly, as when the behavior of a parent directly affects the development of a child. Other contextual effects occur through their impact on some other setting, however; stress in the parent's workplace may affect the child indirectly, through its impact on the family. In this instance, the second setting (in this case, the family) is said to 'mediate' the impact of the first setting (i.e., the workplace). And still other contextual effects occur by transforming, or 'moderating,' the impact of other contexts. Neighborhoods, for example, often exert their strongest impact on individuals not directly, but by attenuating or enhancing the impact of other contexts, such as the family or school. Within the context of an affluent and safe neighborhood, close parental monitoring may have deleterious effects on the child (because such monitoring may be experienced by the child as overprotective or intrusive), but the very same level of parental monitoring may have beneficial effects within the context of a dangerous, economically stressed community. In order to analyze direct, mediating, and moderating effects, researchers have had to develop new classes of multivariate statistical procedures, such as path analysis, structural equation modeling, and hierarchical linear modeling.

4. Concluding Note

The growing appreciation of the importance of context in the study of human behavior and development stimulated a wave of new research in the 1980s and 1990s that sought to understand how individuals are

affected by different levels of the environment, both independently and in interaction with each other. Multidisciplinary and interdisciplinary research that brought together social scientists from different disciplines became increasingly common, as scholars realized that understanding the complex interrelations among individuals and their environments necessitated drawing on the methods and theories of multiple disciplines. Over time, the study of individuals in natural settings has come to dominate research in fields in which controlled laboratory experiments had once been the dominant paradigm. Once considered a nuisance that interfered with the pursuit of 'pure knowledge,' the context of human behavior is now recognized as a necessary and enormously important focus of contemporary social science inquiry.

Contractarianism

Contractarianism offers an intuitively appealing account of political and moral rules and obligations, based on the idea of consent or agreement. Social institutions and moral codes are to be explained and justified by reference to their *eligibility*—the property that they would be chosen or agreed by individuals of a particular type in particular circumstances. Contractarianism was developed by Hobbes and Locke, and by Rousseau and Kant, and a range of contemporary contractarian positions have emerged in the second half of the twentieth century to challenge utilitarian and other idealist approaches to political and moral philosophy. Contractarianism has clear connections with ideas such as individualism, democracy, and pluralism.

1. Introduction

The voluntary act of entering into a contract is the act of choosing to be involved in a specified joint scheme or commitment. Any argument that places an idea of contract, agreement, or consent in a central role in explaining or justifying a particular joint scheme or commitment might then be seen as 'contractarian' in nature. Most prominent among the joint schemes and commitments that might be explained or justified are political, social, and legal institutions such as government, and moral values. Contractarian arguments are distinctive in terms of their emphasis on considerations of eligibility, so that demonstrating that a particular arrangement or commitment was, or might have been, chosen, at least by certain types of individuals in certain circumstances, carries weight in explicating and justifying that arrangement or commitment. But contemporary contractarian arguments differ from each other along several dimensions, most obviously according to the domain of the argument, the role of the idea of contract or agreement in the argument, and the specific nature of the contract in question. These dimensions map out a space that includes many potential contractarian positions. Not all points in this space are tenable, but a number of them are occupied by contemporary contractarians.

In the domain dimension, a very modest contractarianism would seek to explain or justify some particular activity, policy, or other aspect of social life against a background that already includes a rich variety of social institutions and norms. By contrast, a moderately ambitious or *political* contractarianism seeks to explain and justify basic social and political institutions themselves, rather than merely the activities that occur within them. Finally, a highly ambitious or *moral* contractarianism seeks to provide a theory of morality itself.

In the dimension that identifies the role of agreement in any contractarian argument, we note two major possibilities—agreement might play either a shallow, indicative role or a deep, constitutive role. An indicative role might be relevant in cases where the agreement serves as a useful but inessential signal of

some further and more basic property (the signal may be sufficient but not necessary for the realization of the underlying property). By contrast, contract would play a deeper, more constitutive role where the idea of agreement is essential to the argument (so that the voluntary contract is both necessary and sufficient).

In the dimension that identifies the specific nature of the relevant contract, the most obvious range extends from the case of the fully explicit, actual, or historical agreement, to various specifications of tacit, implicit, or hypothetical agreements. But there is also scope for qualifying the nature of agreement in other ways. Thus, some contractarian arguments will emphasize the informational context of agreement, or the extent to which the agreement is grounded in fully rational deliberation.

The basic idea or vision that unites all contractarianism is the conception of society (in the case of political contractarianism) or morality (in the more ambitious case) as human constructions, so that, for example, society is 'a co-operative venture for mutual advantage' (Rawls 1971, p. 4). This places contractarianism firmly in an individualist setting in which society/morality is to be explained and justified by appeal to the extent to which it responds to human needs, supports cooperation, and suppresses various forms of conflict. From this common starting point, contemporary contractarianism may be divided into two major branches—one originates with Hobbes and may be described as interest-based contractarianism, while the other derives from Kant and may be described as impartial contractarianism.

In the Hobbesian tradition the interests of individuals are taken as basic so that agreement is seen as identifying mutuality of interest. The most basic version of such a theory would begin in presocial state of nature, allow individual interests to be whatever the individuals concerned perceive them to be, and would require real, explicit, and unanimous agreement between individuals. Such a theory is open to a range of obvious criticisms: that agreements based on mistaken or misperceived interest cannot carry the normative weight required by the argument; that since explicit, historical agreements of the required type are not a common feature of the real world, the contractarian argument cannot explain or justify the political or moral features of the real world; and so on. The point to be emphasized here is just that, for contractarians in the Hobbesian interest-based tradition, the idea of contract or agreement is important as a means by which to investigate the prospects for mutual advantage for rational individuals.

In the Kantian contractarian tradition, attention shifts from mutual advantage to impartiality or justice. The basic idea here is that the rational contemplation of the world from an impartial standpoint will reveal what political arrangements are just or what is moral. There is no real attempt to link the contractarian idea to real, explicit agreements. The essential nature of the Kantian contractarian method is to construct a hypothetical, impartial position from which to consider what is just.

2. *Contract and Compliance*

Although the possibility of cooperation is a hallmark of the contractarian vision of society in both its Hobbesian and Kantian forms, it is the nature of the conflict that threatens cooperation that sets the more detailed agenda for contractarianism. This agenda may be illustrated by a sequence of simple games which have become staples of the literature—the pure coordination game, the mixed-motive game, and the prisoners' dilemma. In developing these illustrations, I will use the language of a simple Hobbesian, interest-based contractarian argument, where the contract is explicitly entered into.

In the pure coordination game each player has an interest in coordinating with others, and no other relevant interest. This is illustrated in the simple two-person, simultaneous-play game of Fig. 1, where the pay-offs from each combination of actions are shown in the form (payoff to row, payoff to column).

All that matters in this game is that the two players should take the same action—both should X, or both should Y—since the interests of the two players are perfectly aligned. In this setting is easy to see how preplay communication between the players might allow an agreement which identifies a *convention* in the sense of Lewis (1969). So there is little difficulty in identifying the potential grounds for agreement (although there might be a minor difficulty in identifying which of the actions is to be coordinated on). It is equally easy to see that such an agreed convention will be self-enforcing in that neither player has any reason to depart from the convention once it is established. There is no compliance problem here. This, then, is a model in which a simple contractarian argument promises to work well—agreement seems likely to pick out social or political conventions that are self-enforcing in the relevant population. However, the obvious criticism is that a model of pure coordination is an inappropriate starting point for even moderately ambitious political contractarians since, although it may capture the essential features of some social and political issues, it can hardly claim to capture the

		Column	
		X	**Y**
Row	**X**	**(1,1)**	**(0,0)**
	Y	**(0,0)**	**(1,1)**

Figure 1
Pure coordination

Row	X	(2,2)	(0,3)
	Y	(3,0)	(1,1)

Figure 3
Prisoners' dilemma

fundamental nature of society where competition and conflict must be recognized.

A move towards incorporating conflict is made in Fig. 2, which represents the mixed-motive game. The benefits of cooperation are still clear—each player still has an interest in doing what the other does—but now the two players have divergent interests concerning the action to coordinate on. Row has an interest in coordinating on X, while Column has an interest in coordinating on Y. This introduces a difficulty into the contractarian argument, the difficulty that any preplay agreement must now overcome an essential conflict of interests. If we are willing to assume that some agreement is reached, we might still argue that such an agreement forms a convention and is self-enforcing. Consider the case in which Row and Column agree that both should X, Column now has good reason to suppose that Row will X and, given this belief, Column will also have good reason to X. There may be no compliance problem here despite the *ex ante* conflict between players.

A further step in the direction of conflict is illustrated in the standard prisoners' dilemma game of Fig. 3. Here each individual has a private reason to Y, since this is the dominant strategy. The potential and mutual gains from cooperation in this case come from shifting the behavior of both players from Y to X. In a sense, the problem here is the opposite of the problem in the mixed-motive game. The nature of any agreement seems clear enough, precisely because the coordinated shift from Y to X does offer mutual benefits, while no other route to mutual benefits exists. But now the existence of a severe compliance problem may undermine any agreement to X. If both agree to X in preplay negotiations, it is not clear that either will comply with the agreement, since it will be in their individual interests to renege on the agreement regardless of whether they believe the other will keep to the agreement or not (this is just what it means to say that Y is the dominant strategy). The preplay agreement may be dismissed as 'cheap talk' that does not actually impact on individual decision making. If the compliance problem is so severe as to render prior agreement ineffective, there will be no reason for individuals to waste their time in reaching ineffective contracts.

These simple illustrative games serve to identify two of the basic issues facing contractarians, and the relationship between these issues. On the one hand, the issue of the nature and content of any agreement given the likely presence of *ex ante* conflict between individuals and, on the other, the issue of compliance with any agreement given the *ex post* conflicting private incentives facing individuals.

3. *Contemporary Contractarian Positions*

The last two sections have identified two broad traditions within contemporary contractarianism—the Hobbesian interest-based tradition and the Kantian impartiality-based tradition—and two broad issues facing contractarians—the *ex ante* agreement issue and the *ex-post* compliance issue. The remainder of this article will briefly consider contemporary contractarian positions—representing both traditions and offering different approaches to the basic issues. The intention is both to sketch some salient features of contemporary contractarianism, and to reveal some of the strengths and limitations of contractarian argument.

3.1 Hobbesian Contractarianism—Buchanan and Gauthier

Both Buchanan's and Gauthier's contractarianism are clearly and explicitly Hobbesian in nature, but an initial difference between these two contemporary contractarians lies in the scale of their ambition. Buchanan ties his contractarian argument to political constitutionalism, so we might view Buchanan as an essentially *political* contractarian. Buchanan takes contractarianism as providing a justification for political and constitutional structures, rather than merely an explanation, so that he is committed to contractarianism as a means of moral enquiry; but he does not set out to derive any specific or substantive moral principles from the idea of agreement. Buchanan is certainly a moral individualist, but he may be interpreted as allowing individuals to hold whatever moral views they may happen to have (including none at all), insisting only that agreement or contract is the means by which individual moral values, as well as individual desires or preferences, must be brought together in any exercise in normative social or political theory. By contrast, Gauthier's ambition is that of a full moral

contractarian. *Morals by Agreement* sets out an argument (with some of the details revised and extended in later work) for the contractarian construction of morality. More specifically, 'Moral principles are introduced as the objects of fully voluntary *ex ante* agreement among rational persons. Such agreement is hypothetical ..... But the parties to the agreement are real, determinate individuals, distinguished by their capacities, situations and concerns ..... As rational persons understanding the structure of their interaction, they recognize a place for mutual constraint, and so for a moral dimension in their affairs' (Gauthier 1986, p. 9). These differences in ambition between Buchanan and Gauthier relate to further differences in the treatment of both *ex ante* agreement and *ex post* compliance.

A basic distinction in Buchanan's argument is that between 'constitutional' and 'in-period' choices. Constitutional choices are described as choices of rule-systems, while in-period choices are described as choices within rules. The *ex ante* agreement issue, for Buchanan, is then the question of why individuals who may differ markedly in their interests (and values), and in their in-period behavior, may nevertheless agree on rules. Buchanan's approach to this issue focuses on considerations of the nature of the objects of choice rather than the choosing agents. As already noted, Buchanan does not impose on his individuals any restriction in the set of interests or values that they might have. On the contrary, Buchanan frequently insists that 'we start from here' and that individuals must be taken 'as they are', recognizing their diversity. Rather, Buchanan argues that the nature of constitutional choice itself will present alternatives in such a way as to reduce conflict between individuals, and so enhance the prospects for agreement. One key element of this argument is that constitutional provisions are 'general', in that they are expected to apply both across many particular in-period choice situations and across time, so that any individual contemplating the choice between rule-systems will have good reason to judge the alternative rule-systems in terms of their general properties, rather than in terms of the implications for any particular in-period decision. Thus, for example, in choosing a voting rule to be applied to a broad class of in-period political decisions, any individual at the constitutional stage will have good reason to balance the implications of each potential voting rule across a wide range of issues, and this suggests that different individuals may judge voting rules similarly, even if their specific preferences are rather different. This argument seems secure—surely the move from the level of the particular in-period decision to the more abstract constitutional level will tend to suppress at least some of the potential conflict between individuals and so allow potential agreement. However, this apparent success in at least diluting the *ex ante* agreement problem may simply transfer the problem to an arena of compliance. The *ex ante* agreement problem is still more severe for Gauthier. To the extent that Gauthier simply argues for the 'recognition of mutual constraint' at the *ex ante* level, then there is no substantial difference between Gauthier and Buchanan—'mutual constraints' may be identified with constitutional rules without much loss. However, Gauthier needs to go a step further to argue that individuals will come to agree on moral principles rather than just particular, institutionalized constraints or rules. To take this extra step Gauthier relies on a model of bargaining (although the specific theory of bargaining is an area in which Gauthier has revised his views) and a version of the Lockean proviso. The proviso is of particular interest since it seems to be a moral principle, but is not argued to arise out of agreement. It is, rather, a precondition for agreement. Essentially, the proviso states that initial bargaining between individuals should be constrained so that no individual should be worse off in the initial bargaining situation than they would be in a nonsocial context of no interaction. This effectively introduces a minimal set of rights into the original bargaining situation. Gauthier argues that such a proviso has to be accepted by each individual if agreement is to be possible. In one sense this proviso might be thought of as a technical device to ensure that the bargaining outcome actually realizes mutual advantages, and therefore stays true to the underlying Hobbesian idea; but in another sense it reveals a potential weakness of any bargaining model in that the outcome will reflect bargaining power relative to some baseline rights. If such power is to be viewed as illicit in some cases—and ruled out by the proviso—why should the outcome of power be granted moral status in other cases?

The basic compliance question for any Hobbesian contractarian is simply why any individual should feel him- or herself to be bound or obligated by a prior agreement (whether on political rules or moral principles), even if that agreement was explicit and real. This question may be put in terms of the *ex post* motivational impact of the *ex ante* agreement, and whether the motivational impact is sufficient for the agreement to be self-enforcing. If interests are the currency both of *ex post* decision making and *ex ante* agreement, it would seem to place these two activities on all-fours with each other so that the claimed priority of the *ex ante* contract over the *ex post* decision is threatened.

The prospects for wholly self-enforcing contracts seem to be hopeless if we are to take individual interests either as being entirely unspecified, so that any individual may have any interests at all, or if we insist on interests being modeled in terms of narrow self-interest along the lines of the standard depiction of *homo economicus*. In either of these cases, the fact of the contract (if it is a fact) and the content of the contract (whatever it might be) would seem to have no independent or reliable role in determining in-period behavior in situations such as the prisoners' dilemma

where in-period incentives are clear. In order to generate reliable compliance in such cases, we seem to need to assume at least some motivational relevance or status for the contract itself. Without such a move, the range of political and moral principles that might be explained or justified by a Hobbesian contractarian would seem to be limited to those which can be analyzed as self-enforcing conventions. Gauthier attempts such a move by arguing for what he terms 'constrained maximization' rather than straightforward maximization as the appropriate interpretation of rational decision making, where 'A constrained maximizer has a conditional disposition to base her actions on a joint strategy, without considering whether some individual strategy would yield her greater expected utility ....in other words, a constrained maximizer is ready to co-operate in ways that, if followed by all, would yield outcomes that she would find beneficial and not unfair, and she does co-operate should she expect an actual practice or activity to be beneficial' (Gauthier 1986, p. 167). The basic point here is that Gauthier is attempting to ground his moral contractarianism in a specific interpretation of what rationality requires. The detailed claim about rationality is clearly contentious, but without some similar claim, there would be little prospect for contractarianism that goes much beyond the securing of conventions.

A second aspect of the question of compliance relates to the possibility of enforcement. Clearly this is of much more relevance to a political contractarian than a moral contractarian since a moral contractarian must by necessity be concerned with the acceptance and internalization of moral principles but, even for a moral contractarian, it is clear that enforcement may play some role. So, can enforcement resolve the compliance problem? As usual, the answer is both yes and no. Of course, the possibility of more complex contracts which include enforcement mechanisms will extend the range of political and social situations that can be treated. Such complex contracts need raise no new issues at the *ex ante* stage. For example, if a group of individuals contract to engage in a joint venture that has the characteristics of the provision of a public good (the draining of a swamp, perhaps), it will be appropriate for them to recognize that a simple contract in which each person agrees to contribute to the in-period effort and cost may founder since each individual will face strong in-period incentives to free-ride. In such a case, a form of enforcement, perhaps raising taxes against the credible threat of some further punishment if taxes are not paid, seems both to solve the *ex post* compliance problem and be something that offers appropriate mutual advantage so that it will be eligible at the *ex ante* stage. However, this is too fast. Enforcement of the type required cannot simply be assumed to be available. Typically, enforcement requires enforcers and their motivations and decisions to be explicitly considered. Assuming that judges will virtuously apply the law, or that policemen will act regardless of their own individual interests, is not to solve the compliance problem but simply to relocate it. This is not to deny that enforcement is sometimes possible and useful, but merely to suggest that while a political or social arrangement may involve enforcement within its structure, the structure as a whole must be seen to be self-enforcing in the sense that the behavior of all individuals—including those who act as enforcers—are seen to be consistent with their motivational characters and the incentives facing them.

3.2 Kantian Contractarianism—Rawls and Scanlon

Some of the discussion of the Hobbesian positions of Buchanan and Gauthier applies with only minor modification to the Kantian positions of Rawls and Scanlon. In this section I will concentrate on rather different concerns to avoid repetition.

The Kantian nature of Rawls's contractarianism is most obvious in the formulation and discussion of the original position. This position, with its relatively thick veil of ignorance, is the basic means by which Rawls attempts to overcome the potentially conflictual nature of the *ex ante* agreement and generate the impartial conditions under which to explore what justice requires. To (over)simplify, the original position attempts to strip away all of the distinctive and partial characteristics of specific individuals, their particular circumstances, interests, and so on, so reducing the extent of conflict between individuals. In the limit, this process reduces the idea of rational agreement among individuals in the original position to the idea of the rational choice of a single hypothetical and representative individual. This then places almost all of the burden of identifying the institutions and principles that should govern society on the idea of rationality. The danger here is that the original position must satisfy two rather conflicting conditions. On the one hand it must be sufficiently removed from the real world to satisfy the requirement of impartiality, that is, it must strip away almost all the recognizably human aspects of the individual, while on the other hand it must retain sufficient structure to allow the idea of rationality and rational choice to be meaningful and recognizable. This is no trivial task. The standard thin theory of rationality favored by economists and endorsed by Rawls is one in which rational choice is defined in terms of the desires and beliefs of the particular individual; absent of specific desires and beliefs, it is not clear what the thin theory of rationality entails.

Scanlon's contractarianism differs from that of Rawls in several key respects—first in terms of its ambition where Scanlon is explicitly more ambitious than Rawls in arguing for a moral rather than a merely political contractarianism, and second in his formu-

lation of the idea of *ex ante* agreement which makes no major use of the construction of an original position. Scanlon offers the following definition of his account of contractarianism: 'An act is wrong if its performance under the circumstances would be disallowed by any system of rules for the general regulation of behaviour which no one could reasonably reject as a basis for informed, unforced general agreement. This is intended as a characterisation of the kind of property which moral wrongness is' (Scanlon 1982, p. 110). Contractarianism, in this view, is concerned with providing a distinctive basis for moral reasoning by individuals. Thus, for example, 'A satisfactory moral philosophy will not leave concern with morality as a simple special preference, like a fetish or a special taste, which some people just happen to have. It must make it understandable why moral reasons are ones that people can take seriously' (Scanlon 1982, p. 106) and again, 'According to contractualism, the source of motivation that is directly triggered by the belief that an action is wrong is the desire to be able to justify one's actions to others on grounds they could not reasonably reject' (Scanlon 1982, p. 116). This formulation ties together the *ex ante* agreement and *ex post* compliance issues in a particular way. By formulating the idea of agreement in terms of principles 'which no one could reasonably reject', Scanlon allows a degree of flexibility—there is no argument to suggest that there exists a unique set of principles that could not be reasonably rejected—and so weakens the requirement of agreement in Rawls' formulation. But, at the same time, the specification that the hypothetical 'agreement' (or nonrejection) is something that occurs in the minds of real individuals (rather than individuals in an original position) who are also motivated to justify their actions to others provides a route to compliance. It is the desire to justify action to others that seems to drive the motivational side of the problem, and the requirement of 'reasonableness' in the nature of justification that bears the strain in terms of identifying particular justifying arguments. But the dangers here are clear: that the desire to justify my action to others is simply smuggled in as a 'simple special preference like a fetish or a special taste', which is not itself grounded in any contractarian logic; and that the idea of 'reasonableness' is insufficiently detailed to bear the strain placed on it.

There is a final concern that is shared by moral contractarians, whether Hobbesian or Kantian. Even if we grant that it may be possible to parlay rational agreement, in whatever interpretation of that phrase, into moral principles, will the moral principles that emerge be recognizable as our moral principles. In particular, will the resources of contractarianism be sufficient to ground the range of moral views that we actually have and, if not, what would be the implications of that fact? Would it point to the possibility that some of our 'moral' views are not really moral after all, but mere tastes or preferences? Or would it point to the possibility that there may be other means by which moral principles may be grounded, so that contractarianism might not be the only means of approaching moral principles? Of course, this issue only arises once substantive moral principles have been derived from the contractarian method, and there is certainly no consensus, even among contractarians, as to precisely which substantive moral principles can be so derived.

4. *Finale*

Contemporary contractarianism offers approaches to political and moral theory that share as their basic commitments a form of individualism and the recognition of the central role of rationality in human affairs. In a simple sense, contractarianism is dedicated to the question of how rational people can live together. This simple and appealing structure goes a long way to explaining the continuing appeal of contractarianism. Of course, not all accept this vision. Communitarians and others who take society as prior to the individual, for example, must object to contractarianism in all of its forms by reason of its individualism. Equally, not everyone accepts that the basic idea of eligibility is compelling or even interesting. A question to all such critics of contractarianism is how they might expect to persuade individuals (even beyond the range of philosophers and political theorists) that their preferred alternative is valid without falling into a form of contractarianism themselves. For if a particular substantive moral theory or political constitution can be justified to others, then it might be presumed that it could be derived by a contractarian argument that emphasizes that mode of justification. This is simply a way of pointing to the fact that debate between contractarians and others is sometimes guilty of a mismatch between the contractarian method and particular substantive positions that might, at least in principle, be derived from that method.

Contemporary contractarianism is engaged in the study of the relationships between the idea of rationality, the nature of individual interests and dispositions, self-interest and morality, political and social rules, and moral psychology. While there are many areas in which these relationships are still obscure, and while there are surely noncontractarian approaches that may prove rewarding, it seems difficult to deny the importance of these relationships, or the potential of the contractarian enterprise to illuminate them.

Contracts: Legal Perspectives

A contract is a legally recognized agreement made between two or more parties which may be enforced in law, the default of which may give rise to legal liability. In limited circumstances, a contract may be legally unenforceable because it is illegal, contrary to the Statute of Frauds, or procured by fraud. In practical terms, contracts are legally binding because legislatures and courts so determine. Agreements that are not legally binding still may have moral, social, or economic significance.

Contracts must satisfy specified legal requirements in order for there to be a binding agreement. These requirements are contained in legal principles, rules of law, and standards of application. The key legal principle is the liberty of parties to contract (Atiyah 1979). Applicable rules relate, among others, to the exchange of offers between the parties and their performance under the contract. Legal principles and rules of application, in turn, are subject to standards of reasonableness. The liberty to contract must be exercised reasonably. Offers and acceptance must be reasonably certain. Performance must comply reasonably with the promise. What is reasonable, however, is a matter of construction that may vary according to the context.

A contract can be described analytically according to the correlative rights and duties that arise from it. A contract arises when one, but usually two, parties assume correlative rights and duties, usually towards each other (Trakman and Gatien 1999). Contract rights and duties arise in individual or discrete transactions between parties. They also arise in ongoing relationships between parties. Whether contracts are discrete or relational (Macneil 1980), they entail correlative rights and duties between the parties to them. The seller has a duty to provide the goods or services promised; and the right to be paid for them. The buyer has the right to the goods or services promised by the seller; and the duty to pay for them.

Contracts also entail the rights and duties of third parties. For example, parties to marriage contracts owe duties, not only towards each other, but also to the state and other third parties to their contract. They have a duty to register their marriage contract and not to commit bigamy. The state, in turn, owes them a duty to enforce it, but not if one party is a bigamist. Others, such as employees, have a duty not to discriminate on the basis of marital status. The rights and duties of third parties arise as a consequence of the contract, not under the contract itself. Only the parties to a contract ordinarily have rights and duties in terms of it.

Contracts ideally are freely and voluntarily concluded. Such freedom entails the right of parties to choose the terms and conditions of their contracts. For example, parties to marriage contracts cannot be forced to marry, or to agree to particular terms of marriage. However, they can be required to comply with legal rules governing marriage, such as not to enter into incestuous marriages.

Some argue that contracts should be efficient (Kronman 1980). However, efficiency is not a legal requirement of a contract. The terms of a contract must be reasonable, even if they are inefficient (Dworkin 1980). For example, a court may declare that a contract is unenforceable in law for violating public policy even though it is efficient. What is reasonable engages the subjective determination of the party reaching it. Courts, however, are expected to comply with principles of contract law, and rules of application, in deciding what is reasonable.

1. *Legal Requirements of a Contract*

Contracts are concluded between real and artificial persons. Individuals, companies, and governments all enter into contracts. There are many different kinds of contracts. Some relate to family, religious, and cultural life. Some relate to business dealings, others to relations with the state. Parents and children enter into domestic contracts when they agree to share car expenses. Consumers and supermarkets conclude consumer contracts to purchase groceries and other household goods. Merchants enter into business contracts when they purchase goods and services for resale, when they insure them, ship them, and secure credit. Governments enter into contracts when they grant individuals and companies licenses to trade, when they conclude agreements with multinational corporations or other governments, and when they sign multilateral conventions.

Some contracts are subject to formal requirements. Marriage contracts must be solemnized publicly through registration. Sales of property must also be registered. Most contracts, however, are not subject to registration. Some must be in writing. Most are concluded informally. A nod of one's head may constitute a legal agreement. Even complex business contracts may be concluded informally, such as on the golf course or at a party.

Contracts may be subject to substantive requirements. One substantive requirement is that the parties to contracts must intend to create binding relations, or such an intention may be imputed to them. A related requirement is that they must exchange promises, or one party must perform an act or acts in terms of a promise by the other. A further requirement is a bargained-for-exchange or consideration in common-law jurisdictions (Sutton 1974). Civil law jurisdictions require a *causa* or reason for contracting (von Mehren 1959). A contract is distinguished from a gift in both common and civil law. The parties to a gift do not ordinarily enter into a bargain or an exchange. Nor do they have a reason for contracting. What is a contract or a gift, however, is a question of construction upon which jurists may differ.

Most contract requirements are satisfied in stages. The formation stage occurs when a party makes an offer or promise which the other party accepts. For example, a party offers to sell goods to another, and the other party accepts the offer. The performance stage occurs when the parties perform the contract, such as when the seller delivers the goods and the buyer pays for them. A nonperformance stage *may* occur if the seller fails to deliver the goods or the buyer fails to pay. This failure to perform ordinarily gives rise to a duty, such as to compensate the other party for losses incurred. Absent nonperformance, the final stage, is the termination of the contract, as when all goods are delivered and paid for under the contract.

Non- or defective performance can give rise to litigation for default or breach of contract. For example, a seller may deliver goods which the buyer alleges are defective. The buyer may sue for the contracted goods, substitute goods and/or damages for losses. In Anglo-American jurisdictions, the most frequent remedy is for the defaulting party to pay damages to compensate the other party for breach (Fuller and Perdue 1936). In civil law jurisdictions, the most common remedy for default is specific performance. The seller in default is required to perform specifically in terms of the contract, for example, by delivering the goods as promised. Both civil and common law jurisdiction, however, recognize a range of remedies, varying from compensatory to punitive damages, and from specific to modified performance.

Law and economics scholars sometimes conceive of contract default as *amoral*, not immoral (Coleman 1980). They maintain that a seller should be entitled to default, without moral judgment, so long as the seller compensates the buyer for damages arising from that default. This attempt to legitimize efficient breach is suspect, however, when it produces inequities and losses that cannot readily be quantified, such as sentimental or emotional loss. Breach may also be inefficient when an 'innocent' party accepts inadequate compensation in response to litigation threats by the other party.

2. *Construing Contracts*

In the nineteenth and early twentieth centuries, the interpretation of contracts was grounded in a subjective theory of contracting. A contract was formed as a result of ascertaining the subjective or intention of the parties to it. Significantly, this subjective theory was replaced over the twentieth century by an objective theory. Here, the intention of the parties is determined, less by their subjective intention, than according to the objective circumstances surrounding their contract. Judges resorted to this objective intention because the subjective intention of the parties was allegedly ambiguous, or to prevent a party from manipulating its subjective intention at the time of dispute. In some measure, the objective theory incorporates a tort standard of due care into contract law. Contracting parties are required to communicate with due care and not to rely on a doubtful subjective intention (Sharp 1939). Ultimately, the objective intention of the parties derives from the courts' construction of what it believes is reasonably intended in the circumstances. Their objective intention is expressed subjectively by the court. At its most objective, the court examines the parties' course of dealings, past practices, and usages of trade (Devlin 1951). At its most subjective, the court applies its own conception of reasonableness in determining the objective intention of the parties.

This does not infer that, while parties may manipulate their subjective intention, courts manipulate the objective theory. Courts ordinarily choose to apply the subjective or objective theory of contracting along a continuum. The presence of clear and unambiguous evidence of a subjective intention by both parties supports use of the subjective theory. The absence of such evidence supports use of the objective theory. The application of the objective theory used, in turn, depends on the contractual circumstances. These include, among others, the complexity of the transaction, the bargaining power of the parties, and changed circumstances since the date of contracting (Trakman 1985). In applying the objective theory of contracting, courts are likely to be influenced significantly by an implied duty of care owed by the parties. For example, courts are likely to construe the subjective intention of a producer in a take-it-or-leave-it consumer contract restrictively, in accordance with its implied duty of care towards its customers. They

are more likely to construe the subjective intention of the parties expansively, in the absence of such adhesive elements (Kessler 1943).

Courts use different methods of interpretation to identify the intention of the parties. At one extreme, they use literal methods to establish what the parties actually intended, based on the plain word meaning of their contract. On the other extreme, they use open-textured methods, varying from party practices and trade usages, to the courts' own construction of what is reasonable (Farnsworth 1968). These open-textured methods of interpretation ordinarily give rise to judicial 'gap-filling.' Judges fill gaps in contracts on grounds that contracts are incomplete and reasonably warrant filling (Costigan 1920). They make different assumptions in doing so. One assumption is that, had the parties considered the gap, they would have filled it, as did the court. Had the seller and buyer anticipated a breakdown in supply, they would have provided for it by contract. Another assumption is that the buyer and seller knew of the gaps, but did not fill them in order to clinch the deal. Business people sometimes fail to provide for default in the hopeful expectation that default will not arise (Macaulay 1963). Courts fill contract gaps on behalf of such parties. A further assumption is that judges fill gaps in 'interpreting' contracts to avoid injustice. They imply warranties of merchantability into contracts of sale to prevent sellers from excluding their liability to customers.

The extent to which courts ought to fill gaps in contracts is controversial. Excessive gap filling is considered incompetent contracting and a threat to the liberty of contract. Judges who avoid gap filling are viewed as opening the door to between the parties bad faith dealings. Courts respond to this controversy according to the perceived nature of the gap, the parties' anticipation of it, the injustice arising from not filling it, and the courts' discretion in filling it (Farnsworth 1968).

3. *From Form to Substance*

The nineteenth and early twentieth centuries were marked by formalism in contract law. Contracts consisted of distinct forms associated with categories of contracts, such as marriage contracts and contracts for the purchase and sale of property. Each form of contract had its own characteristics, and each gave rise to distinct legal consequences (Atiyah 1979).

The pervasive use of formal contracts declined in the early years of the twentieth century. Jurists emphasized increasingly the substance of contracts. This shift from form to substance developed, in part, in response to the evolution of legal pragmatism. Pragmatists argued for a functional approach towards law (James and Castell 1948, Dewey 1924). Some stressed the substantively position of contracting parties and the functional role of courts in relation to them (Kessler 1943). Others scrutinized how law-makers and judges ought to address business risks arising in contract (Patterson 1924). Yet others challenged the classical theory of liberty of contract. Their concern lay in substantive abuse in contract practice. They maintained that, for there to be true liberty of contract, contracting parties ought to be free *both* to conclude contracts, *and* to influence their terms (Pound 1908, Williston 1921). The result was a functional analysis of fine-print disclaimer and warranty clauses used by dominant parties to limit or exclude their liability by contract. The purpose was for consts to construe such adhesive contract clauses against the drafter and in favor of the weaker party.

This functional approach towards contract law was supported by the belief that the law should be developed and applied in light of contract behavior. Contract law was regarded as less an aloof juridical science, than a response to social behavior. Contract practices were to be regulated, less through principled ends inhering in contract law, than through social ends imputed by law (von Jhering 1913, Pound 1943). This engineering of law through social science was supported by two schools of thought: sociological jurisprudence; and in regard to the judiciary, legal realism. Sociological jurisprudence identified the relationship between social behavior and the law. Legal realism concentrated on predicting how judges made law, including contract law. Both emphasized the interdependence between the law and social or business practice (Powell 1956, Devlin 1951). This interdependence also became central to an evolving Law and Society movement (Stone 1966, Selznick 1959) and contract law scholars within it. Some established the distinction between long-term relationships and discrete transactions (Macneil 1980). Others scrutinized the manner in which business communities devised noncontractual as distinct from contractual relations (Macaulay 1963).

The relationship between law and social sciences gave rise to critical attacks on the liberal roots of modern contract law in the late twentieth century. Critical Legal Theorists charged that *laissez-faire* principles and standards of modern contract law favored the privileged elite, disempowering workers and consumers (Unger 1986). Irrationalists demolished such principles as internally contradictory (Singer 1984). Critical scholars deconstructed contract law rules and standards as incoherent (Dalton 1985). Philosopher kings reconstructed contract law values away from individual autonomy and towards communal solidarity (Unger 1986).

The end of the twentieth century saw an uneasy balance between ideological conflicts over liberty of contract and subset individual and community values. Critical scholarship facilitated the partial reconstruction of contract law principles along communitarian lines. Strident communitarians who confronted *laissez-faire* contracting (Sandel 1982) were offset by

moderates who balanced individual free choice against family and religious values (Glendon 1991).

The early twenty-first century is likely to rekindle neoclassical models of free choice theory. Innovations in contracting, such as Internet transacting, are likely to be heralded as exemplifications of *laissez-faire* practices at work. New technologies are likely to enhance modes of communicating, including contracting. Courts are likely to resort to more refined plain-word methods of interpreting contracts and fewer open-textured ones. Judicial gap-filling in contracts is likely to be constrained. Disparities in contract bargaining power are likely to be construed more narrowly on grounds that consumers enjoy improved levels of literacy, foresight of risk, and bargaining power (Bernstein 1996).

These neoclassical developments likely will produce healthy tensions in contract law. Those who champion a neoclassical freedom *to* contract will accentuate the right of parties to conclude contracts of their own free will. Those who accentuate the abuse of free choice will argue for freedom *from* contract in an imperfect market. The debate over 'the rise and fall of freedom of contract' likely will be revitalized. Practices, such as the exchange of marriage vows over the Internet, will evolve; as will restrictions imposed on them in the interests of public policy and morality. Nation-states are likely to sanction the Internet as an instrument of contract practice. But they will try to constrain excesses in its usage.

The early twenty-first century is likely to include greater resort to structuralism in contract to redress internal contradictions in contract law principles and undue variance in substantive rationality (Shamir 1993). It is also likely to work towards greater analytical coherence in relating contract law to contract practice.

4. Conclusion

Almost a century ago, Sir Henry Maine (1917) wrote that the shift from ancient to modern society involved a shift from status to contract. The twentieth century represented a partial shift back to status. A model of perfect competition, applied in the early Industrial Revolution, was replaced by a model of imperfect competition in the post-Industrial Revolution period. The assumption that contracting parties had perfect knowledge and equal ability was replaced by the assumption that they enjoyed unequal education, legal know-how, and economic and political power. Against this background, jurists stressed the substance of contract law over its form. They evaluated contracts functionally, according to the nature of contract relations and discrete transactions. They construed them in light of the imperfect nature and value of the bargain, and the disparate positions of parties.

The early twenty-first century has revitalized the formal rationality of a century earlier. This renewal comes at a time of a new technological revolution. New technologies have opened the door to new contract practices. Contract bargains may be reached through inventive methods of communication that transcend differences in legal systems and national boundaries. Contract formalism is an understandable response to such developments. The new technological era has augured the appearance of a panacea in which sophisticated, informed, and educated parties contract freely across the globe in the absence of regulation. This perception has rejuvenated the image of *laissez-faire* contracting. Parties choose the terms of their contracts freely. Courts construe them literally according to their plain-word meaning; and nation-states enforce them.

This *laissez-faire* revitalized formalism in contract relations is likely to diminish over the course of the twenty-first century. Debate over the freedom *to* contract and the freedom *from* contract in unequal bargaining relations is likely to renew. Lawmakers are likely to challenge the assumption that the masses who have access to sophisticated technology are equally able to use and enjoy it in concluding contracts. Despite the access of billions of consumers to new technologies, including ways of contracting, their disparate understanding and use of those technologies will expand over time, not decline. Nation-states and their courts will return, perhaps with greater vengeance than before, to examining the substance of contract relationships. Contract forms will be scrutinized for their palpable social impact, beyond the form itself. The reasonable contracting party will be subject to increasing standards of due care. Motivated by both public and self-interest, nation-states will extend their regulation of contracts. Debate will rage over the extent to which contract law should inform, or be informed, by contract practice. Contract jurists will take sides; and resolution will remain elusive.

L. E. Trakman

Control Behavior: Psychological Perspectives

The scope of control-related phenomena is extensive. It encompasses numerous concepts such as perceived control, personal control, cognitive control, vicarious control, illusory control, proxy control, outcome control, primary and secondary control, decisional control, and predictive control (Skinner 1996). In her review of a decade of control-related research, Skinner (1996) identified some 100 different control-related constructs, and cautioned that 'the large number of terms has produced some theoretical confusion about the boundaries of the topic of control, about the interrelationships among constructs, and even about which constructs can be appropriately included in the study of control' (Skinner 1996, p. 550).

1. Conceptual Distinction Between Control Behavior and Perceived Control

The field of control-related research has suffered from conceptual confusion between constructs addressing control behavior on the one hand and constructs about perceptions or beliefs about control on the other (see also review in Schulz and Heckhausen 1999). Although a functionalistic analysis of control-related behavior would view control behavior as more critical for determining outcomes, research on control since the 1970s has been dominated by constructs and assessments of perceived control and related concepts (e.g., self-efficacy, Bandura 1977). This almost exclusive emphasis on perceived control rather than control-directed behavior or realized control has lead to widespread conceptual confusion, in that all kinds of control are subsumed and not differentiated from perceived control (see, e.g., Skinner 1996).

Before reviewing the key findings from the different bodies of research, specific definitions for the major control constructs are given. *Control-related behavior* is directed at producing contingencies between own behavior and events. When the events targeted are located in the outside world, the control-related behavior is *primary control behavior*. In contrast, when internal events are targeted it is *secondary control behavior*. *Control* is realized contingency between behavior and event. *Perceived control*, by contrast, refers to the extent to which an individual believes to control behavior–event contingencies. It thus becomes clear that perceived control does not reflect behavior, but internal representations, and may thus be involved in secondary control.

2. Research About Perceived Control

Perceived control and related constructs have a long-standing history in the psychology of motivation and self-regulation. Five major conceptions have guided

research in this area: locus of control (Lefcourt 1981, Rotter 1990) (see *Control Beliefs*: *Health Perspectives*), causal attributions (Weiner 1985) (see *Motivation and Actions*, *Psychology of*), learned helplessness (Seligman 1975, Abramson et al. 1978) (see *Control Beliefs*: *Health Perspectives*), self-efficacy (Bandura 1977) (see *Control Beliefs*: *Health Perspectives*), and perceived own intelligence as fixed vs. malleable (Dweck and Elliott 1983). Locus of control refers to the issue whether an event is controlled or produced by factors inside or outside the individual. Causal attributions refer to the retrospective explanation of outcomes of behavior by internal factors such as effort or ability and external factors such as task difficulty and luck. Learned helplessness focuses on the issue of whether events are contingent on the organism's behavior, and further distinguishes between stable and unstable and specific and unspecific causes of events. Finally, the distinction between fixed vs. malleable intelligence addresses inter-individual differences in the tendency to view intelligence as either an unchangeable entity or as a modifiable resource for performance. All these characteristics addressed by the five theories have been found to hold important implications for behavior and the evaluation of outcomes (Weiner 1986, Heckhausen 1991, Skinner 1995, Dweck 1999). Depending on the outcome, internal, stable, and general control beliefs are conducive, in the case of success, or detrimental, in the case of failure, to effort investment, ambitious task choice, persistence, and improvement in performance. Moreover, the temporal direction of control perceptions is critical, with prospective expectations of control influencing goal choice, and persistence, and retrospective attributions of control guiding the way in which success and failure are interpreted as indicative of future control potential.

Recently, researchers in this field have called for conceptual and domain-specific distinctions to be discussed in more detail here (for more detailed information about research traditions, see *Control Beliefs: Health Perspectives*; *Motivation and Actions*, *Psychology of*). Perceptions about personal control involve two components, 'agents of control, and means of control' (Skinner et al. 1988, Skinner 1996, p. 552). These two components are often not sufficiently differentiated, but confounded in a summary construct of perceived control. First, control beliefs imply conceptions about the controllability and the relevant means to attain an outcome. This component of control beliefs is captured by various closely related concepts (see review in Skinner 1996): *contingency judgment*; *means–ends beliefs*, and *strategy beliefs*. Second, control beliefs involve conceptions about the agent's resources for control in terms of having access to means for bringing about an outcome. This component of control beliefs is referred to as *competence judgment*, *agency beliefs*, and *capacity beliefs*.

Research about perceived control falls into two broad areas: (a) normative age changes in perceptions of control across the lifespan, and (2) the association of perceived control and various functional outcomes, such as task-performance, school grades, subjective well-being, and health (see also review in Schulz and Heckhausen 1999).

Research on childhood development of perceived control has shown that control beliefs become increasingly realistic, thus moving away from illusory gross overestimations of control in early childhood (Weisz 1983). However, the extent to which perceptions of personal control become realistic in mid-childhood, adolescence, and adulthood is a function of cultural variation (Little et al. 1995). School children in the United States, for instance, hold beliefs about their competence to attain good grades (i.e., agency beliefs), which have little relation to their actual school grades, whereas children in the former German Democratic Republic reported agency beliefs which closely resembled their actual school achievements.

In addition, developmental research has revealed that the agency and the means–ends components of control beliefs, as well as beliefs about different causal factors (e.g., ability, effort, luck, teacher) were increasingly differentiated during mid-childhood and exhibit unique developmental trajectories and relations to outcomes. Skinner et al. (1998), for instance, showed that during mid-childhood, cycles of influences between perceived personal control and school achievement were focused on different components at different ages. Beliefs about effort dominated the cycles in younger school children, whereas beliefs about ability were the focus of the regulatory cycles in older children (see *Self-regulation in Childhood*).

As to normative age changes during adulthood the findings to date provide a mixed picture (see review by Schulz and Heckhausen 1999). While earlier reviews of the literature reported little evidence for age-related changes in generalized measures of control (Lachman 1986a), more recent research has identified decreases in perceived control across adulthood (e.g., Mirowsky 1995). However, Lachman was the first to emphasize and provide evidence for domain specific perceptions of control and their age-related trajectories (Lachman 1986b). Lachman's research shows that older adults report decreasing perceptions of control for those domains for which their more constraint social roles and declining physical fitness yield deteriorated opportunities and resources for control.

The association of perceived control and health has been studied extensively using field experimental paradigms involving interventions improving objective control opportunities (e.g., Langer and Rodin 1976, Schulz and Hanusa 1978, Baltes and Baltes 1986), quasi-experimental methods exploiting naturally occurring environmental changes of control potential (e.g., Timko and Moos 1989), and large sample surveys (e.g., Krause 1987, Menec and Chipperfield 1997). Findings from all these studies, research paradigms, and assessments of perceived control and health

outcomes converge to show that having high perceptions of control benefits one's health, and having low perceptions of control can be damaging (see also review in Schulz and Heckhausen 1999) (see *Control Beliefs*: *Health Perspectives*; *Health*: *Self-regulation*; *Self-regulation in Adulthood*).

3. *Evolutionary Origin and Ontogenetic Potential of Human Control Behavior*

A common characteristic of all motivated behavior is that the organism attempts to achieve outcomes in the environment by its own activity. In all activities relevant for survival and procreation, such as foraging, attracting a mate, or competing with a rival, the organism strives for control in terms of bringing about desired outcomes and preventing undesired ones. Thus, the most fundamental and universal motivational tendencies relate to this basic strive to control the environment referred to as *primary control striving* (Heckhausen and Schulz 1995, Heckhausen 2000).

The striving for control is shared with a broad range of species and goes back far into the phylogenetic past, probably as far back as to those species which first acquired a notable flexibility in their behavior programs (see review by Heckhausen 2000). This assumption converges with White's (1959) classical article on the motivation for competence, effectance, and mastery as a universal striving of humans and mammals in general.

The fundamental status of control striving in behavior regulation is supported by findings about neonatal behavioral preferences (see review by Heckhausen and Schulz 1995). Neonatal humans are able to detect behavior–event contingencies, learn head movements to control milk reinforcement, and, most importantly, continue to show the control behavior even when after complete satiation the milk reinforcement has lost its consummatory value and merely provides a contingency event to the infants' head-turning behavior.

Humans hold a unique potential for control in terms of pursuing goals, which can involve multiple subgoals and cover extensive time spans. This capacity is based on the mental representation of goals, which renders the organism independent of immediate external response elicitation and feedback, and sets it free for self-regulation.

Another important characteristic of humans' control-related behavior is their sense of self, and their quest for learning about and feeling good about the characteristics of their own self (e.g., about competence). The sense of self is acquired in early childhood, and in itself becomes a motivational incentive for control striving (see review by Heckhausen and Schulz 1995). Control goals are pursued not only for the sake of their outcomes, and the behavior–event contingency they represent, but also in view of the anticipated enhancement or confirmation of self-ascribed capacities to control outcomes. Mental representations of one's own control capacity and of the control potential inherent in a situational challenge are referred to as *perceived control* (Skinner 1996).

Particularly for challenging control pursuits, the anticipation of positive information about one's own competence implied in a successful completion of the control striving becomes a major resource for motivation. Anticipatory positive self-evaluation motivates the individual persistently to invest effort into acquisitional processes. Only this way can time-extended acquisitional processes of expertise development be sustained motivationally. However, this ability to develop conceptions about one's own competence and control also renders the human motivational system vulnerable to experiences of failure (see *Self-regulation in Childhood*). From about 4 years of age, humans perceive failure as negative feedback about their own competence and react with embarrassment and shame (see review by Heckhausen and Schulz 1995). For humans older than 4 years of age, failure may thus undermine self-ascribed competence and perceived control, both important motivational resources needed for persistent primary control striving.

The system of control behavior in humans therefore needs to involve processes that protect and restore conceptions of own competence and mastery. Heckhausen and Schulz in their lifespan theory of control (Heckhausen and Schulz 1995, Schulz and Heckhausen 1996) have proposed to subsume diverse, mostly cognitive processes, which serve to protect motivational resources and focus them on a given goal (i.e., volitional commitment) of primary control striving, under the construct of *secondary control striving*. Among such secondary control processes are those that help the individual to disengage from a futile goal (e.g., devalue goal, increase value of alternative goals) and protect the self against unfavorable implications of failure and loss (e.g., downward social comparison, egotistic causal attributions). In addition, secondary control strategies are also needed for generating and maintaining motivational commitment to a chosen goal (e.g., enhance value of chosen goal, devalue alternatives, overestimate perceived control for goal attainment, Gollwitzer and Kinney 1989, Heckhausen 1999, Wrosch and Heckhausen 1999).

4. *Research About Control of Development*

The study of actual control behavior and control striving, as distinct from perceived control, is an emergent field of research (Heckhausen and Schulz 1995, Brandtstädter 1998, Schulz and Heckhausen 1999). Two major models of developmental regulation, which address processes of individual control

in developmental change, are considered here: the dual-process model of coping by Brandtstädter and colleagues (overview by Brandtstädter 1998), and the life-span theory of control by Heckhausen and Schulz (Heckhausen and Schulz 1995, Schulz and Heckhausen 1996).

4.1 The Dual-process Model: Assimilation and Accommodation

Brandtstädter and colleagues (Brandtstädter 1998, Brandtstädter et al. 1999) view personal control of development as motivated by the fundamental goal of preserving personal continuity and identity. In the service of self-continuity and consistency, the individual can profit from two processes, assimilation and accommodation, which both help to bring desired and actual situations or states into congruence. Assimilation encompasses all intentional action directed at achieving goals. In contrast, accommodative processes are subintentional and help the individual to protect the self by adjusting mental representations (e.g., lowering goal aspiration) to external constraints. These two processes are conceptualized as antagonistic but complementary modes of coping.

In the context of psychological aging, Brandtstädter proposes that accommodative processes play a major role in bringing about the seeming paradox of aging-related decline without costs to psychological well being. He argues that it is through processes of downscaling goals, and adjusting aspirations to attainable outcomes, that individuals maintain their sense of consistent self. Accordingly, the two modes of coping follow inverse developmental trajectories across the lifespan: assimilation decreases, and accommodation increases towards old age.

A particularly important contribution of Brandtstädter's model is its inclusion of subintentional processes (Brandtstädter et al. 1999), by which evaluations of goals and aspiration levels can be adjusted, when goal attainment has become uncontrollable. Without intent and even awareness, the attractiveness of a goal, which has become unattainable in old age, might fade away. Also, cognitions that immunize the self against failure experiences (e.g., deflect self-blame) unwittingly emerge in the individual's mental account of a loss-relevant episode. Such subintentional and subconscious accommodations have been demonstrated in experimental studies, and were shown to be closely associated with superior psychological well being.

4.2 The Lifespan Theory of Control

Heckhausen and Schulz (Heckhausen and Schulz 1995, Schulz and Heckhausen 1996) have developed the lifespan theory of control which proposes that the desire to exert control over ones environment and thus realize primary control rules the system of control behavior. The lifespan theory of control elaborates the distinction between primary and secondary control, originally proposed by Rothbaum et al. (1982) and applies it to the human lifespan. Primary control *striving* is expected to remain the dominant motivator of behavior across the lifespan, while the potential to realize primary control undergoes radical changes across age (see also Heckhausen 1999). The potential for primary control, in contrast, increases during childhood, adolescence, and young adulthood, then reaches a maximum and plateau during mid-life, and declines with the loss of social roles and physical fitness associated with old age. The increasing discrepancy between primary control striving and primary control potential at older ages provides a challenge for the individual, in that it can only be managed by disengagement from age-inappropriate goals and engaging with new more age-adapted goals (see *Coping across the Lifespan*). Such cycles of goal engagement and disengagement can only be mastered by activating specific processes addressing the internal world of the individual in terms of goal hierarchies and motivational commitment. Such strategies are conceptualized as *secondary control strategies*. Brandtstädter's conception of accommodative coping processes emphasizes the nonintentional nature of some goal disengagement and self-protective processes, which he contrasts with assimilative coping that comprises intentional attempts to control developmental losses (Brandtstädter 1998) (see *Coping across the Lifespan*).

Heckhausen and Schulz (Heckhausen and Schulz 1995, Heckhausen 1999) distinguish between four types of control strategies. *Selective primary control* refers to the investment of internal behavioral resources such as effort, time, and skills in the pursuit of a goal. *Compensatory primary control* is required when internally available behavioral resources of the individual are insufficient to attain the goal, and external resources such as help or advice from others or technical aids (e.g., wheelchair) have to be recruited. *Selective secondary control* serves to enhance and maintain motivational commitment to a chosen action goal, particularly when it is challenged by unexpected obstacles or attractive alternatives. Selective secondary control strategies include enhanced valuation of the chosen goal, and devaluation of nonchosen alternatives, as well as positive illusions about one's control, potential for the chosen goal. *Compensatory secondary control* is required when the individual experiences a loss of control and when the goal becomes unattainable or excessively costly. Compensatory secondary control can be attained by disengaging from the obsolete goal. In addition, compensatory secondary control involves specific self-protective strategies, such as self protective causal attribution (avoid self blame; see also *Attributional Processes: Psychological*) and

downward social comparisons, which deflect the potential negative effects of failure experiences on important motivational resources of affective balance and self-esteem.

The theory of control behavior can be integrated with modern motivational action theory, which views motivation behavior as organized in action cycles of goal engagement and goal disengagement Heckhausen 1991). Specifically, goal engagement involves the strategies of selective primary and selective secondary control as well as, in cases of obstacles, compensatory primary control. Goal disengagement relies of the compensatory secondary control strategies of goal distancing and self-protection.

The use of primary and secondary control strategies was investigated in various developmental ecologies during the lifespan (Chipperfield et al. 1999, Heckhausen 1999, Wrosch and Heckhausen 1999). Heckhausen (1999) found in a socially heterogeneous sample of East and West German adults that striving for primary control remained constant across age groups, whereas the flexibility of adjusting one's goals, a key component of compensatory secondary control, increased with higher ages. Chipperfield et al. (1999) investigated the effectiveness of primary and secondary control strategies in a sample of older adults experiencing either acute temporary or chronic severe health stress. They found that primary control strategies had positive health implications for the young–old, but that the same strategies appeared to be detrimental to health in advanced old age.

One way to study the responsiveness of control behavior to different control potential is to study developmental regulation across distinct life-course transitions in control potential (Heckhausen 1999) (see *Self-regulation in Adulthood*). Developmental regulation across the lifespan is organized along a timetable of waxing and waning opportunities to attain important developmental goals, such as graduating from school, building a career, finding a permanent partner, and having a child. The age-graded opportunity structures for various developmental goals involve final time constraints, conceptualized as developmental deadlines. An example is the so-called 'biological clock' for child-bearing.

Developmental deadlines were shown to be the watersheds between urgent predeadline goal engagement and postdeadline goal disengagement and self-protection (Wrosch and Heckhausen 1999). Individuals approaching a developmental deadline, such as the early 40s in the case of child-bearing, activated goal engagement strategies of control (i.e., selective primary, selective secondary, compensatory primary control) fervently striving to attain the goal before the time runs out. In contrast, once a deadline has been passed, (e.g., women in their early 40s or 50s with regard to child-bearing) control strategies of goal disengagement, such as devaluing the goal and self-protective downward comparison with others were preferred. Moreover, it was shown that the employment of phase-congruent control strategies (i.e., goal engagement in the predeadline phase and goal disengagement in the postdeadline phase) was associated with greater psychological well-being and mental health (e.g., less depressive symptoms, more positive affect) than phase-incongruent control strategies.

5. *Future Directions of Research*

Future research about control behavior and control perceptions should take a functionalistic perspective and analyze the consequences that objective changes in opportunities for control have for domain-specific components of perceived control and their behavioral correlates. Specifically, future research can exploit the model of action cycles. In both developmental and non-developmental contexts, control processes associated with goal engagement and goal disengagement can be investigated in terms of their congruence with control opportunities. This approach also allows to study interindividual differences in the ability to recognize changes in opportunity structures and in the flexibility of switching between goal engagement and goal disengagement. This may provide an avenue to investigate interindividual differences in vulnerability versus resilience to developmental transitions.

Control Beliefs: Health Perspectives

Control refers to the ability to influence what is happening or what will happen. *Beliefs* about control in the context of health refer to the thoughts (or cognitions) an individual has regarding the ability to influence health behavior, health status (or other health outcomes), or health care. Control beliefs are one of a number of determinants of health behavior and health outcomes. A person's health status can be influenced by and can influence his or her control beliefs. Individuals who believe they have control over their health behavior are more likely to engage in healthy behavior; thus, they are more likely to have better health outcomes (see *Health Behaviors*). Better health outcomes are associated with more positive control beliefs. Also relevant are beliefs about control over health-care delivery. Believing that one can influence one's own health care is a primary determinant of satisfaction with health care. Perceived control over one's health behavior, health outcomes, and/or health care is different from *desire* for control over these aspects. It is assumed that most individuals desire control over their health behavior and health outcomes; no such assumption is made regarding control over how health care is delivered.

1. Locus of Control

'Locus' refers to the *place* where control (over outcomes) resides—either 'internal' to the individual (i.e., based on his or her own behavior or enduring characteristics) or 'external' to the individual (e.g., due

to other people's behavior, fate, luck, or chance). Although it was once thought that *internal* and *external* beliefs were at opposite ends of a continuum (Rotter 1966), it is now understood that these two belief orientations are independent of one another. That is, a person might simultaneously hold internal and external beliefs about the locus of control of a given phenomenon (e.g., his or her health status; Wallston 1989, 2001). For example, a person newly diagnosed with lung cancer might attribute the diagnosis to such internal factors as a lifetime of smoking cigarettes in addition to poor dietary and exercise habits. At the same time, the person might attribute the lung cancer to such external causes as 'bad genes' (inherited from one's parents), punishment from God, pollution in the environment, and/or poor luck. Furthermore, one's locus of control orientation about the cause of a health problem (its etiology) is unrelated to one's beliefs about responsibility for the course of the problem (i.e., whether it will get better or worse). It is possible to attribute the etiology of a disease to external causes (e.g., a virus) and to adopt an internal orientation to dealing with the condition once diagnosed (e.g., learn everything one can about the condition and its treatment). Many patients with a medical condition believe that health-care professionals either fully or partially control what happens to their health status.

Better health outcomes are typically associated with more internal beliefs about control of one's health. However, an internal health locus of control orientation does not necessarily signify that one attributes only good health outcomes to one's own behavior. For some individuals, having 'internal' beliefs may mean blaming oneself for one's poor health outcomes. Being 'responsible for' one's outcomes does not always translate into being in control of those outcomes. Furthermore, internal beliefs about one's health are only weakly predictive of engaging in healthy behavior or avoiding health risks. Internal beliefs are somewhat more predictive of healthy behaviors for people who highly value having good health compared with those for whom good health is less important, but locus of control only explains a relatively small amount of variance in health behavior even for people who highly value good health (Wallston 1992). Valuing good health and believing that one's health is contingent on one's own actions are necessary, but not sufficient, determinants of health behavior.

2. *Self-efficacy, Mastery, and Competence*

Locus of control is only one type of control belief. Other psychological constructs that are similar to locus of control are *self-efficacy* (Bandura 1977), *mastery* (Pearlin and Schooler 1978), and *competence* (White 1959). Self-efficacy, or the belief that one *can do* a specific behavior in a specific situation, is much more predictive of actually engaging in that behavior in that situation than is an internal locus of control orientation (see *Self-efficacy and Health*). Both mastery and competence are more generalized constructs than self-efficacy, and they encompass control over the situation and outcomes as well as control over behavior. Individuals with a sense of self-efficacy, mastery, or personal competence (and also those with an internal locus of control orientation) generally feel very good about themselves (i.e., have high self-esteem and psychological well-being) and are receptive to learning about and engaging in new behaviors. An internal locus of control orientation coupled with a high degree of self-efficacy, mastery, or personal competence is a potent resource for helping individuals cope with health-related stressors.

3. *Perceived Behavioral Control*

Ajzen (1988) introduced the construct 'perceived behavioral control' into his theory of planned behavior as a determinant of both behavioral intention and of the behavior itself. On a conceptual basis, perceived behavioral control is similar to self-efficacy—both constructs refer to the person's belief that the behavior in question is under his or her control—but, operationally, perceived behavioral control is often assessed by the ease or difficulty of the behavior (e.g., 'I find it difficult to exercise three times a week'), while self-efficacy is operationalized by the individual's confidence in being able to carry out the behavior in the face of extenuating circumstances (e.g., 'I am confident that I can exercise three times a week even when I am away on vacation').

Like Ajzen's theory of planned behavior, most psychosocial theories of health behavior (e.g., the health belief model (Rosenstock 1990), the protection motivation theory (Prentice-Dunn and Rogers 1986), and the health-action process approach (Schwarzer 1999) have incorporated perceived behavioral control as a major determinant of intention to engage in a health behavior and/or as a determinant of actually engaging in the behavior, but these last three theories explicitly label this construct as 'self-efficacy.' Regardless of the label attached to the construct, believing that one has control over a behavior is highly associated with actually doing that behavior.

4. *Perceived Situational Control*

Beliefs about control encompass control over one's situation, as well as control over one's behavior and outcomes. One example of a situation is being a patient in a clinical facility. Does the patient know why he or she is there? Does the patient know what will happen to him or her, and why? What it will feel like? Does the patient have any choice over what will

happen? The answers to these questions partially determine the patient's degree of perceived situational control. In turn, the more control the patient believes he or she has in that situation, the less distressed and more satisfied the patient will be, and the more likely the patient will be able to participate in his or her own care, including adhering to situational demands. This is true regardless of how much control the patient wants in that situation (cf. Wallston 1989).

5. *Helplessness*

Helplessness is the belief that there is nothing that anyone can do to improve a bad situation (such as being diagnosed with an illness). In many ways, then, helplessness is a belief that control over the situation or its outcomes is impossible. Like all beliefs, helplessness is learned (Seligman 1975). Learned helplessness is analogous to a chance locus of control orientation (i.e., the belief that one's outcomes are due to fate, luck, or chance). Helplessness beliefs can be either *universal* (i.e., there is nothing that *anyone* can do) or *personal* (i.e., there is nothing that *I* can do). Either type of helplessness belief is associated with motivational, behavioral, and/or affective deficits. People with learned helplessness are not inclined to learn or engage in new, potentially effective behaviors, and they exhibit higher than normal levels of anxiety and depression.

6. *Assessing Control Beliefs*

A number of well-developed, standardized instruments exist for the purpose of assessing individual differences in control beliefs applicable to health and health-care settings (Wallston 1989, in press). Some of these measures (e.g., Pearlin and Schooler's mastery scale) are general, personality-like instruments, consisting of a single dimension. Others, such as the health locus of control scales developed by the author and his colleagues, are multidimensional and can be adapted to assess control over one's health status in general or control over specified health conditions (e.g., cancer or diabetes). Researchers have also had some success in asking one or two pointed questions about subjects' perceptions of control (see Wallston 2000 for examples), but the psychometric soundness of this approach is questionable. Measures of desire for control are only weakly correlated with measures of perceived control

7. *Altering Control Beliefs*

Because control beliefs are learned, they can easily change as a function of life events (e.g., receiving a new medical diagnosis), or they can be systematically modified through the application of some form of cognitive-behavioral therapy. Shapiro and Astin (1998) have developed an integrated approach to psychotherapy, health, and healing that they term 'control therapy.' Their therapeutic approach is based on a unifying theory of human control 'which is organized around three broad postulates: (a) gaining and maintaining a sense of control is a major motivational force across the human life cycle; (b) there are both higher and lower levels of control-related goals, desires, and strategies by which people seek to gain a sense of control; and (c) there are individual differences with respect to how and why control is sought' (Shapiro and Astin 1998, p. 20).

Control Variable in Research

An important goal of empirical research is to support causal assertions about the effects of explanatory variables on outcome variables (see *Causation (Theories and Models): Conceptions in the Social Sciences*; *Explanation: Conceptions in the Social Sciences*). Extraneous variables that influence the outcome represent potential confounds whose effects must be eliminated before causal assertions regarding the explanatory variable can be made. In its broad sense, the term 'control' refers to a researcher's systematic attempts to eliminate the confounding effects of extraneous variables associated with sampling, measurement, experimental manipulation, randomization, and statistical adjustment. The term 'control variable' is used most commonly in the narrow context of statistical adjustment of potential confounds.

The current presentation of 'control variables' is guided by three broad tenets. (a) Strategies of statistical control and its interpretation depend on an understanding of the nature of the relationship between extraneous variables and the explanatory and outcome variables. The term control variable is best understood within this broader explanatory framework. (b) The nature of potential confounds and therefore the need for their statistical control depends on the specific research design. The need for statistical control increases as the inherent controls imposed by the research design diminish. (c) The potential confounding variable may be observed or unobserved. Although most methodological and empirical literature on statistical control focuses on the control of observed variables, this article is organized around prototypical methods of controlling for both observed and unobserved sources of extraneous variability. This approach highlights the importance of a causal framework for understanding statistical control and also pinpoints the most common cause of the failure of observed variables methods, i.e., the presence of unobserved sources of confound.

1. *Controlling for Observed Variables*

Several methods of control are available when it can be assumed that the potential confounding variables are measured including regression, matching, and propensity score. Regression (Pedhazur and Pedhazur 1991) or analysis of covariance (ANCOVA; Hutiema 1980) based approaches are the most commonly used methods of statistical control. The purpose and interpretation of regression adjustment depends on the specific research design employed.

1.1 *Regression and ANCOVA Based Approaches*

Regression of a dependent variable Y on an independent variable X provides an estimate of the causal effect of X on Y under the critical assumption that all omitted variables C that influence Y are uncorrelated with X. If an omitted extraneous variable C that influences Y is also correlated with the independent variable X, then the regression parameter is biased as a measure of direct effect of X on Y. In this case, the effect of explanatory variable X is confounded with the extraneous variable C. The true direct effect of X on Y (a in Fig. 1) may be obtained by measuring and including C in the model. The key assumption made in regression based approaches is that all extraneous variables are measured without error and included in the analysis.

Figure 1
Path '*a*' shows the direct effect of the treatment on outcome after controlling for the effect '*b*' of the observed covariate

1.1.1 Regression adjustment in randomized experiments. Randomized experiments (Cook and Campbell 1979; see *Laboratory Experiment: Methodology*; *Random Assignment: Implementation in Complex Field Settings*) offer the most robust method for making causal inferences and imply two powerful means of control. These are: (a) the independent or explanatory variable is controlled by direct manipulation. (b) All other sources of extraneous variability are controlled by randomization or chance. Random assignment, *if successful*, makes experimental and control groups probabilistically equal with respect to all potential confounding variables and hence minimizes bias due to initial differences among treatment conditions. As a result, extraneous variables are expected to be uncorrelated with the manipulated variable or the treatment assignment and their exclusion does not bias the estimates of treatment effects. On the other hand, including such variables in analysis reduces the unexplained within-group variability in the outcome, thus increasing the power for detecting treatment effects. Pretest measures of the dependent variable are frequently used for this purpose. It is important to note that randomization may fail to make the experimental conditions equal with

respect to various confounders. In addition, noncompliance and attrition may render various treatment conditions noncomparable.

1.1.2 Regression adjustment in quasi-experimental and nonexperimental designs. In quasi-experimental designs, the independent variable is manipulated in the absence of random assignment (see *Nonequivalent Group Designs*). In these designs, subjects may be nonrandomly assigned to or may self-select themselves into different conditions. For example, in a study investigating the effects of remedial education on achievement, students who are expected to benefit the most may be assigned by the researcher into the treatment condition (see *Selection Bias, Statistics of*). As a result, the groups may not necessarily be equal at baseline with respect to various observed and unobserved characteristics that may influence the outcome of the treatment. In nonexperimental settings, the researcher may wish to infer causation from the observed association between a hypothesized independent variable and an outcome, e.g., the effect of smoking on lung cancer (see *Selection Bias, Statistics of*).

The purpose of regression adjustment in nonexperimental designs is to make the experimental conditions statistically equal with respect to various observed characteristics that may also influence the outcome. The success of regression based approaches in quasi-experimental and observational research depends on the plausibility of the assumption that all potential confounding variables are measured without error and included in the analysis. This assumption may not be tenable in most quasi-experimental settings where self-selection or assignment to treatment may be based on unmeasured expectations about outcome under treatment and control conditions (see *Selection Bias, Statistics of*).

The observed characteristics that are typically controlled to include the pretest measure of the outcome variable and background characteristics such as gender, age, and socioeconomic status. The control variable frequently serves as a proxy for some other unmeasured theoretical variable of interest. This method of controlling for theoretical variables is a common practice in applied settings and leads to a number of additional problems. Proxy variables, unlike the measured indicators of a construct, contain *both* random error as well as unspecified sources of systematic errors. The presence of random measurement error in regressors leads to biased estimates of the regression parameters. On the other hand, the presence of systematic variability other than the hypothesized construct introduces new and unspecified sources of bias. As a result, the use of background characteristics as proxies in evaluation research may result in contradictory findings regarding the effects of the explanatory variable in question depending on the specific set of covariates included in the analysis.

1.1.3 Control variable: validity and differential treatment effectiveness. The use of control variables for statistical adjustment is motivated primarily by a desire to increase the internal validity of the study (see *Internal Validity*). An alternative way of eliminating confounding due to extraneous variables is to include only those individuals at a specific level of the confounding variable. For example, if ethnicity and gender are related to the treatment assignment and to outcome, the researcher may choose to include only white males in the study. Such control by exclusion limits the generalizability of the findings to the population actually included in the study. In contrast, the regression based approach allows generalization across all levels of the controlled covariate present in the sample if the treatment effects are the same within each level of the covariate (see *External Validity*). In other words, the possibility of differential treatment effects across levels of the covariate must be ruled out before the results can be generalized. For example, a specific intervention for treating childhood aggression may be more effective at higher levels of initial aggression. In this case, the initial level of aggression could be included in the analysis along with an interaction term with the manipulated variable to test if the magnitude of the treatment effect depends on the level of the observed covariate. When the interaction between the independent variable and a covariate is significant, the covariate is said to moderate the effect of the independent variable on the outcome (see *Moderator Variable: Methodology*; *External Validity*). In this situation, the arbitrary distinction between an explanatory and a control variable begins to blur. The researcher must now explore the mechanism of differential treatment effectiveness and ascribe proper causal status to both the covariate and the explanatory variable.

1.2 Propensity Score

In contrast to the regression approaches, the propensity score approach explicitly models the treatment selection/assignment process using the *observed* background characteristics (see *Selection Bias, Statistics of*). The *propensity score* $P(\mathrm{T}|\mathrm{C})$ is the probability that an individual with a given set of background characteristics C will be assigned to a particular treatment group (Rosebaum 1995). If C also has an effect on the outcome variable, then conditional on the propensity score, the treatment assignment will be random with respect to the outcome. The propensity score captures the collective influence of all observed covariates on

Figure 2
Path '*a*' shows the direct effect of the treatment on outcome after controlling for the effect '*b*' of the Propensity Score estimated using two observed variables C1 and C2 (not shown)

treatment assignment. In other words, by controlling for the propensity score, it is possible to control for all observed characteristics that determine treatment assignment. This can be achieved by including the propensity score in the regression equation (Fig. 2) or by matching on propensity score. The propensity score may be estimated using logit or probit regression by regressing observed treatment assignment on the set of covariates and their interactions.

2. *Controlling for Unobserved Variables*

Both the regression and propensity score methods make a strong assumption that all potential sources of confound are measured and included in the analysis. It is likely that selection into or exposure to a treatment depends on a subject's expectations regarding the outcome. For example, an individual's implicit beliefs regarding expected outcomes in the treatment and control groups may influence their decision to participate in a particular treatment as well as the eventual outcome. Even in randomized experiments, treatment compliance and attrition may be related to such unobserved variables. In this situation, observed background characteristics may not contain relevant information regarding a subject's decision process. As a result, methods of control based on observed variables are likely to produce biased estimates of treatment effects. Rosebaum (1995) provides methods of assessing the sensitivity of the results to potential hidden biases in the context of observational studies. The problem of isolating true causal effects from observed association in the presence of latent confounds can be thought of as an identification problem. If one is willing to make certain assumptions about the

Figure 3
Path '*a*' shows the direct effect of the treatment on the outcome independent of the correlation (*r*) between the residuals for the treatment (*u*) and the outcome (*v*). This effect is identified by the presence of an instrumental variable that is presumed to influence the outcome exclusively via its effect on the treatment assignment (path *b*)

nature of treatment effects under various conditions, it is possible to express treatment effects using inequalities or bounds (Manski 1995).

Alternatively, the identification issue can be resolved by measuring additional variables that are causally related to the explanatory and outcome variables but are *assumed* to be independent of the unobserved confounds. In other words, the presence of such variables allows the true causal effects of an independent variable to be isolated from the unobserved sources of confounds. Such variables can help identify the true causal effects under two circumstances: (a) if the effects of these variables on the outcome are entirely mediated by the independent variable or (b) if the variable mediates the effect of the independent variable on the outcome.

2.1 *Instrumental Variable Method*

The instrumental variable approach for controlling unobserved sources of variability is the *mirror opposite* of the propensity score method for controlling observed variables (Angrist et al. 1996, Winship and Morgan 1999). Unlike an observed control variable, an instrumental variable is *assumed not* to have any *direct effect* on the outcome. Instead, the instrumental variable is thought to influence only the selection into the treatment condition. In other words, the effect of the instrumental variable on the dependent measure is entirely *mediated* via its effect on treatment assignment (*b* in Fig. 3). This condition is also known as *exclusion*

Figure 4
The direct effect of the mediator on outcome is represented by '*a*' and that of the treatment assignment on the mediator is represented by '*b*'. The unobserved common-cause of treatment assignment and outcome is assumed not to influence the mediator. As a result, the mediated effect of the treatment on the outcome ($a \times b$) is independent of the confounding due to plausible common cause

restriction (see *Endogeneity: Methodology*). If the independent variable were regressed on the instrumental variable, the residual would contain all unobserved sources of variability that determine treatment assignment and also influence the outcome variable (represented by the correlation *r* in Fig. 3). As a result, the existence of an instrumental variable *identifies* or *isolates* the average direct effect (*a* in Fig. 3) of the treatment on the outcome independent of the unobserved sources of variability. The success of this strategy rests on the reasonableness of the assumption of exclusion restriction.

2.2 Mediator Variable Method

The effects of unobserved confounds may be isolated in a radically different fashion by modeling the causal mechanism by which the treatment influences the outcome (Pearl 2000). In this approach, the goal is to find an observed variable that *mediates* the effect of the independent variable on the outcome *but is unrelated to the unobserved common cause* (see *Mediator variable*; Fig. 4). For example, in the past cigarette companies have claimed that the relationship between smoking and lung cancer is spurious: a result of a gene (common-cause) that leads to craving for tobacco and also causes lung cancer. If such a common cause in fact existed, it is still possible to isolate the independent effect of smoking on lung cancer by identifying a variable that mediates the effects of smoking on cancer but is *not influenced by the hypothesized common-cause*. For example, tar in lungs is one such variable known to cause cancer which accumulates in lungs as a result of smoking, passive smoke inhalation, and environmental pollution. It is reasonable to argue that the level of tar in lungs is not caused by the common-gene, especially among the passive smokers. The existence of such a mediator variable can statistically identify the effect of the independent variable on the dependent variable ($a \times b$ in Fig. 4) even in the presence of unobserved sources of confounding. It is to be noted that the instrumental and mediator variables are not control variables themselves. Instead, the use of these variables identifies true treatment effects by isolating the confounding effects of other unobserved sources of variability.

Control: Social

An important concept of US sociology at the beginning of the twentieth century, social control referred to those aspects of social life contributing to the social order. It was used to answer a perennial question in sociology: How is it that social order is possible? In the 1970s, a shift in meaning became noticeable. Sociologists and historians studying state institutions designed to deal with deviants, like prisons and mental health facilities, gave it a pejorative connotation: Social control came to mean coercion, manipulation, labeling, and stigmatization. At the beginning of the twenty-first century, the term is more often used in criminology than in sociology. Two different meanings can be found. First, in control theories, it means informal social controls imposed on juveniles within the family and the school. Second, it is sometimes used

as a synthetic term to include all the actions and institutions intended to curb crime.

1. The Original Meaning in Sociology

In the eyes of the early sociologists, the question of how society curbs individual passions and interests so as to perpetuate itself in peace, was of paramount importance. Social control 'referred to the capacity of a society to regulate itself according to desired principles and values' (Janowitz 1975, p. 82). In 1901, E. Ross published a book called *Social Control. A Survey of the Foundation of Order* which was influential in putting the concept at the center of US sociology. The question he undertook to answer was: 'How is it that people come to live together and cooperate with that degree of harmony we see about us?' A kind of natural order emerges first from people living together with their capacities for sympathy, sociability, sense of justice, and resentment. Second, society develops a certain measure of control over the individual. The means of control surveyed by Ross (1901) cover a whole range of social practices and institutions: public opinion, law, belief, social suggestion, education, religion, personal ideals, ceremony, art, social valuation, etc. According to Ross, social control includes all those aspects of social life inducing conformity amongst individuals and contributing naturally to the social order.

Ross shared the preoccupations of Emile Durkheim, who was also trying to discover the roots of social harmony. The French sociologist used the term 'social constraint' to refer to the influence of the 'collective conscience' on individuals. The pressures of society on the individual does not take only the form of external constraints, it also creates a sense of moral obligation to accept duties and to obey the rules (Durkheim [1893] 1960, 1895, 1923).

Following Ross, sociologists of the Chicago School, like Park, Burgess, and Thomas, continued to place social control at the center of sociology. 'All social problems turn out to be problem of social control' (Park and Burgess 1921, p. 785).

While developing the concept of social control, the early sociologists had another agenda besides explaining social order. They wanted to demonstrate the capacity of sociology to explain social facts more completely than economics or plain common sense. They first wanted to show the limitations of Adam Smith's analysis of the natural harmony of interests fostered by the famous invisible hand of the market. Economic self-interest cannot fully account for the existence of the social order (Pitts 1968, Janowitz 1975). They also wanted to debunk the common sense assumption that order resides in the hands of the police, judges, prison guards, and the like. Cooperation, harmony, and organization do not rest predominantly on coercion nor on utilitarian calculations but on subtle pressures, expectations, and informal sanctions in the family, in the peer group, the workplace, the local community, etc. However, if social control is neither market regulation, nor state control, nor coercion, we are left with a notion referring essentially to informal social control. But if we stick to the ambition of taking into account most of the social order, how is it possible to ignore the utilitarian and coercive ways of achieving it?

Another problem emerges: by its very nature, social control is a static concept. When it occupies a central place, sociology becomes the science of social order, unable to analyse social disorder or social change. During the 1920s and 1930s, 'sociologists became so caught up with the source of cohesion that they neglected to examine the source of change' (Rothman 1983, p. 108).

Those problems cooled the enthusiasm of sociologists for the concept. Some restricted it to the control of deviance. In many contemporary textbooks and handbooks of sociology, one finds a chapter on deviance and social control (e.g., Scull 1988). After the 1970s, the few sociologists attempting to write on general theory do not make more than a passing mention of the term. The search for the foundation of social order is no longer conceived in terms of the control of society on individuals. A major sociologist like Coleman (1990) explains the social order with the concepts of interdependence; transaction (including exchange, bribes, threats, promises, and resource investment); authority relations; rights; and norms.

2. The Skeptic Reaction

In the 1960s and 1970s, sociologists critical of the rhetoric and reality of the institutions dealing with deviants (mainly prisons and mental hospitals) gave a whole different tone to the term. Social control came to mean first those stigmatizing actions putting in motion an amplification of the deviance process, and second those bureaucracies pretending to reform and treat deviants but, in fact, indulging in manipulation and coercion.

2.1 Labeling

In labeling theory, social control refers mainly to those reactions of police officers, judges, psychiatrists, etc. which consist of arresting, condemning, classifying, and incarcerating. Somebody comes to be classified as criminal, mentally disturbed, dangerous, or deviant in one way or another, and is set apart in a prison, an asylum, or any other place of exclusion. Those reactions mark such individuals, they stigmatize them, they attach a label to their personality. Doing so, they not only modify the social identity of the individuals but also their self-perception, their way of life, and their behavior. 'The experience of being caught and publicly labelled as a deviant … has important conse-

quences for one's further social participation and self-image' (Becker 1963, p. 31). 'Treating a person as though he were generally rather than specifically deviant produce a self-fulfilling prophecy. It sets in motion several mechanisms which conspire to shape the person in the image people have of him' (Becker 1963, p. 34). Instead of producing order, the attempt at social control amplifies the deviant tendencies of the labeled person (Wilkins, 1964). The arrest, the sentence, the psychiatric diagnostic, the imprisonment, or the institutionalization in a mental hospital puts individuals subjected to one of those treatments at risk of internalizing the infamous label while putting them at the margin of society. They might feel obliged to become part of a deviant group and act as one of the gang. Accordingly they might become more deviant after being labeled than before.

The labeling theory has been criticized mainly on two counts. The labeling process is not totally arbitrary nor completely unrelated to the pre-existing deviant behavior and characteristics of the labeled individual. More often than not, the court condemns accused people who really committed a crime, and generally, the more serious the crime, the more severe the sentence. The number of crimes committed in the past by an individual is also related to the severity of the punishment. If such is the case, the question to be asked is: Does the label create a new social identity or is it just a disclosure of a deviant identity already there?

Empirical tests of the labeling hypothesis provide an inconsistent picture, with some researchers finding a weak effect of social reaction on subsequent offending, others failing to find one. The overall impact is small. 'The preponderance of research finds no or very weak evidence of labeling effects. The more carefully the research keeps other factors constant, the less likely it is to find evidence that labeling has significant effect on criminal or deviant behavior' (Akers 1994, p. 134, see also Braithwaite 1989).

2.2 The History and Sociology of State Dealing with Deviants

A related trend of research focuses not so much on the effects of social control but on the characteristics and evolution of state institutions dealing with offenders, mental patients, and other deviants. In this context, social control is defined as 'the organized ways in which society responds to behavior and people it regards as deviant, problematic … or undesirable' (Cohen 1985, p. 1). As with labeling theory, the concept carries strong pejorative overtones. Gone are the benevolent informal controls to be replaced by coercion, the repressive state, and the manipulation used by the powerful against the lower classes. The negative overtones come also from a disenchantment with the rehabilitative ideal and from skepticism concerning the so-called reform movement with its self-serving ideologies (Rothman 1983). The historians and sociologists working in this perspective embark upon a work of demystification, confronting the official discourses with the real functioning of the social control apparatus. Psychiatrists and correctional officials pretend to treat and rehabilitate; in fact, they cannot help but keep on putting mental patients in total institutions and incarcerating offenders. Reformers speak of decarceration, decriminalization, and diversion, but in fact the old prison system remains, more crimes are created by the law, and new deviants are caught in the social control net. 'Overall, the system enlarges itself and becomes more intrusive, subjecting more and newer groups of deviants to the power of the state and increasing the intensity of control directed at former deviants' (Cohen 1985, p. 38).

This discrepancy between discourse and reality, between what officials say they do and what they do in fact, is an enlightening exercise provided that it goes beyond plain conspiracy theory.

The main contribution of authors working in this perspective is in the history of changes in punishment in Europe and the USA beginning at the end of the eighteenth century. Foucault (1975) and Ignatieff (1978, 1983) documented the following trends: (a) a sharp decline in physical punishments inflicted in public in order to inspire terror in the spectators; (b) the emergence of the prison as the dominant punishment for serious crimes; (c) the creation of the penitentiary, an institution pretending to reform, deter, and isolate prisoners not only from the outside world but also from the criminogenic influence of their fellow prisoners.

In a related vein are sociological studies of the internal functioning of mental hospitals and prisons, like *Asylum* by Goffman (1961). The thesis of the book is that institutions like prisons, mental hospitals, concentration camps, and even monasteries share some basic characteristics. They are all total institutions in which guards, nurses, doctors, etc. are given the mission and the power to control the inmates and isolate them from the outside world. In those total institutions, the dominating group organizes everyday life in minute details for maximizing their control over inmates. They impose detailed regulations so as to make the inmate's behavior most predictable. Swift punishment and degrading measures are visited upon the rebellious.

3. Social Control in Criminology

Nowadays, it is mostly in criminology that the term social control is found. It is often used in the same skeptical spirit in which the term was used by sociologists criticizing the state's apparatus of control. Some criminologists, though, remain faithful to the orientation of the early sociologists preoccupied with the foundation of social order. One aspect of this

social order which, for obvious reasons, is the focus of criminologists, is a society having a tolerable level of crime. Accordingly, social control is conceived as the means to achieve it.

3.1 Control Theory

Instead of asking the usual question, 'Why do people commit crimes?,' criminologists who developed the control theory turned the problem around and asked 'Why do people obey the rules of society?' 'Deviance is taken for granted; conformity must be explained' (Hirschi 1969, p. 10). Basically, this is the kind of questioning which was at the center of the works of Hobbes, Durkheim, and Ross.

Control theory was mostly used to explain juvenile delinquency or, more precisely, its absence. Such was the intention of Reiss (1951). He was able to show that delinquency is a result of 'a failure of personal and social control.' Of interest is his definition of social control: 'the ability of social groups to make norms or rules effective.'

It is Hirschi's (1969) formulation of control theory that is the most influential in criminology. His basic proposition is that 'delinquent acts result when an individual's bond to society is weak or broken' (p. 16). For adolescents, the bond materializes in the family, at school, and with their peers. This bond is made of four elements: attachment, commitment, involvement, and belief. Attachment means the close emotional ties to parents, school teachers, and peers, and caring about their expectations. Commitment is the investment in conformity, in education, and in a future career that would be jeopardized by violating the law. Involvement is the time spent in legitimate activities, like studying, taking part in sports, or leisure activities in the family. Belief refers to the adhesion to the rules of society, to the conventional values, to the idea that law has a moral value and should be obeyed. Hirschi provided the measures for those elements of the bond and a persuasive demonstration that the stronger young people's ties to society (in fact, the family and the school) are, the fewer delinquent acts they report.

Later research found many confirmations of the theory, especially with the attachment and involvement constructs. It is beyond contest that juveniles attached to their family and school do not tend to indulge in delinquency. Also, strong involvement, measured by educational and occupational aspirations, is related to a low level of delinquency (Akers 1994, pp. 116–20, Braithwaite 1989, pp. 28–9).

3.2 Promising Trends

Control theory refers to informal social control, leaving aside the law and other formal controls. This is not to say that the latter are neglected in contemporary criminology. On the contrary the focus is increasingly on official controls and the evaluation of their effectiveness. The revival of deterrence theory is a case in point. In its classic formulation, the deterrence hypothesis predicts that the frequency of crime will vary inversely with the certainty, celerity, and severity of punishment handed by the state. Recent researchers cannot find much deterrent effect of severity on crime, but crime rates tend to be low when the certainty of punishment (often measured by the police clearance rate) is high. It is also the case that there is much more evidence of a general effect of certainty on crime rate (general deterrence) than on the level of recidivism of punished offenders (specific deterrence) (Andenaes 1974, Gibbs 1975, Blumstein et al. 1978, Cook 1980, Nagin 1998).

However, there are other ways to limit crime than deterrence and informal controls. The state uses nonpunitive ways to keep crime at bay, like therapies to rehabilitate or reform offenders and crime prevention measures such as street lighting, surveillance of public areas, gun control, and regulations on car antitheft systems. In civil society, crime control activities are very common. Everybody devotes time, money, and effort to protect their goods against theft and to safeguard their person against aggression. People put their money in banks, lock the doors of their houses, avoid dangerous places; in some cases, they even buy guns for self-protection. Businesses and other organizations spend considerable amounts of money to protect their assets from loss or crime: They hire private guards, control access to their premises, use safes, install CCTV, etc.

All those actions and precautions—public and private, formal and informal, repressive and preventive—are clearly aimed at reducing the probability of a crime occurring. As such, their common goal is crime control. This leads us to a last definition: the social control of crime refers to all the means specifically aimed at reducing the probability or severity of crime.

The reader will note that social control is now defined by its intention or aim, not by its results. By doing this, we follow Gibbs (1989, pp. 23–4) who criticizes the sociological concept for belittling the intentional quality of social control. In its common use, the term 'control' conveys intention: one tries deliberately to control, to direct, to influence another. Actions having the unintended effect of preventing crime no doubt exist. For example, Felson (1998) explains the sharp decline of crime rates starting in 1994 in the USA by the coming of a cashless society. People use more credit cards and the like, so they have less cash in their pockets and their houses. Having less cash to steal, the offenders become less active. In this instance, we should not speak of social control but of an unintended preventive effect of an economic evolution.

Results (more or less crimes) are important matters but should not be included in the definition of social

control. Attempts at social control, including failures, are social control. The latter's impact is not a matter of definition but of evaluation. Because of their exclusive focus on scientific evaluation, Sherman et al. (1998, p. 2) chose another path. They define crime prevention not by its intention but by its consequences. It is 'any practice shown to result in less crime than would occur without the practice.'

If social control is made of intentional actions and choices, is it possible to conceive its impact on offenders in terms of actions and choices? The potential offender—that is, the individual having the intention to commit an offence—might choose to do it despite social controls or not to do it because of them. Such an individaul is a decision maker acting under the constraints of social control.

The impact we try to have on offenders when we attempt to control crime is essentially to: (a) increase the effort of commiting crime (e.g., by target hardening or gun control); (b) increase the risks (by surveillance, punishment, burglar alarms, and the like), (c) reduce the anticipated rewards of crime (by target removal, identifying property, etc.), and (d) removing excuses used by offenders to minimize the moral opprobrium cast on crime (e.g., by rule setting and public condemnation of crime) (Clarke 1997). If potential offenders live in a well-ordered society where those impacts are achieved, they will find themselves in a radically different choice situation than in a disorganized society where social controls are erratic. Most of the time they will find commiting crime difficult, risky, unrewarding, and reprehensible. If they are minimally rational (Cornish and Clarke 1986), they will tend to look for noncriminal alternatives. This means that where and when the social controls operate reasonably well, they shape the alternatives of choice for social actors. They close most of the criminal options for of us. They attach quite negative utilities (in the economic sense) to the criminal options. To commit crime in such a situation, one needs a fair amount of greed, temerity, disregard for long-term consequences, or plain foolishness.

Logically, the more serious a type of crime is, the more it should be worthwhile controlling. In fact, we find that guardianship is lax when minor valuables are to be protected and increased when major valuables or life must be protected. Police detectives work harder investigating murders than burglaries. The positive relation between the gravity of crime and the severity of punishment, as well as between the gravity of crime and the certainty of punishment are basic facts of research on penal decision making (Gottfredson and Gottfredson 1980). This heightened pressure of social controls on the most serious crimes will give incentive to offenders to choose the least criminal option, the least severe offence in the eventuality that they persist in crime. That should explain the inverse relation one finds between the frequency of a type of crime and its severity (there are fewer murders than robberies, and fewer robberies than burglaries). Those pressures on criminal choices can be called the structuring effects of social control (Cusson 1993).

However, the lesson learned by sociologists and historians, showing that social controls often operate in an erratic manner, should not be forgotten. Formal and informal controls are not in place where they should be for a number of reasons: groups are too disorganized, resources are lacking, the acts do not follow the rhetoric. This is to mean that the quality and intensity of social control have every reason to be highly variable in space and time. In turn, this uneven quality and intensity of social control should not be unrelated to the uneven distribution of crime rates in space and time.

Conventions and Norms: Philosophical Aspects

The predominant view of 'convention' is that it describes a kind of equilibrium behavior among individuals in a strategic situation, a basic feature of which is the existence of at least one potential alternative equilibrium. A convention is therefore an arbitrary but stable social regularity. 'Norm' has several meanings. It can refer to a mere statistical regularity or, in moral theory, a prescriptive rule for human behavior. In the sense pursued here, however, a norm describes a regularity of behavior among a population of individuals, the central feature of which is that most or all of the individuals approve conformity to the regularity and/or disapprove nonconformity. Thus, conventions and norms are distinct but overlapping social regularities.

1. Introduction

A few (putative) conventions will identify the topic and illustrate its importance. A common example is the regularity of driving on only one side of the road (left or right). Another is monetary currency (see Hume [1740] 1978, p. 490). The convention here is to treat a particular form of metal or paper as having value sufficient to exchange it for goods and services whose value is otherwise (without the convention) far greater. In each case, an individual wishes to follow the regularity once it arises—to avoid the danger of driving into oncoming traffic or the inefficiency of barter. Yet these conventions are arbitrary: everyone driving on the left works like everyone driving on the right; everyone accepting one paper form as currency works much like everyone accepting another.

Language is similarly thought to be conventional because different sounds could be used to refer a given thing, but to communicate successfully, an individual is better off using the sound that others use. One might object to the idea that *all* of language is a convention if a convention is thought to require a *convening*, i.e., an actual agreement. An agreement to use certain sounds as language must be expressed in language, so some language must exist prior to any agreement based convention (see Quine [1936] 1967). Lewis (1969) and others have since argued that a convention can occur without any agreement, suggesting that language may indeed be conventional.

Language provides one example of the significance of conventions. A clear understanding of conventions may illuminate a variety of other important social phenomena. Hume ([1740] 1978, pp. 477–513) contended that justice, particularly the institution of property, was based on convention (see Vanderschraaf 1998). Some theorists give conventions a central role in the theory of morality or law (see *Law and Morality: An Analytic Perspective* and *Law and Morality: A Continental-European Perspective*; *Ethics and Values*). Conventions and norms (discussed below) also explain 'spontaneous order' that arises without a centralized force such as the state. If so, conventions (or norms) might sustain some forms of cooperation in the 'state of nature' and thereby complicate or refute social contract theories that justify the state by the disorder that exists in its absence (see Skyrms 1996, Taylor 1987). Once the state exists, spontaneous order may limit the domains in which state power is necessary

(see Ellickson 1991), or contrarily, state action may be necessary to restrict or unsettle undesirable conventions (or norms) (see McAdams 1997, pp. 409–32).

2. Defining 'Convention'

2.1 Convention as Agreement or Jointly Accepted Principle of Action

In one view, a convention is a 'jointly accepted principle of action' (Gilbert 1989, p. 377). A principle of action is a rule prescribing (at least presumptively) how to behave in certain situations. An individual can adopt a principle of action unilaterally or jointly. Gilbert (1990, p. 16) gives an example of the latter: *A* chastises *B* for failing to adhere to a previous regularity they had observed (about who phones back when they are accidentally disconnected) without prior agreement. *B* acquiesces in the criticism and apologizes. By this communicative exchange, Gilbert says the parties have created a convention by 'jointly accepting' a principle of action requiring behavior they previously engaged in without convention.

Joint acceptance does not, however, explain the common intuition that conventions are in some sense arbitrary. Suppose two individuals face the prospect of a recurrent situation in which neither can survive unless each takes some specific action. On this view, if the individuals jointly accept the only principle of action that will save their lives, the principle is a convention although it is in no sense arbitrary. In addition, Gilbert's example reveals how close this understanding of convention is to the idea that conventions are agreements. Arguably *A* and *B* have implicitly agreed because each believes that *A*'s criticism impliedly asserted the existence of a mutual obligation and that *B*'s acquiescence revealed *B*'s assent to this assertion. The joint acceptance idea clarifies how agreements produce conventions, but not how conventions arise without agreement.

2.2 Conventions as Solutions to Recurrent Coordination Games

Lewis' *Convention* (1969) is the origin of an alternative view of convention, one that explicates the way in which they are arbitrary and contends that no explicit or implicit agreement is necessary. Lewis (1969, p. 42) initially modeled conventions as solutions to recurrent coordination games. A *game* is a situation in which the outcome of any one's action depends on the decisions of other individuals as well as one's own. In game theory, *players* (usually) rationally choose among alternative *strategies*. Each combination of the players' strategies produces an *outcome*, which consists of a utility index for each player (see *Rational Choice Explanation: Philosophical Aspects* and *Game Theory: Noncooperative Games*).

	C1	C2	C3
R1	1 1	0 0	0 0
R2	0 0	1 1	0 0
R3	0 0	0 0	1 1

Figure 1
A pure coordination game

Pure coordination games involve purely common interests among the players. Consider people who want to meet each other but who have failed to communicate in advance where to meet. Lewis (1969, p. 9) uses the matrix in Fig. 1 to describe such a coordination game involving two players and three possible meeting places. One player—'R' for Row-chooser—can play strategies R1, R2, or R3, which consist of going to places P1, P2, or P3, respectively. The other player—'C' for Column-chooser—can play strategies C1, C2, and C3, which consists of going to the same three places, respectively. The players choose their strategies simultaneously, not being able to observe what the other has done. Each receives more utility from meeting (1) than from not meeting (0). (The number in the lower left corner of a cell represents the utility of Row-chooser; the upper right number states the utility of Column-chooser.) Each player therefore has an interest (equal in this example) in coordinating his or her action with that of the other player.

Specifically, R wants to coordinate by playing R1 if C plays C1, R2 if C plays C2, and R3 if C plays C3. C wants to play C1 if R plays R1, C2 if R plays R2, and C3 if R plays R3. Taken together, these observations identify three pure-strategy *Nash equilibria*, outcomes in which no one player can gain by changing his or her strategy: R1/C1, R2/C2, and R3/C3. For example, R1 is the best response R can make to C1 and that same strategy—C1—is the best response C can make to R1. Thus, given R1/C1, neither player would want to switch strategies unilaterally. The same is true for R2/C2 and R3/C3. (There are also *mixed strategy*

Nash equilibria, as where R and C each go to each of the three places with a probability of one-third.)

This analysis reveals the need for *coordinated expectations*. Except by accident, players 'solve' a coordination game only if they have accurate expectations about what the other(s) will do. In the example, each player needs to *expect* the other to go to the same place, for example, P1. But if each player knows the other wishes to meet, then, except by accident, it seems that R will expect to meet C at P1 only if R believes that C expects to meet R there as well. But C will expect to meet R at P1 only if C believes that R expects C to go there. Lewis (1969, pp. 52–60) claims the need for *common knowledge*. Common knowledge of a fact x means that everyone in the relevant population believes x, believes that everyone believes x, believes that everyone believes that everyone believes x, and so on, *ad infinitum*. Except by accident, coordination seems to require that each player have common knowledge of what the other(s) will do.

Finally, consider how a coordination game can recur. Such a situation would exist if, on repeated occasions, R and C find themselves involuntarily separated in a crowd and in need of a meeting place. More generally, the question of which side of the road to drive on, what paper to use as currency, and what sounds to use to communicate, all arise repeatedly.

A convention may then be provisionally understood as a pure-strategy Nash equilibrium to a recurrent coordination problem. A convention consists of the coordinated expectations that produce the equilibrium and the regularity of behavior the equilibrium represents. Because the situation is a coordination game, the equilibrium is arbitrary in that there is at least one alternative equilibrium.

2.3 Convention as an Arbitrary Equilibrium

In several ways, Lewis' approach is narrow. First, Lewis (1969, p. 78) requires common knowledge even of the fact that there is an alternative equilibrium. This condition is not necessary to make the regularity stable; knowing the alternative might even make it less stable. The condition thus excludes an arbitrary regularity from being a convention merely because most individuals never discover, or later forget, what the alternative is. On this view, a population's language would not be conventional if the population were unaware of the possibility of other languages (see Burge 1975).

Moreover, certain aspects of a pure coordination problem seem unnecessary to the definition of convention. Lewis' final definition (1969, p. 78) generalizes beyond coordination games, but only to overcome a problem in describing the recurrent situation when the behavior is continuous rather than discrete. Lewis retains two significant features of pure coordination games, requiring that (a) 'almost everyone has approximately the same preferences regarding all possible combinations of actions,' and (b) 'almost everyone prefers that any one more conform to [the regularity], on condition that almost everyone conform to [it].' The latter point means that most individuals conditionally prefer both their own conformity *and* the conformity of others. Each requirement excludes regularities that are plausibly conventions.

	C1	C2
R1	1 5	0 0
R2	0 0	5 1

Figure 2
A simple mixed motive game

First, there is an element of coordination in many games that also involve conflict. As long as there is some common interest, one may wonder why the equilibrium outcome, when others are possible, is not a convention. For example, in Fig. 2 (sometimes called 'the battle of the sexes' based on an early illustration), each player prefers coordinating at Nash equilibria R1/C1 or R2/C2 to either other outcome. But each player also strongly prefers one equilibrium to the other and these preferences conflict. Thus, the players do not have 'approximately' the same preferences for outcomes (which they would if we replaced each 5 with, say, 1.05). Lewis would not count a solution to this game as a convention even though it were one of two equilibria and the players each prefer coordinating at an equilibrium than reaching a nonequilibrium outcome.

Another weakness in Lewis' account is his requirement that the players conditionally prefer *other* players' conformity even though the stability of a regularity depends only on players preferring their own conformity. With a mix of common and conflicting interests, players may prefer that other players deviate from any of the multiple equilibria. In Fig. 3, R1/C1 and R3/C3 are the only Nash equilibria. As in Fig. 1, the players are indifferent between these equilibria and prefer to coordinate on either than to reach other outcomes that are worse for each (R1/C3, R2/C2, and R3/C1). But unlike Fig. 1, in each of these equilibria, the players do *not* prefer that the other conform to the equilibrium because each would gain by the other playing a different strategy. At R1/C1, R

	C1	C2	C3
R1	4 5	2 7	3 1
R2	5 3	0 0	5 2
R3	2 4	3 7	4 5

Figure 3
Adapted from Kornhauser 1996, p. 209

prefers that C plays C2 and C prefers that R plays R2. The same is true at R3/C3.

Lewis (1969, pp. 45–6) acknowledges the point with this example: suppose those planning to attend a party wish to wear the same style of clothing that others wear. But suppose many 'nasty' people prefer that many others fail to conform to the regularity and thereby suffer embarrassment. Because these nasty people do not conditionally prefer that most others conform, Lewis would not consider it a convention even if, based on coordinated expectations, everyone arrives at the party dressed in the same style. The more common intuition is that, regardless of nasty preferences, a stable and arbitrary clothing regularity is a convention (see Miller 1986, p. 123).

These examples suggest dispensing with the requirements that players have approximately the same preferences for all outcomes and conditionally prefer that others conform. A convention may then be broadly defined as *the coordinated expectations that sustain a pure-strategy Nash equilibrium, in circumstances where multiple pure-strategy equilibria are possible, and the behavioral regularity that the equilibrium represents*. Some would add stability conditions that narrow the definition. Others would expand the equilibrium concept (see Vanderschraaf 1995) and possibly include mixed strategy equilibria where individuals play different pure strategies, each with some probability.

On such a broad view, many more regularities are conventions. For example, in an iterated prisoner dilemma game, there can be multiple equilibria, some of which involve strategies of contingent cooperation. Contingent cooperation can then be conventional even though the players do not have approximately the same preferences for all outcomes. Iterated 'hawk/dove' games may produce conventions even though players do not always prefer others to conform (see Bicchieri 1993, Sudgen 1986). The definition still excludes behavioral regularities (a) that do not arise from situations of strategic interaction (e.g., breathing and sleeping) and (b) that arise in games with only one equilibrium (e.g., a one-shot prisoner's dilemma).

3. *How Conventions Emerge*

The simplest way to produce the coordinated expectations necessary for a convention is by *agreement*. When the parties have sufficiently (not necessarily purely) common interests, there is no need to enforce the agreement. If C and R desire to meet, the agreement to meet at P1 may give each a reason to expect the other to go to P1. Neither has a reason to defect from the agreement. But the game theory account of convention purports to explain their emergence without agreement. Some conventions—language and other forms of spontaneous order—seem to require such an origin. How could people form coordinated expectations without agreement?

Much of game theory addresses how players reach equilibrium (see *Rational Choice Explanation: Philosophical Aspects* and *Game Theory: Noncooperative Games*). The issue is complex and unsettled. It is often quite difficult to demonstrate that players will reach any equilibrium using the common assumption that players are perfectly rational. In a single instance of a coordination game, for example, there is no purely rational basis for expecting a player to select one particular equilibrium outcome. Game theorists believe, however, that players might coordinate on a 'salient' equilibrium or, if the game is recurrent, that players' strategies might evolve to an equilibrium.

Empirical data suggests that people can solve coordination problems without agreement. Schelling (1960, pp. 54–8) experimented with such problems and found that the psychological 'prominence' of certain solutions provided the players 'focal points' for coordinating. For example, when the game was selecting a single time of day to meet another, most players selected noon; when asked to select the same positive number, two-fifths selected 1; and when asked to pick a meeting spot on a map, most players selected the only unique feature on the map (for similar results, see Mehta et al. 1994). Apparently, people sometimes solve coordination problems by selecting what each believes the other is most likely to perceive as unique. Lewis (1969, pp. 35–6) calls this psychological feature *salience*. As he observes, what is salient need not be the most desirable, but may even be the least desirable equilibrium (but is still more desirable for each than noncoordination).

The empirical effectiveness of salience seems sufficient to demonstrate that conventions can arise

without explicit or implicit agreement. But salience itself is difficult to analyze. Salience does not seem to work by rationality alone. Knowing that one equilibrium strategy 'sticks out' from the rest does not justify expecting other players to select it unless one knows that those players favor salient outcomes, which is not required by rationality. Also, rationality alone does not explain what *is* salient, that is, it does not explain how to select among various dimensions by which to evaluate uniqueness. Similarly, in recurrent games, *precedent* may supply a means of coordinating, but the selection of precedent requires something beyond rationality. Before expectations are coordinated, there is always uncertainty about whether or which past behavior is a precedent for the present behavior. There are many dimensions from which to evaluate whether or which past incident 'sticks out' as being like the present one (see Sugden 1998, Gilbert 1989).

For recurrent games, theorists increasingly offer evolutionary accounts to explain the emergence of an equilibrium. The evolution in these models typically does *not* occur through greater sexual reproduction of players who enjoy greater success in the recurrent game. Rather, evolution occurs by players, often imperfectly rational, *learning* from experience in the game and switching to strategies that provide greater expected utility. (see). Evaluating the success of these models is beyond the scope of this article. Some argue, however, that the same problem of induction that affects salience also infects evolutionary models, to the extent they require players to detect the patterns that constitute a game and other players' strategies in that game (see Sudgen 1998).

4. *Defining 'Norm'*

As noted above, a norm can be a mere behavioral regularity among individuals, as the fact that most people in a population drink coffee or tea nearly every morning. In moral theory, a norm can be a prescriptive rule or reason for action. Thus, one could sensibly assert the existence of a moral norm obligating certain behavior even though no one actually adheres to the norm. In a third sense, a norm is a behavioral regularity but not 'merely' one. It is a regularity sustained in part by the fact that individuals generally approve (and otherwise reward) conformity and/or disapprove (and otherwise punish) nonconformity. Norms are, therefore, perceived by individuals in the relevant population as obligatory, a regularity one 'ought' to follow, whether or not they are justified in moral theory. This rest of this article discusses this third sense of the term.

The definition of norm (in the sense indicated) entails at least three elements (see Pettit 1990). First, it is a behavioral regularity generally followed by the individuals in a population. This requirement distinguishes a society's mere aspirations for behavior from the norms that its members actually follow. One might want to expand the definition, however, to include cases where most do not follow the regularity but most *either* follow the regularity *or* bear significant costs to avoid having their nonconformity discovered. Second, a norm is a regularity in which conformity is approved and/or nonconformity is disapproved. On a broad view, the approval and disapproval need not be morally justified or even based on principle but may include the simple attitudes of being positively or negatively inclined toward—liking or disliking—the behavior. Pettit (1990, p. 731) suggests a third requirement: that the pattern of approval and disapproval 'helps to ensure' the existence of the regularity. The causal contribution may be unconscious and contingent, in that other considerations may usually suffice to sustain the regularity but the (dis)approval pattern fills in when those considerations fail.

One may also follow Pettit (1990, p. 751) in requiring some kind of common belief or knowledge of the existence of the above three elements. Even given these elements, if most people were unaware of the regularity, thinking that contrary behavior is equally common, it would seem odd to label the covert regularity a norm. The same might be true if people were aware of the regularity but not of the pattern of (dis)approval, or perhaps even if people were aware of both but attributed the regularity solely to other forces, thinking the pattern to be epiphenomenal. Finally, people might generally believe that all three elements exist, but might make mistakes about what others believed of these facts, or what others believe other believe, and so on. One may require some higher order beliefs, or at least the absence of contrary beliefs, although not necessarily full-scale common knowledge.

Norms may then be distinguished from conventions, which do not require approval of conformity and/or disapproval of nonconformity, but may be sustained entirely by other means. There is substantial room for overlap, but individuals may approve of conformity to behavioral regularities that are not conventions and they may follow conventions without approving others' conformity or disapproving their nonconformity.

5. *The Origin of Informal Norms*

Legal norms are formal; they are promulgated and enforced by the centralized authority of the state. Nongovernmental organizations also formally promulgate and enforce norms. But some norms arise and are enforced informally and without centralized authority. Informal negative sanctions include censure, gossip, ostracism, and violence. Positive sanctions include praise and the provision of social and economic opportunities. Beyond external sanctions, one may

approve or disapprove one's own conformity or nonconformity, respectively, and experience pride or guilt. Informal norms are important because they contribute to spontaneous order, which has implications for, among other things, political theory.

A key question is how informal norms first arise. What causes the behavioral regularity and what causes people to embrace it as obligatory? Some theorists emphasize nonrational forces and, indeed, view norm-based explanations of behavior as an alternative to rational choice explanations. As implied above, norms can be 'internalized' so that one feels guilt or anxiety from violating a norm, and pride or self-satisfaction from complying, even if no one else is aware of one's behavior. Elster (1989, pp. 97–151) emphasizes this emotional feature of norms. He claims that, contrary to rational behavior, a defining characteristic of norm-based action is that it is not 'outcome-oriented.' Internalization, however, seems a poor candidate for explaining norm origin. However it occurs, it seems more likely to follow than to precede the approval of conformity and/or disapproval of nonconformity.

By contrast, rational choice theorists have offered two nonexclusive ways of explaining norm origin (see Pettit 1990). They differ by whether one explains the behavioral regularity as arising before or after the pattern of approval and disapproval.

5.1 *Deriving Norms from Regularities*

The common way to derive a norm from interest is to explain first how a regularity arises and second how people come to approve conformity to the regularity and/or disapprove nonconformity. Game theory addresses the first issue—regularities—by its study of the mechanisms by which equlibrium is achieved. The (dis)approval patterns may subsequently arise for various reasons. Lewis (1969, pp. 97–100), for example, notes that conditions of a convention may easily give rise to approval of conformity. Even if conventions need not include his requirement that most individuals conditionally prefer that *others* conform (discussed above), it will often be the case that the condition holds. For example, one driving on the conventional side of the road desires that others follow the convention. In this circumstance, it is easy to imagine that self-interested individuals begin to *approve* of others conforming to the convention, given the danger they each face from nonconformity. Similarly, if contingent cooperation is a convention in an iterated prisoner's dilemma game, one will not only expect but also prefer that another engages in the conventional cooperation (see Bicchieri 1993).

A consequence of this analysis is that a regularity might first be a convention, become both a convention and a norm, and end up as a norm only. After the regularity became a norm, it might cease to be arbitrary in the sense described above. The incentives created by the norm—particularly if it is ultimately internalized—might change the payoffs so that the only equilibrium outcome was conformity with the norm regularity.

5.2 *Deriving Norms from Patterns of Approval and Disapproval*

A less common means of deriving norms from interest is to explain first how a pattern of approval and disapproval arises and second how this produces a behavioral regularity. Various mechanisms might produce the attitudinal pattern, the most obvious being the egoistic effect just discussed. Despite there being no regularity at this stage, it is easy to imagine that one person disapproves (approves) of another for conduct that harms (benefits) the former. Thus, prior to a regularity, an individual may negatively regard a neighbor who makes loud and disturbing noises and positively regard those who clean up common areas. The same result could occur through moralistic rather than egoistic reasoning, if individuals each tend to disapprove (approve) of behavior they believe generally harms (benefits) others.

These patterns of (dis)approval can create behavioral patterns if individuals sufficiently value *esteem*, i.e., the approval and good opinion of others, as an end. In some circumstances, individuals may (a) acquire information about the behavior of others without bearing any cost for that purpose, and (b) form an esteem judgment of approval or disapproval, which, being essentially reflexive and involuntary, is also costless. If so, the allocation of esteem creates a costless means of punishing or rewarding others. The desire for approval and the fear of disapproval may cause individuals to conform to a known pattern of esteem judgments (see Pettit 1990, McAdams 1997).

Elster (1989, p. 133) observes that *expressing* disapproval is always costly, as it takes time and risks the retaliation of the target. One might add that selectively expressing approval risks retaliation by those not approved. But these costs need not prevent esteem-judgments from operating as a sanction and producing a norm. First, judgments of disapproval need not be expressed to be perceived. Introspection may suffice: if *A* hates having her sleep disturbed by a loud noise, she may simply guess that others will disapprove of her for waking them with a loud noise (see Pettit 1990, p. 740). Second, there may be a cost to concealing one's esteem judgment that offsets the costs of expression. Suppose *B* prefers to socialize only with people he esteems. For *B*, inviting to a social gathering people he does not esteem (or forgoing the gathering altogether) is more costly than revealing his negative esteem judgments. *B* therefore rationally invites only those whom he esteems and, despite the costs, *indirectly* expresses his negative judgments about others. As to both points, if individuals value esteem, they will seek evidence of

how to get it, so even a trivial clue may cause people to form beliefs about the judgments being made. Once individuals perceive a pattern of approval and disapproval, they may gain (net) approval by directly expressing views consistent with the pattern.

Because individuals will tend to approve commonly beneficial behavior more than commonly harmful behavior, the discussion implies that norms derived from (dis)approval patterns will tend to be socially beneficial. A more detailed analysis would reveal several offsetting effects. However norms are derived, they can cause harm in a variety of ways, particularly by allowing one group to benefit itself at the expense another (see Hardin 1995, Ullman-Margalit 1977, pp. 134–97).

Conversation Analysis: Sociological

Conversation analysis (CA) is a field of sociology concerned with the norms, practices and competences underlying the organization of social interaction. Notwithstanding the name, CA is concerned with all forms of spoken interaction including not only everyday conversations between friends and acquaintances, but also interactions in task-focused social contexts such as medicine, the mass media, education and socio-legal contexts. Originating in the 1960s in the privately circulated lectures of Harvey Sacks (1992), CA has grown into a field of research that is practiced worldwide.

1. Background

CA emerged from the confluence of two theoretical initiatives in sociology. The first derives from Erving Goffman who, in a long series of theoretical writings, argued that social interaction forms a distinct institutional order comprised of normative rights and obligations that regulate conduct in interaction, and that functions as the medium for the operation of other societal institutions. From Goffman, CA adopted the essentially Durkheimian perspective that these normative conventions are autonomous and independent of the social and psychological characteristics of persons and their particular motivations and projects, and indeed are the vehicles through which the particular characteristics of interactants are made manifest in conduct. The second influence derives from Harold Garfinkel's ethnomethodology, which stresses the contingent and socially constructed nature of both action and the understanding of action in the social world. From Garfinkel, CA adopted the perspective that a common body of normative conventions and practices are the basic resources for the methodical production and recognition of action, and for the achievement of common understandings of joint activities in a dynamic social context that is maintained or altered with each successive contribution.

These two perspectives were fused into a methodology that focuses on the sequential production of interaction. Analysis of the normative practices through which interaction and its outcomes are built is possible because participants display their understandings and analyses of one another's conduct in each successive contribution to interaction. The systematic 'choices' involved in each successive move are resources for grasping the practices—conceived as a domain of massive order and empirical regularity—through which these choices are implemented.

2. *Basic Assumptions*

Underlying this sequential methodology are a number of fundamental ideas. First, in performing some current action, participants normally project (empirically) and require (normatively) the production of a 'next' or range of possible 'next' actions to be done by another participant. Second, in constructing a turn at talk, they normally address themselves to preceding talk and, most commonly, the immediately preceding talk. Participants design their talk in ways that exploit this basic positioning, thereby exposing the fundamental role of this sequential contextuality in their utterances.

Third, by the production of next actions, participants show an understanding of a prior action and do so at a multiplicity of levels—for example, by an 'acceptance,' an actor can show an understanding that the prior turn was possibly complete, that it was addressed to them, that it was an action of a particular type (e.g., an invitation) and so on. These understandings are (tacitly) confirmed or can become the objects of repair at any third turn in an on-going sequence. Within this framework, the grasp of a 'next' action that a current projects, the production of that next action, and its interpretation by the previous speaker—are the products of a common set of socially shared practices. CA analyses are thus simultaneously analyses of action, context management and intersubjectivity because all three of these features are simultaneously, if tacitly, the objects of the actors' actions.

Embedded in this perspective is the notion that social action is both context-shaped and context-renewing, and that social context is not a simple 'container' of social interaction, but rather something that is dynamically created, sustained and altered across an interaction's course. Similar conclusions hold for the relevant social identities of the participants, which are also activated, sustained or adjusted on a temporally contingent basis. Finally, the procedures that inform these activities are normative in that actors can be held morally accountable both for departures from their use and for the inferences which their use, or departures from their use, may engender. The sequential methodology arising from these assumptions has proved highly productive in generating findings about the basic organization of interaction, and its modifications in a wide range of more specific institutional settings.

For the first two decades of its existence, CA research focused on ordinary or casual interaction between friends and family members, rather than on the intersection between interaction and specific social institutions. This focus on the institution of conversation reflected the stance that ordinary conversation is in various ways a fundamental domain for the analysis of interaction, and that its analysis is a basic resource for the extension of CA into more specialized interactional domains (Sacks et al. 1974). There are various reasons to treat ordinary conversation as fundamental, and indeed as a 'primordial form of human sociality' (Schegloff 1992). It is the predominant form of human interaction in the social world and the primary medium of communication to which the child is exposed and through which socialization proceeds. It thus antedates the development of other, more specialized, forms of 'institutional' interaction both phylogenetically in the life of society and ontogenetically in the life of the individual.

Moreover the practices of ordinary conversation appear to have a 'bedrock' or default status. They are less historically mutable and subject to discursive justification (by reference, for example, to equity or efficiency) than practices of communication in legal, medical, pedagogical and other institutions manifestly are. Research is increasingly showing that communicative conduct in more specialized social institutions embodies task- or role-oriented specializations and particularizations that generally involve a narrowing of the range of conduct that is generically found in ordinary conversation (see below). The latter thus embodies a diversity and range of combinations of interactional practices that is unmatched elsewhere in the social world. Communicative conduct in institutional environments, by contrast, embodies socially imposed and often irksome departures from that range.

3. *Domains of Research on the Study of Ordinary Conversation*

CA research into ordinary conversation addresses practices of interaction that are organized as systems. These practices are clustered in a range of domains. These include the following:

(a) Turn-taking comprises the organization of coordinated access to the interactional floor and its social regulation, together with the management of failures in coordination and regulation (manifested in overlapping talk and various forms of competitive interruption).

(b) Sequence organization focuses on the practices through which courses of action are built, and how

alternative pathways within them are activated and structured. Beginning with simple paired actions—such as question-answer, or invitation response—the study of sequence organization focuses on the various ways in which the interior structure of these sequences are managed and expanded. Many sequence organizational practices, including expansions, are oriented to issues of affiliation and social solidarity between the speakers, handled under the related topic of 'preference.' Sequence expansions, for example, are, in large part, designed to avoid, minimize or otherwise mitigate disaffiliative actions which are potentially ubiquitous, and which would otherwise undermine the social solidarity of interactants. For example, the simple pre-expansion inquiry 'Are you doing anything tonight?' permits a recipient, by responding with an alternative activity, to forestall an upcoming suggestion and thus to avoid the face-threatening action of rejection. Correspondingly, a 'No' response permits a would-be inviter to proceed with more confidence since a less face-threatening opportunity to reject the invitation has already been passed.

(c) Repair concerns the resources with which participants deal with problems in speaking, hearing and understanding talk, including the interactional mechanics of self- and other-initiated repair, and the ongoing management of problems in sustaining intersubjective understanding.

Other domains of research include story-telling and narrative, the internal structuring of turns at talk, word selection, prosody, and the intersection between talk and body behavior. Taken together, this research has generated a very large range of findings that link the sociological study of social interaction to convergent perspectives in linguistics and communication. These findings have increasingly been enriched by parallel analyses from other languages, including most European languages and a number of prominent Asian languages, including Japanese, Korean, and Mandarin.

4. *Interaction and Social Institutions*

During the past two decades, the findings emerging from the study of ordinary conversation have found increasing application in the study of interaction in various kinds of institutional settings, including education and social work, socio-legal contexts, police work, the mass media, medicine, and the human-machine interface. These are all areas in which social interaction is a prominent feature of the working activities of participants. Research in this field addresses the ways in which the work of institutions is realized in interaction.

Initial interest in the analysis of social institutions focused on how participants' actions embodied their understandings of relevant aspects of the settings which, through these same actions, they constitute as real and binding on one another. As noted earlier, institutional interactions tend to involve reduction in the kinds of practices and actions that are deployed in ordinary conversation and a specialization of those that remain. In this context, research initially focused on the ways in which turn-taking arrangements and basic facets of sequence organization undergo modifications in such contexts as classrooms, law courts, news interviews and business meetings, and the ways in which these modified arrangements structure opportunities for action among the participants that impact on other dimensions of interaction in these settings.

Subsequent research has focused on the ways in which the particular demands of institutional roles, tasks and identities are managed in the sequential structure of interaction, in the specific design of turns at talk, and in the ways that the different knowledge bases possessed by the interactants play out as bases for inference and action. More recent work increasingly ties specific practices of interaction to participants' perceptions and expectations, and to the outcomes of interactions, particularly in medicine and related fields where outcomes are measurable. Finally, with the passage of time and the growth of an historical record of recorded data, it is becoming possible to chart changes in interactional practices over time and to examine them as indices and vectors of social change.

5. *Methodologies*

CA embodies a significant methodological departure from most extant sociological perspectives. First, it is premised on the assumption that all aspects of social interaction are organized and orderly and that social participants attend to interaction in fine detail, albeit with varying degrees of reflexive awareness. Thus gaze, body posture, prosody, intonation, pacing, self-interruption, word selection, grammar, etc., have been shown to be the objects of systematic orientation in both the production and interpretation of interaction. This conception of order contrasts markedly with other positions in the social sciences—from Parsons to Chomsky—which start from the presumption that social interaction is 'noisy' and needs to be cleansed of accidental detail if analysis is to be successful. It effectively mandates that CA investigations be based on audio- and video-recordings of interaction, rather than data arrived at through invention, reconstruction, recollection or precoding, because all the latter foreclose on the levels of detail and organization that conversation analysts have repeatedly found to be relevant to participants in recorded specimens of interaction.

Beyond this point, there are some divergences. The study of ordinary interaction focuses on practices which are putatively of general provenance, and usable

by anyone who knows how to talk. While large numbers of specimens of such practices are valuable in determining their nature and function, statistical analysis has played little role in the field, largely because in the matter of interactional practices, as in the case of biological species, large numbers are not essential to establishing their existence. In the field of institutional interaction, however, and especially in its applied aspects, where practices of interaction are being linked to tasks, identities, perceptions, expectations and outcomes, a more statistically-focused methodology is appropriate and is increasingly used.

6. Conclusion

CA is a large and diversifying field of study. Its basic outlook and methodology have achieved 'paradigmatic' status in Thomas Kuhn's sense, and is widely accepted across the range of social science disciplines to which it has contributed. It seems likely that its methodology will continue to evolve and that it will contribute, not only to sociology, communication science and linguistics, but also to medicine, neuroscience, artificial intelligence and the life sciences with which its practitioners are in increasing contact.

Conversation: Linguistic Aspects

Conversations are social creations. They are produced one step at a time as people carry out certain joint activities. A joint activity is one in which two or more people have to coordinate with each other to succeed (Clark 1996). These include not only waltzing, playing a piano duet, playing tennis, but gossiping, planning a party, and negotiating a contract. In waltzing, duets, and tennis, people coordinate moment by moment by means of gesture, touch, and other actions; but in gossip, planning, and negotiation, they use speech as well—they converse. What people do and say is not determined beforehand. It emerges as they negotiate their way through these activities.

Conversations reflect the joint activities they coordinate. Every joint activity has participants—the people actually taking part, who are distinct from nonparticipants (bystanders, onlookers, overhearers)—and so do the conversations that emerge from them. The participants take particular roles, such as doctor and patient, teacher and student, or friend calling and friend called, and the roles constrain what the participants do and say. Every joint activity has public goals—mutually agreed-upon purposes for carrying them out. The overall goal may be to exchange gossip, plan an outing, or negotiate a contract, and these have subgoals. Although some of these goals are set from the start, most get established as the participants go along. The participants also have private goals—to be polite, not to lose face, or to finish quickly, for example—and these, too, constrain what the participants do and say. Finally, people often engage in two or more joint activities at a time—such as gossiping and eating dinner together—so their conversation switches back and forth between them.

Working together in a joint activity takes commitments and actions by all the participants. Joint activities have boundaries—distinct beginnings and ends, and transitions from one part to the next—but these boundaries don't exist until the participants agree to them. To enter a planning session, for example, two people must agree on (a) what the joint activity is to be, (b) who is to take part, (c) in what roles, (d) at what time and (e) at what place, and (f) whether or not they are each committed to taking part. They must reach these agreements at each transition point as well. What is remarkable is that people

Table 1
An adjacency pair

Ann	whereabouts are you going,
Betty	I've got a job at Columbia University, in New York, -
Ann	have you,

Table 2
A pre-question

Duncan	Edgar, I I . may I ask you a question,
Edgar	surely,
	[Duncan and Edgar exchange fifteen turns as Duncan describes an author's claim about Danish usage.]
Duncan	it is it it really so, that that is the common usage in Denmark, I don't know if you've heard, of that,
Edgar	- - umm . I'm . I would be surprised, if it was accepted usage,

accomplish all this locally, turn by turn (Sacks et al. 1974).

One basic unit of conversation is the *adjacency pair* (Schegloff and Sacks 1973), as in the spontaneous example shown in Table 1 (all examples are from Svartvik and Quirk 1980).

Adjacency pairs each have two parts, by different speakers, where part 2 is conditionally relevant given part 1. Part 1 is a *proposal*, and part 2 is expected to be the *uptake* of that proposal. In Table 1, Ann proposes that Betty tell her whereabouts she is going, and Betty takes up the proposal by saying that she's got a job at Columbia University. In just two turns, Ann and Betty manage to coordinate on the content, participants, roles, time, place, and commitments of their joint action. They would have failed if Betty had replied 'What do you mean?' or 'You mean me?' or 'I don't know' or 'I won't tell you.'

Adjacency pairs are available for a wide range of joint actions. These include not only requests for information (as in Ann and Betty's exchange), but greetings ('Hi,' 'Hi'), farewells ('Bye,' 'Bye'), offers ('Have some cake,' 'Thanks'), orders ('Sit down,' 'Yes, sir'), and apologies ('Sorry,' 'Oh, that's okay') (Stenström 1994). They are used for even the simplest exchanges of information ('I've got a job … ' 'Have you?').

Adjacency pairs take only two turns, but they can be used to project larger sections, as in Table 2 (the disfluencies are in the original).

Duncan's first turn is a *pre-question* (Schegloff 1980). With it he proposes to ask Edgar a question, and Edgar agrees. Duncan now has the freedom to take up preliminaries to his question, and it takes the two of them fifteen turns to do that. Only then does he ask his question, and Edgar answers it. Pre-questions project not only the eventual question, but preliminaries to that question.

Table 3
Types of pre-sequences

Pre-request	Customer	Do you have hot chocolate?
	Waitress	Yes, we do
Pre-invitation	Man	What are you doin'
	Woman	Nothin.' What's up?
Pre-narrative	June	Did I tell you I was going to Scotland
	Kenneth	No
Pre-conversation	Caller	[rings telephone]
	Recipient	Miss Pink's office

Table 4
Opening of telephone conversation

Karen:	(rings Charlie's telephone)
Charlie:	Wintermere speaking? -
Karen:	hello?
Charlie:	h*el*lo
Karen:	Charlie
Charlie:	yes
Karen:	actually it's
Charlie:	hello Karen
Karen:	it's me
Charlie:	m
Karen:	I (- laughs) I couldn't get back last night, [continues]

Pre-questions and their responses are one of a large family of so-called *pre-sequences*. Table 3 gives a few more examples.

Each pre-sequence prepares the way for another joint action. The pre-request sets up a request ('I'll have one'); the pre-invitation sets up an invitation ('Would you like … '); the pre-narrative sets up a narrative; and the pre-conversation sets up an entire telephone conversation. So pre-sequences are useful in organizing longer sections of conversation.

Opening a conversation takes special coordination as two or more people move from not being in a conversation to being in one. Table 4 gives the opening of a telephone conversation between acquaintances.

First, Karen and Charlie coordinate contact through a proposal to have a conversation (the telephone ring) and its uptake ('Wintermere speaking?'). Next, they mutually establish their identities. Karen tells Charlie that she recognizes him in line 5, but Karen has to say 'hello?' 'Charlie,' and 'actually it's' before he identifies her in line 8. Only then does Karen introduce the first topic. It took ten turns for them to coordinate on the participants, roles, time, place, and commitment to the conversation.

Closing conversations is no easier (Schegloff and

Table 5
Closing of telephone conversation

June	and I'll . I'll ring again, as soon as I can on the tenth, uhh to definite confirm it,
Kathryn	right,
Kathryn	okay,
June	right,
June	thanks a lot,
Kathryn	r . right,
June	bye bye,
Kathryn	bye

Table 6
A pre-narrative exchange

Nancy:	I acquired an absolutely magnificent sewing-machine, by foul means, did I tell you about that
Kate:	No
Nancy:	well when I was . doing freelance advertising - [proceeds to give a five minute narrative]

Table 7
A pre-narrative exchange

Connie:	did I tell you, when we were in this African village, and [- they were all out in the fields, - the]
Irene:	[yes you did, yes, - yes]
Connie:	babies left alone, -
Irene:	yes .

Sacks 1973), as illustrated in Table 5 (an ending to a telephone conversation).

Although June and Kathryn finish a topic in lines 1 and 2, they cannot hang up without agreeing to hang up. So in line 3, Kathryn proposes to close the conversation ('Okay'), and although June could now introduce a new topic in line 4, she agrees to Kathryn's proposal ('Right'). That opens up the closing in which the two exchange thanks ('Thanks a lot' 'Right') and then goodbyes. The two must *agree* to close the conversation before they can actually close it.

Conversations are opportunistic: The paths people take depend on the opportunities that become available with each agreement. Consider the pre-narrative and its response in Table 6.

Nancy proposes to tell Kate a story ('Did I tell you about that'), and Kate accepts ('No'). But partners can also decline, as in Table 7.

Irene interrupts Connie (the speech in brackets is overlapping) to say that she *has* heard the story, and the two of them then go down a different path. Nancy and Connie used their pre-narratives to discover how best to proceed and, receiving different replies, took different routes.

Table 8
A side sequence

Duncan	well wha- uhh what shall we do about uh this boy then, - -
Ed	Duveen?
Duncan	m,
Ed	well I propose to write, [continues]

People help signal which opportunities they are taking by using *discourse markers* (Schiffrin 1987). For example, Nancy used 'well' to signal that she was introducing a change in perspective as she began her story. Other discourse markers indicate such boundaries as the start of a new topic (e.g., 'so,' 'then,' 'speaking of that'), the start of a digression ('incidentally,' 'by the way'), or the return from a digression ('anyway,' 'so'). All of these help in coordinating on what is happening next.

People carry out joint activities against their common ground—their mutual knowledge, mutual beliefs, and mutual assumptions. They infer their common ground from past conversation, joint perceptual experiences, and joint membership in cultural communities. When Ann asked Betty 'Whereabouts are you going?' she presupposed certain common ground—for example, that Betty has been looking for a university job in America, and that Ann doesn't know where. Ann also adds to their common ground that she wants to know. Conversations proceed by orderly increments to the participants' current common ground.

Conversations cannot succeed, therefore, unless the participants *ground* what they say. To ground what is said is to establish the mutual belief that the addressees have understood the speakers well enough for current purposes (Clark and Schaefer 1989). One technique for grounding is the adjacency pair itself. When Betty said 'I've got a job at Columbia University,' she displayed to Ann how she had interpreted her question. If Ann hadn't been satisfied with that interpretation, she could have corrected it, e.g., by replying 'No, I meant … ' (Schegloff et al. 1977). In fact, she followed up Betty's reply with 'have you,' displaying to Betty that she accepted her interpretation. Another technique is the *back-channel response*, *acknowledgment*, or *continuer* (Schegloff 1982). In two-party conversations, addressees are expected to add 'uh huh' or 'mhm' or 'yeah' at or near the ends of certain phrases. With these, they assert that they have understood the speaker so far and imply that the speaker should continue.

Grounding is sometimes achieved through *side sequences* (Jefferson 1972), as illustrated in Table 8.

When Ed didn't understand to whom Duncan was referring as 'this boy,' he initiated an embedded adjacency pair, a side sequence, to clear up the problem. Only when he had cleared it up did he answer

Duncan's original question. Side sequences are initiated to clear up not only mishearings and misunderstandings, but also other pre-conditions to taking up the first part (e.g., 'Why do you want to know?'). Grounding is also accomplished sometimes by overlapping speech. When Irene interrupted Connie's offer 'Did I tell you … ' to say, 'yes you did, yes, yes,' she was signaling to Connie that she already understood and Connie didn't need to go on.

The structure of conversations, in summary, is not determined from the outset. It emerges step by step as people coordinate on each new move in joint activities. People have to coordinate on the content, participants, roles, time, place, and commitment to each joint action, and they do that in a sequence of local, opportunistic agreements. It is these techniques that lead conversations to have the structure they do.

Cooperation and Competition, Psychology of

1. *Introduction*

During the twentieth century, there have been a series of social forces that have highlighted the importance of cooperation and competition and often created a creative tension between them. In the early 1900s, the advent of the industrial revolution and the ending of colonialism focused attention on (a) the importance of well functioning, cooperative groups, and (b) competition as the secret to increased economic success. During the 1920s and 1930s, with the worldwide depression and the rise of dictatorship in Europe, the importance of cooperation was again highlighted. Business and industry groups, such as the Liberty League in the USA, increased their emphasis on competition in business and industry, education, and other areas of life. In the aftermath of the Second World War there was great concern about the future of democracy and the need to better understand how democratic organizations could be made to function more effectively. The health of a democratic society, it was thought, depended on the effectiveness of its component groups. Strengthening of the quality of cooperation in the family, the community, and the multitude of groups within society was viewed as the primary means of ensuring the vitality of democracy and the successful solving of the existing social problems. At the same time, the rise of social Darwinism promoted competition as the natural order of life. In the early 1960s, anthropology and ethnology proposed that competition over weapon systems sparked human evolution. The civil rights movement and concerns about the possibility of nuclear war, on the other hand, created great interest in cooperation among diverse individuals. The tension between, and interest in cooperation and competition sparked discussions in three major theoretical orientations: cognitive-developmental, behavioral, and social interdependence.

2. *Cognitive-developmental Theory*

The 'cognitive developmental perspective' is largely based on the theories of Piaget (1950), Vygotsky (1978), cognitive science, and academic controversy (Johnson and Johnson 1995). To Jean Piaget (1950), cooperation is the striving to attain common goals while coordinating one's own feelings and perspective with a consciousness of others' feelings and perspective. From Piaget and related theories comes the premise that when individuals co-operate on the environment, socio-cognitive conflict occurs that creates cognitive disequilibrium, which in turn stimulates perspective-taking ability and cognitive devel-

opment. Cooperative learning in the Piagetian tradition is aimed at accelerating a student's intellectual development by forcing him or her to reach consensus with other students who hold opposing points of view about the answer to the school task.

Lev Semenovich Vygotsky (1978) and related social constructionist theorists claim that our distinctively human mental functions and accomplishments have their origins in our social relationships. Mental functioning is the internalized and transformed version of the accomplishments of a group. Knowledge is social, constructed from cooperative efforts to learn, understand, and solve problems. A central concept is the 'zone of proximal development,' which is the zone between what a student can do on his or her own and what the student can achieve while working under the guidance of instructors or in collaboration with more capable peers. Unless students work cooperatively, they will not grow intellectually and the time students work alone on school tasks should therefore be minimized.

From the cognitive science viewpoint, cooperative learning involves modeling, coaching, and scaffolding (conceptual frameworks provided for understanding what is being learned). The learner must cognitively rehearse and restructure information for it to be retained in memory and incorporated into existing cognitive structures (Wittrock 1990). An effective way of doing so is explaining the material being learned to a collaborator. Tutoring, when it is viewed from the perspective of the benefits that accrue to the tutor, is also a form of cooperative learning.

'Controversy theory' (Johnson and Johnson 1995) posits that being confronted with opposing points of view creates uncertainty or conceptual conflict, which creates a reconceptualization and an information search, which results in a more refined and thoughtful conclusion. The key steps are organizing what is known into a position, advocating that position to someone who is advocating the opposing position, attempting to refute the opposing position while rebutting the attacks on one's own position, reversing perspectives so that the issue may be seen from both points of view simultaneously, and creating a synthesis to which all sides can agree.

3. *Behavioral-learning Theory*

The 'behavioral learning perspective' assumes that individuals will work hard on those tasks for which they secure a reward of some sort and will fail to work on tasks that yield no reward or yield punishment (Bandura 1977, Skinner 1968). Cooperative efforts are designed to provide incentives for the members of the group to participate in a group effort since it is assumed that individuals will not intrinsically help their classmates or work toward a common goal. Skinner focused on group contingencies, Bandura focused on imitation, and Homans as well as Thibaut and Kelley focused on the balance of rewards and costs in social exchange among interdependent individuals. Recently, Bandura (2000) has conceptualized cooperation as collective agency. In 'collective agency' individuals have to work together to secure what they cannot accomplish on their own.

The most developed behavioral theory of cooperation and competition was developed by Kelley and Thibaut (1978). They assumed that individuals act to maximize their self-interests by behaving in ways to maximize their rewards and minimize their punishments or costs. 'Rewards' are defined as positive interaction experiences that yield outcomes that promote physical or emotional well being, self-esteem, or personal growth such as enjoyment, fulfillment, or contentment. 'Costs' are defined as negative interaction experiences that yield physical or emotional pain or failure. People attempt to recreate experienced interactions that yield pleasure and avoid interactions that yield pain. 'Cooperation' is thus defined as acting in ways perceived to maximize joint rewards and minimize joint costs, 'competition' as acting in ways to maximize ones own rewards and minimize ones own costs relative to others, and 'individualistic efforts' as acting in ways to maximize ones own rewards and minimize ones own costs with little or no regard of the outcome for others. In evaluating outcomes, individuals have a 'comparison level' about what constitutes an acceptable outcome and a 'comparison level for alternatives' about how those outcomes compare to other possible outcomes. Cooperation tends to occur when outcomes are correspondent and competition tends to occur when outcomes are noncorrespondent.

4. *Social Interdependence Theory*

The roots of social interdependence theory lie in the early 1900s when Kurt Koffka (one of the founders of the Gestalt School of Psychology) proposed that groups were dynamic wholes in which the interdependence among members could vary. In the 1920s and 1930s, Kurt Lewin refined Koffka's notion, proposing that the essence of a group is the interdependence among members (created by common goals), and that interdependence results in the group being a 'dynamic whole' so that a change in the state of any member or subgroup changes the state of any other member or subgroup. Continuing Lewin's work, in 1949 Morton Deutsch (1949, 1962) formulated social interdependence theory.

'Social interdependence' exists when individuals share common goals and each individual's outcomes are affected by the actions of the others (Deutsch 1962, Johnson and Johnson 1989). It may be differentiated from social dependence (i.e., the outcomes of one person are affected by the actions of a second person but not vice versa) and 'social independence' (i.e., individuals' outcomes are unaffected by each other's

actions). There are two types of social interdependence: cooperative and competitive. The absence of social interdependence and dependence results in individualistic efforts.

'Cooperation' exists when individuals work together to accomplish shared goals. When a situation is cooperatively structured, individuals' goal achievements are positively correlated; individuals perceive that they can reach their goals if, and only if, the others in the group also reach their goals. Thus, individuals seek outcomes that are beneficial to all those with whom they are cooperatively linked. 'Competition' exists when individuals work against each other to achieve a goal that only one or a few can attain. When a situation is structured competitively, individuals' goal achievements are negatively correlated; each individual perceives that when one person achieves his or her goal, all others with whom he or she is competitively linked fail to achieve their goals. Thus, individuals seek an outcome that is personally beneficial but detrimental to all others in the situation. 'Individualistic efforts' exist when individuals work by themselves to accomplish goals unrelated to the goals of others. When a situation is structured individualistically, there is no correlation among participants' goal attainments. Each individual perceives that he or she can reach his or her goal regardless of whether other individuals attain or do not attain their goals. Thus, individuals seek an outcome that is personally beneficial without concern for the outcomes of others.

5. *Interaction Patterns*

The basic premise of social interdependence theory is that the type of interdependence structured in a situation determines how individuals interact with each other which, in turn, determines outcomes (Deutsch 1949 1962, Johnson and Johnson 1989). Positive interdependence tends to result in promotive interaction; negative interdependence tends to result in opposition or contrient interaction, and no interdependence results in an absence of interaction. 'Promotive interaction' occurs when members help and assist each other, exchange resources, give and receive feedback, challenge each other's reasoning, and encourage increased effort. Group members focus on maximizing the success of their groupmates as well as their own. 'Oppositional interaction' occurs as individuals discourage and obstruct each other's efforts to achieve. Individuals focus both on increasing their own success and on preventing anyone else from being more successful than they are. 'No interaction' exists when individuals work independently without any interaction or interchange with each other. Individuals only focus on increasing their own success and ignore as irrelevant the efforts of others. Each of these interaction patterns creates different outcomes.

Deutsch (1949, 1962) noted that depending on whether individuals promote or obstruct each other's goal accomplishments, there is 'substitutability' (i.e., the actions of one person substitute for the actions of another), 'cathexis' (i.e., the investment of psychological energy in objects and events outside of oneself), and 'inducibility' (i.e., openness to influence). Essentially, in cooperative situations the actions of participants substitute for each other, participants positively cathect to each other's effective actions, and there is high inducibility among participants. In competitive situations the actions of participants do not substitute for each other, participants negatively cathect to each other's effective actions, and inducibility is low. When there is no interaction, there is no substitutability, cathexis, or inducibility. The relationship between the type of social interdependence and the interaction pattern it elicits is assumed to be bidirectional. Each may cause the other.

6. *Outcomes*

The investigation of cooperation and competition is the longest standing research tradition within American social psychology. Between 1898 and 1989, researchers conducted over 520 experimental studies on social interdependence and over 100 correlational studies (Johnson and Johnson 1989). Since research participants have varied widely as to sex, economic class, age, and cultural background, since a wide variety of research tasks and measures of the dependent variables have been used, and since the research has been conducted by many different researchers with markedly different orientations working in different settings and in different decades, the overall body of research on social interdependence has considerable generalizability.

The numerous outcomes studied may be subsumed within three broad categories (Johnson and Johnson 1989): (a) effort to achieve; (b) positive relationships; and (c) psychological health. In terms of productivity and achievement, a meta-analysis of all available studies (Johnson and Johnson 1989) found that the average person in a cooperative situation performed at about 2/3 a standard deviation above the average person learning within a competitive (effect size = 0.67) or individualistic situation (effect size = 0.64). These results held constant when group measures of productivity were included as well as individual measures, for short-term as well as long-term studies, and when symbolic as well as tangible rewards were used. In terms of relationships, over 180 studies indicate that cooperative efforts, compared with competitive and individualistic experiences, promoted considerable more liking among individuals (effect sizes = 0.66 and 0.62, respectively) even when individuals were from different ethnic and historical backgrounds, or were handicapped. In addition, over 106 studies indicate that cooperative experience promoted greater task-oriented and personal social support than did competitive (effect size = 0.62) or

individualistic (effect size = 0.70) efforts. Finally, the research indicates that (a) working cooperatively with peers and valuing cooperation result in greater psychological health than does competing with peers or working independently and (b) cooperative attitudes are highly correlated with a wide variety of indices of psychological health. Competitiveness was in some cases positively and in some cases negatively related to psychological health, and individualistic attitudes were negatively related to a wide variety of indices of psychological health. In addition, over 80 studies indicated that cooperative experiences promoted higher self-esteem than do competitive (effect size = 0.58) or individualistic (effect-size = 0.44) experiences. Cooperative experiences also tended to increase perspective-taking ability while competitive and individualistic experiences tended to promote egocentrism (being unaware of other perspectives other than your own) (effect sizes of 0.61 and 0.44, respectively). It is through cooperative efforts that many of the attitudes and values essential to psychological health (such as self-efficacy) are learned and adopted. Social skills and competencies tend to increase more within cooperative than in competitive or individualistic situations (Johnson and Johnson 1989). These outcomes of cooperative efforts (effort to achieve, quality of relationships, and psychological health) form a gestalt where each influences the others and they are therefore likely to be found together.

7. *Basic Elements*

In order for cooperative efforts to be effective, five elements must be structured in the situation: positive interdependence, individual accountability, promotive interaction, social skills, and group processing. 'Positive interdependence' exists when one perceives that one is linked with others in a way so that one cannot succeed unless they do (and vice versa) and that one must coordinate one's efforts with the efforts of others to complete a task (Johnson and Johnson 1989). Cooperative efforts may be built on outcome interdependence (i.e., goals and/or reward interdependence or each group member's success in achieving a goal or receiving a reward depends on the joint efforts of all group members) and means interdependence (i.e., resource, role, and task interdependence or group members being tied together by complementary resources, interlocking roles, or a division of labor).

'Individual accountability' exists when the performance of each individual student is assessed and the results given back to the group and the individual. It is important that the group knows who needs more assistance, support, and encouragement in completing the task and group members know that they are responsible for doing their share of the work. 'Promotive interaction' may be defined as individuals encouraging and facilitating each other's efforts to complete tasks and achieve in order to reach the group's goals. Promotive interaction is characterized by group members helping and assisting each other, exchanging information and resources, and encouraging each other to learn.

'Social skills' are the actions needed to effectively interact with other people. Leadership, decision-making, trust building, communication, and conflict-management skills are examples. Social skills form the basic nexus among individuals, and if individuals are to work together productively, they must have a modicum of these skills. 'Group processing' may be defined as reflecting on group efforts to (a) describe what member actions were helpful and unhelpful in achieving the group's goals and maintaining effective working relationships among members, and (b) make decisions about what actions to continue or change. The purpose of group processing is to clarify and improve the effectiveness of the members in contributing to the joint efforts to achieve the group's goals.

8. *Enhancing Factors*

Deutsch (1962, 1973, 1985) has posited that trust, conflict, and distributive justice are mediators of the effectiveness of cooperation. The greater the trust, the more effective cooperative efforts tend to be, the more constructive conflicts tend to be, and the more positive relationships tend to be. Effective cooperative requires that conflicts of interest are resolved constructively and when decisions involve diverse points of view individuals strive to reach agreement through a process of argument and synthesis. In cooperative efforts the distribution of benefits is based on equality and need while in competitive situations benefits are distributed according to equity (high performers receive more than low performers).

9. *Competitive and Individualistic Efforts*

Competition tends to result in constructive consequences when it occurs within a broader cooperative context, clear and fair rules, and criteria for winning are present, the task is appropriate, the task may be completed individually, competitors have an equal chance of winning, and winning is of low importance (Johnson and Johnson 1975/1999; Stanne et al. 1999). The conditions under which individualistic efforts have an advantage over cooperative efforts are unclear.

10. *Future Directions*

The tension between cooperation and competition has not ended. Considerably more research is needed on the nature of cooperation and the variables that mediate its effectiveness. There is new interest in

collective agency (Bandura 2000). The nature of competitive and individualistic efforts the conditions under which they are effective need to be further investigated. There is a current interest in the values inherently taught by participating in cooperative and competitive situations (Johnson and Johnson 1999). Cooperation, for example, may promote a concern for the well-being of others and a desire to contribute to the common good, while competition may promote a desire to be better than others and a concern for self-gain at the expense of others. Finally, one of the least understanding aspects of cooperation and competition is inducibility, the willingness to be influenced by others. Inducibility is the center of constructive power, which occurs, in cooperative but not competitive situations. World events, furthermore, such as increasing economic interdependence among countries but fractionalization within countries, will keep interest in the study of cooperation and competition high in the future.

Cooperation: Sociological Aspects

Individuals cooperate if each willingly acts in a manner that contributes to the others' welfare. Cooperation is one of the oldest and most revered topics in sociology even though it has appeared under a variety of headings, such as 'social order' and 'solidarity.' The classical sociological answers to the question of how cooperation among individuals comes about differ in detail but share a common core: Cooperation is the result of shared values and norms and norm-conforming behavior.

A problem with this 'obligation-centered' solution is that there is no explanation of where norms come from and why the degree of norm conformity varies even for the same individual over time. Theories that might solve these problems were not developed until the 1970s when a sea change in the basic assumptions on human action took place within sociology. At that time, analyses of cooperation among rational egoists (mostly rooted in game theory) began to shed new light on the way one might analyze cooperation, norms, and norm-conforming behavior. For some time, game-theoretic analyses of cooperation had become the most serious attempt to explain cooperation. Big advances were made but many problems remained, especially the problem that individuals do not seem to be as self-centered as they are assumed to be in game theory. Still, the game-theoretic analyses were powerful enough to suggest that there was no way back to explanations of cooperation that ignored human rationality all together. More recently, analyses based on some form of social rationality have arisen in order to address some of the unsolved problems. The following sections first present the most important aspects of sociological research on cooperation among rational egoists, and then discusses some contributions on cooperation with social rationality.

1. Cooperation Among Rational Egoists

It may not be quite realistic to assume that individuals are always looking out for themselves and that they do so by weighing the costs and benefits of their behavior. However, this assumption of 'rational egoism' seems to have four strong points in its favor. First, it allows one to pinpoint why cooperation is an interesting problem. Second, it allows rigorous theory formation with tractable structures of argumentation. Third, everyday experience and research give this assumption

enough support to make it worthwhile to use it in the light of its analytic advantages, especially when analyzing interaction among interdependent individuals. Fourth, at later stages of theory formation, this assumption can be relaxed in favor of more realistic assumptions.

Game theory has furnished the most important instruments for such analyses, and since the late 1970s—inspired by developments in political science and economics—sociologists have begun to use it to study questions concerning cooperation, typically bringing sociological aspects into the analyses, such as network embedding. The crucial first step in the 'new' analysis was to identify typical situations in which cooperation is problematic: social dilemmas. A social dilemma is—roughly speaking—a situation in which the rational decisions of individual actors are likely to lead to a collectively suboptimal outcome. An outcome is suboptimal (i.e., not 'Pareto-optimal') if one or more actors could improve their position without worsening the position of any other actor(s). In a social dilemma, individual and collective rationalities are in conflict. Cooperation can now be succinctly defined: An actor cooperates if and only if he or she chooses a course of action that will lead to a collectively rational outcome when other actors behave cooperatively as well. Social dilemmas occur when Pareto-superior behavior cannot be achieved by enforceable contracts. This may have many different reasons. For example, it may be impossible to communicate with others in order to come to an agreement; or, if communication is possible, transaction costs may be too high to actually reach an agreement. If agreements are within reach, it may be practically or epistemically impossible to specify all relevant future contingencies in the contract. Even if a contract can be drawn up, there may be no court with sanctioning power; or if there is such a court, it may not be possible to prove uncooperative behavior in court.

There are structurally different variants of social dilemmas, and game theory helps to distinguish them. For example, there is the *common's dilemma* (Hardin 1968, Ostrom 1990) in which various actors have free access to a resource (such as fishers from different nations in international waters); there are *step-level public goods* (Taylor 1987), for which only a limited number of actors have to cooperate in order to produce the public good for a much larger group. A special case of this is the *volunteer's dilemma* (Diekmann 1986), for which only one volunteer is necessary to produce the public good for all, such as rescuing a drowning child with a crowd of onlookers; there is the *trust game* (Dasgupta 1988) in which the trustee can honor or opportunistically exploit the cooperation of the other (as when you lend money to an acquaintance who promises to pay it back with interest).

The *Prisoner's Dilemma* (PD) is by far the best known variant of a social dilemma. It involves an arbitrarily large number of people. The special case of a two-person PD has been explored the best so far. In a two-person PD, both players have the option to cooperate or to defect (see Fig. 1). If both cooperate, each gets a payoff of value R. If one defects while the other cooperates, the defector gets T and the cooperator gets S. If both defect, both will get P, with $T > R > P > S$. There is a dominant strategy for each player (i.e., an individually rational choice, no matter what the other does) leading to a 'Nash equilibrium' (in which no player can unilaterally improve his or her position by deviating from the equilibrium strategy) and to a Pareto-inferior result. The assumption of rational egoism leads to two motives in a PD: the defensive motive to shield against exploitation (if the other defects you are better off defecting yourself), and the aggressive motive to exploit a cooperative player (if the other cooperates, you get even more by defecting). Together, these motive result in the conflict between individual and collective rationality. Mutual cooperation would be the Pareto-optimal result but the two motives lead to mutual defection.

Figure 1
Prisoner's Dilemma Game. In the Axelrod simulation is T (temptation) = 5, R (reward) = 3, P (punishment) = 1, and S (sucker's payoff) = 0

1.1 The Embedding of Cooperation

Raub and Weesie (2000) have suggested that game-theoretic work on solutions to social dilemmas can be divided into three kinds of embeddings of potential cooperation: embedding in time, in institutions, and in social networks. We follow their suggestion for this overview.

1.1.1 Time. When actors find themselves in a social dilemma that is iterated indefinitely over time, new sources for cooperation arise. First of all, defection can be sanctioned by the other player(s) in later moves, and the resumption of cooperation by the defector can be rewarded by a similar response of the

other player(s). Friedman (1977) and Taylor (1987) have shown that if the value of future outcomes is high enough, this opportunity to make one's cooperation conditional on that of the other leads to cooperative strategies with Nash equilibrium and Pareto optimality. Axelrod (1984) built on this result to ask the question which strategy would be most conducive to lead to cooperation in an iterated PD. In order to answer this question, he conducted computer simulations in which various strategies played against each other for about 200 rounds. Axelrod had invited suggestions for the strategies that would create the most cooperation. The winner was the conditional strategy 'tit for tat' (TFT) suggested by the mathematician and psychologist Anatol Rapoport.

TFT is very simple: (a) always begin with cooperation; (b) for the present round, copy the move of your partner in the previous round. TFT has a number of distinct features. It is 'nice,' because it starts with cooperation; it cannot be provoked, because it sanctions exploitation; and it is forgiving, because it returns to cooperation after the other has done so. Contrast this for example with 'permanent retaliation' in which defection is answered by unforgiving defection, a strategy that did much worse than TFT. TFT won against other strategies but it is not ideal under all circumstances. It does not do well against all sorts of strategies and it has not the property of 'evolutionary stability.' The heart of Axelrod's results, however, is thoroughly in line with a classical sociological insight: that the norm of reciprocity is probably the most essential norm generating cooperation in time-embedded interactions. As sociologists have argued for quite some time, homogeneity of a group in terms of important characteristics (including the use of 'nice' strategies) will increase the likelihood of reciprocity, as does smallness of the group because it helps identification of defection. Similarly, a low rate of fluctuation of membership helps reciprocity because it increases the shadow of the future. A related argument has been made in terms of 'social capital' (Coleman 1990).

1.1.2 Institutions. When reciprocity norms work, they are self-enforcing because no player can do better by unilaterally deviating from the cooperative strategy (Nash equilibrium). However, under many conditions, norms of reciprocity will not work properly. For example, when future contingencies are so complex that it is difficult to determine *a priori* what constitutes defection and/or difficult to detect defection, a reciprocity norm is not enough to secure cooperation. Similarly, such self-enforcing norms do not work well for the production of collective goods in larger groups, the less so the more unhomogeneous and fluctuating the group membership. In such situations, expectations concerning the relative importance of one's own and others' contribution are likely to be low and individuals tend to free ride rather than to contribute to the production of the collective good.

When self-enforcing norms do not work, cooperation may be achieved by embedding interactions in formal and/or informal rules which create 'selective incentives,' that is, added rewards for cooperating and/or punishments for not cooperating. This argument was first forcefully made by Olson (1965) and has been refined by sociologists and other social scientists (e.g., Hechter 1987, Marwell and Oliver 1993, Ostrom 1990). For example, the state punishes tax evasion and provides some standard instruments for contracting; in many countries labor unions offer extra benefits (such as cheaper insurance) for joining the labor union. The formation of institutional solutions has been explained by Hechter (1987) as a two-stage process. First, groups for the joint production of private goods are established (such as insurance). They are small enough that noncooperators can be detected and excluded (hence no free rider problem, see Lindenberg 1998). The profits made from the joint production can then be used to establish selective incentives for the joint production of collective goods. In this way, labor unions may be born out of mutual insurance groups. Abell (1996) adds to this kind of analysis that a proper institutional explanation of cooperation should include the explanation of how cooperation can be combined with rivalry and competition. More work in this direction is needed.

Williamson (1985) has pointed to the importance of 'private orderings' in which, in the shadow of the law, contract partners may voluntarily restrict their own options, thereby creating selective incentives for their own cooperative action. For the partner, such measures work if there are 'credible commitments,' for example, by posted hostages and granted warranties. Sociologists have used this idea successfully to study contractual behavior (e.g., Weesie et al. 1998).

Often, credible commitments are difficult to establish (due to the size of the group) and formal institutional arrangements (with enforced sanctions) may not be available. In such groups, informal rules (social norms) that govern selective incentives for cooperation are needed. Like all rules, informal rules only work if they are enforced, and this creates the second-order free rider problem. Sanctioning noncooperators is itself a (step-level) collective good. There seems to be an infinite regress. How do groups get out of this problem? There is no handy solution to this problem within the rational egoist approach. However, as Heckathorn (1996), following Marwell and Oliver, has shown, public good production is not always subject to the first and second order free rider problems. In fact, the production function (i.e., the function that relates the proportion of cooperators to the level of the public good production) is likely to be S-shaped and only for certain values of the function will the situation have the structure of a PD. The reason for this is that an S-shaped production function

implies a changing marginal utility from cooperation as the proportion of cooperators increases. Interestingly, Heckathorn also found that in certain phases 'hypocritical cooperation,' in which people criticize others for not cooperating even though they do not cooperate themselves, is quite effective in eliciting contributions to the collective good (see also Yamagishi 1986). The main lesson to be learned from Heckathorn's analysis is that collective action should be analyzed dynamically, a conclusion one can also draw from Hechter's analysis of institutional controls mentioned above.

1.1.3 Social networks. It has long been known in sociology that it often matters to people what other people say about them. Cooperation is helped by the effects of reputation within networks. For example, DiMaggio and Louch (1998) found in a national sample that consumers, when they are uncertain about products and performance, prefer to buy goods and services from suppliers with whom they have social ties outside the transaction itself. If the suppliers in such a network are clearly unreliable, the consumers are likely to have heard about it. If these suppliers begin to be unreliable, the network relations can be turned against them. Thus, networks have an information function (people learn about the cooperativeness of certain others) and a control function (people can use the network to sanction noncooperators).

Both aspects have been worked out game-theoretically by Buskens (1999). For dyadic transactions, characteristics of the network (such as density, 'indegree,' and 'outdegree,' i.e., the number of others with whom people are connected) play an important role but it turns out that reputation effects are quite complex and there are indications that they might be less important than the temporal embeddedness. For economic transactions, Uzzi (1996) has found interesting additional effects of networks on tacit knowledge and joint problem solving. Network embeddedness for collective action has apparently not been studied yet in any rigorous way.

Yet another use of networks for the explanation of cooperation has been suggested by Coleman (1990). He points to the importance of intermediaries for the creation of trust and thus for cooperation. Intermediaries can play a number of roles: as advisors who introduce interested parties and facilitate the interaction necessary to create trust; as guarantors who absorb the risk if trust turns out to be misplaced; and as entrepreneurs who combine the resources of several actors to place them into the hands of others who are expected to realize gains. For future research, a sociologically interesting question is under what conditions structures with certain kinds of intermediaries will emerge.

2. *Cooperation Among Socially Rational Individuals*

There is a growing sociological literature on cooperation that holds on to the assumption of rational action but adds specific 'bridge theories' on preferences, learning, and/or framing, the effect of which is to render regard for others quite prominent in the analyses. Hence the term 'social rationality.' While the traditional literature on the effects of socialization was unrelated to the analysis of scarcity and choice, the social rationality literature connects effects of socialization with purposeful action in the face of scarcity. In this literature the trade-off between empirical richness and analytical tractability is different than in most game-theoretic analyses. In the latter, added analytical power and tractability is often achieved by the 'rational egoist' assumption at the expense of some loss in closeness to reality, whereas in the former, some analytical power and tractability is sacrificed in favor of added closeness to reality. Clearly, each kind of approach profits from the existence of the other. In this review, there remains room for the discussion of only a few developments.

2.1 *Goals (Preferences)*

By far the largest amount of literature on cooperation in the 'social rationality' category is concerned with 'social preferences.' Although the term 'preference' is often used in this context, a better term would be 'social goals.' One variant of this approach, found in social-psychological and sociological research, is the 'social orientation' research, in which individuals are differentiated according to their orientation towards others. This orientation is often assumed to be more or less stable and the joint result of nature and nurture. Different types of orientation are distinguished, most frequently the following three: 'cooperative' (the goal is to maximize joint payoffs); 'individualistic' (the goal is to maximize individual payoff); 'competitive' (the goal is to maximize the positive difference between own and other's payoff). Such 'types' can be combined with game-theoretic analyses and/or with analyses of evolutionary learning at the population level.

Sociologists and economists focus especially on questions of signaling and the spread of strategies over time, some of them using genetic algorithms taken from evolutionary biology . This makes *trust* a central concept in the analysis of cooperation. For example: 'Are the tendencies to trust and to honor trust correlated?' (Snijders 1996); 'How can cooperative types convincingly signal their type to others so that they will be trusted and cooperation comes about?' Or 'Under what conditions will effective rules for trusting (i.e., conventions for detecting cooperators) evolve in neighborhood interactions and spread across the population through contact with strangers?' (see Macy

and Skvoretz 1998). Another question concerns the explanation of preferences themselves. For example, Frey (1997) has linked a long tradition in sociology to study the effects of voluntary sacrifice (the 'gift') on others' willingness to cooperate with psychological research on autonomy. He argues forcefully that a cooperative orientation (he speaks of 'intrinsic motivation') is driven out by monetary rewards and by forced cooperation. Conversely, Raub and Voss (1990) investigated circumstances that would create or increase a pro-social orientation.

One problem with the concept of social orientation is that it does not allow for situational influences. Couldn't there be situations in which one is pro-social and others in which one would be quite egoistic? A different approach to social goals incorporates answers to this problem. It consists of assumptions on general human goals that imply different social orientations, most notably the achievement of status (leading to an emphasis on outcome differences), behavioral confirmation (leading to an emphasis on own outcomes) and affection (leading to an emphasis on joint outcomes) (see Lindenberg and Frey 1993). Even if a person has a particular disposition, it now depends on the situation which goal and thus which orientation becomes particularly salient. Note that all three goals are inherently directed towards others.

2.2 Framing Effects

The willingness to cooperate may also depend on how people define a situation. Of particular importance is the difference between gains and losses. Kahneman and Tversky have shown that individuals are keener on avoiding losses than on achieving gains, *ceteris paribus*. This leads to the hypothesis that it is easier to bring about cooperation concerning the defense of a common pool resource than the achievement of a (new) public good. For example, it should be easier to bring about a campaign to preserve a rainforest than a campaign to create a wildlife preserve. The evidence for this is somewhat mixed (see van Assen 1999), but when the disturbing effects are carefully controlled, the framing prediction finds support, especially for initial stages of cooperation (see Sell and Son 1997). There is also a claim that people often cognitively transform a PD into a game with conditional cooperation ('assurance game'). The interesting question then is how the beliefs that others will cooperate are influenced by social circumstances or by cultural beliefs (see, for example, Hayashi et al. 1999), and what influence certain thresholds of cooperation have for triggering conditional cooperation in a larger group (see Yamaguchi 2000).

A different framing effect comes from 'framing through goals' (see Lindenberg 1998). Goals are assumed to have a strong impact on the way individuals define a situation and thereby create a difference between 'foreground' and 'background' information and preferences. What is in the foreground will have a much stronger impact on behavior than what is in the background, *ceteris paribus*. For example, if the goal (the action frame) 'to act appropriately' is salient, then information on normative expectations and ways to meet them are in the foreground, whereas the goal to minimize costs (of meeting these expectations) is in the background. As a result, when the action frame is normative (i.e., driven by the goal to act appropriately), costs of cooperation must be much larger in order to reduce people's willingness to cooperate than when the action frame is, say, gain. In addition, people are likely to signal their action frame to others through their behavior (through 'relational signals') which puts a high premium on including symbolic behavior in the analyses of cooperation, even in game-theoretic analyses.

All in all, in sociology, studies on cooperation are both based on the assumption of rational egoists and on some kind of social rationality. The latter are clearly on the rise in number and sophistication.

Cooperative Learning in Schools

Cooperative learning, instructional methods in which students work in small groups to learn academic material, is one of the most extensively studied and widely used classroom innovations. Hundreds of studies have compared cooperative learning to other instructional methods on various social and academic measures. By far the most frequent objective of cooperative learning research has been to harness its effects on student achievement. Field and laboratory studies of the achievement effects of cooperative learning have been conducted in every major subject, at every grade level, and in all types of schools the world over. Cooperative learning is not only the subject of research and theory, the knowledge generated by that labor is used at some level by hundreds of thousands of teachers. A national survey of US teachers found that 79 percent of elementary teachers and 62 percent of middle school teachers reported making some sustained use of cooperative learning (Puma et al. 1993).

While there is little doubt about the facilitating effect of certain forms of cooperative learning on student achievement, there is still great disagreement over how and why cooperative learning affects achievement. Perhaps more importantly, there is intense debate over the conditions under which cooperative learning practices are effective. Some researchers describe theoretical mechanisms underlying the achievement effects of cooperative learning that are completely different and at odds with those assumed or described by others. In particular, some scholars emphasize the role of incentive structure while others attribute achievement effects to students' interactions in the types of task structures used in cooperative learning. Though often working in parallel, there has been remarkably little cross-fertilization in the work of cooperative learning researchers. Applications and investigations of cooperative learning emerging from different perspectives typically differ in their operationalization of aspects of both the incentive and task structures. As a result, it is difficult to determine which is responsible for which outcomes.

This article summarizes and updates earlier discussions of the major theoretical perspectives that seek to explain the facilitating effects of cooperative learning (Slavin 1995). It describes motivational, social cohesion, and cognitive elaboration perspectives on cooperative learning and explores the conditions under which each may operate. Finally, it suggests future research that will be needed to sustain the study and practice of cooperative learning in the twenty-first century.

1. Four Major Theoretical Perspectives on Cooperative Learning and Achievement

1.1 Motivational Perspectives

Motivational perspectives on cooperative learning emphasize the reward and/or goal structure of the

learning environment (Slavin 1995). In order to achieve personal goals, each student must attend not only to his or her own efforts but to those of other group members as well. Cooperative incentive structures (e.g., group rewards based on the learning of all group members) encourage students to engage in behaviors that help the group achieve its goals. These behaviors include maintaining self-motivation, giving or withholding praise, sanctioning, assisting, and encouraging others. According to the motivational perspective, the beneficial effects of cooperative learning for achievement are primarily due to the incentive provided for students to encourage and help one another to learn.

The motivationalist critique of traditional classroom organization holds that competitive grading and the informal reward system common in classrooms creates and maintains negative goal interdependence among students. Since one student's success lessens the opportunities others will have to succeed, students may hope for others' failure. They are discouraged from supporting each other's efforts. Such conflicts may ultimately lead to peer norms opposing academic achievement.

Motivational theorists build criterion-based group rewards into their cooperative learning methods. In strategies developed at Johns Hopkins University (Slavin 1995), students work to earn certificates and other recognition for their efforts if the average score of each team member exceeds a pre-established criterion (see also Kagan 1995). Methods developed by Johnson and Johnson (1994) and their colleagues often give grades based on group performance. The theoretical rationale for these group rewards is that if students are encouraged to value the success of the group, they will encourage and help one another to achieve. This mode of operation stands in contrast to the negative goal interdependence common in traditional competitive classrooms.

1.1.1 Empirical support for the motivationalist perspective. There is a great deal of empirical support for the motivationalist assertion that group rewards are essential to the success of cooperative learning in classrooms, with one critical qualification. A number of studies have concluded that the use of group goals/rewards enhances achievement only in cases where the group reward is based on the individual learning of each student in the group (Slavin 1995). Most often this means that team scores are derived from quizzes that the team members take individually, without help. When group rewards are given based on a single group product (i.e., without individual accountability), there is little incentive for students to cooperate and one or two group members may do all of the work. In student team-achievement divisions (STAD) (Slavin 1995), students work in mixed ability teams to master material initially presented by the teacher. After working in their teams, students take individual quizzes on the material. Teams can only succeed if they make sure that all team members have learned, so the work sessions focus on team members explaining concepts to one another.

A review of 99 cooperative learning studies that involved durations of at least four weeks compared achievement gains in cooperative learning and control groups. Of 64 studies of cooperative learning methods that provided group rewards based on the sum of group members' individual learning, 50 (78 percent) found significant positive effects on achievement and none found negative effects (Slavin 1995). The median effect size for those studies for which effect sizes could be computed was $+0.32$. Studies which gave rewards based on a single group product, or which gave no rewards, found few positive effects, with a median effect size of only $+0.07$. Studies which compared different modes of cooperative goal structure within the same study found similar patterns. Group goals with rewards based on individual learning were important to the instructional effectiveness of cooperative learning models.

1.2 Social Cohesion Perspective

According to Cohen (1994 pp. 69–70), 'if the task is challenging and interesting, and if students are sufficiently prepared for skills in group process, students will experience the process of group work itself as highly rewarding… never grade or evaluate students on their individual contributions to the group or product.' Cohen's work may be described as social cohesion theories. They emphasize that the effects of cooperative learning on achievement are largely mediated by the cohesiveness of the group. As such, they downplay the role of incentives and accountability (Cohen 1994, Johnson and Johnson 1996). As such, their work often emphasizes team-building activities in preparation for cooperative learning and processing or group self-evaluation during and after group activities.

Cohen et al. (1992) all use forms of cooperative learning in which students take on individual roles within the group. A major purpose of these techniques is to create interdependence within the group and in the classroom. Slavin (1983) terms this 'task specialization.' In Aronson's Jigsaw method (1978), students study material on one of several topics distributed among group members. They meet in expert groups to share information on their topics with members of other teams who have been assigned the same topic, and then take turns presenting their topic to their respective teams. In Sharan's group investigation method, groups take on topics from a unit presented to the entire class and further subdivide them among members of the group. They then

investigate their assigned topics as a group and ultimately present their findings to the class.

The social cohesion and motivational perspectives differ in that social cohesion theorists assume that students will work together because, and to the extent that, they care about each other, the group, and achievement. Motivational theorists, on the other hand, assume that students help their classmates at least in part because it serves their own interests to do so. Both perspectives focus primarily on motivational rather than cognitive explanations for the instructional effectiveness of cooperative learning. Both models treat motivation as the critical variable to be manipulated toward fostering achievement and both regard cooperation as a way to affect student motivation. The relationship (and tension) between the social cohesion and motivationalist perspectives is apparent in the work of Johnson and Johnson (1994). While their models do make use of group goals and group incentives such as recognition and grades, their own and related theoretical writings emphasize the development of group cohesiveness and social group processing strategies.

1.2.1 Empirical support for the social cohesion perspective. The achievement outcomes of cooperative learning methods that emphasize social and task variables are inconsistent. Concerning task specialization, there is evidence that, when well implemented, group investigation can significantly increase student achievement (e.g., Sharan and Sharan 1992). However, research on the original form of Jigsaw has not typically yielded positive effects on achievement, except in cases where group rewards have been added to the original model (Mattingly and Van Sickle 1991). In studies of at least four weeks' duration, the Johnson and Johnson (1994) methods have not been found to increase achievement more than individualistic methods unless they incorporate group rewards (grades) based on the average of group members' individual quiz scores (see Slavin 1995).

Research on the practical applications of methods based on social cohesion theories provide inconsistent support for the proposition that building cohesiveness among students through team-building without group reward incentives will enhance student achievement. Yager et al. (1986) found that group processing activities did enhance the achievement effects of cooperative learning. However, other investigations of the Jigsaw model have found that team building activities had no effect on achievement outcomes.

With the exception of the group investigation model, there is inconsistent evidence that social cohesion and group process forms of cooperative learning that do not include individual accountability are superior to traditional instruction. Further, group investigation methods include an evaluation based on group efforts that is composed of individual team member contributions. This may amount to a type of group reward with individual accountability, and may thus reconcile the findings with the assertions of motivationalist theory.

1.3 Cognitive Perspectives

The cognitive perspectives offer explanations for the beneficial effects of cooperative learning which are quite different from those presented thus far. Under the general heading of cognitive perspectives, these theories can be said to place the value of cooperative learning in the interactions among students during group work. These interactions are said to affect students' mental processing of information to be learned rather than their motivation to learn the material. Within that general heading some work is focused on cognitive development, while other work concerns cognitive processes more generally.

Developmentalist theorists work under the fundamental assumption that children's interactions around appropriate tasks increase their mastery of critical concepts. Vygotsky's 'zone of proximal development' is the distance between the child's actual developmental level as determined by independent problem solving, and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers (Vygotsky 1978, p. 86). Collaborative activity among children promotes growth because children of similar ages are likely to function in each other's zones of proximal development, modeling in the collaborative behaviors more advanced than each could perform as individuals.

Similarly, Piaget (1926) held that social-arbitrary knowledge—language, values, rules, morality, and symbol systems—can only be learned in interactions with others. Interaction is also essential to logical and mathematical thought development in disequilibrating a child's conceptions and in providing feedback about the validity of logical constructions. For example, if a child has an incorrect conception, interaction with peers increases the chances that the child will move to a more sophisticated understanding. There is considerable support for the notion that peer interaction can help nonconservers become conservers, and for the importance of peers working in each other's zones of proximal development.

On the basis of these and other findings, Piagetian and Vygotskian, theorists have prescribed increased use of cooperative activities in schools. Damon (1984) draws on these ideas in proposing a conceptual foundation for peer-based learning which explicitly rejects the use of extrinsic incentives. Nonetheless, despite wide theoretical and laboratory support for the cognitive models of cooperative learning, there is as yet little evidence from classroom experiments done for meaningful intervals that 'pure' cooperative meth-

ods, without group rewards and individual accountability, produce higher achievement. Still, it seems likely that the cognitive processes described by developmental theorists underlie the effectiveness of cooperative learning in any form; motivation to help or encourage others is likely to increase the quantity or quality of peer interactions, which in turn lead to cognitive growth.

1.4 Cognitive Elaboration Perspective

Research in cognitive psychology has long held that that if information is to be retained and integrated in memory, the learner must engage in some sort of cognitive restructuring or elaboration of the material. It is also widely accepted that one of the more effective means of elaboration is explaining the material to another. Noreen Webb (1989) found that the students who gained the most from cooperative activities were those who gave elaborated explanations to others. This contention also is supported in empirical work concerning peer tutoring, and cooperative scripts. Classroom investigations have yielded similar findings in writing instruction and in reciprocal teaching for reading comprehension.

2. Reconciling the Perspectives

The perspectives discussed above are typically debated in the theoretical and empirical literature as if they were contradictory. They arise out of deeply differing metatheoretical orientations, each with well-established theoretical bases and sufficient supporting evidence to assure that they apply in some circumstances. By the same token, their variety assures that none of them is both necessary and sufficient in every setting. The debate is complicated because research in each tradition tends to establish settings and conditions that favor that perspective. For example, most cooperative learning research from the motivationalist and social cohesion perspectives is conducted in classrooms where students may be accustomed to working for extrinsic rewards, and over extended time periods since social cohesion may be expected to take time to develop.

In contrast, studies from developmental and cognitive elaboration views tend to be brief, making issues of motivation moot. These latter paradigms also tend to use pairs, rather than groups of three or more; pairs may involve more simple interaction dynamics and require less time to develop modes of working together. Developmental research almost exclusively uses young children and traditional Piagetian tasks which bear little resemblance to the social-arbitrary learning that characterizes most classroom learning. Cognitive elaboration research mostly involves college student samples.

The various perspectives should be seen as complementary, not contradictory. While cognitively oriented strategies may not explicitly focus on motivation, motivational strategies invariably include peer interaction and cognitive engagement among groupmates. Figure 1 depicts a path through which group goals might directly affect students' behavior to in turn enhance cooperative learning outcomes (from Slavin 1995).

Motivational theorists would not argue that the processes prioritized in cognitive models are unimportant, they simply argue that motivation drives such cognitive processes, which in turn produces learning

Figure 1
Effect of group goals on students' behavior with respect to cooperative learning outcomes

effects. They would argue that over an extended period, students may not engage in the types of elaborated explanations that Webb (1989) credits for cooperative learning effects, without strategies directed at enhancing motivation. By extension, motivational theorists would hold that extrinsic incentives might affect achievement indirectly, by motivating students to engage in peer modeling, cognitive elaboration, and/or practice with one another. Extending this chain of influence farther, the provision of group goals may lead to group cohesiveness, increase caring, and concern among group members, and make groupmates feel responsible for one another's achievement, thus motivating students to engage in cognitive processes that enhance learning. In addition, group goals may motivate students to take responsibility for one another independently of the teacher, thereby solving important classroom organization problems and providing increased opportunities for cognitively appropriate learning activities.

Referring to the model in Fig. 1, researchers from the cognitive perspective attempt to intervene directly on mechanisms considered mediating variables in the motivational view. For example, social cohesion theorists attempt to directly increase group cohesiveness by engaging in elaborate teambuilding and group processing training. One group investigation study suggests that this can be done successfully, but that it takes a great deal of time and effort. In this study, teachers were trained over the course of a full year, and then teachers and students used cooperative learning for three months before the study began. Earlier research on group investigation failed to provide a comparable level of preparation of teachers and students, and the achievement results of these studies were less consistently positive.

Cognitive theorists would hold that the cognitive processes that are essential to any theory relating cooperative learning to achievement can be created directly, without the motivational or affective changes discussed by the motivationalist and social cohesion theorists. This may turn out to be accurate, but at present demonstrations of learning effects from direct manipulation of peer cognitive interactions have mostly been limited to studies of very brief durations and to tasks that lend themselves to the cognitive processes involved. Most of the Piagetian conservation tasks studied by developmentalists have few practical analogs in the school curriculum. At the same time, there is research on reciprocal teaching in reading comprehension which shows promise as a means of intervening directly in peer cognitive processes. Long-term applications of Dansereau's (1988) cooperative scripts for building comprehension of technical material and procedural instructions also seem likely to be successful.

The previous discussion has summarized evidence that generally supports the motivationalist view that group goals and individual accountability can be important to realizing the potential benefits of cooperative learning. This position is by no means absolute and there are conditions under which achievement gains have been found for cooperative learning treatments that lacked group goals, individual accountability, or both. Structured dyadic tasks (e.g., Dansereau 1988) and voluntary study groups, as are often seen among college and graduate school students, are two other instances where factors inherent to the task or scenario may affect students sufficiently to render instructor-imposed group goals and individual accountability unnecessary. By the same token, there is little evidence that the presence of group goals or individual accountability would reduce the outcomes of these methods, and they are likely to enhance their effects. There is a clear need to explore such cases further, if only because the deeply rooted mistrust among educators for extrinsic incentives makes reward-free cooperative learning a practically valuable goal.

The practice of cooperative learning is entering a new phase. On one hand, it is so widely used and so infused in preservice and inservice education that it is no longer seen as an innovation. On the other, much of the application of cooperative learning is informal, unstructured, and inconsistent with the principles of effectiveness derived from any of the schools of thought described here. Cooperative learning often means students sitting together with no particular goal or structure. Where cooperative learning is most appropriately used is in more structured, comprehensive approaches that provide extensive professional development and materials designed specifically for use in cooperative learning. Examples include reciprocal teaching (Webb and Palincsar 1996), writing process, Cooperative Integrated Reading and Composition, and Success for All (Slavin and Madden 2001). These and related programs may represent the future of cooperative learning in the twenty-first century, where cooperative learning is becoming a basic element of comprehensive reform rather than only a generic process to be applied to every subject and grade level to the extent teachers wish to do so.

Research on cooperative learning is needed both to further understand cognitive and motivational mechanisms underlying its effects on achievement and to use this research to develop and evaluate new and increasingly effective forms of cooperative learning. After more than 30 years of research, the potential power of cooperative learning has been demonstrated and causal mechanisms have been extensively explored, but there is still much to be done to achieve the full potential of students working with students to achieve.

The evidence is strong indicating that cooperative learning has the potential to serve as a foundation upon which education in the twenty-first century will be built. Research must strive to provide practical, theoretical, and intellectual guidance to the efforts of

educators the world over in the service of both traditional and innovative goals.

Coping across the Lifespan

'… how a man rallies to life's challenges and weathers life's storms tells everything of who he is and all that he is likely to become' (Saint Augustine).

Coping did not appear as a term in *Psychological Abstracts* until 1967. Since that time, research has been voluminous. A search of *PsycINFO* on 'coping' from 1967 to 1998 yielded about 23,000 entries, making it one of the fastest growing areas in psychology (Sommerfield and McCrae 2000). Studies span infancy to oldest age, and examine coping in almost every imaginable life domain, including health, work, finances, family, parenting, school, peers, bereavement, unemployment, and aging, as well as nonnormative life events, like accidents, crime victimization, cultural upheaval, economic downturns, war, and relocation. (See *Chronic Illness, Psychosocial Coping with*; *Coronary Heart Disease (CHD), Coping with*; *Disasters, Coping with*; *Job Stress, Coping with*; *Illness: Dyadic and Collective Coping*; *Well-being and Health: Proactive Coping*.)

1. Definitions

Coping is a process integral to adaptation and development. As an organizational construct, coping includes 'all those efforts to deal with environmental pressures that [can] not be handled by reflexes or organized skills, but [involve] struggles, trials, persistent focused energy directed toward a goal. So responses to threats and dangers, frustrations and defeats, obstacles, loss, strangeness and the new or unknown, demands from adults and others in the environment, all required study' (Murphy 1974, p. 71). No consensus exists about a more precise definition. Given the current prominence of transactional views, coping is often defined as 'constantly changing cognitive and behavioral efforts to manage specific external and/or internal demands that are appraised as taxing or exceeding the resources of the person' (Lazarus and Folkman 1984, p. 141). Closely related terms include stress, stressor, stressful life events, defense, challenge, threat, adversity, risk, resilience, mastery, vulnerability, thriving, hardiness, and social support. (See *Stress and Coping Theories*.)

Coping incorporates processes from many levels. It

reflects evolution; humans come prepared to recognize and react to environmental demands in ways that promote survival. Coping has a tightly integrated physiological, psychological, and social basis. Many features of psychological functioning, such as emotions, motivation, attention, volition, cognition, and communication are organized in ways that allow them to contribute to coping. For example, emotions signal and organize interactions of adaptive significance. Many aspects of social relationships and cultural systems also contribute to coping. For example, attachment relationships provide a safe haven of protection during times of distress.

Coping has both normative and individual difference features. Normatively, humans are prepared to cope adaptively. In fact, stress is likely necessary for the kinds of sustained constructive interactions that facilitate development. However, human responsiveness to stress is also a vulnerability; too much stress can overwhelm and damage people. In addition, there are enormous differences in how physiological, psychological, social, and cultural resources for coping are distributed across individuals and social groups.

Finally, coping is a process that unfolds over time. Coping takes real time; any specific stressful transaction involves sequences of moment-to-moment interactions. Coping also takes place over episodic time; dealing with demands encompasses a protracted series of specific real-time transactions. As noted by White, 'Described not inappropriately in military metaphors, adaptation often calls for delay, strategic retreat, regrouping of forces, abandoning of untenable positions, seeking fresh intelligence, and deploying new weapons' (White 1974, p. 50).

Given its complexity and centrality to adaptation, it is not surprising that coping has been approached from a wide range of theoretical perspectives. It has been defined as a specific person–context transaction, personality in action under stress, a repertoire of strategies, a hierarchically organized set of ego processes, an indicator of competence, a function of emotion, an outcome of temperament, an expression of stress physiology, and a quality of action regulation. Although it has sometimes been suggested that coping is primarily a manifestation of other phenomena, most researchers vigorously argue that coping processes have an independent causal status; more specifically, they maintain that coping makes a material difference to how stressful interactions are resolved and is a key factor influencing long-term mental and physical heath, well-being, and development in the face of adversity. (See *Stress and Coping Theories*.)

2. *Historical Contexts*

Historically, work on coping started well before the 1960s. It has early forerunners in psychoanalytic work on defenses and has been influenced heavily by the study of stress. Work with children and the elderly reflects a focus on development. Theories have been informed by a host of interventions designed to help people of all ages cope more adaptively with trauma and stressful life events. (For historical overviews, see Lazarus 1993, Lazarus and Folkman 1984, Murphy 1974, Parker and Endler 1996, Snyder 1999.)

2.1 *Coping and Defense*

The concept of defense, as it first appeared in psychology in the early writings of Freud ([1894] 1962), referred to psychological mechanisms (such as repression or projection) used to protect the psyche from disturbing thoughts and emotions, mainly by distorting reality or removing the distressing material from conscious awareness. These ideas were expanded by Anna Freud (1936/1946), who argued that individuals have particular styles of defense which are linked to specific forms of psychopathology.

This formulation influenced several generations of ego-psychologists (e.g., Haan 1977, Valliant 1986, see Cramer 1998). These theorists argued explicitly for a hierarchical model of ego processes, in which some defenses are more mature than others. For example, Haan (1977) posited a three-tiered taxonomy of ego-processes: coping, considered more forward looking, flexible, largely conscious, and attentive to reality; defense, considered to be inherently organized around issues from the past, rigid in operation, unconscious, and distorting of reality; and ego-failure or 'fragmentation.'

Many notions from this approach appear in current theorizing. They include the idea that coping occurs in response not only to environmental demands, but also to intrapsychic pressures; that some ways of coping are inherently superior; and that people consistently show characteristic styles of coping with threat that reflect personality or ego development. Moreover, this work introduced several themes which are resurfacing in current discussions of coping, including the idea that some modes of adaptation are unconscious and unintentional, that distortions of reality can be adaptive, and that the self (or ego) and its regulatory functions are central to processes of coping.

2.2 *Stress and Coping*

A second strand of work on coping emerged from research on stress, a concept prominent in the social and health sciences since the 1930s. Systematic attempts to link stress exposure to specific psychological or somatic outcomes revealed marked individual differences in stress effects. Explicit recognition that living organisms 'fight back,' as captured in terms like 'host resistance,' galvanized interest in the social and individual factors that determine vulnerability or

resistance to the effects of stress. An important branch of this work contributed to the study of coping (Coelho et al. 1974, Lazarus and Folkman 1984, Moos and Billings 1982, Pearlin and Schooler 1978). (See *Stress and Coping Theories*.)

The transactional perspective, currently the most prominent view, was articulated by Lazarus and his colleagues, and held that the experience of stress is shaped by interpretations or appraisals of the meaning of environmental demands. Coping itself is seen as a transactional process, iterating with (re)appraisals and environmental changes, and as having two primary functions: to deal directly with the environmental stressor (referred to as problem-focused coping) and to deal with the emotional consequences of the stressful transaction (emotion-focused coping).

The basic tenets of a transactional perspective include the notion that coping does not directly reflect personality but varies in accordance with the situations in which it occurs; that no ways of coping are inherently better; that any stressful event (such as illness or job loss) gives rise to a complex host of specific and changing demands; and that, in order to cope with these, any individual can and does use a wide variety of strategies. Perhaps most critical is the emphasis on coping as a process that changes over time.

Several methodological shifts in research accompanied this new approach. The measurement of coping shifted from clinical assessment to self-report, and efforts were made to unconfound measures of coping from assessment of outcomes. In addition to a focus on coping with traumatic events (e.g., life-threatening illness or victimization), research also came to include the study of chronic stressful conditions, and relatively minor everyday stressors or 'daily hassles.' Moreover, research became more specialized by type of stressor (e.g., health problems, work stress, or bereavement; see *Disasters, Coping with*; *Job Stress*, *Coping with*). Even within domains, research has become more finely segregated; for example, different medical conditions are often studied separately. (See *Chronic Illness, Psychosocial Coping with*; *Coronary Heart Disease (CHD), Coping with*; *Illness: Dyadic and Collective Coping*; *Well-being and Health: Proactive Coping*.)

2.3 Coping and Development

Child psychologists have had a long-standing interest in the impact of adversity on children and, since the early 1900s, have attempted to document the effects, for example, of maternal deprivation, serious illness, hospitalization, and wartime conditions, as well as more recent attention to the effects of parental mental or physical illness, unemployment, poverty, and divorce. The first formal study of children's coping is often traced to Murphy and her colleagues at the Menninger Clinic, who used intensive observations and interviews to conduct an 18-year longitudinal study of ways in which normal children cope (Murphy and Moriarity 1976).

The 1980s witnessed an explosion of quantitative work, sparked by the publication of seminal works on stress and coping in children by Garmezy and Rutter (1983) and by Compas (1987). Although the current wave of research on children closely resembles work on adults, it nevertheless highlights several important themes. It makes evident that coping is inherently shaped by social partners, close relationships, families, and communities (Hetherington and Blechman 1996) and that cognitive coping strategies, so prominent in adults, are not commonly used by children until late childhood. Research on children also encourages a renewed focus on physiological and temperamental antecedents of coping, as well as attention to coping with normative developmental tasks (Wolchik and Sandler 1997).

Finally, a shift in focus to development across the lifespan spurred interest in how adults successively deal with life transitions, social change, and the challenges of aging (Aldwin 1994, Baltes and Baltes 1990, Brandtstadter et al. 1999). Research on successful aging, in documenting that most people maintain a high level of psychological functioning despite objective biological declines and social losses, focuses attention on positive coping strategies, like selection, compensation, planning, and proactive coping. It also highlights the importance of 'accommodative' modes of coping which allow people to relinquish goals and withdraw from goal pursuit.

2.4 Interventions to Improve Coping

A relatively distinct strand of work involves psychological and behavioral medicine interventions which have succeeded in helping people deal adaptively with traumatic events and their associated ongoing stressors. In contrast to traditional therapy, these interventions focus on providing information and social support, and on helping people build coping resources and skills for dealing more effectively with particular stressors, such as illness, chronic pain, divorce, or bereavement (Sandler et al. 1997).

3. Research on Coping

Since the advent of the transactional approach, mainstream research has focused on the correlates of coping (Compas et al. 2001). Typical studies examine a single population at a single time, assess self-reported ways of coping (e.g., problem solving, help seeking, avoidance) with either a variety of unidentified stre-

ssors or a prespecified narrow class of stressors, and then examine their associations with self-reports of personal and social predictors (e.g., perceived control or social support) and with various outcomes (usually indicators of mental or somatic functioning, such as emotional adjustment or physical symptoms).

This work has identified several clusters of adaptive coping. One is organized around problem solving (information seeking, strategizing, planning, prevention) and seems to be supported by opportunities for control and perceptions of efficacy. (See *Hope and Hopelessness*.) A second is organized around relying on trusted others for comfort, discussion, help, advice, and aid; these ways of coping are supported by the presence of warm and caring social partners and the perception that they are available. A possible third cluster is organized around processes of accommodation (negotiation, compromise, prioritizing, and goal setting) and may be supported by a sense of self-determination and autonomy support from others. In addition, several maladaptive ways of coping have been identified, including catastrophizing and panic, social isolation, venting, rumination, blame of self or others, and escape. These ways of coping are exacerbated by certain situational features and interpretational biases. Such reactions to stress are maladaptive because they tend to exhaust personal and social resources and to interfere with recruiting and implementing effective action.

As a body, however, this work has come under attack on both conceptual and methodological grounds. Studies have been criticized for being light on theory, for inconsistent use of coping categories, for relying heavily on self-reports, for using designs that cannot examine change, and for including only a narrow range of short-term outcomes. (See *Coping Assessment*.) As noted by Sommerfield and McCrae (2000, p. 620), 'The seemingly boundless enthusiasm for coping research seen in the 1980s has been replaced by widespread disaffection, intense scrutiny, and corresponding calls for change.' Cutting-edge research has already moved away from this empirical format and reflects the use of several interesting new approaches.

3.1 Categories of Coping

One factor impeding research has been widespread disagreement about taxonomies of coping. No consensus exists about core categories. Years of exploratory factor analyses have failed to converge on a set of higher-order categories, nor do theorists agree on systems for rational classification. Given the seemingly infinite variety of specific coping responses, even the possibility of identifying a core subset of ways of coping has been questioned. (See *Coping Assessment*.)

One promising approach uses theory and confirmatory factor analysis to identify multiple core categories. For example, researchers attempt to identify a finite set of basic adaptive processes and then to classify multiple heterogeneous ways of coping as belonging to a 'family' of ways of coping that serve each function. Examples of theories used in these attempts include functionalist theories of emotion, theories of motivation, regulation, primary and secondary control, and ego processes. Such discussions expand on the distinction between problem-focused vs. emotion-focused coping and on coping styles (e.g., repression vs. sensitization) as well as reopening discussion of the functions of coping in adaptation.

3.2 Individual Ways of Coping

One productive empirical strategy has been to make particular categories of coping the focus of detailed process-oriented programs of laboratory and naturalistic research. Such studies have produced relatively well-accepted conclusions about positive ways of coping, such as mastery-oriented thinking, disclosure and discussion, constructive thinking, accommodation, and optimism, and about the generally maladaptive consequences of rumination, helplessness, blaming others, catastrophizing, and social isolation. Programs of research on other ways of coping, such as help- or support-seeking, positive illusions, avoidance, denial, and relinquishing control, have produced less conclusive results, including evidence that their effects depend on characteristics of the situations in which they are employed.

It should be noted that almost every activity that is considered a way of coping also has its own well-developed body of research. These include problem solving, information seeking, planning, negotiation, compliance, self- and other-blame, help seeking, social support, opposition, venting, selective optimization, compensation, rumination, disclosure and discussion, primary and secondary control, optimism, and positive illusions. Most of these areas of research are largely independent of work on coping, although some examine the functioning of these processes under stress.

3.3 Coping as a Process

Despite consensus that coping unfolds over time, research methodologies able to capture process are just beginning to (re)appear. These include case studies, ethnographic narratives, interviews, and observations, which were popular decades ago (Folkman 1997, Murphy and Moriarity 1976, Valliant 1986) as well as more recent quantitative methods, such as intra-individual time series analysis (Tennen et al. 2000). Designs are longitudinal, repeating measures over short times (e.g., daily) or over several years, often including markers of the progress of stressful

events (e.g., diagnosis and surgery, or caretaking, deterioration, and death of a partner).

For microgenetic approaches, patterns of intra-individual relations among variables (e.g., problem- and emotion-focused coping) across time are determined. Then interindividual difference variables (e.g., depression or optimism) are used to form groups which are compared on their patterns of intraindividual relationships. Observations of coping interactions with social partners (e.g., mothers and their children) can also be used to examine the sequential effects of individual coping efforts and partner reactions over time. Narratives and interviews capture a wider range of experiences and can track their progress over longer intervals. The yield from this labor-intensive research seems promising. For example, such studies already suggest that both generation of and focus on positive experiences are critical in dealing constructively with chronic stress; that depression influences day-to-day reactions to chronic pain; and that maternal interpretations of negative events shape children's subsequent appraisals and coping.

Additional strategies for capturing coping processes may be suggested by related research, in which fine-grained studies focus on how children and adults deal with certain classes of environmental demands, such as noncontingency, failure, unpredictability, separation, loss, interpersonal conflict, competition, and coercion. Relevant studies come from areas as diverse as learned helplessness, self-efficacy, perceived control, reactance, self-determination, compliance, attachment, interpersonal problem solving, attributional biases, Type-A personality, and self-regulated learning. Many consider the study of coping as a process to be the most important goal of the next generation of coping researchers (Lazarus 1993).

3.4 Coping as Regulation

An explicit theme resurfacing in discussions and research is the notion of coping as an inherently regulatory process (Aspinwall and Taylor 1997, Barrett and Campos 1991). A focus on adaptation suggests that the cognitions, appraisals, motivation, volition, behaviors, and emotions, which are clearly parts of coping, must be assembled into actions which are sequentially coordinated with internal and external conditions. Labels under which such processes are studied include ego functioning (e.g., ego-control and ego-resilience), conscience, functionalist theories of emotion, and theories of volition and regulation of behavior, attention, emotion, and action. Conceptions of coping as a dynamic regulatory process may contribute to the next phase of coping work. Features of the self involved in recognizing and creating 'relational meaning' (Lazarus, 1993) may be studied as integral organizers of regulation. (See *Self-regulation in Childhood*; *Self-regulation in Adulthood*.)

3.5 Future Directions

'Stress' is not inherently damaging to people, and the primary function of coping is not simply to shield people from stressful experiences. Coping is a process which is intrinsic to psychological and relational growth and one which individuals and groups are predisposed to do well. Current interest in positive coping (Snyder 1999) and the study of growth from adversity or transformation in the face of trauma, can be viewed as attempts to conceptualize and study the growth facilitating functions of coping. Analysis of the role of coping in resilience in children (Haggerty et al. 1994) and the relationship of coping and development across the lifespan (Aldwin 1994, Skinner and Edge 1998) may help put these issues in a larger perspective. Future research will likely feature process-oriented studies in both naturalistic and lab settings, using a variety of assessments (interviews, narratives, daily reports, observations) and examining intra-individual relations and change over time. The promise of the area of coping, and its challenge to researchers, is to examine coping as an engine of development or a catalyst for change, to determine if conceptions of coping can provide a process mechanism which explains how people (individually and collectively), in the face of adversity, are able to find and create opportunities for development.

Coping Assessment

Coping with stress has become a major subject of health and clinical psychology over the last decades. Coping assessment is not only an active area of scientific research, but has also found practical application in the fields of health and clinical psychology as well as in organizational and educational counseling. Its primary object is to discover the relative competence or deficit of patients and clients in mastering stressful situations. The omnipresence of stressful events in modern life gives particular importance to coping competence and its assessment.

1. What Is Assessed by Coping Assessment?

Coping with stress as an adaptive response refers to demands appraised as exceeding or taxing the subject's resources (Monat and Lazarus 1991). These demands can consist of microevents such as daily hassles, critical life events, i.e., divorce or loss of a loved person, and chronic strain such as work stress. The responses, termed 'coping with stress,' include different psychological processes and activities: attention processes such as vigilance or cognitive avoidance with respect to threatening stimuli; appraisal of the stress agent (stressor) concerning its significance for one's well-being; cognitive activities altering the meaning of stressful encounters and actions influencing the stress-loaded person–environment relationship.

Several coping responses classifications circulate in research and applications. The most influential distinction emphasizes two fundamental categories: the problem-focused and the emotion-focused coping responses (Lazarus and Launier 1978). Some researchers add a third category: the 'appraisal-focused coping.'

The types of questions which coping assessment should answer concern two major goals: (a) reliable and valid methods for observing, recording, and describing relevant features of coping processes; and (b) methods allowing the estimation of the probability of particular appraisal or coping modalities characterizing individual subjects (interindividual differences).

These probabilities may or may not depend on situation specific conditions.

Coping research, developed over the last decades, uses different strategies for accessing psychological characteristics of coping tendencies and processes. The methods differ according to (a) the information sources, (b) the types of measures, (c) the developmental stage of the subjects, and (d) the diagnostic techniques.

2. Data Sources

The first data source that can be distinguished is *self-report*. Typical, and especially retrospective self-report data, mirror the subjects' cognitive representation of their stress experience and coping behavior, and not how they really behaved. The assessment takes place outside the stressful situation, and memory plays a primordial role.

A second source is direct *systematic self-observation* inside the current stressful situation. This observation focuses on cognitive, emotional, and behavioral processes involved in concrete stress and coping episodes from daily life or experimentally arranged situations. The third data source is assessing coping behavior by systematic *external recording* of psychological features by trained observers. Such methods have been commonly used in the laboratory, for coping at the industrial workplace, and also applied to the family and school context. A fourth potential data source is the direct recording of *psychophysiological and biochemical parameters*.

3. Measurement Type in Relation to the Stressful Situation

A central aspect that differentiates the gamut of assessment procedures concerns the question: how does the method assess coping with respect to the stressful situation?

Some methods measure coping tendencies using *hypothetical situations* that describe potentially stressful scenarios. Participants are asked to imagine how they would probably act in well-described hypothetical situations. These procedures presuppose that the person is able to report reliably and validly his or her probable responses to hypothetical stressful situations. The 'Mainz Coping Inventory' (ABI) of Krohne (1993) measures separately 'vigilance' and 'cognitive avoidance' with respect to ego-threatening and physical-threatening hypothetical situations. ABI contains, for both situation types, four hypothetical scenarios that are followed by ten binary scale items describing possible coping actions. The reliability scores are satisfactory. Miller's Behavioral Style Scale (MBSS; Miller 1987) also measures, on the base of two hypothetical physical and two ego-threat situations, the coping modalities 'monitoring' and 'blunting' that are close to the vigilance–avoidance concept.

Other questionnaires focus on coping with more *complex stressful domains* (including chronic strain), for example the family (Buehler 1990), workplace (Semmer et al. 1996), or critical life events. Such assessments try to answer how people cope with a rather complex and temporally enduring situation, for example an illness or a difficult transition in family development (e.g., the birth of the first child). Most instruments use self-report measures and some self-observation or external observation (Semmer et al. 1996). For example, the Family Crisis Oriented Personal Evaluation Scales (F-COPES) from McCubbin et al. (1987) were created to assess problem-solving and behavioral strategies of families in problematic situations. Thirty coping items focus on features of intra and extrafamilial coping activities. Parent and adolescent norms have been elaborated on the basis of large samples for the five subscales and the total scale.

Various assessment approaches refer the assessed coping to real *experienced stressful situations* in the recent past or to actual ongoing stress encounters. The Ways of Coping Questionnaire (WCQ), the successor of the Ways of Coping Checklist (WCC) from Folkman and Lazarus (1988) can be considered as a variant of such measures. WCQ contains eight subscales measuring coping strategies such as 'Confronting Coping,' 'Positive Reappraisal,' or 'Seeking Social Support.' Participants have to respond to 50 items on a four-point Likert scale on how they coped with a recently experienced stressful situation.

Approaches to assessing ongoing daily coping, record coping activities by daily checklists, or by the experience sampling method (ESM). Here participants record, using a time sampling schedule, at least six times a day for several days, their emotional states, coping activities, and other relevant information.

A fourth group of instruments does not specify the type of stressful situation. These *situation-unspecific* methods ask with what coping modalities participants respond if they encounter a stressful or upsetting situation. For measuring situation-unspecific coping tendencies, Endler and Parker (1990) devised the Coping Inventory for Stressful Situations (CISS), which focus on 'task-oriented,' 'emotion-oriented,' and 'avoidance-oriented' coping in stressful situations. Coping tendencies, for stressful situations in general, are also measured by the questionnaire Stressverarbeitungsfragebogen (SVF) from Janke et al. (1997), which assess 20 different types of coping modalities. Both procedures inform on stable interindividual differences and have good psychometric qualities.

The last group of situations, to which coping assessment has been related, are *laboratory situations* with real (or video-recorded) stressors. The laboratory setting is destined for research purposes. The validations of some questionnaires has profited from such laboratory assessments (e.g., Miller1987).

Table 1
Data resources and situation types characterizing assessment approaches

Data source	Situation type				
	Hypothetical situations	Complex stressful domains and macro events	Concrete life situations in the natural setting	Situation unspecified	Laboratory situation
Self-report	Krohne (1993), Miller (1987), Reicherts and Perrez (1993)	McCubbin et al. (1987)	Folkman and Lazarus (1988)	Endler and Parker (1990), Janke et al. (1997), Brandtstädter and Renner (1990)	Lazarus et al. (1962)
Self-observation (actual)		Cartwright et al. (1995)	Perrez et al. (2000)		
External observation of psychological features		Semmer et al. (1996)	Fabes and Eisenberg (1992)		Miller (1987), Krohne (1993)
External observation of psychophysiological features			Fahrenberg (1996)		Lazarus et al. (1962)

Table 1 summarizes the different data sources and the different types of situations that are used in coping assessment, illustrated with selected examples of instruments.

4. *Coping Assessment Across Life Span*

The type of technical procedure, item format, and content in questionnaires depends not only on the theoretical background and the type of stressors studied, but also on the age of the population which is the focus of the instrument. If it is evident that the same technical procedures can not be applied for illiterate preschool children as for adults, it is less clear, and indeed controversial in the literature, if the quality of coping modes changes across life span, or if at some life phases different frequencies predominate as a function of development-specific needs.

For preschool children, the only means available of assessing coping behavior are systematic observation of the overt behavior in the natural family setting or care institutions, and the use of rating scales by parents who evaluate the coping behavior of their children. Fabes and Eisenberg (1992) describe the modalities to observe systematically the coping behavior of 3.5- to 6-year-old children in anger-eliciting situations at full-day care institutions with categories such as 'active resistance attempts,' 'adult-seeking attempts,' 'revenge-attempts,' and others. The Coping Inventory of Zeitlin (1985) assesses measures for self- or environment-oriented coping tendencies by 3 to 15 year old children and adolescents with respect to the features 'productivity,' 'activity,' and 'flexibility.' 'Coping with Self' concerns the behaviors a child uses to meet personal needs, and 'Coping with Environment' the behaviors to adapt to the demands of the world. Zeitlin considers these properties as relevant for adaptive behavior independent from situation and age. Parents and teachers serve as data sources. An adapted version can be used as self-rating by adolescents and adults.

Most instruments were devised for adults. For the elderly, only few instruments have been developed and evaluated. One of them is the questionnaire of Brandtstädter and Renner (1990) to assess preferences for assimilative and accommodative modes of coping. Assimilation and accommodation processes are supposed to be of first importance to reduce the discrepancy between aspirations and achievements, which are progressively imbalanced in later adulthood. The two statistically independent 15-item scales assess the disposition for tenacious goal pursuit (TGP-scale) and for flexible goal adjustment (FGA-scale). The psychometric qualities of the scales are satisfactory. The above-described instruments illustrate the dependency of the measures (with respect to their content and their technical format) on theoretical assumptions and the developmental stage of the subjects chosen.

5. Technical Procedures

Most assessment procedures work on the base of self-report questionnaires. For an overview see Schwarzer and Schwarzer (1996). They mainly assess coping features and tendencies using multi-item scales. By measuring a coping modality using a set of items loading on the same coping factor, the reliability of the measure is improved. For constructing such scales, classical psychometric methodology offers a rich range of procedures and parameters, such as reliability, validity, and measurement quality evaluation.

Only a few methods observe appraisal and coping behavior within the situation by systematic self-observation. One example is the Family Self-Monitoring-System (FASEM-C), which runs on a palmtop computer. FASEM-C records information on current emotional and somatic states, on antecedents of (stress-) emotions such as the setting, events and appraisal, individual and social adaptive, or maladaptive coping responses (what subjects actually did), and on their short-term effects. All family members (or couples) have to record simultaneously, prompted by an acoustic signal based on a time sampling schedule, six times a day for a weekly period, their own experience and behavior, and the coping behavior of other family members present. Coefficients for reliability, reactivity, and validity are satisfactory (Perrez et al. 2000).

6. What Questions Can be Answered by Coping Assessment?

The types of questions coping assessment can answer depend on the accuracy with which it can observe the underlying psychological phenomena. Most present assessment methods have focused on the cognitive representation that participants have of their appraisal and coping tendencies with respect to specific situations or to stressful situations in general.

Questionnaires with normative data from reference populations allows reliable information on *inter-individual differences*, e.g., CISS or SVF; others permit information on *within-subject descriptions* of appraisal and coping modalities (intraindividual measures), sometimes with respect to one single episode (e.g., WCQ). Questionnaires specially for intra and inter-individual measures have been developed for different age groups (Aldwin 1994).

A third type of information concerns *process-related measures*: process measures assess features of the appraisal-coping processes that can be observed in concrete processes.

The development of such instruments is still in its infancy. The Stress and Coping Process Questionnaire (SCPQ) models the perception/appraisal-stress emotion and coping sequence, starting with a hypothetical stressful situation that the participant has to imagine (Reicherts and Perrez 1993). The subject gives relevant scaled information about his of her probable cognitive, emotional, and behavioral responses. Then the situation is presented with an evolved second and third stage asking similar information. The questionnaire, with satisfactory psychometric qualities, allows the computing of scores on individual differences for process-relevant features. It has the disadvantage of being somewhat time-consuming for the participants. Alternative approaches to access process-relevant features are computer aided self-monitoring procedures.

7. Perspectives on Future Research

As far as the theoretical frameworks deal more with cognitive and behavioral processes and activities than with their subjective representation, it can be expected that the future development will give more emphasis to information on within-situation recorded cognitive activities, emotions, and behaviors rather than on information depending on post-situation reports and the participant's own cognitive representation. The actual method-theory discrepancy is due to parsimonious reasons that have been in favor of representation-oriented questionnaires. Modern miniaturized computer technology now opens rich possibilities, including the concurrent assessment of psychological and physiological measures under real-life conditions (Fahrenberg 1996), but also the simultaneous recording of appraisal and coping behavior of dyads and small groups such as the family. One interesting development, which goes beyond the pure assessment function, is the development of ambulatory expert systems. These systems can aid the user in improving his or her coping behavior.

Coronary Heart Disease (CHD), Coping with

1. Introduction

Coronary heart disease (CHD) is a chronic illness with acute manifestations. Two clinical aspects are angina pectoris (pain) and myocardial infarction (heart attack). CHD refers to illnesses caused by the narrowing of the coronary arteries. Coronary arteries supply the heart with oxygen and when narrowing occurs, the flow of oxygen is reduced. A mild shortage of oxygen causes pain in the chest and arm, while a severe shortage may result in a heart attack. CHD accounts for about 40 percent of all deaths in North America. Both men and women are prone to CHD, although the age of onset for women is about 15 years later than it is for men. Many premature deaths occur as a result of CHD.

2. Antecedents of CHD

2.1 Genetic and Biochemical Factors

CHD is more common among individuals who have a parental history of the disease. This is partially due to genetic predisposition and to family lifestyles that may include risk factors for CHD. Additionally, personality factors related to CHD (e.g., hostility) may be heritable. As one ages, environmental factors (i.e., lifestyle choices) play a more important role than genetics (Rice 1997). Furthermore, family history is an important unmodifiable factor in determining risk for CHD, as are age and gender (Rice 1997). Other risk factors, like lifestyle choices, can be modified.

2.2 Poor Lifestyles

Many behavioral health risk factors have been linked to the development of heart disease, including smoking, alcohol consumption, high serum cholesterol level, hypertension (high blood pressure), obesity, and a sedentary lifestyle. Review studies have shown that risk for CHD is doubled for inactive compared to active persons (Leon 1997). The incidence of heart attacks is directly related to the average number of cigarettes smoked, and smoking affects other risk factors: it results in increased cholesterol levels, increased heart rate, and increased blood pressure (see *Health Behaviors*).

2.3 Stress

Selye (1976; as cited in Endler 1997) proposed his 'General Adaptation Syndrome' in which stress was

defined as the body's nonspecific response to any demands placed on it. Furthermore, Selye distinguished between good stress (eustress) and bad stress (distress).

There are both physical stressors, which include environmental factors, and psychological stressors. Situations that are stressful induce a physiological arousal that mobilizes a fight or flight reaction. This can be adaptive; however, under continued stress, this arousal can be harmful (see *Stress and Health Research*).

Heart rate accelerates when a person is under stress. Exposure to chronic stress has been linked to the development of CHD, and acute stressors have been found to precipitate heart attacks. The amount of stress one experiences at work (occupational stress) has been found to be related to the incidence of CHD. Job factors such as job strain, low job security, and high work pressure are related to increased risk for CHD (Taylor 1999).

2.4 Personality Factors

In the 1970s and 1980s, researchers thought that a particular behavioral style, the Type A behavior pattern, was related to the development of CHD. The Type A behavior pattern consists of a hostility component, a competitiveness component, and a need for everything to be done in a hurry (Friedman 1996). More recently, other researchers have concluded that it is the hostility component (a cynical form) of Type A behavior that is most strongly implicated in the development and progression of CHD (Taylor 1999). This cynical hostility consists of anger, suspiciousness, distrust towards others, and resentment. People who are hostile and have a defensive personality style have been shown to be at a particularly high risk for CHD. Other research has shown that it is the expression of hostile emotions that is related to CHD, not merely being in a hostile state. This research has been predominantly carried out in men, and the relationship between hostility and CHD in women has not yet been clearly established (see *Coronary-prone Behavior, Type A*).

Hostile people manifest more physiological reactivity in response to stress. Stress causes both an increased heart rate and blood vessel shrinkage in some individuals, causing the heart to transfer more blood through narrower blood vessels. Other mechanisms of action include sympathetic nervous system activation resulting in the transfer of lipids into the bloodstream and hormonal based reactions. Alternatively, hostility may not be related to CHD through cardiovascular reactivity, but rather through the relationship between hostility and poor lifestyle choices (i.e., smoking, consumption of alcohol, higher weight, higher lipid level, and hypertension).

Strong relations have also been found between CHD and negative emotional states other than hostility (i.e., anxiety, depression, and aggression). Additionally, optimism has been found to play a positive role. Individuals who are optimistic recover faster following surgery, have better adherence to the treatment regimen, and have better health outcomes (Irvine and Ritvo 1998).

3. Consequences of CHD

3.1 Physical and Psychological Changes

CHD may result in mortality or disability leading to a restriction of activities. Individuals with CHD who have experienced a heart attack may be restricted in social and leisure activities and may be forced to quit working. These physical, social, and occupational changes may affect an individual's self-concept, self-worth, and self-efficacy. There also may be an affect on interpersonal relationships.

4. Coping

4.1 Coping: General Styles vs. Specific Strategies

Coping mediates between antecedent stressful events and distressing consequences. A coping style is a typical manner of confronting a stressful situation and dealing with it. There are three basic coping styles: task-oriented, emotion-oriented, and avoidance-oriented (Endler 1997). Task-oriented coping consists of efforts aimed at solving the problem. Emotion-oriented coping involves emotional reactions; and avoidance-oriented coping involves activities and cognitions aimed at avoiding the stressful situation and can be of a distraction or social diversion nature. One can also conceptualize and investigate coping in terms of how individuals respond to specific stressful situations, such as coping with an illness (see *Stressful Medical Procedures, Coping with*).

4.2 Coping with Illness

There are four strategies that individuals use for coping with illness: (a) distraction coping involves attempts to think about anything other than the health problem or to engage in unrelated activities; (b) palliative coping involves strategies aimed at alleviating the unpleasantness of the illness; (c) instrumental coping involves a task-oriented approach such as seeking medical advice; and (d) emotional preoccupation coping consists of affective strategies such as ruminating about the health problem (Endler and Parker 2000).

5. *Factors Influencing Coping*

5.1 *Personal and Situational Factors*

The individual's personality in a stressful situation affects how one copes with the event. Personality characteristics such as optimism, perceived control, and self-esteem, in part, determine how one copes with stressful situations. There are particular types of situations for which specific coping behaviors are more likely to be effective than others. External factors such as socioeconomic status, time, and social support also affect coping methods. Thus, persons, situations, and their interactions each affect coping styles.

5.2 *Social Support Systems as Resources*

Social support, a resource for coping, is important for adjustment. People seek advice from others, emotional support from others, and others provide opportunities for distracting activities. People with high levels of social support from family, friends, and/or the community may experience less stress and cope more effectively than people without strong support networks. Recovery from cardiac surgery is facilitated by social support (Schröder et al. 1997). In addition to social support, individuals with CHD should seek medical and possibly psychological support (see *Social Support and Recovery from Disease and Medical Procedures*).

6. *Rehabilitation and Prevention*

6.1 *Effective Coping Styles*

Avoidance or distraction coping has been shown to be effective in the early stages of CHD, especially during the first few days following a heart attack. At later stages of CHD, avoidance-oriented coping strategies are not as effective. At this point, an instrumental or task-oriented coping approach is more adaptive (Zeidner and Endler 1996). Furthermore, individuals coping with a chronic illness who use a variety of coping strategies may cope better than those who use one predominant coping style (Taylor 1999).

6.2 *Changes in CHD Risk Behavior*

There are a number of lifestyle changes that result in decreased risk of CHD. These include: (a) changing to a low-fat diet, (b) quitting smoking and decreasing excessive drinking, (c) reducing stress, (d) exercising, and (e) psychological counseling.

The three primary CHD risk factors are hypertension, elevated cholesterol levels, and smoking (Rice 1997). Furthermore, the presence of these factors is of a synergistic nature. Fortunately, all three of these risk factors can be modified. Changes in diet and exercise have been found to reduce blood pressure and decrease cholesterol levels. Exercise tends to decrease heart rate, reduce blood pressure, and improve the overall efficiency of the heart (Leon 1997). Exercise also typically results in weight reduction, which consequently results in the reduction of cholesterol. To reduce blood pressure, the reduction of both salt intake and alcohol consumption are also indicated. The cessation of smoking, which may not be easy, also reduces the risk of CHD substantially (see *Smoking and Health*).

Cognitive-behavioral stress reduction programs have been found to modify personality factors which contribute to CHD (Johnston 1997). Stress and pain management techniques have been shown to be effective in reducing angina and may be part of a rehabilitation program. Rehabilitation programs are directed at both altering risk factors for and reducing symptoms of CHD. These programs include medical evaluation, prescribed exercise, education regarding risk factors, and counseling (Leon 1997). Furthermore, medication such as beta-blocking agents, ACE inhibitors, calcium channel blockers, or diuretics may be prescribed to control blood pressure and for chest pain.

7. *A Systems Model for Reducing Prevalence of CHD*

7.1 *Stress, Anxiety, and Coping Interaction Model*

The multidimensional interaction model of stress, anxiety, and coping is process-oriented and consists of person variables (e.g., heredity, cognitive style) which may interact with one another and with situation variables (e.g., illness, hassles). The interaction of person and situation variables leads to a perception of threat and consequent changes in state anxiety. Changes in state anxiety lead to a modification of physiological reactions and coping responses (Endler 1997).

Stress, anxiety, and coping with illness all involve complex processes that interact with one another. Therefore, it is important to consider all aspects of this process when facing a stressor, especially one as significant as CHD. Person variables interact with situation variables in determining the coping strategies used to face the stressor and affect the physiological arousal and illness experienced.

8. *Conclusions*

There are several factors that one cannot control in terms of risk for CHD (e.g., heredity) but many factors can be controlled, either in terms of prevention or for rehabilitation. The cessation of smoking, engaging in physical activity, and following an appropriate diet all

decrease the risk for CHD. Furthermore, avoidance-oriented coping strategies appear to be more adaptive early on in the illness, while task-oriented coping strategies appear to be most adaptive later on. Psychological counseling may be effective in reducing personality factors, such as hostility, which are related to increased CHD risk.

Coronary Heart Disease (CHD): Psychosocial Aspects

1. Introduction

A comprehensive review of the epidemiology and prevention of cardiovascular disease is given in Labarthe (1998). In industrialised countries, the commonest cause of death is coronary heart disease (CHD). This article will thus focus on CHD and its associated risk factors. Consideration of all of these risk factors is relevant, as virtually all are strongly influenced by psychosocial processes. Large differences in disease rates between countries, evidence that risk of disease changes on migration, large differences within countries according to socioeconomic position and area of residence, and relatively rapid changes over time, suggest that the disease is preventable.

CHD has been defined as 'myocardial impairment due to an imbalance between coronary blood flow and myocardial requirements caused by changes in the coronary circulation.' Atherosclerosis is an important underlying pathological process. The process of atheroma deposition in coronary arteries, however, cannot be observed directly in life without the use of invasive clinical procedures. Even so, the study of symptomatic disease may actually be more appropriate. The clinical disease is, after all, what is experienced and may represent the culmination of a number of pathological processes.

Large differences in disease rates between countries, evidence that risk of disease changes on migration, large differences within countries according to socioeconomic position and area of residence and relatively rapid changes over time, suggest that the disease is preventable. To illustrate this international variation the rates of death attributed to CHD in men and women from the populations participating in the World Health Organisation MONICA (monitoring trends and determinants in cardiovascular disease) study are shown in Fig. 1.

CHD was until recently viewed largely as a twentieth century epidemic. In retrospect it seems clear that CHD occurred before this. William Heberden described the typical symptoms of angina pectoris in 1768. Later in the eighteenth century Dr Samuel Black of Newry, County Down, described many cases of angina pectoris and produced a list of factors associated with increased and decreased susceptibility to angina, which are similar to those currently considered plausible (Evans 1995). While angina pectoris occasionally was recorded as a cause of death, less than 2 percent of all deaths attributed to heart disease in Britain fell into this category even by the early part of the twentieth century.

Atherosclerosis has been demonstrated in Egyptian mummies, but the first contemporary descriptions occurred in the sixteenth century. As CHD is associated with advanced coronary atherosclerosis, the increase in CHD mortality in the first half of the twentieth century would be expected to be accompanied by increases in severe atheroma. However, studies of postmortem records of the London Hospital suggested that there was no such increase. Later data comparing the coronary arteries at postmortem of US soldiers who died in the Korean and Vietnam War reported more atheroma in the early 1950s than the

Figure 1
Male and female IHD (ischemic heart disease) mortality rates in men and women aged 35–64 in 35 MONICA populations in the 1980s Source: The World Health Organisation MONICA project. Ecological analysis of the association between mortality and major risk factors of cardiovascular disease. *International Journal of Epidemiology* 1994; **23**: 505–516

1960s, while CHD mortality in the USA was high and stable over this period. The relative contribution of atherosclerosis and other pathological processes, such as thrombotic tendency, to trends over time and differences between countries in CHD mortality is unclear.

2. International Trends in CHD

Nonsocialist developed countries have generally shown a similar pattern of rise and then fall in CHD mortality. Some, like the United States, experienced an early and rapid fall, whereas others, such as the UK, experienced a relatively late onset decline. Rates in Japan and the Mediterranean countries of Europe are low. These international time trends for men are illustrated in Fig. 2. The MONICA (Monitoring Trends and Determinants in Cardiovascular Disease) study has shown that the recent trends in mortality are attributable to both changes in event rates and changes in case fatality. Changes in case fatality suggest that medical interventions are reducing mortality in groups with existing CHD.

3. Migrant Studies

Migrant studies provide valuable insights into the heritability of disease and the stage of life at which risk is determined. Studies of Japanese migrants to Hawaii and mainland America suggest that as they adopt Western lifestyles their CHD risk increases. More puzzling is the fact that migrants to Australia from Greek islands, despite adopting many of the detrimental habits of their host country, are at lower risk of CHD. It may be that Greek Australians adopt healthier lifestyles in other respects that counterbalance their increased fat consumption and smoking prevalence (Powles 1994).

4. Overview of Risk Factors for CHD

There are a number of personal attributes, often described as risk factors, associated with the development of CHD. Some of these—like age—are fixed. Others, like smoking, are modifiable. And some, like serum cholesterol, though modifiable, are a product of the interplay between an individual's genetic make-up and environmental exposures. A list of some of the

Figure 2
Age standardized death rates attributed to ischemic heart disease from 1968–1997 in men aged 35–74 in selected countries. Source: Peterson S, Mockford C, Rayner M 1999

attributes associated with CHD is set out in Table 1. This list is not dissimilar to the list proposed by Samuel Black 200 years earlier, although Black considered that more affluent people were at greater risk of CHD.

Stamler suggests that the major modifiable risk factors are smoking, high blood pressure, high serum cholesterol, and diet. These major risk factors are powerful predictors of CHD. In a large study of middle-aged US men, smokers in the highest quintiles for serum total cholesterol and systolic blood pressure were around 20 times more likely to die from CHD over the next 12 years as nonsmokers in the lowest quintiles of serum cholesterol and blood pressure (Neaton and Wentworth 1992). Though they are powerful individual predictors of risk these factors only accounted for 23 percent of the variance in CHD incidence in men and 14 percent of the variance in women observed between populations in the WHO MONICA study.

4.1 Age

Age is a strong risk indicator for CHD incidence and mortality. Compared to men aged 40, 50-year old men have five times the risk, 60-year old men have 15 times the risk, and 70-year old men have over 40 times the risk of dying from CHD (Labarthe 1998). A similar steep gradient with age is seen for women. Risk continues to increase into older age groups. Recent evidence suggests that the elderly benefit from risk factor control. This combined with their higher absolute level of risk means that sizeable absolute reductions in CHD risk can be achieved in older people and where therapies may be particularly cost effective.

4.2 Gender

Rates of death attributed to CHD in men are consistently three to four times higher than those in women. There are, however, marked variations in the rates of death between countries, such that women in Northern Ireland or Scotland have CHD death rates that are four times higher than those experienced by Japanese men. The rates of death attributed to CHD in women correlate closely with those in men, suggesting that common environmental factors explain these international differences.

Despite the fact that women have been under represented in epidemiological studies of CHD, it nevertheless appears that risk factors such as serum total cholesterol, blood pressure, and smoking perform similarly in women. But as the disease is commoner in men, the differences in absolute risk are much greater for men.

Men are more likely to smoke than women are, but differences in smoking and other coronary risk factors do not fully explain the observed excess of CHD seen in men. The lower risk of coronary heart disease among women has understandably led to studies of sex hormones. There is at present, however, little evidence to support a decisive role for sex hormones. Many observational studies (of women who had elected to take hormone replacement therapy (HRT)) appeared to support this contention, but the findings of randomized controlled trials (where women were allocated at random to HRT or placebo), while still preliminary, suggest no such protection is given by HRT (Barrett-Connor 2001).

4.3 Family History and Genetic Factors

A family history of CHD in first-degree relatives is associated with an increased risk of CHD (Labarthe 1998). Currently identified major single-gene conditions, for example, familial hypercholesterolemia, are uncommon, so while they are associated with a large increase in risk for an individual, they contribute little to population CHD rates. Other polymorphisms with lower relative risks but greater prevalence are under investigation. Individuals with a family history of premature CHD are at higher risk and thus may have more to gain from risk factor control.

4.4 Early-life Influences

The majority of epidemiological research on CHD has focussed on risk factors acting in adulthood. More recently, it has been appreciated that environmental factors acting *in utero* or in childhood may be important. A series of studies has demonstrated that birth weight is inversely related to risk of CHD, suggesting that suboptimal intrauterine environments result in offspring who, many years later, are more likely to succumb to CHD (Barker 1998). Furthermore, several CHD risk factors have been shown to be related to birth weight. However, taking these risk factors into consideration does not appear to fully account for the influence of fetal development on CHD risk, which seems to involve other, as yet unspecified, pathways. It is also possible that genetic factors could underlie both low birth weight and increased disease risk in adulthood. Whether modifying fetal development will modify later CHD risk is a matter which requires further investigation.

Exposures acting in infancy, childhood, and adolescence may also be of importance. A frequently replicated and long-standing observation is that taller individuals are at reduced CHD risk. Recently, it has been shown that stature in childhood is inversely related to later CHD risk, indicating that the association between height and CHD mortality is not due to differential shrinkage occurring in adulthood amongst individuals most prone to CHD (Gunnell et al. 1998). Growth occurs during infancy and childhood, being influenced by nutrition and infections, as well as genetic factors. Childhood growth may also be

Table 1
Personal attributes associated with ischemic heart disease

Fixed factors	Exposure	Composite markers of risk
Age	Smoking	Serum lipids
Sex	Physical inactivity	Blood pressure
Family history	Diet	Lung function
Socioeconomic-position	Psychosocial stress	Hemostatic factors

	Infections	Insulin resistance
	Climatic factors	Hormonal status
		Homocysteine

Figure 3
Ecological comparison between percentage of calories from saturated fat consumed at baseline and IHD mortality over fifteen years in 15 cohorts from seven countries recruited between 1958 and 1962 (Source: Keys A, Menotti A, Karvonen M J, et al. The diet and 15-year death rate in the seven countries study. *American J Epidemiol* 1986; **124**: 903–915)

influenced by stress. Of the infections acquired in childhood, *Helicobacter pylori* infection has been most widely investigated, but the overall evidence does not strongly point in the direction of a direct causal association between this infection and CHD risk.

4.5 Diet

Various dietary characteristics have been associated with risk of CHD. These include alcohol, dietary fat, and dietary antioxidants such as ß-carotene.

Moderate consumption of alcoholic drinks appears to protect against CHD, with higher rates of CHD in teetotallers and heavy drinkers. Ecological comparisons suggest that wine may exert additional protection but cohort studies appear to show that the type of beverage is unimportant. People who indulge in sporadic—or binge—drinking appear to be at increased (rather than reduced) risk of CHD.

The Seven Countries Study compared the diets of individuals from populations with different rates of CHD. It showed a strong ecological association between CHD mortality and saturated fat consump-

Figure 4
Meta-analysis of results of observational cohort studies of beta-carotene intake and cardiovascular mortality and of randomised controlled trials of the same issue

tion. The results of this study are shown in Fig. 3. The relationship between fats and CHD may be complex with different fatty acids increasing, decreasing or having no effect on CHD risk.

Prospective studies of β-carotene intake showed a significantly lower risk of cardiovascular death among those consuming more β-carotene. The results from the trials, however, indicated a moderate adverse effect of β-carotene supplementation. The results are summarized in Fig. 4

It is likely that the apparent protective association in observational studies represents confounding evidence, as people who eat diets rich in β-carotene or who take supplements are more socioeconomically advantaged and adopt a number of protective health-related behaviors. This finding is of importance both in itself, and as a demonstration of the kinds of spurious findings which can be observed in observational epidemiological studies. The same cautious approach to the interpretation of evidence is certainly required with respect to studies of psychosocial factors.

4.6 Smoking

Smoking was identified as a cause of lung cancer by German researchers in the 1930s and 1940s. Since the results of prospective epidemiological studies in the 1950s it has been clear that heavy cigarette smokers have approximately twice the risk of CHD (Labarthe 1998). This risk is reduced by giving up cigarettes, and returns to that of non-smokers after about 10 years.

4.7 Obesity

Very obese individuals have an increased risk of CHD. A U-shaped association between adiposity and CHD mortality has been seen in many studies. It seems likely that the high mortality among thin people occurs because some thin people are ill and some thin people smoke or drink heavily. Obesity is at least partially related to higher CHD risk because it is associated with higher blood pressure and an unfavorable blood lipid profile (Labarthe 1998). Hereditability models suggest that obesity is, to a remarkable degree, a genetic characteristic of individuals, with only a small proportion of the variance being accounted for by environmental factors. However, the substantial changes in the prevalence of obesity which have occurred within populations such as the UK over a relatively short period of time indicate that environmental factors (notably low levels of physical activity) are of great importance.

4.8 Physical Inactivity

Initially, it was thought that exercise predisposed to coronary heart disease, through cardiac strain. How-

Figure 5
Social class differences in mortality of men 15–64 between 1976 and 1989 from various causes of death
Source: Harding S. Social class differences in mortality of men: recent evidence from the OPCS Longitudinal Study. *Population Trends* 1995; **80**: 31–37

ever, research starting in the mid-twentieth century suggested that occupational physical activity was associated with reduced risk of CHD. Clearly, health-related selection is a serious problem in studying the relationship between physical activity and coronary heart disease, since those with early signs of the disease will be less active. Engagement in leisure time physical activity is also associated with other important risk factors for CHD, such as socioeconomic position. However, the evidence suggests that increased physical activity does protect against CHD, although there is uncertainty about the type, intensity, and frequency of exercise required. A formulation consistent with the current data is that physical activity, which is at a sufficient level to produce cardio-respiratory training, reduces the risk of coronary heart disease, while the value of lower intensity physical activity is unclear. The level of activity which is protective will therefore depend upon the fitness level of an individual. For the unfit individual, even very mild exercise would produce a cardio-respiratory training effect. As the individual gets fitter, a higher degree of exercise will be required.

4.9 Cholesterol

Circulating blood cholesterol is strongly and positively associated with CHD risk. A series of large therapeutic trials of cholesterol reduction demonstrated that this process is reversible and risk reductions of the magnitude predicted from the observational data can be produced. A 20 percent reduction in cholesterol is associated with around 25 percent reduction in coronary heart disease mortality risk (Ebrahim et al. 1998). Early epidemiological studies only measured total circulating cholesterol, but it is evident that subfractions of cholesterol have differential effects on CHD risk. The adverse effects are restricted to the low-density lipoprotein cholesterol fraction, with high-density lipoprotein cholesterol (HDL) levels being inversely associated with coronary heart disease risk.

4.10 Blood Pressure

There is a strong dose–response relationship between increased blood pressure and increased risk of CHD. Large randomized trials of pharmacological blood pressure reduction in middle age have confirmed that blood pressure reduction reduces subsequent risk of CHD (Collins and MacMahon 1994). Several observational studies have also shown that increased blood pressure in early adult life is associated with increased CHD mortality in later life, suggesting that risk trajectory may be set early (McCarron et al. 2000).

4.11 Hemostatic Factors

In the middle of the nineteenth century, Karl Freiherr von Rokitansky of Vienna proposed that CHD had a thrombogenic basis. Since the 1980s, a number of cohort studies have examined the association between

hemostatic factors and coronary disease (Labarthe 1998). There is a consistent independent association between increased fibrinogen levels and increased risk of coronary disease. Some prospective studies have reported increased coronary risk with factors VII and VIII but the data are less extensive and less consistent. Smokers have higher fibrinogen levels than non-smokers and this may in part explain the excess coronary risk observed in smokers. However, the causal nature of these associations is still unresolved, as both risk factors and pre-existing disease may alter hemostatic factor levels, generating associations between hemostatic factors and disease which are noncausal.

4.12 Socioeconomic Position

In most industrialized countries CHD risk is higher amongst people living in worse social circumstances. Whether the apparent gradients in the opposite direction seen during the early stages of the CHD epidemic in industrialized countries, and in newly industrialized countries currently, are real or reflect differential disease coding and reporting, remains uncertain (Davey Smith 1997). Social disadvantage can influence CHD risk in a wide variety of ways, and act across the entire lifecourse. People born into worse social circumstances are likely to have lower birthweight. Socioeconomic deprivation in childhood is associated with poor nutrition and growth, and possibly higher incidence of childhood infections. Behavioral patterns—in particular with relation to diet, physical activity, alcohol consumption, and smoking—are developed in childhood in a socially patterned manner and track into adulthood. In most industrialized countries smoking and dietary patterns associated with increased CHD risk are more common among poorer adults.

Given this wide array of exposures associated with socioeconomic deprivation which could increase the risk of CHD, it is not surprising that studies which have taken into account a limited number of these find they fail to account fully for the socioeconomic distribution of CHD. The large (and in many countries increasing) socioeconomic differentials in CHD risk provide both a model for testing etiological hypotheses and also evidence of an important potential locus for public health interventions. Figure 5 shows the threefold difference in CHD mortality between men in unskilled manual occupations in Britain compared to those in managerial and professional occupations, and the graded difference in risk between these occupational extremes. Clearly, reducing CHD risk among the less socioeconomically advantaged to the same level as that of the most advantaged would have a dramatic influence on overall diseases rates in the population. A further implication is that since socioeconomically disadvantaged people have a considerably increased risk of CHD, which is not purely dependent upon conventional risk factors, they have the most to gain from intervention (see *Socioeconomic Status and Health*).

4.13 Stress

Stress is considered by the general public to be an important cause of CHD. Stress is, however, difficult to define or measure. Epidemiological studies have examined a wide range of potential exposures that fall under the general heading of 'stress.' These include measures which are essentially of personality traits—such as the Type A behavior pattern—through to records of stressful life events or global measures of perceived stressfulness of daily activities. A broader conceptual category of 'psychosocial factors' is now widely used in the epidemiological literature. This includes aspects of social life such as the strength of social support networks or the level of control over their work which people have.

The type A behavior pattern was investigated from the 1950s as a potential cause of CHD. Type A individuals—those who are involved in an incessant struggle to achieve more and more in less and less time—were found to have higher risk of CHD in several early prospective studies (Labarthe 1998). More recent studies have failed to find any association between type A behavior and CHD. It may be that this association no longer exists because CHD is not now considered a disease of the wealthy, stressed, businessman, who in the past was more likely to be diagnosed with the condition. Research on behavioral traits now focuses on those elements of the original type A classification, which are related to adverse social background (such as hostility). These may predict CHD risk because of this, rather than because of any causal link with the disease. Ongoing studies should help to resolve this issue in particular trials of stress management instituted to establish whether interventions in this area can produce beneficial changes (see *Coronary-prone Behavior, Type A*).

Measures of self-reported global stress and other self-reported indicators such as low control at work or poor social networks tend to be related to self-reported CHD symptoms. They less consistently relate to objective measures of CHD. This may reflect an underlying reporting tendency such that people who report higher levels of adversity also report higher levels of symptoms. People with low control over their work (e.g., shift workers in a factory) are, in general, in less favorable social locations than those with higher control over their work. It is not surprising that the former have higher rates of CHD, given the strong social patterning of the disease. Whether these adverse psychosocial factors are one of the causes of the high CHD mortality in the less advantaged or is merely

another consequence of material inequalities is currently not clear.

Further, more methodologically robust, studies employing objective measures of both stress and CHD outcomes are required. It is remarkable that the supposed biological mediators between stress and disease–disturbed functioning of the hypothalamo-pituitary-adrenal axis and possible immune system outcomes of this—have not themselves been related to CHD risk in prospective observational studies. The current controversy—with enthusiastic proponents of stress as a cause of CHD on one side lined up against the majority of academic and research cardiologists and epidemiologists who dismiss the association as spurious—will only be resolved when studies employing better methods report their findings.

5. *Lifecourse Approach*

The long incubation period for CHD has been recognized for many years (Rose 1982), and a lifecourse approach to its etiology is a natural extension of this view. In this discussion we have focused on studies for which the main focus is the social patterning of CHD risk.

However, most of the important risk factors identified for CHD are socially patterned. Table 2 summarizes factors which are putative or established CHD risk factors and/or are of particular interest from a lifecourse perspective, according to their period of influence. It is clear that CHD can be considered the archetype of diseases whose determinants should be sought across the entire lifecourse—from conditions existing at the time of conception and during intrauterine development, through nutrition, growth, and health in childhood, to social conditions, occupation, diet, physical activity, and smoking throughout adult life. In Table 3, we combine a marker of early life circumstances—father's social class—and behavioral and socioeconomic factors acting in adulthood and demonstrate their joint influence on CHD mortality. If factors acting at different stages of life—such as childhood social circumstances, education, deprivation level of area of residence in adulthood, adulthood occupational social class, smoking, and drinking in adulthood—are combined, then very large differences in cardiovascular disease risk can be observed (Davey Smith and Hart 2001). Socioeconomic inequalities in CHD can only be understood through consideration of how a variety of exposures which increase CHD risk are influenced by social circumstances, how this social dependence leads to them clustering across time, such that some individuals are adversely influenced by a wide array of risk factors, and thus how the accumulation of—and interaction between—influences acting at different stages of life determines the pattern of CHD within and between populations.

Table 2
Lifecourse risk factors for coronary heart disease

Maternal health, development and diet before and during pregnancy
Parental history of CHD
Low birth weight
Socioeconomic deprivation from childhood onward
Stress from childhood onward
Poor growth in childhood
Short leg length in childhood
Obesity in childhood
Certain infections acquired in childhood
Diet from childhood onwards
Blood pressure in late adolescence
Serum cholesterol in late adolescence
Smoking from late adolescence onwards
Little physical activity from late adolescence onwards
Blood pressure in adulthood
Serum cholesterol in adulthood
Obesity in adulthood
Job insecurity and unemployment in adulthood
Short stature in adulthood
Binge alcohol drinking in adulthood
Diabetes and components of syndrome X in adulthood
Elevated fibrinogen and other acute phase reactants in adulthood
Certain infections acquired in adulthood

Table 3
Age adjusted relative rates of CHD mortality by father's social class and later life risk factors in the West of Scotland Collaborative study

Father's social class	Smoking	
	Other	Current cigarette

Manual	1.56 (1.18–2.07)	2.78 (2.12–3.63)
	Alcohol	
	< 15 units/week	⩾ 15 units/week
Nonmanual	1	1.17 (0.80–1.70)
Manual	1.44 (1.18–1.75)	1.86 (1.50–2.31)
	Screening social class	
	Nonmanual	Manual
Nonmanual	1	1.53 (1.06–2.21)
Manual	1.46 (1.18–1.82)	1.78 (1.45–2.17)

6. *The Prevention of Coronary Heart Disease*

There are two differing but complementary approaches to prevention: the high-risk approach and

the population approach. The high-risk approach seeks to identify those at highest risk of developing disease and intervene to prevent disease. With this approach it may be easier to encourage people at high risk to alter their lifestyles as these people have a considerable amount to gain personally. The recent results from the WHO MONICA study seem to confirm that the widespread use of effective treatments can reduce the number of symptomatic episodes and deaths attributed to CHD. Such an approach, however, requires that those at high risk be identified and ignores the people who develop symptomatic disease who are at moderate risk. For example, in the Whitehall study only around 40 percent of the coronary deaths occurred in the 20 percent at highest risk.

The alternative approach is the population approach, which seeks to alter behavior across the whole population. The advantage is that it is likely to produce large improvements in population health, for fairly modest changes in behavior. The disadvantage is that the absolute benefit for each individual who makes a lifestyle change is small. This mismatch between the likely size (Rose 1985) of the benefits to the individual and population has been called the 'Prevention paradox.'

It has been shown that brief advice from physicians leads to small, but worthwhile, reductions in smoking rates. Nicotine replacement gum can also aid smoking cessation. School-based antismoking programs have, however, shown disappointing results. The detection and treatment of high blood pressure reduces the risk of CHD and has the added benefit of substantially reducing the risk of stroke. Similarly, lowering cholesterol levels with the statin drugs reduces CHD risk in primary prevention.

Health-related behaviors are influenced strongly by societal, legislative, and fiscal forces, perhaps more so than by individual levels of knowledge and degree of willpower. This is the case with smoking, where cigarette use in a country is responsive to the competing incentives offered by tobacco companies and government policies. The prevention of smoking can only be ultimately successful if the world community accepts the need to restrict the growing, marketing, and use of tobacco (see *Smoking and Health*).

The differences in both behaviors and CHD disease rates clearly illustrate the capacity for populations to change. While simple invocations have modest effects on behavior, social change can result in profound improvements in health. Conversely, where cultures fail to adapt or social structures collapse (as happened in Russia with the demise of the Soviet Union) CHD can increase. Effecting societal change is complex but the potential public health benefits are profound. The concentration of CHD among those in society who are least advantaged suggest that any such policies will be more effective if we seek to improve their lot by improving their income, opportunities, and self-esteem. More inclusive and extensive programs that seek to reduce inequalities in health and improve health for all offer real opportunities to reduce CHD.

Coronary-prone Behavior, Type A

In the late 1950s, two cardiologists working in San Francisco described what they referred to as an 'action–emotion complex' that seemed to characterize patients who developed coronary heart disease (CHD) at an early age. Meyer Friedman and Ray Rosenman suggested that this set of behavioral characteristics, which they labeled the Type A Behavior Pattern, represented a risk factor for CHD. In their view, individuals characterized by intense achievement striving and competitiveness, a persistent desire for recognition and advancement, constant involvement in multiple tasks and activities, a rapid pace of speaking and behaving, time urgency and impatience with others, and easily aroused hostility and aggressiveness were at greater risk of developing CHD than were more relaxed, easy-going, and agreeable persons, who they labeled 'Type B.' In the following 20 years, this concept had a major impact on the emerging fields of health psychology and behavioral medicine, as well as the science and practice of cardiology. The concept even penetrated popular culture, where the labels Type A and B have become widely recognized.

1. *Rebirth of a Mind–Body Hypothesis*

The notion that characteristic patterns of emotion and behavior could confer risk for the development of CHD was not novel at the time of Friedman and Rosenman's initial description of the Type A pattern. Over 100 years ago, Sir William Osler, one of the pioneers in the clinical description of CHD, observed that this illness befell, 'not the neurotic, delicate person … but the robust, the vigorous in mind and body, the keen and ambitious man, the indicator of whose engine is always at full speed ahead.' Prior to the 1950s, psychoanalytically oriented clinicians had also suggested that personality traits such as excessive ambition and aggressiveness seemed to characterize coronary patients and hence might indicate that personality traits somehow contributed to the development of the disease. However, these observations were not subjected to thorough scientific investigation, and as a result had limited impact on behavioral or medical science and even less on the clinical care of coronary patients.

Early in their program of research, Friedman and Rosenman reported controlled studies in which patients with and without CHD differed in the behavioral characteristics included in their description of the Type A pattern. Further, they found that Type A and B individuals differed in physiological characteristics that could be involved in the development of the disease. For example, Type A persons displayed greater daily levels of excretion of catecholamines and other stress hormones compared to Type B individuals. In this early work, Friedman and Rosenman intentionally avoided framing their research as an investigation of personality characteristics because of the limited impact and skepticism surrounding the previous, psychoanalytic speculations about the role of personality in CHD. Most importantly, in the late 1960s they launched a large prospective, longitudinal study of the association between the Type A pattern and subsequent CHD. The prospective design provided a more rigorous test of the hypothesis that Type A behavior somehow influenced the development of CHD when compared to the cross-sectional research they had conducted up to that point. The Western Collaborative Group Study (WCGS: Rosenman et al. 1975) demonstrated that among initially healthy men, Type A's were about twice as likely to develop CHD over an eight-year follow-up period than were Type B's. This relationship remained significant even when established CHD risk factors (e.g., smoking) were statistically controlled. This study provided the first prospective evidence that the Type A pattern was an independent risk factor for cardiovascular disease, at least in a sample of predominately white, North American, middle-class males.

The results of the WCGS prompted a variety of other investigations, and evidence regarding the health implications of the Type A pattern accumulated rapidly. In 1978, the National Heart Lung and Blood Institute sponsored a panel of neutral experts and charged them with the task of reviewing this evidence. The panel's report concluded that the Type A pattern was indeed a reliable, independent risk factor, and that it was about as important in the development of CHD as were the established risk factors such as smoking and high blood levels of cholesterol (Review Panel 1981). This represented a unique development in the study of CHD, as it was the first time a psychological construct had been endorsed as a risk factor by a panel of biomedical experts. The Type A pattern quickly became a central focus of a rapidly emerging emphasis on psychological aspects of cardiovascular disease (Steptoe 1981). However, as discussed below, subsequent years witnessed the accumulation of a more mixed body of evidence concerning the association between Type A behavior and CHD, and a reformulation of what are the key aspects of the Type A syndrome related to CHD and other health outcomes.

2. *Assessment and Underlying Mechanisms*

A variety of methods have been developed to assess Type A, coronary prone behavior. The 'gold standard' of these assessment procedures is the Type A Structured Interview. This approximately 10-minute interview consists of a series of questions concerning the individual's work habits, daily routines, and aspects of the Type A pattern. A semistructured set of prompts and follow-up questions are also included, and many questions are presented in such a way as to evoke Type

A responses from predisposed persons. For example, the interviewer is occasionally somewhat challenging and even provocative, or hesitates and delays the completion of a rather obvious question. The content of the individual's answers is not the primary source of information in making a judgement about the presence and degree of Type A characteristics. Rather, the assessment is based primarily on the style of response. A loud, rapid, and vigorous vocal style, interruptions and 'talking over' the interviewer, and subtle or nonverbal expressions of impatience (e.g., an exasperated sigh), hostility or irritation toward the interviewer (e.g., sarcasm or condescension) are weighted heavily in the classification of an individual as Type A or B, although self-reports of competitiveness, impatience, overinvolvement in work, and easily provoked anger are considered as well. This emphasis on displayed rather than self-reported characteristics is consistent with Friedman and Rosenman's prior clinical observations that Type A individuals were often unable or unwilling to give accurate descriptions of their emotions and actions, perhaps reflecting a lack of insight or a defensive, uncooperative, or mistrusting nature. Although the Structured Interview procedure can produce quite reliable ratings, it has obvious limitations stemming from the need for expert interviewers and raters. Hence, several self-report questionnaires have been developed as alternatives to the Structured Interview. The most widely used of these in the history of Type A research is the Jenkins Activity Survey (JAS: Jenkins et al. 1974). This instrument consists of several multiple-choice questions about the various components of the Type A pattern. Factor analyses have indicated that the primary dimensions of the JAS are hard-driving competitiveness, impatience and speed of activity, and job involvement. Importantly, the JAS does not thoroughly sample the aggressive verbal style, anger, and easily evoked hostility that are weighted heavily in the ratings derived from the Type A Structured Interview. Like many other self-report measures of the Type A pattern, the JAS scores are not closely correlated with the Structured Interview ratings, and are not consistently related to CHD in prospective studies. Further, the various self-report scales are typically only modestly correlated with one another, and in many instances have unique correlates with other psychological characteristics. This suggests that although often grouped together as Type A research, studies using different assessment procedures are likely to be examining what are actually only weakly related personality and behavioral characteristics. These important differences across measures of the construct have contributed to inconsistency in the body of research on the Type A pattern, in part because they identify possibly quite distinct persons as Type A. For example, the self-described competitive, achievement striving, overextended, hurried, and impatient person who scores high on the JAS may or may not have the emphatic, rapid, dominant, and unfriendly vocal and interactional style that would warrant a classification of Type A in The Structured Interview.

A variety of models of the underpinnings of the Type A pattern have been proposed. Among the more influential of these views is that of Glass (1977). He suggested that Type A characteristics reflected a strong desire to exercise control over the people and events of one's life, and a low threshold for perceiving threats to control. From this perspective, the overt Type A characteristics themselves represent a well-developed aggressive style of asserting control in response to perceived threats of loss of control. In another influential model, Price (1982) suggested that a set of beliefs comprise the psychological core of the Type A pattern. She argued that Type A's believe that one must continuously demonstrate self-worth through achievement, that the resources and opportunities for such achievement are limited and often scarce, and that there is no universal moral principle to ensure that other people will be fair in their pursuit of these valued achievements. As a result, in contrast to the more relaxed and trusting Type B, Type A individuals are engaged in a continuous struggle to demonstrate their self-worth, through competitive and adversarial interactions with unprincipled others. Hence, the overt Type A characteristics are the manifestations of this continuous struggle to sustain externally-referenced self-esteem or value, in real or imagined competition with adversaries. These conceptual models have stimulated a great deal of research on the psychological basis of Type A persons, and have served as guides to the development of interventions for the reduction of Type A behavior (Rhodewalt and Smith 1991).

In most models of Type A behavior, the impact of this psychological variable on the development of CHD is seen as occurring through the mechanism of physiological responses to psychological stress. Briefly, Type A's are believed to respond to challenges, threats, and demands with larger, sympathetically-mediated increases in heart rate, blood pressure, and various stress hormones. Over long periods of time, the repetition of this physiological reactivity can initiate and hasten the development of coronary artery disease (CAD) or coronary atherosclerosis, the underlying condition common to the various clinical manifestations of CHD. CAD begins with microscopic injuries to the inner lining, or endothelium of the coronary arteries, and continues through the progressive buildup of fatty deposits at these injury sites. In later stages, a hard, fibrous cover forms, and these advanced plaques can rupture or bleed. At the location of these coronary artery lesions, the passage through which blood would otherwise pass becomes narrowed and oxygen supply to the heart muscle is consequently impeded. Once CAD has advanced to a sufficient degree, exaggerated psychophysiological reactivity can increase the heart's need for oxygen as it beats

more rapidly and forcefully during sympathetic activation. Further, this reactivity can contribute decreased blood and oxygen supply to the heart through the transient narrowing of the coronary artery at plaque sites. Through either or both increased demand or decreased supply of oxygen, psychological stress can evoke an insufficient supply of oxygen to the heart muscle. The resulting myocardial ischemia can provide the clinical manifestations of CHD, such as angina pectoris (chest pain), myocardial infarction (death of heart muscle), or sudden coronary death. A large body of evidence suggests that compared to Type B's, Type A persons do respond to potential stressors with more pronounced psychophysiological responses (Houston 1988). Further, other evidence indicates that such responses can contribute to the initial development of CAD and to myocardial ischemia in individuals with advanced CAD (Rozanski et al. 1999).

In an extension of these models of the connection between Type A behavior and CHD, Smith and Anderson (1986) suggested that Type A individuals not only respond to everyday stressors with heightened physiological reactivity; relative to Type Bs, they are also exposed to more frequent, severe, and prolonged stressors. This greater exposure to challenges, demands, and hassles in everyday life reflects a stress-engendering process, in which the ambitious, competitive, controlling, and hostile style of Type A's leads to more tasks, commitments, and obligations, and to competition, opposition, and antagonism in interactions with others. Hence, the exaggerated psychophysiological reactivity that links Type A behavior to disease comes from two sources—the stressors all individuals face and the additional challenges, threats, and demands Type A's create for themselves.

Another important view of the association between Type A behavior and CHD was suggested by Krantz (Krantz and Durel 1983). He argued that the overt manifestations of Type A behavior are the consequence rather than the cause of the psychophysiological reactivity associated with this pattern. In this constitutional vulnerability model, Type A behaviors are produced by an underlying biologic predisposition to heightened sympathetic nervous system (SNS) responsivity. This underlying responsivity, in turn, also fosters the development of CAD and CHD. Consistent with this view, twin studies have indicated that the Type A pattern is at least partially heritable, and pharmacological studies suggest that the pattern is related to an underlying SNS responsivity (Smith and Gallo 2001).

3. *Evolution of Type A Research*

Shortly after the initial conclusion that the Type A pattern was a reliable, independent risk factor for CHD, several large prospective studies failed to replicate this effect. This led to skepticism in the scientific community about the actual importance of the construct. However, a careful analysis of the evidence revealed possible explanations for the inconsistencies in this literature. In a quantitative review of the available evidence, Miller et al. (1991) found that the Structured Interview was a much more reliable predictor of subsequent CHD than the JAS and other self-report measures of Type A, and that the association between Type A and CHD was larger in initially healthy samples than it was among high-risk samples and among samples with established CHD. The apparent temporal trend of increasing failures to replicate the association between Type A behavior and CHD apparently reflected a growing use of high-risk samples and self-report measures of the behavior pattern. When defined by the Structured Interview, the combined evidence still indicated that Type A behavior was a reliable risk factor for the development of CHD among initially healthy individuals, and that the weaker association in high-risk individuals and clinical samples of CHD patients could be attributed to methodological problems inherent in such study designs. Hence, although the emergence of inconsistent evidence led many researchers and clinicians to lose interest in the Type A concept, this waning importance seems to have been unwarranted.

Inconsistent findings and growing skepticism also had a very positive consequence for the study of coronary-prone behavior. Following earlier seminal work by Matthews et al. (1977), many investigators began to examine the predictive utility not of the global Type A pattern but of its individual components. In these more specific and refined analyses, hostility quickly emerged at the most 'toxic' component among the array of individual Type A characteristics, confirming a centuries-old hypothesis about the negative health effects of anger (Siegman 1994). As an umbrella term, hostility refers to individual differences in the tendency to experience anger, negative beliefs and attributions concerning the motives and intentions of others (e.g., cynicism and mistrust), and overtly aggressive verbal and physical behavior. Achievement striving, competitiveness, and impatience, in contrast, did not seem to be reliable risk factors for cardiovascular disease.

Because measures of hostility existed in several large studies in which individuals had completed personality tests decades earlier and were followed over many years, independent tests of the health consequences of hostility could be conducted without the need to begin additional long-term, prospective studies. For example, hostility scales could be derived from the true–false item pool comprising the Minnesota Multiphasic Personality Inventory (MMPI), and this psychological test had been in wide use for many several decades, nearly throughout the world. Hence, a literature on this element of the Type A pattern grew rapidly. As with the global Type A pattern, these

prospective studies of hostility and subsequent health included mostly positive or confirmatory findings regarding the negative health consequences of hostility, but some failures to replicate the effect as well. However, in a recent quantitative review of this literature, behavioral ratings of hostility and self-report measures of the construct were found to be reliable predictors of the later development of CHD and premature mortality (Miller et al. 1996).

As in the case of the global Type A pattern, research on the mechanisms linking hostility and CHD has focused on psychophysiologic responses to potential stressors (Williams et al. 1985). In response to potential social stressors administered in the laboratory such as disagreements, conflicts, debates, and harassment, hostile persons respond with larger increases in heart rate, blood pressure, and stress hormones (e.g., circulating catecholamines) than their less hostile counterparts. Further, ambulatory studies indicate that this exaggerated psychophysiological reactivity is also characteristic of the responses of hostile persons to their natural, daily environments (Smith and Gallo 2001). Other research has indicated that among persons with CAD, episodes of anger can precipitate myocardial ischemia and even infarction (Rozanski et al. 1999), and that hostile persons with CAD may be particularly prone to such responses. Hence, the psychophysiological responsiveness of hostile persons may be the key mechanism through which they are at increased risk of disease.

Hostility is also associated with greater exposure to interpersonal stressors such as heightened levels of conflict with and reduced levels of social support from friends, family members, and co-workers (Smith and Gallo 2001). Further, much of this 'psychosocial vulnerability' associated with hostility may stem from the impact of the hostile person's thoughts and actions on his or her social environment. Given their mistrusting, cold, and antagonistic interpersonal style, hostile persons may undermine sources of social support and create conflicts, thereby creating more frequent, prolonged, and extreme social stressors to which they react with heightened reactivity. This discordant, unsupportive social environment would also tend to maintain and perhaps even exacerbate the hostile personality style.

Hostility may not be the only 'toxic' element within the global Type A pattern. In a reanalysis of the original Structured Interviews from the WCGS, Houston et al. (1997) found that behavioral ratings of hostility and a vigorous, dominant interactional style were separate predictors of later CHD and premature death. These authors suggested that hostility and social dominance are separate coronary-prone characteristics. The possible health consequences of social dominance have a clear parallel with one of the best-developed animal models of stress and individual differences in social behavior as risk factors for cardiovascular disease. Kaplan et al. (1994) demonstrated that socially dominant, male cynomolgus monkeys develop more severe coronary artery disease in response to chronic social stress (i.e., recurrent exposure to novel cage mates) than socially subordinate males. Further, this differential impact of social stress among dominant males on vulnerability to coronary disease is apparently mediated by sympathetic nervous system activity. When dominant male animals receive pharmacologic blockade of beta-adrenergic input to the heart, they no longer display vulnerability to coronary atherosclerosis even when under chronic social stress. Hence, chronic sympathetic nervous system activation of the heart and vasculature, as dominant males recurrently assert their status and respond to related challenges and threats, may underlie this psychosocial effect on atherosclerosis. In humans, efforts to assert dominance or control over others is also associated with increases in blood pressure and heart rate (Smith et al. 2000), again suggesting that psychophysiological reactivity could connect a second 'toxic' component of Type A behavior—social dominance—to the later development of CHD.

4. *Application of Type A Research*

The most obvious benefit of research identifying risk factors for the development and progression of CHD is the design of related, risk reducing interventions. In the case of Type A, coronary-prone behavior, this actually raises two questions. First, can Type A behavior be changed? Second, if so, do such changes reduce the risk of CHD? These questions were the focus of a large, controlled clinical trial conducted by Friedman et al. (1984)—the Recurrent Coronary Prevention Project (RCPP). Compared to a control group receiving typical information and counseling to make appropriate changes in health habits to reduce cardiac risk (e.g., smoking cessation, diet, exercise), postmyocardial infarction patients who had undergone group therapy designed to identify and reduce Type A behavior were indeed able to change these characteristics, as measured by Structured Interview ratings. Further, patients receiving this psychological intervention were much less likely to experience a recurrence of their coronary disease such as a second myocardial infarction. Among patients with mild initial coronary disease, the intervention also reduced the incidence of subsequent coronary deaths (Powell and Thoresen 1988). Based on the conceptual model of Price described above, this intervention consisted of cognitive restructuring directed toward altering the beliefs underlying the Type A pattern, reducing exposure to environmental cues that activate Type A tendencies, rehearsing alternative, Type B responses to such situations, and instruction and practice of relaxation exercises and other stress management skills.

A variety of other programs have been developed to modify the Type A pattern, but few have been evaluated in large controlled trials with definitive medical outcomes as in the RCPP. However, the general approach of stress management and related psychological interventions for coronary patients has been found to be successful in reducing recurrent events in this population (Linden et al. 1996). For example, Blumenthal et al. (1997) found that a stress management intervention reduced the frequency of episodes of myocardial ischemia occurring during the daily activities of patients with advanced CAD. Although not specifically targeted at Type A behavior, such interventions are designed to reduce complications from heart disease by altering emotional and physiological stress responses.

5. *The Future of Research on Coronary Prone Behavior*

Since the height of scientific and popular attention in the 1970s and 1980s, the number of research studies published each year on Type A behavior has steadily decreased. However, this reflects an evolution rather than growing neglect. The focus on hostility as the toxic component within the global Type A pattern continues in epidemiological, psychophysiological, and intervention research. Further, other individual differences have emerged as reliable risk factors as the search for coronary prone behavior continues and broadens. For example, symptoms of anxiety and depression appear to be reliable risk factors for the initial development of CHD, and are associated with poor prognosis among patients with established disease (Januzzi et al. 2000). These other coronary-prone behaviors will also be the focus of additional studies of their predictive utility, the psychobiological mechanisms through which they impact the development and course of CHD, and the effectiveness of related interventions. The addition to the specific research discussed above, the seminal work of Friedman and Rosenman represents a cornerstone of the study of behavioral aspects of cardiovascular disease. In fact, despite an inconsistent reputation in the scientific community and the popular press, the Type A concept played a central role in the rapid development of the broader fields of health psychology and behavioral medicine. It also has been influential in the expanded attention to psychological factors in the clinical care of patients with CHD.

Corporate Culture

1. *How to Think About and Define 'Culture'*

To understand corporate culture one must first understand the concept of culture. A chronic issue in conceptualizing culture is whether to think of culture as a static *property* of a given organization—its shared customs, beliefs, norms, values, and tacit assumptions, or whether to think of culture as a *dynamic human process* of constructing shared meaning (Frost et al. 1985). Culture *creation* is one of the unique characteristics of humans, being based on our capacity to be self-conscious and able to see ourselves and others from each others' points of view. It is this reflexive capacity of humans that makes culture possible. At the same time, it is the human need for finding meaning that creates the motivation for culture stabilization. Without some predictability, social intercourse becomes too anxiety provoking. Developing shared meanings of how to perceive, categorize, and think about what goes on around us is necessary to avoid the catastrophic anxiety that would result from reacting to everything as if it were a new phenomenon (Weick 1995).

Given these human characteristics, it then becomes clear that culture is both a process and a state. In new situations, shared meanings must be constructed through a social learning process. As these meanings help the participants to make sense of their world they become stabilized and can be viewed as 'states.' At the same time, as the members of a group interact, they not only recreate and ratify prior meanings but also construct new meanings as new situations arise.

A useful way to think about this issue is to take a cue from the anthropologist Marshall Sahlins (1985), who argues that one cannot really understand certain social phenomena without understanding both the historical events and the cultural meanings attributed by the actors to those events. While it is undeniably true that we produce and reinforce culture through perpetual enactment and sense making, it is equally true that the actors in those same social events bring to them some prior meanings, stereotypes, and expectations that can only be understood in a historical context. Culture production in the enactment sense, then, is either the perpetuation of or a change of some prior state, but that prior state can be thought of as 'the culture' up to that point. And one can describe that culture as if it were a 'state' of the existing system, even though one knows that the system is dynamic and perpetually evolving. The direction of that evolution will be a product of several forces: (i) technological and physical changes in the external environment; (ii) changes in the internal dynamics of the social system; and (iii) historical circumstances that are fortuitous or serendipitous.

For example, let me offer my oversimplified summary of Sahlins's very sophisticated analysis of the death of Captain Cook at the hand of the Hawaiians. Because Captain Cook was viewed as a God (as predicted in the Hawaiian mythology), the sexual favors offered to his sailors by the Hawaiian women were viewed as gifts and as opportunities to relate to the divine. The sailors' cultural background defined this as a version of prostitution, however, for which they felt they should pay. When they offered the women something in exchange for the sex, the women asked for something that was scarce in the society, namely metal. Once the loose metal on board the ships had been used up, the sailors began to pull nails from the ship itself, weakening it structurally. Hence, when Captain Cook set sail he discovered that the ships needed repair and ordered a return to harbor. In Hawaiian mythology a God returning under these circumstances had to be ritually killed. At the same time, Hawaiian social structure was undergoing change and became permanently altered because the subordinate role of women in the society was altered by their ability to acquire metal, a scarce resource that gave them social power.

When one contemplates this wonderful analysis it appear pointless to argue whether culture should be viewed as a state of the system or as a process of enactment. Clearly there was a culture in Hawaii and a different culture on board the British ship, and clearly the interaction of these two cultures produced events that had a profound impact on both of these cultures.

2. Implications for 'Organizational' Culture Analysis

The major lesson of Sahlins's analysis is that *when we have access to historical data we should use it*. Organizations have defined histories. Therefore, when we analyze organizational cultures we should reconstruct their histories, find out about their founders and early leaders, look for the critical defining events in their evolution as organizations, and be confident that when we have done this we can indeed describe sets of shared assumptions that derive from common experiences of success and/or shared traumas. And we can legitimately think of these sets of assumptions as 'the culture' at a given time. That description will include subcultures that may be in conflict with each other, and there may be subunits that have not yet had enough shared experience to have formed shared common assumptions. In other words, culture as a state does not have to imply unanimity or absence of conflict. There can be some very strongly shared assumptions, and large areas of conflict and/or ambiguity (Martin 1992) within a given cultural 'state.'

At the same time, we can study the day-to-day interactions of the members of an organization with each other and with members of other organizations to determine how given cultural assumptions are reinforced and confirmed, or challenged and disconfirmed. We can analyze the impact of these perceptual interactive events in order to understand how cultures evolve and change. This process could be especially productive in mergers, acquisitions, and joint ventures of various sorts. Whether one chooses to focus one's cultural research on building typologies of cultural 'states,' categories that freeze a given organization at a given point in time, or on analyzing the moment to moment interactions in which members of a given social system attempt to make sense of their experience and, in that process, reinforce and evolve cultural elements, becomes a matter of choice. Both are valid methodologies and in practice they should probably be combined.

3. A Formal Definition of Culture

Culture as a property or process of any group can now be defined as: a pattern of shared basic assumptions that the group has learned as it solved its problems of external adaptation and internal integration, that has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way to perceive, think, and feel in relation to those problems (Schein 1992).

Once these patterns have been learned they function to reduce anxiety and provide moment-to-moment meaning and predictability to daily events. Or, as Trice and Beyer (1993) put it: 'Human cultures emerge from people's struggles to manage uncertainties and create some degree of order in social life' (p. 1). Note that patterns of overt *behavior* are not part of the formal definition because such patterns can arise through other causes such as common instinctive patterns (e.g., ducking when we hear a loud noise) or by common reactions to a common stimulus (e.g., everyone running in the same direction to avoid some threat). If one understands the shared basic assumptions, one can determine which regularities of behavior are 'cultural' and which ones are not. One cannot, however, infer the assumptions just by observing behavior.

4. A Conceptual Model for Analyzing Culture

Whether one chooses to analyze culture as a state or as a process, it is helpful to differentiate the levels at which culture as a shared phenomenon manifests itself. Any group, organization, or larger social system can be analyzed in terms of (i) its visible and feelable 'artifacts,' (ii) its espoused beliefs and values; and/or (iii) its less visible, taken for granted shared basic assumptions (see Fig. 1).

This model is useful in two ways: (i) it helps a novice observer of organizational culture to differentiate the superficial manifestations and espoused values that most organizations display from the cultural substrate or essence, the tacit, shared assumptions that drive the day-to-day behavior that one observes; and (ii) the differentiation of levels is a necessary conceptual tool in helping an organization to decipher its own culture.

To further understand these distinctions, especially the distinction between espoused values and shared tacit assumptions, it is necessary to take a historical evolutionary point of view toward culture formation. If we take a typical business organization, the process starts with one or more entrepreneurs who found a company based on some personal beliefs and values. As they hire others to work with them they will either choose those others on the basis of their compatibility or will socialize newcomers to the beliefs and values that they regard as core to running the new business. The founders' beliefs and values will cause the organization to make decisions in its environment, and if those decisions are successful, the newcomers will begin to entertain collectively the idea that the founder's beliefs and values must be 'correct.' As the environment continues to reinforce the behavior of the organization, what was originally the founder's *personal* beliefs and values gradually come to be *shared* and imposed on new members as the organization grows. If this success cycle continues, these shared beliefs and values gradually come to be taken for granted, drop out of awareness, and can therefore be thought of as 'taken for granted assumptions' that become increasingly non-negotiable.

This process of culture formation will occur not only in reference to the organization's primary task in

The levels of culture

its various external environments but also with respect to its internal organization as well. Those founder beliefs and values, which make life livable and reduce interpersonal anxiety, will gradually come to be taken for granted and come to be tacit assumptions about the 'correct' way to organize. But in both domains the driving force is what works. Culture is the *result* of successful action. If things do not work out the group will disappear.

A basic need in human groups is to justify what they do. And, paradoxically, the justifications often are not the same as the tacit assumptions that actually determine the behavioral regularities. Thus groups create ideologies, aspirations, visions, and various other kinds of 'espoused values' which may or may not correspond isomorphically with the tacit assumptions. The most difficult aspect of deciphering organizational cultures, then, is to determine to what extent the claimed espoused values actually correspond to the behavioral regularities observed and, if not, to determine what the shared tacit assumptions are.

5. *How to Describe Cultures*

There are three approaches to describing cultures: (i) profiling them on various preselected dimensions; (ii) creating conceptual typologies into which to fit given cultures; and/or (iii) clinical or ethnographic descriptions that highlight unique aspects of a given culture.

Among the profiling approaches, one of the most widely used is Hofstede's four dimensions based on factor analyzing questionnaire responses—Individualism (vs. Groupism), Masculinity (the perceived gap between male and female roles), Tolerance for Ambiguity, and Power Distance (the perceived distance between the most and least powerful in the society). These dimensions used originally to describe national cultures but have also been extended to descriptions of organizational cultures (Hofstede 1980, 1991).

A different approach has been to use sociological dimensions developed by Parsons (1951) and elaborated by Kluckhohn and Strodtbeck (1961) as a way of creating profiles of a given organization and identifying critical value issues—universalism vs. particularism, individualism vs. collectivism, affectively charged vs. neutral, specific vs. diffuse, time orientation, and degree of control over nature (Hampden-Turner and Trompenars 1993, Trompenars 1993). A third version of this approach is to take one or two dimensions, consider them to be conceptually central, and create a typology based on a two-by-two table with those dimensions. Cameron and Quinn (1999) use (a) Flexibility vs. Stability and Control and (b) Internal Integration vs. External Differentiation to create four types of cultures—Clan, Adhocracy, Hierarchy, and Market. Goffee and Jones (1998) use the dimensions of Degree of Solidarity and Degree of Sociability to create four types—Networked, Communal, Fragmented, and Mercenary. Among the typologies we have Likert's Systems 1 to 4, Harrison

and later Handy's 'Gods of Management,' McGregor's Theory X and Theory Y, Ouchi's Theory Z, and the more popular distinctions between 'command and control' vs. 'committed and empowered' (Likert 1967, Handy 1978, McGregor 1960, Ouchi 1981).

The clinical or ethnographic approach attempts to deal with any given culture as a unique pattern of shared assumptions around issues that are not known before the clinician/researcher is on the scene as an observer and active inquirer (Schein 1987, 1992, 1999). The prime objection to questionnaires as research tools for the study of *culture* is that they force us to cast the theoretical net too narrowly. The advantage of the ethnographic or clinical research method is that we can train ourselves consciously to minimize the impact of our own models and to maximize staying open to new experiences and concepts we may encounter. In the end we may well sort those experiences into the existing categories we already hold. But at least we will have given ourselves the opportunity to discover new dimensions and, more importantly, will have a better sense of the relative salience and importance of certain dimensions within the culture we are studying. The issue of salience is very important because not all the elements of a culture are equally potent in the degree to which they determine behavior. The more open group oriented inquiry not only reveals how the group views the elements of the culture, but, more importantly, tells us immediately which things are more salient and, therefore, more important as determinants.

As to the categories themselves I have found it empirically useful to start with a broad list of 'survival functions'—what any group must do to survive in its various environments and fulfill its primary task, and 'internal integration functions'—what any group must do to maintain itself as a functioning system. This distinction is entirely consistent with a long tradition of empirical research in group dynamics that always turns up two critical factors in what groups do—(i) task functions; and (ii) group building and maintenance functions. Ancona and others have pointed out that we must add a third set to these two—boundary maintenance functions (Ancona 1988). Task and boundary maintenance functions are external survival issues, and group building and maintenance functions are internal integration issues. We may then construct different lists of what specific dimensions of behavior, attitude, and belief we will look for in each domain, but at least we have a model that forces us to cast the net widely, and a reminder that culture is, for the group, the learned solution to all of its external and internal problems.

If we then look a little deeper, drawing again on anthropology and sociology, we find broad cultural variations around deeper, more abstract issues such as those developed by Kluckhohn and Strodtbeck. Also useful is the work of England (1975) on managerial values which deals specifically with how in a given culture one arrives at 'truth.' If one combines these dimensions with some of the dimensions identified by Edward Hall (1966, 1976, 1983) on concepts of space and spatial relationships, and with more recent concepts about the nature of the 'self' in different cultures, one has a pretty good template of what culture covers at this deeper level.

6. *Does Corporate Culture Matter?*

Several claims based on various different kinds of research have tried to show a connection between the strength and/or type of culture and economic performance (Deal and Kennedy, 1982, Denison 1990, Kotter and Heskett 1992, Collins and Porras, 1994). The problem is that different kinds of cultural dimensions relate to different kinds of environments in ways that are not entirely predictable. The best way to summarize, then, is to say that culture certainly influences economic performance, but the manner in which this occurs remains highly variable. A culture that can be very functional in one environment or at one stage in a company's evolution can become dysfunctional and cause that same company to fail. Culture needs to be analyzed and understood, but until much more research has been done, one cannot make generalizations about its impact.

Corporate Finance: Financial Control

Corporate finance is concerned with financial decisions made by corporations. These decisions can be grouped easily into two major categories: investment decisions and financing decisions.

Regarding the first major decisions a firm must take, each company needs real assets (tangible and intangible) to carry on its business and keep its operations going. How much a firm should invest and what specific assets a firm should invest in are the typical questions related to investment decisions. Investment decisions, then, determine the total amount of assets held by a company and the composition of these assets. The economic evaluation of investment projects aims at orienting corporations' choices connected to their asset allocation process. This process that leads a company to allocate its capital to investment proposals whose benefits are to be realized in the future is generally referred to as *capital budgeting*.

All the assets we mentioned above are to be paid for. To raise the money necessary to their investments policy, corporations issue securities on financial markets. These financial assets have value since they represent claims on companies' real assets. Securities issued by corporations include not only shares of stock but also bonds, bank loans, lease obligations, and any other form of financing. How the cash required for investments should be obtained is the answer that financing decisions must give. Financing decision, in fact, are concerned with determining the best mix of financial sources in the form of equity and debts. In other words, financing decisions define the total amount and the composition of a company's capital structure. The definition of capital structure referred to is that which takes into account the explicitly costly forms of financing raised from the company's investors. For sake of simplicity, they are divided into financial debts and equity without dwelling on the different form of financing.

According to what has been highlighted about corporate finance decisions, financial management attempts to find specific answers to needs arising from both investment and financing areas.

After defining what corporate finance decisions are concerned with, the next step in this analysis will be to reread investment policies and capital structure decisions in the light of the theory of shareholders' value. Since the principle of maximizing shareholders' wealth largely is accepted as the rational guide for running a business and for the efficient allocation in an economy, it is assumed to be the objective in considering how financial decisions should be made.

Investment decisions and financing decisions must contribute together to create value for the company's shareholders. From one hand, a financial manager that acts in its shareholders' interest should invest in those projects that increase the overall firm's value and, then, its shares' value. From the other hand, the mix of financial resources that maximizes the company's value should be adopted. From this point of view, it becomes crucial to understand how corporate borrowing affects its shareholders' wealth according to Modigliani and Miller proposition II. In their article, Modigliani and Miller (1963) state that, in a world with taxes, the value of a levered firm increases in proportion to the debt–equity ratio (Debt/Equity). As we will show in Sect. 6 this is due to the fact that financial charges are tax deductible whereas dividends and retained earnings are not; an increase in debts will reduce the company's cost of capital and raise the firms' value.

In addition to that, it must be kept in mind that investment decisions and financing decisions interact, sometimes producing different consequences on the company's value. In fact, any change in the firm's capital structure influences the cost of capital that a company applies to discount investments cash flows. Consequently, any rise in the cost of capital could make any investment less profitable, reducing its contribution to the overall company's value.

From what has been said, it can be concluded that both investment and financial decisions have to be analyzed in relation to their impact on the firm's major objective: to make the firm's shareholders as well off as

possible. As a result, an optimal combination of the two areas of decision will maximize the value of the firm for its shareholders.

Consistent with that, the financial manager must act as an intermediary between the firm's operations and capital markets where the firm's securities are traded. The purpose of capital markets is allocating savings efficiently in an economy, from ultimate savers to ultimate users of funds who invest in real assets (companies). In fact, companies issue securities and raise cash by selling those financial assets to investors. Then the cash is invested in the firm's operations and used to purchase real assets. Later, if the firm does well, the real assets generate cash inflows that more than repay the initial investment. Finally, once the firm's operations generate new cash, this is either reinvested in the company or returned to investors who hold the securities originally issued. The last decision is not completely free for the financial manager, but it depends on several factors such as the characteristics of the specific financing, the dividend policy, the financial needs of the company.

1. Corporate Finance Decisions and Financial Control

In order to make optimal financial decisions in keeping with the major objective of the firm (i.e., maximizing its shareholders' wealth), the financial manager must implement inside the firm an effective process of analysis, planning, and control and make use of some analytical tools. In fact, financial analyses are a necessary condition for making appropriate financial decisions in the meaning as stated before. From a very simplistic point of view, in order to create value for all the company's investors (debtholders and stakeholders), the asset allocation process must yield more than the company's cost of capital.

Since the financial manager has to grant that the cash flow ability of the firm will properly remunerate its financial sources over the long run, they must evaluate the size and timing of cash flows and monitor the company's capital structure, its major sources and uses of funds, and its profitability over time. As a measure of the company's profitability ROI (return on investments = operating income/capital invested) is taken into consideration. According to that, the financial manager is concerned on one hand with the profitability of the company's investments and with the efficiency of the implemented asset management decisions. It means that they have to make use of rational tools to evaluate capital budgeting decisions. On the other hand, the financial manager is interested in keeping constantly under control the changes in the company's capital structure that can affect both the firm's cost of capital and the yield required by capital suppliers. If the company's cost of capital is defined as the weighted average cost of capital (WACC) and represents the net cost of debts and equity weighted by their percentage on the total capital structure, an increase in the percentage of debts, for instance, can reduce the WACC since they are less costly than equity, due to their fiscal deductibility; at the same time, an excessive rise in debts can make the company be perceived as a riskier investment and thus induce investors to require higher yields on debt and equity. Both these effects have to be taken into account once the financial manager is approaching any financing decision.

In the light of what financial managers must do to maximize shareholders' value, *financial control* can be defined as the whole of the activities and tools that enable financial managers to carry out financial analyses for the purposes of internal and external control. By internal control, we mean evaluating the investments profitability and the efficiency/effectiveness of the capital budgeting process. In addition to that, a form of internal control is considered as any analysis turned to keep under observation the composition of the company's capital structure. External control is any aspect of financial analysis that outside suppliers of capital take into consideration in evaluating the firm and that the financial manager should be interested in the endeavor of bargaining more effectively for outside funds.

So far it has been stated that the main corporate goal is to increase the shareholders' wealth. According to that, a company creates value if its shareholders' wealth rises. It is worth mentioning that, recently, financial markets and investors have taken into account new parameters in the evaluation of financial investments. These parameters add a social and ethical appraisal of financial investments to a pure financial valuation. Such parameters aim at reminding companies of their social responsibilities and spur them to give constructive contributions to society and bring positive energy to the solutions of its problems.

As a consequence of the new approach to interpreting the corporate role within the society, investors choose to invest their money only in those companies that behave ethically. On the other hand, financial products suppliers are tailoring new financial products which are labeled as ethical, and that respond to the new evaluation requirements.

The Dow Jones Sustainability Index (DJSGI) can be seen as an example of this new trend inside financial markets. That index, in fact, consists of more than 200 companies that represent the top 10 percent of leading sustainability companies in 64 industry groups in the 33 countries covered by the DJSGI.

The companies included in the DJSGI have shown over time a strong commitment on the achievement of the five corporate sustainability performance principles: innovation, high standard corporate governance, shareholders' requirements, best practices, and social behaviors.

From what has just been highlighted, managers must be aware that new principles beyond those suggested by financial theories have to be pursued in running their business.

2. An Integrated System of Financial Analyses

An effective financial analysis, planning, and control process is critical to enhance enterprise value and, then, shareholders' wealth. To make rational decisions in the shareholders' interest, financial managers need to be supported by an integrated system of financial analyses and reports. These tools enable financial managers constantly to control both the profitability of the company (in the meaning of the firm's ability to generate cash flows from its operating activities) and the cost of resources applied to undertake operating investments that determine the company's cost of capital.

Since they need to keep under control both the profitability of capital invested and the cost of resources raised from investors, financial managers make use of an integrated system of analyses that includes financial statements, ratios, financial planning, investment valuation, and capital structure analysis. Each of these tools plays a key role with reference to the financial control activity, providing the financial manager with a wide range of information that helps in orienting the company's investment and financing decisions. Even if financial analysis, planning, and control activities are often considered as different tools, they have to be viewed as a whole since they together aim at accomplishing the maximization of shareholders' value.

In large companies it often happens that different managers carry out the above-mentioned analyses in different departments. It becomes important, then, to construct an integrated system of data exchange that allows the different tools to work jointly. To assess an investment's profitability, for instance, it is necessary to forecast the company's market share in order to determine its potential incremental revenues and cash flows. In addition to that, the composition of the expected capital structure will be also needed to calculate the new cost of capital and discount future cash flows at that rate.

3. Financial Accounting

Financial accounting (financial statements, ratios, and cash flow statements) gives the financial manager a picture of the firm's past performance and its current standing. These analyses help the financial manager to understand the company's current economic and financial situation and make forecasts for the future. It also allows the manager to represent the firm's position according to its competitors and its evolution over time.

The reorganization of financial statements (assets and liabilities statement and income statement) according to some predefined schemes is the first step of a process that, starting from accounting information, ends up with the appraisal of a company's performance from both income and cash flow perspective.

One of the criteria applied to reorganize the company's financial statements is, for instance, the activity-related method. With relation to this approach, we group the balance sheet entries in current and noncurrent assets and liabilities according to their pertinence or otherwise to the operating cycle of the company. The same criterion applied to the items contained in the income statement allows us to separate revenues and costs in relation with the four activity areas that can be identified in an ongoing business: current, financial, subsidiary, and extraordinary activities.

Once financial statements have been reorganized, it is possible for the financial manager to combine income statement and balance sheet entries in order to obtain significative ratios. Second, from reorganized financial statements, a cash flow statement can be drawn up as well.

In particular, a complete system of ratios describes the current state of health of the company according to different points of view: liquidity, profitability, leverage. This analysis offers a static diagnosis of the firm that can be helpful for managerial control and for a better understanding of what outside suppliers of capital may expect in terms of a company's financial condition and performance. In fact, both the financial manager and the company's investors are interested in measuring the return on investments of the company, its capability of repaying debts in the short run and in the long run, and the relation between debt and equity. Consistent to that aim, ratios are mostly employed for *ex-post* analysis, to verify the effect of investment and financing decisions on the company's profitability, and for the composition of its assets and liabilities.

The final step in the above-mentioned process of financial analysis is represented by the construction of the cash flow statement. Cash flow analysis can be seen as a dynamic analysis that highlights the company's ability of generating cash flow. Using cash flow, the financial manager identifies the sources and uses of monetary resources during a given period. The cash flow statement groups all the inflows and outflows according to their pertinence to the current activity, the financing and reimbursement activity, the investment activity (operating and nonoperating), and to the remuneration of debt holders and stakeholders. In other words, this tool leads to the quantification of the cash inflows that the company is currently able to generate from its operating activity, and the comparison of them to the flows absorbed by the in-

vestment policy, the debt repayment, and the dividend policy. In fact, it is one thing if a company can provide the monetary resources autonomously to undertake investments and adequately remunerate the capital invested, while it is quite another if the same company regularly needs to find outside sources of capital in order to avoid financial distress caused by an insufficient production of cash inflow.

Consistent with that, the cash flow analysis can be interpreted as an *ex-post* analysis that helps the financial manager to appraise the impact of investment and financing decisions in terms of financial flows.

4. Financial Planning

Financial planning enables financial managers to assess the effects of financing and investment decisions *ex-ante*. Financial planning is a necessary analysis as investment and financing decisions interact and they should not be made independently. Financial planning is concerned with analyzing financial flows of the firm as a whole, forecasting the consequences of investment and financing decisions, and weighing the effects of different alternatives. In fact, any financial decision that affects the investment policy of the firm or its mix of financial sources raised from investors influences the company's future profitability as well as its capital structure (and its cost of capital). The financial manager has to define both a target financing mix and a target return on investments and undertake only the investments/financings consistent with those targets. In order to keep under control any unexpected change that can modify the company's return on investments or its cost of capital, the financial manager has to analyze any financial strategy very carefully and to take into consideration any economic and financial impact that it may have. Moreover, financial planning makes possible the comparison of different investment and financing strategies in order to evaluate which one maximizes shareholders' wealth.

The tangible tool applied in the planning process is the financial plan describing the firm's financial strategy and projecting its future consequences in a proforma balance sheet, income statement, and cash flow statement. In particular, the forecasted cash flow statement provides an effective method for the financial manager to assess the growth of the company and its resulting financial needs as well as to determine the best alternative to finance those needs.

In fact, the plan sets financial goals and it represents a benchmark itself for evaluating subsequent performance. Helping the company to achieve these goals is one of the chief responsibilities of financial planning.

Finally, the planning horizon depends on the company and its business. High-tech companies, for instance, produce much shorter financial plans than most companies do as a consequence of technologies life cycle, whereas public utilities and energy companies make longer financial plans due to the long lead time of their capital projects.

5. Investments Valuation

Capital budgeting involves the entire process of planning capital expenditures whose returns are normally expected to extend beyond one year. Since we stated that investment decisions must be made so that they maximize shareholders' value, capital budgeting decisions forcedly must be related to the firm's overall strategic planning. Capital budgeting must be integrated with strategic planning as excessive investments or inadequate investments could cause serious consequences for the future of the firm. If the company invested too much in fixed assets overestimating its potential growth, it would incur unnecessarily heavy expenses that would reduce its return on investments. On the other hand, if a company has not invested enough in new production capacity it may lose a portion of its customers to rival firms. A related problem is how to properly phase the availability of capital assets in order to have them 'working' at the correct time. An effective process of capital budgeting aims at improving the timing of asset acquisitions and the quality of assets purchased. Another reason that highlights the relevance of the capital budgeting process is that asset expansion typically involves substantial expenditures. Before a company undertakes an expensive investment such as the purchase of a new plant, the launch of a new product, or the signature of a commercial agreement, it needs to plan how to raise funds required for that specific project. A number of factors make capital budgeting one of the major financial management decisions. In fact, not only does any investment decision contribute to determine the company's profitability (and its ROI) and, then, the shareholders' value, but also the capital budgeting process vitally affects all departments of a firm (such as production, marketing, finance, to mention a few). Since financial managers need to keep under control the asset allocation process so as to grant the maximum value to their shareholders, it can be said confidently that one of the most important corporate finance functions is the economic valuation of investment projects. In fact, the first step in undertaking any allocation project is the analysis of its economic and financial profile. The latter aspect is taken into account in drawing up the financial plan, where the financial manager verifies the compatibility of the cash flows related to the project under consideration with those that happen at the overall company's level.

The financial manager must carry out those projects that maximize the incremental value for the company's shareholders. In order to increase shareholders' wealth, a project must yield more than the cost of

funds used to undertake the capital expenditure. It is, then, possible to conclude that the financial manager must judge a certain investment project according to its expected return. If this is higher than the company's cost of capital, the specific investment will create value for the company's shareholders.

As the asset allocation process is led on a continual basis, the financial manager must measure constantly the profitability of the firm's investment activity. Such a form of control makes use of appropriate methods of analysis like the NPV and the IRR. The NPV (net present value) is the present value of the cash lows stemming from the investment project; the IRR (internal rate of return) is that rate that makes the NPV equal to zero and it can be seen as the gross return of an investment project.

The implementation of the above-mentioned tools of financial control on investments prevents the funds being misallocated. In fact, when many alternatives of investment are evaluated, the most profitable will be chosen first, then the others one by one according to their expected rate of return. This *modus operandi* becomes a necessary approach if the company has a limited amount of funds available to finance investment projects (*capital rationing*).

6. *Capital Structure Analysis*

Capital structure refers to how the firm's assets are financed. If the monetary resources that the current activity is able to produce are not enough to offset the cash-outs due to the company's investment activity, the firm needs to raise new funds from investors. Accordingly, capital structure is concerned with explicitly costly forms of financing just as financial debts (bonds, loans, overdrafts) and equity are. In fact, both debt holders and shareholders want to be remunerated for the money they invested into the company. It is then possible to determine the cost of capital as the average of the net cost of debt and equity (WACC). To calculate the average, the impact of debts and equity on the total capital structure has to be taken into account.

The composition of capital structure influences the company's cost of capital from two different points of view. First, any change in the amount of debts and equity will make their weights vary so that we come up with a new WACC, other things being equal. Second, the cost of capital will differently change according to which form of financing is chosen. Since financial charges are tax deductible whereas dividends and retained earnings are not, an increase in debts will reduce the WACC. However, it must not be concluded that a company should be 100 percent debt-financed. In fact, the more debts rise the higher the risk of financial distress will be. This higher risk perceived by investors leads debt holders and stakeholder to ask for being granted a higher rate of return.

The composition of capital structure impacts on the shareholders' value since it influences the cost of capital invested in the company. If the return on investments remains equal, a rise in the cost of capital will cause a decrease in the company's profitability and in shareholders' wealth. The financial manager has to take into consideration the effect on the capital structure when any financing decision is evaluated. Once a financial need arises from the planning activity, the financial manager should simulate what impact a debt or equity issue may have on the overall company. This activity enables the financial manager to quantify the effects of financing alternatives in terms of the firm's cost of capital and financial riskiness.

We are assuming that there are no capital constraints that affect the company so that the firm can count on an unlimited access to both the equity market and the debt market. According to this hypothesis, the financial manager can choose the financing alternative that maximizes the shareholders' value and minimizes the cost of capital. Sometimes, however, the firm has to face with a limited availability of financing alternatives to raise money from investors. In fact, many factors such as capital markets features or aspects related to companies' ownership and control could make some financing decisions unfeasible. At the same time, other aspects such as corporate taxation can make some sources of financing preferable in comparison to others.

Corporate Governance

The term 'corporate governance' refers to the legal rules, institutional arrangements, and practices that determine who controls business corporations, and who gets the benefits that flow from them. Corporate governance issues include how major policy decisions are made in business corporations, how various stakeholders can influence the process, who is held accountable for performance, and what performance standards are applied.

1. *The Governance Problem*

Governance problems arise because corporations are fictional entities, with a legal status that is separate from any of the individuals involved in them. They are not, themselves, actual persons, yet numerous different groups of individuals—investors, employees, managers, suppliers, customers—may have interests at stake in them. Often, they are managed by hired executives. Hence, decision-making authority in corporations generally is separated from personal responsibility and liability. Neither managers (the active decision makers), nor other employees, nor investors (who enjoy the protection of 'limited liability') necessarily bear the full costs of corporate actions.

Hence, the governance problem to be solved in setting up any corporation is to create a mechanism for selecting and overseeing the firm's managers that fosters cooperative behavior among multiple participants, protects the investments made by them, discourages abuses by decision makers, and still provides sufficient freedom of action to encourage innovation and risk taking. Such a mechanism should allocate decision and control rights to parties who have the appropriate incentives and the necessary information to make wealth-enhancing decisions for the firm, while at the same time ensuring that the controlling parties are accountable to all of the other participants who are exposed to risk by the actions of the corporation. Most governance arrangements, of course, do not achieve this ideal, and in practice, governance arrangements are responsive to a variety of political, as well as economic, pressures.

Legal rules that influence corporate governance vary from country to country, but generally they include corporate and securities law, as well as rules from contract, bankruptcy, and antitrust areas of law. Other corporate governance practices may be driven by market pressures, or tradition, or by the structure of equity ownership. Observed governance arrangements and practices at a given corporation may be prescribed by specific terms of that corporation's charter, or they may be merely customary.

2. *Goals of Corporate Governance*

The phrase corporate governance came into prominent use in the 1980s, and is often used narrowly to refer to the mechanisms and rules that govern relationships among direct corporate participants in publicly-traded firms, especially shareholders, directors, managers, and sometimes employees. But, historically, questions about social control over corporate behavior have been quite important. Since the corporate form first emerged as the dominant way to organize big business enterprises in the second half of the nineteenth century, policy concerns about corporations have, at various times, focused on antitrust, consumer protection, pollution control, worker and/or investor protection, corporate involvement in the political process, and corporate contributions of resources to charitable causes.

Broadly speaking, there are two schools of thought about the appropriate goals of corporate governance institutions and arrangements. The 'shareholder primacy' view, which has been dominant in the US and other English-speaking countries since the 1980s, has focused on the set of governance problems that arise in publicly-traded corporations in which equity shares are held and traded by numerous individuals who have little or no management connection to the firm. This problem has been referred to in the literature as the 'agency cost problem' (Jensen and Meckling 1976) resulting from the 'separation of ownership from control' (Berle and Means 1932).

By contrast, in Europe and Asia (as well as in the US in the middle of the twentieth century), corporations are more likely to be viewed as institutions with a quasipublic character and role. Hence, the proper goal of corporate governance is more likely to be seen as a balancing of interests among all of the corporate stakeholders. This so-called 'stakeholder' view of the firm was widely dismissed by leading legal, economics, and finance scholars in the US in the 1980s and 1990s as not being well grounded in a convincing theoretical model of the firm. However, recent scholarship in the US is providing a stronger theoretical basis for this view.

3. *Recent Developments*

The explosion of interest in corporate governance since 1980 has been driven by a number of developments. The first was the dramatic emergence in the US of unsolicited and unwanted tender offers, which became a common threat to corporate independence in the 1980s. In these so-called 'hostile takeover' transactions, outsiders attempted to buy up enough of the outstanding, publicly-traded shares to gain voting

control over a company's board. Closely related to the rise of hostile takeovers was the development of numerous innovative financial instruments used to finance these transactions.

The threat of hostile takeover became a tool by which investors were able to compel managers to cut staff, close plants, redeploy assets, or take other unpopular actions in order to increase corporate profitability. Initially, corporate directors and managers resisted the takeovers, and invented a variety of new mechanisms to prevent the outsiders (whom they pejoratively dubbed 'raiders') from gaining control. This led to numerous court challenges and decisions, and an intense legal and policy debate about the appropriate response of corporate directors to takeover threats.

The second development was the rapid increase in the power and influence of financial investors in general, and institutional investors in particular. By the 1980s, institutional investors such as pension funds and mutual funds had grown to become the largest shareholders in many US corporations, and they began to use their new clout to influence corporate agendas. Among the changes institutional investors sought were corporate governance rules and executive compensation plans designed to make corporate executives more sensitive to shareholders' interests, especially their interest in higher share prices.

The third development was the shifting patterns of corporate performance worldwide. In the 1980s, many US firms lost substantial market share to international competitors, especially in Europe and Japan. In response, scholars and policy analysts asked whether Japanese and European corporate governance systems were somehow better than the US system. The situation reversed in the 1990s. Japanese and European economies slumped, while the US economy, led by a very dynamic high-tech sector, put on one of its best postwar performances. Scholars and policymakers then began asking what aspect of the US system makes it so much better at fostering and financing business innovation. Toward the end of the 1990s, financial crises in numerous countries, especially the formerly high-growth countries of southeast Asia, again forced policymakers and academics to rethink their beliefs about how corporate governance systems work, and what makes one system work better than another.

The fourth development was the collapse of the former Soviet Empire, and the effort by nearly all communist and socialist countries to convert to capitalism. In the early 1990s, Western advisors rushed into Eastern Europe and Asia to help the governments of the transition countries develop corporate laws and securities markets so that they could convert state-owned enterprises to Western-style capitalist corporations. The effort to create new corporate governance structures and practices in transition economies encouraged these policy analysts and scholars to think more deeply about how the corporate governance systems in advanced economies actually work, and what other legal and institutional infrastructures are needed to support them.

The fifth development has been the continued globalization of capital markets and, closely related, the surge in cross-border mergers and acquisitions, both of which create pressures for harmonization of corporate governance standards across countries.

4. *Mechanisms of Governance*

The most important mechanisms of corporate governance in all capitalist economies are boards of directors with fiduciary duties, independent auditors, financial disclosure requirements of securities laws, and the rules determining voting rights. Securities exchanges impose additional disclosure and other governance requirements on firms that list their securities for trading.

4.1 *Boards of Directors*

Although statutory requirements and practices differ from country to country, in every country that has incorporation laws, some provision is made for the establishment of a board of directors at the time the firm comes into being. The board then becomes the locus of legal accountability for the corporation. In the US, state-level incorporation statutes generally are 'enabling' laws, giving founders of corporations wide latitude to establish almost any governance arrangements they want, as long as they create a board, and set up rules by which directors are to be chosen. It is almost always a requirement under state law in the US that directors are elected by shareholders, and a common practice is for directors to be elected for one- to three-year terms by shareholders, on a one-share, one-vote basis.

Directors have the legal responsibility for making virtually all major substantive decisions about the future direction of the company, and for the distribution of corporate income and assets. They decide whether, when, and how much to pay out in dividends; they are responsible for hiring, firing, and compensation of the chief executive officer; and they are responsible for approving the broad strategy, major initiatives, investments, and transactions undertaken by the firm. Other important duties of boards include responsibility for ensuring that adequate books and records are kept, and, in the case of publicly-traded companies, providing for adequate public disclosure and compliance with other laws.

In the US, the authority of duly elected directors over corporate decisions is nearly absolute. They must satisfy the requirements of their corporate charter and bylaws (which are normally quite general and un-

restrictive) and of any external laws and explicit contracts with outside parties. And they must fulfill their fiduciary duties of 'care' and 'loyalty.' The duty of loyalty is taken seriously by the courts in the sense that directors must not engage in self-dealing transactions with the firm (unless such transactions are both substantively and procedurally fair), and must not take advantage of business opportunities that properly belong to the corporation. Beyond that, the courts require little other than that directors must exercise a reasonable amount of diligence in carrying out their duties. If they satisfy these requirements, directors are almost completely protected by the so-called 'business judgment rule,' a common law rule that says that the courts will defer to the 'business judgment' of directors in strategic, policy, or investment decisions made on behalf of the firm.

In the US, anyone can serve on a corporate board, although in recent years, it has become the accepted wisdom that, in publicly-traded firms, a majority of directors should be outsiders, who are not part of the company's management structure. In Europe and Asia, it is common for representatives of large investors, such as wealthy families or large financial institutions such as banks or other companies, to sit on corporate boards. European corporate law also often specifies certain aspects of the size, structure, and composition of corporate boards. In Germany, for example, publicly-traded companies (AGs) and large limited liability companies (GmbHs) are required to have two-tier boards, with up to half of the positions on the upper-tier, or supervisory board reserved for employee representatives. (Most German corporations are also required to have 'works councils,' which provide another formal mechanism for employee voice in some corporate decisions.)

Nominally, corporate law in Japan is similar to that in the US, and in particular, boards of directors in Japanese firms are chosen in a similar fashion and have a similar degree of control and discretion. But as a matter of custom and practice, Japanese directors typically are chosen from among the ranks of senior employees.

4.2 Independent Auditors

One of the most important mechanisms that boards of directors use to ensure that corporations are accountable to their various investors and stakeholders is arranging for audits of records and corporate performance indicators by external, professional auditors. Since the board bears the ultimate responsibility for ensuring the firm's compliance with the law and for the integrity of its public financial disclosures, the board should arrange for and cooperate with auditors to improve the reporting systems (OECD 1999a). In recent years, investors and professional organizations generally have come to agree that the audit function should be performed by individuals who are unaffiliated with the company, and should be under the control of an audit committee with outside directors in the majority. It is a listing requirement at several important stock exchanges (for example, including the New York Stock Exchange) that listing firms have audit committees dominated by outside directors.

4.3 Financial Disclosure

In the US and other common law countries, publicly-traded corporations are required to make regular and frequent public filings of reports providing detailed financial information about the firm. Key parts of this information must be certified by independent auditors, and must conform to standard accounting practices, as determined by independent standard-setters within the accounting profession such as the Financial Accounting Standards Board in the US. Sanctions for officers and directors of companies that report fraudulent information can be severe, and both securities regulators and private investors participate in policing the disclosures. Moreover, insiders are prohibited from trading on information before it is made public. In general, the disclosure requirements are not as strict in other countries and the restrictions against insider trading not as well enforced. An intense debate is underway in the international community about whether these requirements ought to be brought up to the US standards.

Outside the US, the International Accounting Standards Committee and the International Organization of Securities Commissions are working to develop a core set of accounting standards for use in cross-border financings and for listings in global markets.

One of the controversial questions at stake in the policy discussions about accounting standards is the problem of providing better information about 'intangible' assets. Intangibles are assets such as intellectual property rights (patents, copyrights, brand names), reputational capital, organizational capital (including, for example, proprietary software or other management systems), and organizational and intellectual assets, such as the unpatented results of research and development projects or the tacit knowledge and skills of employees. Current accounting rules do not provide a mechanism for such assets to be recorded on the books of firms. Rather, any costs involved in developing these assets are treated for accounting purposes as expenses that, implicitly, do not provide any future return. By some estimates, intangible assets now account for a substantial and growing share of the wealth being generated by the corporate sector, particularly in developed countries. Investors are being provided with very little information about these assets, however, even in countries with relatively transparent accounting systems and strict disclosure requirements.

A related, and equally controversial question at stake has to do with whether corporations should be required to provide public reports on their social and environmental performance. This question links the debate about accounting for intangibles to the debate about shareholder primacy and the social role of corporations.

4.4 Voting Rights

One of the few legal constraints on boards of directors is that the board itself must be elected, and must subject a few important decisions to a vote by affected participants. Generally shareholders must elect directors on a one-share, one-vote basis, for example. In special circumstances, however, other stakeholders may participate in choosing directors. For example, holders of preferred shares or other investors may sometimes have the right to vote for directors if a company fails to pay preferred dividends. Employee representatives to the supervisory boards in Germany are chosen by a process that involves voting both by employees and by their unions. And in a handful of US companies, labor unions have negotiated for the right to choose at least one director.

Shareholders and sometimes other participants often have the right to vote on major corporate transactions, such as a merger or a dissolution. Whatever the formal rules are, however, the voting rules and nomination procedures are easily manipulated so that, in practice, US directors have found they can often get around voting requirements by structuring transactions in different ways. Additionally, control over the nomination process gives existing directors substantial influence over the process of choosing new directors. It is possible for an outsider to wage a campaign to elect an alternate slate of directors, or to amend the charter, or to recommend some other corporate action. Such challenges to boards are called 'proxy fights' because the process requires challengers to solicit other shareholders to gain permission from them to vote their shares by 'proxy.' Proxy fights happen occasionally in the US, but they are costly, and hence, rare.

Nonetheless, shareholders have other informal mechanisms of influence that in most instances are more useful and effective than proxy fights. Financial investors who own large blocks of shares, for example, have the capacity to transfer a controlling block to a raider by selling out, or to dump shares on the market and thereby drive down the price. This inevitably gives large investors considerable informal influence and market control.

4.5 Listing Requirements

Other important mechanisms of corporate governance are the listing requirements for stock exchanges. If a company wants access to public equity markets, it must not only meet disclosure requirements for issuance of securities to the public, it must also make sure that its securities can be traded in organized securities markets. Stock exchanges typically impose governance requirements on firms beyond the requirements of corporate law. As already mentioned, the New York Stock Exchange requires that listed firms have audit committees composed of outside directors.

5. Patterns of Shareholdings

Apart from the formal governance mechanisms, the factor that may have the greatest influence on how decisions get made in publicly-traded corporations, and on the weight given to the interests of various corporate constituencies in those decisions, is the pattern of ownership of equity shares. There is a significant difference between the pattern that prevails in the US and other English-speaking countries, and the pattern that prevails in continental Europe and Asia. In the US, there are thousands of publicly-traded corporations with shares that tend to be very widely held. Typically, no single institutional or individual shareholder controls more than 50 percent of the voting shares, and even 20 percent blocks are relatively uncommon. When no large investor holds a substantial block, it may be hard for shareholders to monitor boards and managers. Moreover, as already noted, it is costly for shareholders to organize themselves in order to wage a proxy fight. These factors tend to make corporate officers and directors quite autonomous and independent. On the other hand, the fact that shares are widely held usually means that there is a liquid market in the shares, and dissatisfied shareholders can easily sell. The market price of the shares provides a constant signal about how well investors think the company is doing.

By contrast, in continental Europe and Japan, there are many fewer publicly-traded companies (even relative to the size of their economies), and companies that are publicly-traded often have very concentrated shareholdings. In German firms, for example, more than half of all publicly-traded companies have a large shareholder with 50 percent or more of the shares. In Japan, groups of industrial companies hold substantial amounts of each others' shares, and in Italy, pyramidal groups headed by families, coalitions, or the state often hold controlling interests in firms. The large shareholders in these firms often have seats on the boards of directors, and inevitably exercise considerable influence on the boards.

Corporate governance scholars have debated the reasons for this pattern. One theory holds that financial institutions in the US were prohibited from becoming large shareholders in industrial companies for political reasons (Roe 1994). The result has been that shares are widely held, and shareholders have

tended to be passive in the US. Managers and directors, in turn, generally operate with much greater impunity than they could if there were more large-block shareholders actively involved in governance. But the fact that shares are widely held and actively traded on deep markets also creates the possibility that outsiders can get control of companies, even against the wishes of boards and managers, by engaging in tender offers. Hence, the 'market for corporate control' may be an effective substitute for direct monitoring.

An alternative theory holds that shareholdings are unconcentrated in the US and other Anglo-Saxon countries because, all else equal, investors would prefer to diversify their risks and make their investments more liquid by holding only small amounts of many different companies in their portfolios. Since their holdings in any one company are typically small (both relative to the size of their portfolios, and relative to the size of the company), investors would prefer to be passive (Black 1990). However, investors could not afford the luxury of being passive if they were not confident that they would be protected from exploitation both by managers and by controlling shareholders. Advocates of this theory note that common law countries have the deepest, most transparent financial markets and the best protections for minority shareholders in the form of strict securities laws. Consequently, these same countries tend to have widely-dispersed shareholders. By this theory, shareholding is more concentrated in European and Asian countries because those countries do not provide sufficient protection for minority shareholders to encourage small investors to hold equities (Coffee 1999).

6. *Supporting Institutions*

These arguments suggest an overarching issue, which is that corporate governance arrangements must be seen as imbedded in a larger set of social and political institutions. In the early 1990s, many of the Western scholars and policy analysts who advised transition economy governments about transforming their economies into capitalist-style free market economies recommended 'shock therapy' approaches. These advisers believed that if productive enterprises could be taken out of the control of governments and placed under the control of private investors, and if subsidies and cross-subsidies could be ended, market pressures would come into play and quickly drive private actors to reorganize themselves into much more efficient configurations. In fact, this had rather conspicuously failed to happen in Russia by the end of the 1990s, and the results were spotty, though generally less disastrous, in other Eastern European countries. As a result, scholars are now turning their attention to the important role played by supporting institutions such as the development of accounting standards; independent and professional accounting firms; court systems that can adjudicate complex contracts and enforce fiduciary duties; professional norms and standards; well-regulated financial institutions; and securities laws with effective systems of enforcement. Empirical studies have shown that in countries without these institutional supports, the corporate sector tends to remain small, and the corporations that do exist tend to be closely held and controlled by families or other networks of economic elites.

7. *Which Way Works Best?*

While the corporate governance systems that have emerged in modern developed economies are obviously superior to the systems in developing and transition countries, scholars are still debating the relative merits of the various systems in developed countries. Is the common law system in the US and other English-speaking countries, with its scattered shareholding, deep and transparent financial markets, and relatively autonomous boards and managers, better in any sense than the large-shareholder dominated, civil code systems of continental Europe and Asia? Each may be an internally consistent system with its own advantages and disadvantages. Where supporting institutions, such as an independent accounting profession and courts that can adjudicate complex contracts and enforce securities disclosure rules, are weak, it may be impossible to provide adequate protection for minority investors. In such circumstances, outside equity investors may only be willing to put capital into firms in which they can get seats on the board and exercise some control. On the other hand, if the legal and social system can effectively limit or discourage self-interested transactions by insiders, then the advantages of widespread shareholding and fluid capital markets can be realized.

But there are tradeoffs. Civil code systems may be more stable in the short run because it is harder in these systems for financial investors to move capital out of companies in search of higher returns. For the same reason, it may be easier to impose 'social' regulations and requirements (to protect jobs, for instance, or to clean up the environment) on companies in civil code countries.

In contrast, capital is extremely mobile in common law countries. In the US in the 1980s and 1990s, the mobility of capital made it easier for financial interests to force corporations to restructure and downsize, a development whose costs and benefits to society as a whole are still being debated (although it seems pretty clear that the restructuring of the corporate sector enhanced wealth for the shareholding class). In other words, capital may, counter intuitively, be more powerful in the long run in countries where shareholdings are relatively small, dispersed, and mobile,

than in countries where large block shareholders have much more direct influence over managers.

The mobility of capital in common law countries has probably made it easier for start-up firms to get new capital, thereby contributing to the dynamism of the high-tech sector in the US in the 1990s. However, increasing the rate of growth and technological change quite possibly reduces social and income stability, and widens the disparities in income distribution—effects that may not be politically acceptable in all societies. Hence, there may be an unavoidable trade-off of social goals, and which path a society chooses is partly a matter of politics and ideology.

On a theoretical level, numerous scholars and commentators, especially in the US, approach corporate governance questions from the perspective of a 'principal-agent' view of the firm, in which shareholders are understood to be the 'owners' of firms, and directors and officers their 'agents' (e.g., Easterbrook and Fischel 1991, Shleifer and Vishny 1997). Analysts who have adopted this point of view tend to be more libertarian and more comfortable with the social ordering that emphasizes private property and limited role for government. The normative implications of this perspective are that corporations should be run solely for the purpose of maximizing value for shareholders, and that corporate governance systems should support this goal alone, and not other social agendas. Hence, the relative impunity with which directors can control the nomination and voting process and resist takeovers is often viewed as a flaw in the US system because shareholders are not given sufficient control to enforce shareholder primacy (e.g., Jensen 1993). However, the freedom with which capital moves is viewed as a strength offsets this weakness. Meanwhile, the legal rules and practices in Japanese and German firms that have made them much more protective of employee interests relative to shareholders' interests are viewed as flaws by scholars and policy analysts who adopt this point of view.

On the other side, a small but growing body of scholarship has argued that the principal-agent perspective is misleading both as a matter of law and of economic theory. Under US law, the role of corporate directors is unique, but is much closer to that of 'trustees' than that of 'agents.' Outside the US, shareholders rarely are referred to as 'owners' of corporations (as if corporations were merely pieces of property). An emerging theoretical perspective emphasizes that the productive activity undertaken by corporations is a form of 'team production,' in which numerous parties in addition to shareholders are involved in the productive activity of corporations and have assets (whether tangible or intangible) at risk in the enterprise. This alternative view has somewhat different normative implications. For example, it suggests that corporate governance should not just be about maximizing value for shareholders. Rather, it should be about creating structures that foster and encourage wealth creation for all of the 'team' members. One mechanism by which this may be achieved in the US is the very mechanism so maligned by agency cost theorists: board independence. Mechanisms that insulate directors from pressures from all stakeholders, including shareholders, may serve to protect minority shareholders (seen as important even by shareholder primacy advocates) and to protect the interests of stakeholders other than shareholders (Blair and Stout 1999, Coffee 1999, Hansmann and Kraakman 2001). Even though shareholders do not exercise tight control over directors or managers of publicly-traded corporations, they enter into the relationship freely, thereby yielding legal control rights to the board. This allows them to make a credible commitment not to use their control over capital to unfairly squeeze out other stakeholders who may make irreversible investments in the enterprise. Hence, shareholders in firms where directors are relatively autonomous are more likely to win the cooperation of other stakeholders in the first place (Blair and Stout 1999).

The question is more than a theoretical exercise. As financial investors have grown in influence, the voices of shareholder primacy advocates have been quite prominent among those who want to see corporate governance standards harmonized worldwide. These voices have clout because capital has become so mobile internationally. Thus, the political question of whether corporate governance rules and standards should be harmonized across countries, and if so, whether international standards should be made to look more like the US or another model, is caught up in powerful economic forces, making it hard for countries to resist financial market pressures to move to a US standard.

Corporate Law

The term 'corporate law' refers to the body of legal rules that govern the creation, life, and extinction of business corporations. Generally speaking, a corporation is a particular type of business firm that is designed to address certain fundamental and universal economic exigencies, primarily the need for entrepreneurs to obtain capital. Thus, it is possible to consider generally the framework of matters regulated by corporate law, even though the nuances of specific countries' corporate law will depend on the distinctive features of their legal systems, histories, and traditions.

An understanding of corporate law must begin by examining the general problems of the theory of the firm, which defines the financing, managing, and organizing needs of business enterprises generally. With this background, it is possible in the second part to examine some basic features of corporate law—including the limited liability of shareholders and the contractual nature of corporate enterprises—and to consider the regulatory competition among corporate law policy makers. In the third section, internal organizations problems will be discussed, in particular the separation of ownership and control and the consequent issues of corporate governance. Finally, the fourth and final section will address the regulation of the financial structure of the corporation, specifically the problems raised by bonds issuance and the role of financial markets such as the market for corporate control.

1. *The Theory of the Firm and Corporation*

The reason why business ventures in modern economies are carried on by organized firms, instead of by individuals, is best understood through the theory of transaction costs (Coase 1937). The basic insight of this theory is that through the firm, it is possible to transform part of the transaction costs of running a business into what might be called control costs or agency costs. A useful example is the employer–employee relationship. Imagine that an entrepreneur has two possible choices to accomplish a particular task. Either the entrepreneur can buy the required service from an independent provider (contracting on the market), or he can hire an employee (creating an organization) to perform the same service. Under the first option, the entrepreneur must draft a detailed contract that specifies the relationship between the parties. Creating a separate contract involves significant expenditures of time and money to draft, monitor and possibly enforce the agreement. In economic parlance, these expenses are called 'transaction costs.' These transaction costs will be further increased every time the entrepreneur must negotiate a new agreement for a different service from a different provider.

Under the second option, if the entrepreneur hires an employee to perform the necessary services, his transaction costs will go down. An employment contract is an 'open' contract, in which the details of the performance do not need to be delineated with great particularity. Instead, an employer can simply direct the work of the employee according to specific and perhaps changing needs. Although this approach reduces transaction costs, it generates a new form of costs. These costs arise because, in contrast to an external provider who likely has an incentive to perform efficiently, an employee has less incentive to be efficient. As a consequence, the employer will need to monitor the employee's performance, thereby expending both the cost of sanctions for deviations and the cost of incentives for proper performance. The increased costs that a principal incurs in monitoring to

ensure that an agent adequately performs are called 'control costs' or 'agency costs.'

In addition to monitoring expenditures by the principal, agency costs also include what might be termed 'bonding expenditures' by the agent. (Jensen and Meckling 1976). Bonding expenditures are costs incurred by the agent to expand resources that guarantee the agent will not take certain actions, like quitting. The classic example of bonding expenditures is training or professional education in the field, which creates a high level of specialization and can make it more costly for the agent to change jobs.

Generally, a firm will prefer to internalize production whenever the agency costs will be lower than the transaction costs of an external relationship. Given the incentives and means for reducing transaction costs, the expected result is an increase in agency relationships for business enterprises, meaning an increasing preference for the firm structure over an integrated network of independent entrepreneurs. The firm can thus be understood as a method of organizing production (Posner 1998).

In addition to organizing production, another fundamental need that firms have is to raise capital with which to operate or expand. Again examining the economics of available choices, the nature and purpose of the corporate structure will be revealed. If an entrepreneur lacks financial resources or does not want to risk his own money in the business, he can borrow capital. Economic analysis demonstrates, however, that if the entrepreneur finances his business only through borrowed capital, the interest rate will rise to an uneconomic level because of the high risks of an unbalanced financial structure (Posner 1998).

There are two potential solutions to this problem. Either the entrepreneur can draft a very detailed loan agreement, which will lower the level of risk faced by the lender, or he can admit partners to the enterprise, who will provide (and risk) the necessary capital, but will also share the profits of the business. This second option can be economically preferable in several respects. First, it lowers the entrepreneur's contracting costs because he no longer has to negotiate the details of a loan agreement, and because it is not necessary to bargain around the interest rate since the partners' return on their investment will be determined by the business's success. In addition, the presence of creditworthy partners can improve the credit rating of the firm, thus lowering the cost of satisfying future capital needs.

If the need for capital increases significantly, however, this option becomes less desirable and the partnership structure shows its limits. The first problem is that partners in a firm have unlimited liability, which means significant agency or control costs. Because they are personally and unlimitedly liable for the conduct of the business, they will seek to intrude in the management of the firm to protect themselves and their investment. Moreover, because the financial strength of the partnership depends on the personal assets of the different partners, before investing everyone of them will want to investigate the other partners' wealth. Additional limitations are inherent in the nature of partnership, which is strictly dependant on the identity of the individual partners and can, for example, be dissolved on the death of one of the partners: the impermanence of the partnership agreement may thus affect the ability of the firm to raise capital from financial institutions.

For all these reasons, it becomes clear that the partnership structure is not suitable for larger, capital-intensive enterprises. Instead, the corporation is the form designed to facilitate further capital-raising activities. The two defining features of the corporate structure that allow it to do this are the limited liability of its owners and the division of ownership into 'shares,' meaning securities that represent a stake in the corporation but can easily be bought and sold. Corporate law is the set of mandatory and default rules that creates these features and regulates the consequences of them.

2. *Basic Features of the Corporation and Corporate Law*

2.1 *Limited Liability*

Notwithstanding attempts to trace back the modern corporation to ancient forms of organization of business enterprises, 'limited liability,' as the term is understood today, was an invention of the seventeenth century, granted to legal entities established for the purpose of raising funds to finance colonial expansions. The increasing need for new capital, which could neither be found in the treasuries of western monarchies nor raised through taxes, made resort to private saving an imperative resource. In order to collect such a considerable amount of money it became necessary to involve also small and medium bourgeoisie classes. Because these groups were risk-averse with their money, it was necessary to ensure legally that if they invested, only the amount of the investment would have been at risk. Limited liability was considered a royal privilege, an exemption from the general principle of unlimited liability, and as a consequence, it was subject to the discretion of the sovereign. It was only later that the 'power' to grant limited liability to corporations became a nondiscretionary power and was entrusted, in continental Europe, to the judiciary.

Borne out of historic necessity, limited liability has remained critical to the development of the modern corporation, and consequently to the development of western capitalism. The predominant economic explanation for the modern importance of the corporate structure is that it reduces the costs generated by the

separation and specialization of ownership and management functions (Easterbrook and Fischel 1985, Woodward 1985). A more detailed account of this economic effect involves several distinct but complementary considerations.

The first major consideration is that limited liability reduces the investor's need to incur monitoring costs. True to its name, 'limited liability' defines and restricts to the original investment the total amount of money an investor can lose. With the fear of unlimited liability gone, the investor no longer has a great incentive to interfere with the management of the corporation or to monitor the financial wellbeing of fellow shareholders.

Another important consequence of limited liability is that it makes freely transferable shares possible. In a setting with unlimited liability, shares would not be readily transferable because it would be highly relevant who is selling the shares and who composes the shareholders' group (they are not, in other words, 'commodities'). Meanwhile, when shares are readily transferable, the investor's incentives to monitor management are further reduced because his shares can be sold if he is dissatisfied with the corporation's performance, which can be easy if there is an active market for the shares. Another consequence of the reduction in the need to monitor and the availability of ownership through shares is that they permit the investor to diversify his investments into several companies, which further attenuates the consequences of poor management or adverse external events in one particular company.

The free transferability of shares, in turn, makes it possible to create a market for corporate control, which can be a powerful mean of external governance of the corporation. In fact, if shareholders are dissatisfied with the management of the corporation, they can sell their shares, thus causing a decline in the price of the shares. The corporation can thus be exposed to hostile takeovers by newcomers that believe to be able to make a profit buying the shares at a low price, manage it efficiently and thus enjoy a capital gain in the value of the shares. Thus, the presence of a market for corporate control represents an incentive for managers and controlling shareholders to act efficiently and not oppress minorities because, as long as shares have a voting right attached, poorly managed companies are exposed to the risk that shareholders will sell their shares and cause a change in control.

Corporate law not only creates limited liability to promote these aims, it also regulates some potentially harmful side-effects of limited liability. One consequence of limited liability and ownership through shares is that ownership can become more and more separate from management: the typical shareholder is not knowledgeable about the firm and, because there are reduced incentives to monitor management, does not expect to participate in its management. This separation between management and control—as will be discussed below—brings with it some potential for problems.

While the basic economic feature of firms and the need to raise capital justify the legal concept of limited liability as a general matter, there are also scenarios experienced by all systems that counsel in favor of exceptions to limited liability. For example, if the corporate structure is used to mislead creditors or perpetrate fraud, or provides inappropriate incentives to corporate actors, the protection of limited liability is no longer justified and it is instead better policy to permit the creditors of the corporation to reach shareholders' personal assets. In light of these potential consequences, all European and North American legal systems provide a mechanism 'to pierce the corporate veil' or to eschew a corporation's limited liability.

In civil law systems, the circumstances in which this mechanism is available are usually strictly defined by law. For instance, under Italian law, article 2362 of the Civil Code permits the corporate veil to be pierced in the case of corporate insolvency if there is a single shareholder. In common law systems, by contrast, there is greater flexibility in determining when the corporate scheme can be disregarded. A general overview of US and British cases on this issue suggests that the most important situation in which courts pierce the veil is when separate incorporation misled creditors. There are also a range of other exceptions, such as when the debtor corporation acted as a mere *alter ego* of the shareholders, when the corporation is not adequately capitalized or when shareholders have deceived creditors on the financial solidity of the corporation. In addition, US courts have demonstrated a willingness to disregard corporate limited liability in tort cases reasoning that without the possibility of such liability, corporations have less incentive to avoid disastrous harm to victims who they will never be required to compensate beyond the limited value of the corporation. In that situation, instead of simply attracting capital, limited liability creates the potential for a 'moral hazard' (Hansmann and Kraakman 1991).

2.2 The Corporation as a Standard Contract

Corporate law provides for limited liability, regulates its consequences and provides for exceptions to it through a set of rules that provide for what can be understood as a standardized contract. Corporate statutes enacted by the different legislators can be seen as a set of default rules that apply once the company is incorporated in a particular state. These comprehensive rules reduce the costs of contracting that parties would face if they had to individually negotiate all of the terms that are provided in the corporate law. The fundamental problem in this respect concerns mandatory versus enabling rules. Should corporate

law provide for some mandatory fundamental rules concerning shareholders' rights, minorities protection, corporate governance, and so on that parties can not opt out? Or, should corporate law only propose some enabling rules, that apply only if parties do not agree to the contrary? Finding the appropriate balance between mandatory and enabling rules is one of the fundamental problems of corporate law.

On one side, providing for mandatory rules ensures a higher level of protection of minorities in systems in which there is no active market for corporate control. When shareholder minorities are not organized and are thus unable to play an active role in controlling managers and shareholder majorities, mandatory legislative protection becomes a necessary incentive for investment. On the other hand, the lack of flexibility that characterizes mandatory rules can be inefficient if those rules differ from the ones that the parties would prefer. For instance, the presence of a mandatory rule concerning corporate disclosure can interfere with the willingness of a risk-averse investor to finance an enterprise that would prefer to opt for a lower level of disclosure. In such situations, default rules that are modifiable by the parties might produce a more efficient result. Enabling rules promote efficient regulation, however, only when investors are able to make their decisions based on accurate assessments of the regulation chosen by managers and controlling shareholders. This prerequisite suggests that default rules will only be efficient when there are organized minorities (usually institutional investors), who do not face information asymmetries and problems of collective actions in 'contracting' around default rules.

Against this basic economic background, it is clear why in common law countries, and the US in particular, the presence of more developed financial markets and of stronger 'organized' minorities (through institutional investors such as mutual funds) made possible corporate statutes that contain primarily default rules, in contrast to the more rigid mandatory systems that prevail in continental Europe. Things are changing at a rapid pace in Europe, and with the development of financial markets and the increasing intervention of foreign investors, even more traditional civil law countries are moving toward a more flexible corporate law that relies more on default rules (Easterbrook and Fischel 1989, Coffee 1989).

2.3 Regulatory Competition in Corporate Law

An important consequence of the fact that different legislators provide for different corporate law statutes, which strike different balances between mandatory and enabling rules, is that a 'regulatory competition' has developed to attract corporate charters (Cary 1974, Winter 1977, Romano 1987). Regulators may desire to have business enterprises incorporating within their boundaries for different reasons, such as incorporation fees, taxes, or indirect effects on the economic system. To achieve their goal, regulators have incentives to enact a body of corporate law that fits the needs of those who will choose the state of incorporation. One risk in this situation, however, is that those who have the power to choose (the controlling shareholder, the directors or the managers) have different incentives than the minority shareholders. Consequently, they may be tempted to choose a jurisdiction that maximizes their utility, but not that of the minority investors. The result is that regulatory competition can lead either to a race to the top (where rules maximize the wealth of all the subjects involved) or a race to the bottom (where rules attract corporations at the expense of minority investors). Between these two possibilities, the final result will depend on the ability of investors to 'penalize' corporations that choose a regime that is bad in terms of minority protection.

In the US, regulatory competition has been possible because corporations are free to incorporate and reincorporate in the different states. This freedom of regulatory competition has produced the so-called 'Delaware effect,' meaning that a majority of corporations, regardless of their physical location, have chosen to incorporate in Delaware (Macey and Miller 1987). The effects of this competition on shareholders' wealth are still discussed by scholars, but it is clear that corporations demonstrate a preference for statutes that provide more default rules.

In Europe regulatory competition has not been possible so far because of a more 'protectionist' approach, based on the so-called *siege reel* principle, which requires that corporation be governed by the law of the state where they have their principal place of business. Some recent decisions of the European Court of Justice seem to suggest a more opened approach that would promote regulatory competition. Most particularly, the so-called Centros Case, decided by the European Court of Justice on March 9th 1999, affirmed the possibility for a business to incorporate in England even though it operated only in Denmark and did not have contacts with England. This case suggests that changing world economic pressures will encourage wider acceptance of enabling rules and regulatory competition in corporate law in Europe.

3. Separation of Ownership and Control and the Reduction of Agency Costs

The separation of ownership and control (Berle and Menas 1932) raises problems of agency costs, analogous to, perhaps even more extreme than, the agency costs discussed above when an employer monitors an employee. Investors are principals who entrust their savings to majority shareholders, directors or managers (depending on the level of the analysis). Internal governance structures, such as corporate

governance rules, and external governance structures, such as the market for corporate control, can be seen as devices designed by corporate law to reduce these costs, allowing principals to oversee, directly or indirectly, the activity of their agents.

3.1 Internal Governance Structures: Corporate Governance and Internal Organization

Corporate governance, strictly speaking, is the set of rules that governs the relationships between and the balances the interests among shareholders, directors, managers and employees. In a more general sense, corporate governance also includes social controls on firms regarding such issues as antitrust, consumer protection, and pollution control. For the purposes of this discussion of corporate law, analysis will be limited to the three major areas that affect the internal organization of corporations: shareholder voting, the board of directors, and control and auditing.

3.2 Shareholders Voting

Shareholder voting regulations address issues such as who should vote, what issues should they vote on, and which procedures they should follow. From an economic standpoint, scholars contend that voting power is granted to the group that has the appropriate incentives (collectivity problems to one side) to make a discretionary decision that maximizes the corporate wealth (Easterbrook and Fischel 1983). For this reason, in most but not all systems, the shareholders' meeting usually has the power to deliberate major changes in the financial and legal structure of the corporation. In common law countries, which are characterized by efficient and strong capital markets, directors are granted expansive discretionary powers in relation to shareholders. By contrast, in the civil law systems of continental Europe, the shareholders' meeting is still seen as the 'central' organ in corporate law. The shareholders' meeting is entrusted exclusive powers concerning the juridical and financial structure of the corporation (such as to amend the corporate charter, and to deliberate over the issuing of new shares).

One of the fundamental problems concerning shareholders' voting is the issue of collective action and individual opportunism. Either when there is a controlling shareholder or widely dispersed ownership, the marginal shareholder will have no incentives to collect costly information in order to vote intelligently. Instead, the marginal shareholder is likely to rely on the possibility that other shareholders will incur those costs and follow their lead in voting. In economic terms, this situation is referred to as the 'free-rider problem.' While rational at the individual level, the choice at the aggregate level can preclude minority shareholders from ever using their *voice* to oversee the management of the corporation. Instead, they will sell the shares or 'exit' if they are dissatisfied with the way the corporation is run.

Meanwhile, for several reasons, institutional investors who hold a minority but non-trivial share can exercise active control on management through voting and it is often rational for them to do so. First, institutional investors encounter significantly lower information costs than individual investors and the availability of a non-trivial number of votes may make it possible to actually influence the management of the corporation. The other traditional alternative for minority shareholders, selling shares, can be difficult without having a bearish effect on the market. The presence of institutional investors, a development of the 1960s and in the 1970s in the US and more recently in Europe, is an important development that affects the effectiveness of corporate governance tools. In fact, without qualified minorities capable of activating them, instruments permitting direct control by minorities, such as derivative suits and proxies, would be absolutely useless (Black 1992).

Proxies and proxy fights are considered one of the most important tools through which minorities can participate in the life of a corporation, even if available data suggests that they are used less frequently than tender offers to transfer corporate control (Pound 1988). A proxy fight occurs when management and dissidents seek to obtain authority to act as designated voting representatives of voting shareholders at shareholder meetings. Virtually all the legal systems provide rules to regulate proxy fights. The regulation of proxy fights aims both to permit the solicitor of proxies an opportunity to reach all shareholders, which can be difficult with public companies if shares are recorded in 'street' names or the name of the nominee that administers the transfer of shares for clients (i.e., brokerage or bank). Corporate law also seeks to ensure that shareholders are provided with fair information and granted the possibility of an unbiased vote.

Another important feature of corporate voting is the potential for categories of shares with different rights attached. Almost all the legal systems statutorily prohibit cumulative voting and provide that every share should have no more than one vote. Nonetheless it is permitted, and indeed common, that corporations issue more than one class of stock, granting different rights for each class (for example, one class of voting shares and one class of non-voting shares with stronger economic rights). Typically, a class of shares granted with limited voting rights is issued for public shareholders, and another class with full voting rights is issued to majority shareholders interested in the actual control of the company (Gordon 1988). Notably, however, not all stock exchanges are willing to list limited voting shares. The New York Stock Exchange, for instance, until recently had very strict rules concerning limited voting shares.

In comparing regulation of proxies and the presence of non-voting or limited voting shares, there are two possible approaches to protecting minorities. On one hand, it is possible to acknowledge minority shareholders' lack of interest and ability in managing or controlling the corporation, and to protect them by reducing their administrative powers but enhancing their economic privileges, such as dividends and residual claims in case of dissolution. On the other hand, it is possible to allow minorities to play an active role in controlling majority shareholders' and managers by providing for specific tools such as proxy fights. The latter option generally requires the presence of institutional investors and organized minorities capable of actually using these tools in an informed and competent way. These different approaches are not mutually exclusive and in fact are often both present in corporate law statutes.

3.3 Boards of Directors

Directors are elected by the shareholders' meeting on a one-share-one-vote basis. They are entrusted with the power to manage the corporation and to represent it to third parties. Usually, directors are organized in a board and, as discussed above, different legal systems allocate competence between the shareholders' meeting and the board differently. Continental European systems usually provide for more extensive competence for the shareholders, while the US and other common law systems permit the board of directors to make the key decisions for a corporation without deferring to the shareholders' meeting.

The internal organization of a board of directors also differs among national systems. In the US, for instance, the flexibility of corporate regulation allows for the possibility of establishing one or more committees within the board of directors, which are designated specific tasks such as compensation or auditing. Another peculiar model is the board of the German corporation, which is characterized by a so-called dualistic system. The *Vorstand* has managing and representation powers, but its members are elected and controlled by the *Aufsichtsrat*, a controlling board directly appointed by the shareholders that can remove them for cause (*wenn ein wichtiger Grund vorliegt*, according to the § 84.3 AktG). German workers are also granted representation by law in the *Aufsichtsrat*, demonstrating a commitment to co-management between the providers of capital and labor (*Mitbestimmung*). In France the dualistic German-like model can be chosen, but is rarely used in practice. Instead, the board of directors is often dominated by the *President Directeur General*, who is both the chairman of the board and the chief executive officer of the corporation. This role was introduced during the German occupation for ideological reasons, but it has nonetheless proven to be efficient (for comparative references Weigmann 1997).

Normally, directors have two major duties, the duty to act with reasonable care in the managing of the corporation's businesses, and the duty to act loyally, which includes to avoid in conflict of interests. Breach of either of these duties can result in civil liabilities either to the company or its shareholders. While the duty of loyalty is strictly enforced, the duty of care is often blurred. Most systems provide for a 'business judgment rule,' which acts as a safe-harbor that prevents judges from second-guessing the merits of the directors' choices.

3.4 Auditors

Finally, most legal systems (but not all) provide for a separate board of auditors entrusted with the task of controlling the activity of the directors, especially with reference to accounting practices. The board of auditors is elected by the same majority that appoints directors, which can lead to problems since the elected auditors by the majority do not necessarily have any incentive to act in the interest of minority shareholders. For this reason, some legislation provides a mandatory rule, at least for public companies, under which the board of auditors must include a member appointed by minority shareholders. An example of this approach is the new Italian law on financial markets and listed corporations (the d. lgs. n. 58 of 1998, art. 148).

4. External Governance Structures: The Market for Corporate Control

Until this point, discussion has been limited to those internal governance structures that reduce the cost of control faced by corporate investors. These costs are also reduced by external forces, most significantly the market for corporate control. The inability of managers or controlling shareholders to create wealth for all shareholders can be reflected in the market price of the shares. As noted above, if shareholders are dissatisfied with the way their agents act, they can exit the investment. The sale of their investment will lead to a drop in the price of the shares, which might allow a shareholder who believes to be better able to manage the corporation to buy control and change management. The threat to managers and present controlling shareholders of loosing control should provide an incentive to align their preferences with those of minority shareholders (Manne 1965, Jensen 1988, Jarrel et al. 1988).

Given this possibility, making transfers of control easy could be seen as the best way to reduce agency costs, although this solution has its own problems. When a new shareholder takes control, he usually pays a premium for control. If the market is not very efficient, liquid, or quick in adjusting shares prices to the new control, it is possible that control can be acquired directly from the controlling shareholder. In

that situation, the premium for control will be paid directly to the controlling shareholder and minority shareholders will not enjoy any of the premium. For this reason, some legal systems have a mandatory tender offer rule, which seeks to distribute the control premium among all the shareholders. Typically in Europe, where there are less efficient markets, corporate legislation requires a public offer to buy shares to acquire control. In the US, by contrast, where the market is considered more efficient and able to minimize exploitation of minority shareholders, there are no—or less stringent—rules requiring specific compulsory offers in case of acquisition of control.

5. *Financing the Corporation: The Issuing of Bonds*

To complete a discussion of corporate law, it is necessary to note briefly an alternative financing option for corporations that is permitted by the corporate law of all legal systems: the issuance of bonds, which is essential to provide a mixed financial structure, thus leveraging financial risk.

Bond-holders can be seen as economic actors who are willing to lend money to the corporation but, different from the shareholders who accept a variable rate of return depending on the profits of the corporation, prefer to receive a fixed interest rate. In economic terms, the reason for this preference could be that they do not want to undergo the controlling expenditures faced by shareholders and prefer instead to contract in advance for a fixed rate of return. Bond contracts are thus written with the explicit purpose of avoiding the bondholder-stockholder conflict (Smith and Warner 1979). The US system provides an interesting illustration of the different interests of shareholders and bond–holders: while Delaware corporate law is usually chosen because its default rules allow greater flexibility, New York law is usually chosen to govern bond issuing because it is considered particularly protective of creditors and its mandatory rules preclude the need for very detailed contracts.

Corporate Taxation

Corporate taxation is an important source of government revenue around the world, and a major consideration in planning business activities. This article identifies the economic incentives created by the taxation of corporate income, and reviews available evidence of their behavioral impact.

1. *Scope and History*

Corporate tax obligations consist chiefly of fractions of corporate income. The corporate income-tax rate structure is usually progressive, meaning that average tax rates rise with income, typically reaching a maximum rate rapidly enough that almost all of the income of large corporations is subject to tax at the highest rate. In the United States in 1999, corporations earning net income up to $50,000 paid 15 percent tax; this tax rate rose to 34 percent on income over $100,000, and was 35 percent on incomes above $10 million. Other countries tax corporate income at similar rates that can vary according to the size, location, and industry of the corporate taxpayer. Thus, desires to rectify geographic income disparities led Germany, Italy, and other countries to offer tax concessions for investment in depressed regions, while mineral-rich countries such as South Africa and Papua New Guinea subject mineral extraction to taxation at supranormal rates.

Much popular and public policy attention is devoted to the tax planning activities and corporate tax obligations of big businesses—and with good reason, since corporate income tends to be concentrated in a relatively small number of large companies. For example, in 1997, there were 4.7 million active corporations in the United States, of which approximately 9,000 had assets exceeding $250 million. These 9,000 large corporations accounted for 86 percent of total US corporate assets, 80 percent of net corporate income, and 78 percent of total corporate tax payments.

The American federal corporate income tax was introduced in 1894 but was found to be unconstitutional the following year; it reappeared as a gross receipts tax in 1909, and was modified to become a genuine income tax following ratification of the 16th Amendment to the US Constitution in 1913. The US corporate tax rate in 1913 was 1 percent. The corporate tax rate rose over time, though it remained below 15 percent until World War II, at which point it rose sharply. Corporate tax was a major revenue source for the US federal government between World War II and the late 1960s, when corporate tax collections consistently represented more than 20 percent of federal government revenue. Corporate tax collections have fallen as a fraction of total government revenue since then, though they exceeded $188 billion in 1998, representing approximately 11 percent of US federal government revenues, or 2.2 percent of US gross domestic product (GDP). This pattern is repeated in other high-income countries, many of whose corporate income tax rates and tax provisions are remarkably uniform. In a typical recent year (1994), top marginal corporate tax rates among the 12 member countries of the European Union ranged from a low of 33 percent to a high of 45 percent, with just a single country (Germany) taxing corporate income at a rate in excess of 40 percent.

2. *Impact on Economic Behavior*

The taxation of corporate income encourages entrepreneurs and managers to structure and conduct their business operations in ways designed to avoid taxes. Corporations generally reduce their tax obligations, and those of their shareholders, by using debt rather than equity finance, investing in assets that can be depreciated rapidly for tax purposes, and those for which generous tax credits are available, and avoiding dividend payments or other tax-disadvantaged distributions to investors.

The major tax consideration in corporate finance is that interest payments to bondholders are deductible from taxable income, while dividend payments to corporate shareholders are not deductible. As a result, corporations generally have tax incentives to issue more debt than they would otherwise, and there is ample evidence (Auerbach in press) that debt/equity ratios are higher as a result. Since dividend payments generate tax obligations for recipients, corporations also have incentives to buy back shares, or to use other non-dividend methods of distributing income to shareholders.

Tax incentives to issue debt are mitigated in situations in which firms anticipate nonrefundable tax losses, or in which there is strong investor preference for returns in the form of capital gains and dividends rather than interest income. The strength of investor preference for stock ownership depends on circumstances. Individual investors most strongly prefer owning a firm's stock to owning its bonds if they reside in countries (such as Australia, France, or the United Kingdom) that permit dividend recipients to claim credits for corporate taxes paid on income generating dividends. In countries without such personal and

corporate tax integration, the favorable tax treatment of accruing capital gains means that some investors, typically those in the highest tax brackets, prefer stock ownership (despite the associated corporate tax obligations) to holding interest bearing debt. With sufficient numbers of such investors, it follows that asset markets will price stocks and bonds so that the economy's debt/equity ratio increases with the corporate tax rate, while any individual corporation is indifferent between debt and equity finance (Miller 1977).

Taxation influences the timing, magnitude, and composition of corporate investment in plant and equipment, inventories, research and development, and other business assets. Higher tax rates generally reduce investment, though this depends on tax treatment of investment expenditures. Investors generally do not reduce taxable income immediately by the full amount of spending on business investment, instead amortizing the cost of investment spending over a period of years in which 'depreciation allowances' are permitted. These depreciation allowances are most valuable if claimed soon after an investment is undertaken, since they are seldom adjusted for inflation and the time value of money. Hence governments that seek to encourage business capital formation often do so by permitting investors to depreciate their investments for tax purposes over short periods of time. Governments also often provide special tax credits for investments in selected asset categories, such as research and development (R&D) (available in Canada, Japan, Spain, the United States, and elsewhere). Depreciation allowances and investment credits together have the potential to stimulate investment by reducing required rates of return (Hall and Jorgenson 1967). These tax considerations are captured succinctly by 'effective tax rates' (Auerbach and Jorgenson 1980) on business investment, which usefully can be compared over time and between countries (King and Fullerton 1984). The available evidence indicates that rates of business investment are inversely related to effective tax rates (Hassett and Hubbard in press).

Corporate taxation also affects business organization by discouraging the incorporation of profitable businesses that can be organized in noncorporate form. In the United States, business organizations whose income is not subject to the corporate income tax include small ('S') corporations, partnerships, sole proprietorships, and limited liability companies.

3. *The Taxation of Multinational Corporations*

Multinational corporations—those with active business operations in more than one country—pose special problems for tax systems, since it is necessary to determine the location and character of taxable income, as well as the means by which double tax relief is to be provided. Double tax relief is essential, because a corporation's home country claims the right to tax all of its income, including the income earned by its foreign affiliates, while host countries in which foreign affiliates are located insist on their rights to tax affiliates' incomes. In the absence of special tax relief, income earned by foreign affiliates would be subject to taxation both by host countries and by home countries at cumulative rates that might approach or exceed 100 percent.

There are two practical systems of international double tax relief, both of which permit countries to tax fully any income earned by economic activity undertaken within their borders. Double taxation is avoided whenever home countries forgo taxing multinational corporations on income earned by their foreign affiliates, or else, when home countries tax the incomes of foreign affiliates but permit taxpayers to claim credits for foreign taxes paid. Use of the credit method effectively subjects income earned by foreign affiliates to home-country taxation at a rate equal to the difference between home and foreign tax rates. Actual methods of double tax relief often resemble a combination of these two methods. A majority of the world's countries exempt from tax most of the income earned by foreign affiliates of domestic multinational corporations, though several major capital exporting countries, including the United States, Japan, the United Kingdom, Italy, and others, subject such income to taxation but permit credits to be claimed for foreign taxes.

There is ample evidence that international tax rate differences influence the timing and location of investment by multinational corporations (Hines 1999). Countries and subnational jurisdictions that tax corporate income at low rates receive unusually large volumes of foreign direct investment, particularly from countries that do not tax foreign income. Furthermore, multinational firms arrange their business transactions to avoid international taxes. Thus, foreign affiliates located in high-tax countries tend to be financed with higher debt/equity ratios than are investments in low-tax countries, and are more likely to remit profits in the form of (deductible) royalty payments than (nondeductible) dividends. Only a small fraction (16 percent in 1984) of the foreign affiliates of American companies pay dividends to their parent companies each year, and those that do tend to have particularly tax advantaged situations (Hines and Hubbard 1990). And the pretax profitability of foreign affiliates is correlated negatively with host country tax rates (Hines and Rice 1994), which is suggestive of tax motivated transfer pricing and unlikely to be the outcome of ordinary investment responses to tax rate differences.

4. *Incidence of the Corporate Income Tax*

The requirement that corporations pay taxes does not mean that owners of corporations necessarily bear the

burden of the corporate tax, since this burden might be shifted, partially or entirely, to consumers in the form of higher prices, or to workers in the form of lower wages. Indeed, there are reasonable situations in which the existence of the corporate tax actually enhances returns to capital owners, including owners of corporations (Harberger 1962).

Corporate tax obligations contribute to the cost of investment and thereby encourage substitution of other productive factors (such as labor) for capital used by corporations. Labor expenses are deductible against taxable income, so the corporate tax does not affect the marginal condition characterizing a firm's decision of whether or not to employ additional labor. While the substitution of labor for capital depresses the demand for capital and thereby reduces its after-tax market return, there exists a separate effect of corporate taxation that stems from its induced intersectoral reallocation of resources.

Corporate taxation increases the cost of producing corporate output, thereby raising output prices, depressing demand, and shifting output from the corporate sector of the economy to the noncorporate sector. This reallocation affects factor demands to the extent that factor input ratios differ between the corporate and noncorporate sectors of the economy. If the corporate sector of the economy has a lower capital/labor ratio than the noncorporate sector, then the introduction of a corporate tax shifts resources into the noncorporate sector and thereby raises the demand for capital. If this effect is large enough, it has the potential to exceed in magnitude the countervailing impact of factor substitution, thereby implying that higher rates of corporate tax are associated with greater after-tax returns to capital—including capital invested in corporations. It would then follow that labor bears the burden of the corporate tax in the form of lower wages. The distribution of the corporate tax burden is an important area for future empirical research. The limited available statistical evidence is inconclusive (Krzyzaniak and Musgrave 1963), thereby leaving open the possibility that corporate taxation ultimately improves the after-tax profitability of owning corporations.

Corporatism

Corporatism can be defined as a specific relationship between organized interests and government where interest associations coordinate some of their key activities with government policy. Such coordination most often presupposes a specific structure of organizations permitting their leaders to represent the particular interests of their members while restraining their demands and obliging them for the pursuit of overarching collective purposes. The concept achieved prominence in the study of industrial relations, of comparative political economy, and of public policy and has in particular been employed to investigate the impact of industrial relations on macroeconomic policy. But it covers a broader variety of sectors and has also been given the wider meaning of self-regulation through 'private interest government.'

1. Prehistory of the Concept

The concept of corporatism (or 'corporativism') initially designated institutional blueprints for 'functional representation' of organized interests as they throve since the late nineteenth century. Responding to the growing intensity of social conflicts between

capital and organized labor, conservative as well as socialist authors propagated the representation of interest groups by organizations with compulsory membership and their insertion into an institutional framework for peaceful conflict regulation. Among the influential proponents of a 'corporative order' were Catholic social theorists whose ideas found their expression in the papal encyclicals *Rerum Novarum* (1891) and *Quadragesimo Anno* (1931). The concept was also endorsed by conservative and fascist ideologues who proposed the replacement of representative parliamentary democracy by a 'corporative state.' It served as a basic institutional formula in the authoritarian regimes of Mussolini, Franco, Salazar, and Pétain (though not in Nazi Germany) and thus had for a long time a distinctly antiliberal and antidemocratic connotation. Similar corporatist features were also introduced in some authoritarian regimes of Latin America (Brazil, Argentina). But in the 1930s, corporatist ideas were advocated even in some liberal parties (e.g., in Switzerland).

The concept acquired a new—and this time explanatory rather than prescriptive—significance since the economic crisis of the 1930s, and notably in and after World War II (in the context of the management of shortages in the war and postwar economy). At that time, institutionalized forms of cooperation between governments and organized interests were observed in a number of democratic countries, especially in Western Europe. Often associations choose voluntary cooperation (notably in wage policy) in order to avoid dirigiste interventions of government. Subsequently such 'social pacts' acquired increasing importance as an instrument of Keynesian macroeconomic policy. Among the social scientists who pointed to the resemblance between these practices and some aspects of the 'corporativist' designs of the interwar years one of the first was Shonfield (1965), later followed by political scientists (also Lehmbruch 1974 and in particular Schmitter 1974) who developed the typological distinction between 'state corporatism' and 'societal corporatism' (or 'authoritarian' vs. 'liberal' corporatism). What distinguished these 'neocorporatist' arrangements from their forerunners was both their more or less informal character and the complete absence of an underlying articulate doctrine. Nowadays the terminological convention of social scientists most of the time ignores the prehistory and employs the term 'corporatism' for these new organizational patterns.

2. *Typological Approaches to the Study of Corporatist Interest Intermediation*

Political scientists employed this more recent version of the concept of corporatism to explain empirical observations that did not square with the established interpretation of interest politics often called 'pluralist.' In the tradition of the 'group approach,' political interest groups were defined as 'shared attitude groups that make claims upon other groups in the society,' eventually 'through or upon any of the institutions of government' (Truman 1951, p. 37), and hence the 'access' of interest groups to government (or, with a somewhat pejorative connotation, 'pressure politics') was a key analytical question. However, such an approach was not particularly suited to explain the emergence, in different countries, of 'social contracts' between government and organized interests for voluntary incomes policy as an instrument of Keynesian economic policy. Since in these instances government was making claims upon interest groups the vectors of influence were inverted.

Generalizing from such observations, the concept of corporatism describes a type of policy formation where organized interests are encouraged to (explicitly or preemptively) coordinate their activities with government and to foster its policy objectives. Thus the analytical problem is not *access* but a process of *exchange* in which interest associations pledge organizational compliance and are often rewarded with specific organizational privileges. As a complementary terminological consequence of this theoretical reorientation of interest group research, the established notion of 'interest representation' was substituted by 'interest intermediation' (Schmitter 1979, p. 93, endnote 1).

A corporatist exchange relationship between government and organized interests tends to benefit from specific structural properties of organizations. In Schmitter's well-known definition of corporatism, a limited number of associations enjoy a monopoly in the representation of specific interests, membership may be compulsory, and leadership is clearly centralized. This enables a corporatist association to obligate the organization in its relationship with government and other associations and permits the government to hold it responsible for obtaining the compliance of the membership. Pluralism, on the other hand, is characterized by a multiplicity of associations that may compete for turf in representing specific interests, in which membership is voluntary, and leadership positions may be subject to internal contestation. A crucial element of Schmitter's influential contribution was thus the conceptualization of 'corporatism' as one building block of a comparative typology of organized interests.

From the original fourfold typology with its strongly deductive flavor, subsequent research has only retained the distinction of 'corporatism' and 'pluralism,' while the constructs of 'monism' and 'syndicalism' turned out to be of limited relevance for empirical research. In this typology, 'pluralism' carries a specific connotation derived from earlier US research on interest associations. In particular the emphasis of the 'group approach' (as it was developed by David Truman 1951) on society as a 'mosaic of overlap-

ping groups of various specialized sorts,' with an inescapable 'proliferation of associations' that may eventually split and compete among each others, formed a striking contrast not only to the organizational monopolies of older 'state corporatism' but also to the all-encompassing 'peak associations' of some European democracies.

The concept of 'corporatism' should not be construed as an alternative to the theory of 'pluralist democracy' or 'polyarchy' with which it is, on the contrary, largely compatible. Rather, the typological distinction from 'pluralism' aimed specifically at modifying the 'pluralist' paradigm of interest group politics: 'pluralism' was no longer treated as a general paradigm but rather as a special type of interest group activity. The swift adoption of the typology in political science was not least due to its innovative contribution to comparative empirical research, where it facilitated the development of measurement concepts that so far had largely been missing.

2.1 *The Measurement of Corporatism*

In empirical research, the constructs of corporatism and pluralism should be considered as extreme types permitting the location of individual cases on (nominal or ordinal) scales. The typology has served not only to describe individual associations but also the structure of 'interest systems' (Schmitter 1979) of whole countries. Indeed, within particular countries the organizational properties of the most important associations and of their relationship with government and among each other are often characterized by a considerable degree of 'organizational isomorphism' (as defined by DiMaggio and Powell 1991). The location of countries on a corporatism scale has, in particular, become a preferred instrument of comparative research on public policies for the investigation of the impact of structures of interest intermediation on policy outcomes.

Operationalization of these typological constructs is subject to the availability of standardized indicators and data. The degree of organizational centralization of labor unions or of the collective bargaining system are most easy to observe and have in particular been employed by economists focusing on the impact of collective bargaining on macroeconomic performance (Calmfors and Driffill 1988). To describe more complex patterns of interest intermediation, some political scientists have preferred to elaborate multidimensional indexes for measuring the strength of corporatism in specific countries, focusing either on associational properties (Schmitter 1981) or on associational participation in policy making (Lehmbruch 1984).

3. *Macrocorporatism and Mesocorporatism*

Corporatist arrangements have been observed mostly in industrial relations, be it on the national level (*macrocorporatism*) or on the level of industries (*mesocorporatism*). But they are also found in other policy domains, such as the social security system or agricultural policy (sectoral corporatism).

3.1 *Macrolevel Concertation and 'Social Pacts'*

As a pattern of policy formation, corporatism was originally largely tantamount to *macrocorporatism*, defined as an interorganizational arrangement in which the national peak associations of business and labor coordinate their autonomous policies through central-level bargaining, with government being often (at least informally) involved in tripartite 'social pacts.' Although the degree of formalization can vary, their central objective is always the consensual coordination of wage setting across the economy, as a decisive contribution to the pursuit of macroeconomic goals such as monetary stability, employment, and economic growth. Such 'concertation' (a term derived from the French *économie concertée*) might also include connected areas such as labor market or tax policy. Up to the 1970s, corporatist concertation was mostly found in the European welfare states with a strong social-democratic tradition, and for a considerable period they succeeded, under the conditions of Keynesian macroeconomic policy, to neutralize the trade-off between economic stability and high employment.

When the objective of full employment was increasingly put into question and Keynesian economic policy was abandoned it was often assumed that, as a consequence of the decline of macroeconomic policy, peak-level concertation would become redundant. In particular it was believed that the monetary instruments available to central banks after the end of fixed exchange rates might be powerful enough to induce spontaneous wage restraint. And when in the 1980s highly centralized bargaining systems were abandoned in several countries this was interpreted as a crisis of macrocorporatism. But subsequent research has maintained that under specific conditions corporatist wage bargaining has remained successful in macroeconomic stabilization.

In Europe, moreover, speculative predictions about the demise of corporatism were challenged by the emergence of a new generation of 'social pacts.' This new type of concertation aims at a negotiated reorganization of welfare state policies, notably of the old-age pensions systems and health policy. In this context, coordinated wage policies have remained important because of the interdependence of wages, nonwage labor costs, and employment. But whereas central tripartite negotiations remain the prevailing forum for the conclusion of social pacts about consensual welfare reform, the macrocoordination of wage policy is not necessarily identical with centralized peak-level wage-setting because there are also decentralized forms of coordination that may even yield superior effects (Soskice 1990).

3.2 Mesocorporatism

The participation of associations in the governance of particular industries has been termed *mesocorporatism*. This covers quite different phenomena: It includes the participation of organized labor and business in the management of industrial crises where government support may be vital (e.g., steel or mining), but also self-regulation by associations that have often been granted binding powers ('private interest government'). Associational participation in the governance of markets is particularly found in agriculture. In manufacturing industries, standard setting is another well-researched field of corporatist 'private interest government.' Moreover, in a number of European countries *sectoral corporatism* is also found in policy domains such as social security or health policy.

4. Cross-national Distribution and Longitudinal Trends

The strength of corporatism varies longitudinally as well as cross-nationally. Variations across time have been the object of many speculations: in the 1970s some authors predicted a secular trend toward corporatism in industrial democracies, whereas in the following decades observers frequently detected a general decline of corporatism. In cross-national empirical research we are on much firmer ground, and the well-established result is considerable variability of the strength of corporatism across industrialized countries. The acknowledged examples of 'interest systems' characterized by strong corporatism are those of Austria, the Netherlands, and the Scandinavian countries; whereas Germany has weaker corporatism, and the USA is clearly characterized by a dominantly 'pluralist' system of interest intermediation. These differences have, in the majority of cases, been relatively stable since the end of World War II and can quite often be traced back to the emergence of modern interest organizations in the late nineteenth and early twentieth century.

However, as far as the countries with strong corporatism are concerned certain trends can indeed be observed. In specific phases, notably in situations of crisis, an older pluralism of interest associations was increasingly superseded by organizational monopolies for the most important associations. The war economy of the two world wars, the world economic crisis of the 1930s, and the economic reconstruction after World War II have contributed most to these developments. While theories of the transformation of the political economy of highly developed industrial societies (e.g., 'organized capitalism') have often overlooked these institutional variations across nations, research on corporatism suggests the existence of a contingent plurality of development paths due to specific historical circumstances. Thus, corporatism was more likely to emerge where premodern forms of interest organization (such as corporations and guilds) have been able to survive and transform themselves instead of being destroyed in the transition to a capitalist market economy. Also, different 'state traditions' are characterized by different approaches to the intermediation of interests (Crouch 1993). Among others, corporatism appears to be strongly related to consociational or 'consensus democracy.'

5. Beyond Corporatism: Comparative Political Economy and Public Policy

5.1 Effects of Corporatism and Composite Models of Coordination in Market Economies

Comparative research on the effects of corporatist interest intermediation on macroeconomic performance and income distribution seems to indicate that macrocorporatism contributes to low unemployment and to lower levels of income inequality. However, the relationship with inflation rates seems to vary over time. Recent research in the policy performance of macrocorporatism has increasingly come to adopt more complex models in which the structure of interest intermediation is assumed to interact with other variables. Such conceptualizations distinguish different production regimes (Hollingsworth et al. 1994) or the coordinated vs. uncoordinated (or liberal) market economies (Soskice 1990). In particular, effects of corporatism on macroeconomic performance are better explained if the interaction with central bank independence is taken into account (Iversen and Pontusson 2000).

5.2 Corporatism and the Borders of State and Society

The emphasis of corporatist theory on the contribution of interest associations to the pursuit of collective goals has raised the question whether the traditional dichotomy of 'state' and 'society' could still be used as an adequate conceptual framework for the analysis of public policies in highly developed industrial democracies. This has led to the replacement of the traditional image of a hierarchical sovereignty of the 'state' by notions such as *governance*, understood as 'all those activities of social, political and administrative actors that can be seen as purposeful efforts to guide, steer, control or manage (sectors or facets of) societies' and where public and private actors work in 'co-arrangements' (Kooiman 1993, p. 2). Corresponding notions employed in European social science are *Steuerung* in the German, or *régulation politique* in the French literature. Research on policy networks has

developed more rigorous analytical instruments to compare corporatist to other patterns (Knoke et al. 1996).

Corpus Linguistics

Corpus linguistics encompasses the compilation and analysis of collections of spoken and written texts as the source of evidence for describing the nature, structure, and use of languages. Developing out of a long tradition of using texts rather than introspection, intuition, or elicitation as the empirical basis for linguistic description and argumentation, corpus linguistics is a methodology or approach for undertaking linguistic description. It is not a theory of language or a separate branch of linguistics such as morphology or sociolinguistics. Indeed, by providing sources of authentic, not made-up, examples of linguistic items, structures, or processes, the use of corpus-based evidence can complement other methodologies used by linguists. This evidence can be used for testing hypotheses, validating the accuracy of descriptions, making generalizations, and answering research questions which arise from theories of language or practical language-related issues in society.

With texts in electronic form as the source of linguistic data, and the speed and reliability of computers to assist analysis, the particular contribution of modern corpus linguistics has been to bring an additional quantitative dimension to linguistic description. On the basis of their occurrence in corpora, linguistic features can be shown to have different probabilities of occurrence in a language according to genres or domains of use. Thus, for example, Francis and Kučera (1982) showed that in US written English almost 15 percent of the verb predications in informative prose occur in the passive voice whereas in fiction, only about 4 percent of the predications are passive. Further, even within informative prose genres there can be considerable variation, with press reportage averaging about 13 percent passives and academic writing across many subject fields averaging 22 percent. Passive voice sentences can occur with an agent (e.g., '*These results were anticipated by the market*'). However, in texts from academic sources over 85 percent of passive voice predications typically occur without an agent. Corpus-based linguistic descriptions typically show not only what items, structures, or processes are possible, but which ones are probable in particular domains of use, thus inviting explanations of why this should be so. It can be argued that by including a quantitative dimension as part of descriptive adequacy, corpus linguistics has helped bring to the study of language a concern for distribution which is characteristic of other sciences.

1. Pre-electronic Corpora

Although corpus-based linguistics since the 1960s has been associated with texts stored and analyzed on computers, the use of texts as the basis for linguistic

description goes back well before electronic computers became available (see Kennedy 1998). In particular we may note the use of texts in lexicography, the study of the meaning and use of words. For example, the first edition of the *Oxford English Dictionary*, which was completed in 1928 after 70 years' work, was based mainly on the analysis of a collection of citations, totaling perhaps 50 million words, from texts from the canon of English literature, representing the use of written English over a period of 800 years.

Educationalists and linguists in the USA also used corpora of up to 18 million words in the first half of the twentieth century to discover the most frequently used words in English so as to develop better curricula for improving literacy education. This work of Thorndike, Sapir, and others was also very influential in the development of language teaching methodology. Their work was carried further in the UK by West and others and had a major impact on the methodology used for the teaching of English to speakers of other languages in substantial parts of Africa and Asia.

The first corpus compiled on a principled basis to be 'representative' of a language was the *Survey of English Usage Corpus* (SEU). Begun in1959 the SEU consists of 200 samples, each of 5,000 words, from some 24 genres of spoken and written British English. Although the corpus was not initially in machine-readable form, the spoken half of the SEU was eventually made available in electronic form as the *London–Lund Corpus*, until recently the largest available corpus of transcribed spoken language. The SEU marked the beginning of modern corpus linguistics and led to a large number of studies of English, culminating in the most extensive modern description of English grammar—*A Comprehensive Grammar of the English Language* (Quirk et al. 1985).

2. Computer-based Corpus Linguistics

Computers have given new impetus to corpus linguistics. The first computerized corpus designed for linguistic research was the *Brown Corpus* of contemporary written American English, compiled by Francis and Kučera. The one-million-word *Brown Corpus* consists of 500 text samples, each of 2,000 words representative of material printed in the USA in the year 1961. It became available in 1964. The careful design of the *Brown Corpus* with texts sampled from some 42 genres of informative and imaginative prose, the speed with which it was compiled and the way it was made freely available for linguistic research set new standards. It is noteworthy that although this first electronic corpus was compiled in the USA and there was an academic tradition there of text-based linguistic analysis and educational applications, most of the major developments in corpus linguistics for the next three and half decades came from Europe. These included the compilation of corpora for linguistic research, software development, and published research. This was partly because the direction of linguistic theory and research in the USA became dominated from the early 1960s by the influence of Noam Chomsky and attention shifted away from the observation of linguistic behavior ('performance') to a more epistemological focus ('competence'), with the study of performance ceasing to be normative except within subdisciplines such as sociolinguistics.

Following the compilation of the SEU and *Brown* Corpora, one million words became for a time the typical corpus size. This was brought about partly because one-million-word corpora were found to provide a reliable basis for many types of linguistic description, and because initially there were limitations in computer processing capacity and difficulty in getting machine-readable versions of texts before electronic text storage and optical scanning became more readily available. Until the mid-1980s most corpora had to be compiled through laborious keyboarding. A number of one-million-word corpora with the same basic design as the *Brown Corpus* were compiled in the 1970s and 1980s. These included, for example, the *Lancaster–Oslo–Bergen Corpus* (LOB) of written British English, the *Kolhapur Corpus* of written Indian English, and the *Wellington Corpus of Written New Zealand English*. All of these corpora and others of similar size compiled for synchronic or diachronic linguistic research purpose are available on CD-ROM from the International Computer Archive of Modern and Medieval English (ICAME) which also distributes the most complete bibliographic resources on corpus-based descriptions of English.

Although a high proportion of corpus-based research has been on English, there are now hundreds of corpora in existence, not only in English but in many other languages. Some have been compiled for commercial purposes such as dictionary making. Many others are available for research purposes and can be analyzed on personal computers (see Biber et al. 1998). Further information about corpora can be found in the journals *International Journal of Corpus Linguistics* and *Computational Linguistics* and through organizations such as the Linguistic Data Consortium and the European Corpus Initiative (see Bibliography).

In addition to the central focus on linguistic description, the study of the phonology, morphology, syntax, and discourse structure of languages, contemporary work in corpus linguistics has focused on four other main areas of activity:

(a) corpus design and compilation;

(b) the development of automatic grammatical annotation of corpora by means of word-class tagging and parsing to assign constituent structures;

(c) methodology for linguistic analysis using corpora; and

(d) applications of corpus-based linguistic descrip-

tions to assist the development of natural language processing and language teaching.

(a) Corpora which are designed for linguistic analysis differ according to the purpose for which they are compiled. Some are highly structured and attempt, by judicious sampling in different domains of use, to be representative of a language or language variety. Such general or 'balanced' corpora are used for making generalizations about a wide variety of linguistic phenomena.

Corpora are also compiled for particular specialized research, such as how speakers bid for turns in conversation, how language develops in children, how teachers use directives in classrooms, the vocabulary and grammatical structures most frequent in academic writing in the social sciences, telephone conversations among familiars, or how a language such as English has developed across the centuries. Corpora are compiled in different ways, with some consisting, for example, of samples from many texts, others consisting of whole texts, the complete works of an author, or all the issues of a newspaper over decades (see Kennedy 1998). By way of illustration, Table 1 shows the structure of one of the most recent and ambitious structured corpus projects, the *International Corpus of English* (*ICE*). This project, when completed, will include 20 one-million-word corpora of English (60 percent from spoken sources) compiled in different parts of the world from texts produced in the 1990s. In addition to the whole corpus forming a representative sample of English as an international language, the 20 individual subcorpora can be the basis of comparative studies of regional varieties of English. The British section of ICE, the first section publicly available, comes equipped with sophisticated search and retrieval software for automatic lexical and grammatical analysis.

For lexicographical purposes and the study of low-frequency words or processes, however, corpora need to be much larger than one million words, in order to provide enough instances of individual items to enable valid and worthwhile generalizations to be made. One of the most notable large structured corpora is the *British National Corpus* (BNC) This corpus of 100 million words (10 percent spoken sources) is carefully designed to represent British English in the 1990s. it has been sponsored by a consortium of government, leading universities, and publishers and has brought

significant changes to our understanding of the lexical, grammatical, and discoursal resources of British English.

However, size or structure does not necessarily make a corpus representative. A major issue in corpus linguistics has been whether corpora should be structured at all. Corpora such as the *Bank of English* are huge, heterogeneous and rapidly expanding collections of texts of all kinds added to the corpus as opportunity arises. Such 'dynamic' or 'monitor' corpora do not have a particular structure or finite size. In some ways, they resemble the even larger text databases of parliamentary proceedings, literary works or newspaper archives now available which can also be used for linguistic research. The rapid expansion of the Internet also provides potential sources of text for certain types of linguistic description. For example, where it is difficult to find enough tokens of low frequency words in a corpus to provide reliable lexicographical description, Internet search engines can often provide more than enough. In the final analysis, because any corpus is useful only so far as it makes possible answers to particular questions, corpora may be best categorized by the uses to which they can be put rather than by their design features.

(b) The automatic grammatical annotation of texts has become increasingly important. Specifically, the identification and counting of words, collocations and grammatical structures in a corpus can be greatly facilitated when variant forms of the same word (e.g., *book/books*, *go/went*) are represented by a single form ('lemmatization') and when all words in a corpus are tagged to show their appropriate word class, and parsed to show their grammatical function as part of the constituent structure of sentences. Such text annotation not only serves linguistic description but can be a prerequisite for other applications of corpus analysis associated with natural language processing.

(c) Particular techniques and procedures have come to be associated with corpus-based analysis. To some extent, available computer software has influenced these methodologies. In addition to producing word lists showing the frequency of occurrence of each word type, corpus-based analysis has depended heavily on concordancing. A concordance is a list of all the occurrences ('tokens') of a particular word or phrase in a corpus in the context of a given number of preceding and following words. Concordancing software has led to a focus on words and on 'collocations,' the company a word typically keeps. For example, linguists have noted that English intensifiers such as *very*, *quite*, *pretty*, *terribly* have a tendency to precede particular adjectives (e.g., *terribly nice*, *pretty horrible*). Corpus-based research on collocations has led increasingly to the recognition that a high proportion of what people say or write consists of prefabricated 'formulaic' groups of words (e.g., *pouring rain*, *strong tendency*, *at the moment*), thereby blurring somewhat the distinction between lexis and grammar.

(d) Important applications of corpus linguistics have occurred in the fields of natural-language processing (NLP) and second-language teaching. Research has been undertaken by computational linguists and others to make progress on the automatic lemmatization, tagging, and parsing of text. Rule-based approaches to annotation have sometimes been used, but increasingly some of the most promising NLP research has employed corpus-based statistical information on the probability of occurrence of linguistic items or processes as a basis for advances in automatic word-class tagging, parsing and disambiguation. Such information is prerequisite for developments in the retrieval of information from databases, speech recognition, speech synthesis, and automatic language translation.

Within second language teaching for the last 80 years there has been a continuing but by no means universal concern among curriculum designers and teachers as to which linguistic items or processes are most likely to be needed by language learners. In English for example, fewer than 100 words typically account for half of all the words used, and about 3,000 words account for 90 percent. According to Biber et al. 1999, just 12 English verbs account for nearly 45 percent of all lexical verbs in conversation. Many language teachers have known since the 1960s that although English verb phrase morphology appears complex and fraught with possibilities, the simple present and simple past tenses account for over 80 percent of all verb phrase structures in most corpora. Similarly, more recent work has shown that there is a much greater tendency for *prepositional phrases rather than relative clauses to be used in English postnominal modification* (e.g., *The person in the car was alone* is likely to be much more frequent than *the person who was in the car was alone*).

3. *Current Issues and Directions*

Corpus research has resulted in descriptive studies of all levels of language. Some of the most innovative work has been on linguistic variation. Biber (1988), for example, pioneered the corpus-based study of how the distribution of linguistic items in texts and the patterns of co-occurrence of these items could be used to characterize the ways in which languages vary diachronically and synchronically in different regional and sociolinguistic contexts. However, frequency of occurrence is not an end in itself. With easier availability of corpora, more powerful computers and more sophisticated software, corpus linguists have new opportunities to move beyond describing the structure and quantitative distribution of linguistic features. Some of the best work in corpus linguistics continues to involve the judicious use of manual analyses supported by the computer. There are opportunities for corpus linguists to illuminate the signifi-

cance of distribution, and to use corpora to test hypotheses and the robustness of linguistic theories. In focusing on the ways in which language users habitually express themselves, corpus linguistics has already thrown new light on how languages vary systematically in different regional and sociolinguistic contexts, genres, and registers. There is potential to provide further insights on the speed and direction of language change and on the factors which contribute to change. Corpus linguistics may also come to give greater support to work in cognitive linguistics through further exploration of the semantic roles and functions of linguistic features.

Correspondence Analysis

Correspondence analysis (CA) handles research data that have the form of rectangular tables containing indications of association strength between row entries and column entries (correspondence tables). The association measure is assumed to be some non-negative quantity. Cells of a correspondence table may contain transition or confusion frequencies (forming a contingency table), binary choices among dyads of persons, for example in sociometric studies, or preference judgments for options by experts on a rating scale from weak to strong endorsement. In other words, response scales have to be unipolar, ranging from zero, indicating absence of association, to some maximal positive value, indicating strongest possible association. Although the scope of application of CA is very broad, it has been most typically used and developed as a method for analyzing contingency tables. Hence some core concepts refer to the frequency domain, even though other justifications of the method exist.

1. Row and Column Profiles

As an illustration consider the eight discrete distributions in Table 1(a) taken from van Ijzendoorn and Kroonenberg (1988). Several studies using the Strange Situation paradigm (Ainsworth et al. 1978) in various countries seemed to show marked cross-cultural differences in distributions of attachment classifications. Most of the studies used a classic three-fold attachment classification into Avoidant (A), Secure (B), and Resistant (C). These three types characterize the enduring socio-emotional bond between child and regular care-giver. To examine the cross-cultural heterogeneity more closely, the authors selected 32 samples from eight countries, representing 1,990 Strange Situation classifications, which have been aggregated in Table 1 to the level of countries. To study similarities and differences of distributions regardless of sample size, it is necessary to divide frequencies by their row total (see Table 1(b)). A row of proportions is called a row profile; analogously, a column profile is formed by dividing the cell frequencies in a column by the column total. The natural comparison standard to assess a row profile against is the marginal profile of the columns, that is, each of the

Table 1
Attachment classifications in eight countries

	(a) Frequencies				(b) Row-proportions		
Country	A	B	C	Total	A	B	C
Germany	48	77	11	136	0.35	0.57	0.08
Great Britain	16	54	2	72	0.22	0.75	0.03
Netherlands	66	169	16	251	0.26	0.67	0.06
Sweden	11	38	2	51	0.22	0.74	0.04
Israel	8	76	34	118	0.07	0.64	0.29
Japan	5	65	26	96	0.05	0.68	0.27
China	9	18	9	36	0.25	0.50	0.25
United States	260	797	173	1230	0.21	0.65	0.14
Total	423	1294	273	1990	0.21	0.65	0.14

Legend: A = avoidant; B = secure; C = resistant.

column totals divided by n, the grand total. Similarly, column profiles are first compared with the marginal profile of the rows, that is, each of the row totals divided by n. From the row profiles it is immediately clear that Germany has a relatively large proportion of Avoidant, for example, Great Britain and Sweden have an overrepresentation of Secure and an underrepresentation of Resistant, while Israel, Japan, and China have an overrepresentation of Resistant.

The aim of CA is to assess similarities and differences of row profiles (and/or column profiles), not only with respect to their marginal profile, but also amongst each other, by constructing a parsimonious approximation of the cell frequencies. The approximation consists of decomposing the correspondence table into one or more components, which through graphical display allows a deeper insight into the original categories by suggesting specific groupings, orderings, or more complicated arrangements.

2. *Deviations from Independence*

The decomposition of CA has two major parts: one consisting of a multiplicative combination of row and column proportions, the usual form used in studying statistical independence, the other consisting of row–column interaction effects. To be more explicit, the following notation is introduced.

The frequency in cell (i, j) of the contingency table is denoted by n_{ij}, where the categories of the row variable A have range $i = 1, \ldots, I$ and the categories of the column variable B have range $j = 1, \ldots, I$, and the categories of the column variable B have range $j = 1, \ldots, J$. Row totals are defined as $n_{i+} = \Sigma_j n_{ij}$ and column totals as $n_{+j} = \Sigma_i n_{ij}$. We also have the grand total $n_{++} = \Sigma_i n_{i+} = \Sigma_j n_{+j}$, frequently denoted simply by n. To keep the results invariant under changes in sample size, CA works with the quantities $p_{ij} = n_{ij}/n$, each of which is the (estimated) probability mass in the cell (i, j) of the bivariate distribution of A and B, $r_i = n_{i+}/n$, the relative mass of row profile i, and $c_j = n_{+j}/n$, the relative mass of column profile j. The CA decomposition is based on the tautologous identity

$$p_{ij} = r_i c_j (1 + q_{ij}) \tag{1}$$

where the quantities q_{ij} are defined as $q_{ij} = (p_{ij} - r_i c_j)/(r_i c_i)$. The q_{ij} are standardized deviations from independence: if the two variables A and B are independent, we have $p_{ij} = r_i c_j$ and every q_{ij} would vanish. Dependences between A and B show up specifically in the q_{ij}: categories i and j are more strongly associated than expected under independence when $q_{ij} > 0$, and less strongly when $q_{ij} < 0$. Spatial and graphical representations that result from CA are representations of the deviations $[q_{ij}]$, not of the data $[p_{ij}]$ themselves.

3. *Basic Geometric Model*

In the CA model each row profile initially is a point $\mathbf{a}_i$ in a subspace of dimensionality $J-1$, with coordinates $a_{ij} = n_{ij}/n_{i+}$. Analogously, each column profile is a point $\mathbf{b}_j$ with coordinates $b_{ij} = n_{ij}/n_{+j}$ in another subspace, of dimensionality $I-1$. The total spread of the points in space is measured by their inertia $\mathscr{I}$, a concept from physics defined as (for the row points)

$$\mathscr{I} = \sum_i r_i \sum_j \frac{1}{c_j} (a_{ij} - c_j)^2 = \sum_i r_i \|\mathbf{a}_i - \mathbf{c}\|^2_{C^{-1}} \tag{2}$$

where $\mathbf{c}$ is the point with coordinates c_j that represents the marginal profile of the columns. The function $\|\cdot\|_{C^{-1}}$ defined implicitly in Eqn. (2) is a Euclidean norm with weights $1/c_j$. It downweights column differences associated with large column mass, because large frequencies tend to be less reliable. There is a parallel expression of inertia for column points, which can be

shown to yield the same numerical value of $\mathscr{I}$. In both cases, large overall differences among the distributions will lead to a spread-out configuration of points with large $\mathscr{I}$, while small overall differences will correspond to a tight concentration of points around their center of gravity, with small $\mathscr{I}$.

Dividing the usual chi-squared statistic by n, so that lack of homogeneity (or independence) is measured regardless of sample size, we have the equality

$$\chi^2/n = \sum_i \sum_j \frac{(n_{ij} - n_{i+}n_{+j}/n)^2}{n_{i+}n_{+j}} = \mathscr{I} \tag{3}$$

In statistics, χ^2/n is known as Pearson's mean square contingency. The relation in Eqn. (3) between the chi-squared statistic χ^2 and the weighted sum of squared distances towards the center of gravity $\mathscr{I}$ defined in Eqn. (2) is the reason that one speaks of heterogeneity being measured in the chi-squared metric $\|\cdot\|_{C^{-1}}$.

Mutual distances between row profiles are determined in the same chi-squared metric, and hence called chi-squared distances. For two profiles i and k we have

$$d_{\chi^2}(\mathbf{a}_i, \mathbf{a}_k) = \|\mathbf{a}_i - \mathbf{a}_k\|_{C^{-1}} = \sqrt{\sum_j \frac{n}{n_{+j}} \left(\frac{n_{ij}}{n_{i+}} - \frac{n_{kj}}{n_{k+}} \right)^2} \tag{4}$$

with again an analogous expression for the column points. In Eqn. (4) columns with small marginal frequency are seen to contribute more to overall lack of similarity than columns with large marginal frequency. For an exhaustive treatment of the geometry of CA, see Benzécri (1992, pt. I).

4. Weighted Least Squares Approximation

Low-dimensional CA approximations of the full-dimensional model are obtained by least squares, where each cell is weighted by the product of the row and column masses (see Andersen 1990). The least squares solution consists of two sets of standardized coordinates, $z_{it}(A)$ and $z_{jt}(B)$, where t indexes the components, with t having range $t = 1, \ldots, \min(I-1, J-1)$. The components are ordered by the size of a third set of quantities σ_t, called singular values. Standardized coordinates $z_{it}(A)$ have the property $\Sigma_i r_i z^2_{it}(A) = 1$; analogously, for $z_{jt}(B)$ we have $\Sigma_j c_j z^2_{jt}(B) = 1$. Also, the coordinates are in deviation from their weighted mean and uncorrelated across different values of t. The singular values σ_t indicate the relative importance of component t in the approximation of $[q_{ij}]$. Practical CA solutions are obtained by dropping components associated with small singular values.

Graphical displays are based upon a mapping from $\mathbf{a}_i$ to $\mathbf{y}_i(A)$, a model point with principal coordinates defined as $y_{it}(A) = \sigma_t z_{it}(A)$, with $t = 1, \ldots, T$ (some chosen dimensionality). Principal coordinates for column points are $y_{jt}(B) = \sigma_t z_{jt}(B)$. For maximal dimensionality $T^* = \min(I-1, J-1)$ it can be shown that

$$\|\mathbf{a}_i - \mathbf{a}_k\|_{C^{-1}} = \|\mathbf{y}_i(A) - \mathbf{y}_k(A)\| \tag{5}$$

i.e., Euclidean distances among model points are equal to chi-squared distances among profile points. In approximations with $T < T^*$ the former are always smaller than latter (see Meulman 1982).

5. Some Important Additional Concepts

The CA solution for the attachment data is shown in Fig. 1, in which the row points are plotted as open circles. Since in this example we have $T^* = 2$, the model exactly reproduces the data ($\chi^2 = 102.42$ with $df = 14$, $\mathscr{I} = 0.051$). Approximation in $T = 1$ implies projecting all points on the horizontal axis, which here accounts for 86 percent of the inertia (see Fig. 2). With the US and China forming the center, the largest contrast in both solutions is between the Western European countries vs. Israel and Japan, while Fig. 1 shows a second contrast between China and Germany versus Great Britain and Sweden related to deviations in their Secure classifications.

5.1 Transition Formulas

Row points and column points reside in two different but intimately related spaces. Their coordinates are connected by the equations

$$y_{it}(A) = \frac{1}{r_i} \sum_j p_{ij} z_{jt}(B) \tag{6}$$

$$y_{jt}(B) = \frac{1}{c_j} \sum_i p_{ij} z_{it}(A) \tag{7}$$

Figure 1
Full-dimensional CA model of countries-by-attachment-classification data, including four supplementary sample points (countries in principal coordinates, categories in standardized coordinates)

Figure 2
One-dimensional approximation of countries-by-attachment-classification data, accounting for 86 percent of the inertia (countries in principal coordinates, categories in standardized coordinates)

These equations are called transition formulas, since they show how the principal coordinates, e.g., $y_{it}(A)$, of one set of points can be obtained from the standardized coordinates, e.g., $z_{jt}(B)$, of the other set of points: by weighted averaging with the data as coefficients. If the correspondence table is binary, principal coordinates are plain averages of standardized coordinates, and CA becomes equivalent to the method of reciprocal averages, which has firm roots in psychometrics (Horst 1935, Guttman 1941), with continued research under the name dual scaling (Nishisato 1994).

5.2 Joint Plot and Coherent Normalization

In Fig. 1 the country points are plotted in principal coordinates, so that their Euclidean distances are equal to the chi-squared distance of Eqn. (5). The distances between the country markings along the line in Fig. 2 approximate these chi-squared distances rather closely. The plots also show the three attachment classes in standardized coordinates. Superposition of row and column points forms a joint plot, also called a 'biplot,' which is easily interpretable due to the transition formulas. For example, Germany is located relatively close to Avoidant, because its location is a weighted average of the three attachment points, weighted with [0.35, 0.57, 0.08] rather than with the average profile [0.21, 0.65, 0.14], which forms the center of the plot. It is also possible to (re)scale the coordinates so as to make the two clouds of points more evenly mixed, but this has to be done with some care (Heiser and Meulman 1983). Rescaling is coherent if we choose points $\mathbf{x}_i(A)$ and $\mathbf{x}_j(B)$ with coordinates $x_{it}(A) = \sigma_t^{\alpha} z_{it}(A)$ and $x_{jt}(B) = \sigma_t^{1-\alpha} z_{it}(B)$ for any α, because it remains true that $\mathbf{x}_i(A)^{\mathrm{T}}\mathbf{x}_j(B) = q_{ij}$. But it should be noted that we no longer approximate chi-squared distance unless $\alpha = 0$ or $\alpha = 1$.

5.3 Supplementary Points

It can be useful to add new profiles to an existing joint plot. These supplementary points are easily obtained if scaling is chosen as $\alpha = 0$ or $\alpha = 1$, since then Eqns. (6) or (7) can be used to find coordinates. In Fig. 1, points were added for four divergent individual US studies, showing that there is at least as much variation within the US as between countries. While US2 closely resembles the total German group, US11 is much more like China, for example.

6. Extensions and Applications

The case of more than two variables, called multiple CA, was pioneered by Guttman (1941). Under the name 'homogeneity analysis,' Gifi (1990) generalized Guttman's technique to ordinal data, and introduced extensions based on partitioning of variables. Greenacre (1984) and Lebart et al. (1984) bridged the gap between the early French work and the inter national literature. The edited volume of Greenacre and Blasius (1994) contains social science applications, versions of CA with various constraints, and versions that achieve clustering of categories.

Corruption: Political and Public Aspects

Although there is fairly general agreement that corruption is a trans-systemic phenomenon endemic to all societies, regimes, and countries, and salient in different periods of the history of mankind, the study of corruption reveals a weaker consensus as to its definition, measurement, and explanation. Empirical studies constantly are faced with three major issues that may hinder further comparative understanding of the phenomenon. First, corruption lacks a precise definition or agreement upon its meaning. Like many other concepts in social sciences, corruption is volatile and subject to historical, social, and cultural connotations. Second, corruption is susceptible to variations across time and space. Its measurement, both in terms of volume as well as the standards qualifying that form of behavior, is prior to any attempt at explaining how the phenomenon expands, grows and mutates contextually. Third, without clearing the first two methodological steps, the empirical testing of a derived hypothesis is bound to show rather limited or disputed results.

1. *Definition*

Idiomatic definitions differ substantially from country to country, a problem first raised by anthropologists, who denoted variations resulting from different social, religious, and cultural backgrounds. Corruption as a political phenomenon adds to that definitional complexity. The different usages of corruption by political scientists, with a broader meaning than those present in most contemporary penal codes, have raised potential ambiguities.

1.1 *Contemporary Social Sciences Definitions*

One could group this rich diversity in three basic definitional types: public-office-centered, market-centered, and public-interest-centered.

1.1.1 Public-office-centered definitions. Traditionally, the largest group of political scientists has opted for a definition focusing on those practices/behaviors that violate the legal/formal standards regulating public office. The most prominent definition is that Nye: 'Corruption is behavior which deviates from the normal duties of a public role because of private-regarding …, pecuniary or status gains; or violates rules against the exercise of certain types of private-regarding influence. This includes such behavior as bribery … nepotism … and misappropriation …' (1967).

Public-office definitions may help to disentangle the complexity of corruption by restricting the variety of potential denominations to the (most) visible or condemnable types. In practice, the standards covered by this set of definitions are not too far from those stated in most Penal Codes. More often than not, penal reforms are a *post facto* attempt to deal with corruption. Rules governing public office have been revised or stiffened, when certain manifestations of corruption have become rampant, provoking widespread convulsion and contempt in political society.

Public-office definitions are stable and objective and, for those reasons, have attracted considerable popularity amongst political scientists and criminologists. Normative aspects are simplified by legal reductionism. Legal norms, it is argued, translate a tangible value system, that can be considered, *a priori*, as an expression of the mores and ethico-juridical structure of a society at a given time. But even then one cannot escape the interpretative differences and imperfections of legal norms and how these evolve through time. The question arises: 'Which statement of the rules and norms governing public office is to be employed?' For most authors, the normative discourse of legislators, judges, and other competing authorities should be used as a definitional criterion. Legal norms are most likely to reflect the ethical standards of a particular group—the ruling elite—hence socially disputable and susceptible to revision.

The usage of legalistic definitions highlights the weaknesses of black-and-white modes of conceptualization. If compliance with public-office rules relies on the degree to which these are embedded in the ethical environment of the society in question, then one is bound to end with a rigid definition of corruption unrepresentative of the ensemble of manifestations occurring in that legal/social context. As Sorokin remarked, '… There always is some discrepancy between the situation as it is depicted in the "official law" and in the psychosocial mentality of members of the society. And the discrepancy is the greater, the quicker the socioethical life of the society changes' Sorokin (1991). Public-office definitions may have an analytical advantage from other definitions as they ease comparison across countries, societies, or regimes, yet, they bear the cost of leaving too many things undefined and, consequently, unexplained.

1.1.2 Market-centered definitions. A more restricted group of academics, deriving their premises from economic theory, conceptualized corruption in terms of an exchange of money for political decisions (asset), which private actors seek to acquire

(demand), and public agents are just too willing to sell (supply) by avoiding being caught (liability). The definition embarks on a public choice assertion that, *ceteris paribus*, all agents will seek rationally to take an advantage from their privileged position in office (rent maximizing) whenever there is a window of opportunity. As van Klareven argues, 'A corrupt civil servant, regards his public office as a business … a "maximizing unit." The size of his income depends … upon the market situation and his talents for finding the point of maximal gain on the public's demand curve' Van Klareven (1989).

The definition is articulated convincingly when dealing with specific types of transaction corruption (bribery, kickback, *pots-de-vin*) in which the legal criterion of infringement–condemnation may not be so clear-cut or nonexistent. Rose-Ackerman, an exponent of this type of definition, stresses that market corruption is essentially about 'all payments (legal or illegal) to agents that are not passed on to superiors,' but includes also a series of 'legal activities with similar public policy consequences,' such as, 'campaign contributions and lobbying' Rose-Akerman (1978).

Definitions of this sort appear to bypass normative considerations, but in reality they do not. Corruption is seen essentially as those exchanges, often between public officials and private entrepreneurs, likely of being susceptible to some disciplinary or criminal punishment. However, if corruption were defined as a rational behavior of maximization of personal advantages, then what would be the stimuli behind the acceptance of a pecuniary benefit that can be sanctioned by law? The definition also neglects 'moral costs' affecting the rationale of actors to engage in corruption such as public condemnation, disapproval by superiors and colleagues in the working place, and individual ethics. Some acknowledge the existence o'moral costs of breaking the law' (Rose-Ackerman 1978), but fail to provide a clear reference of what those 'moral costs' are.

The reliance on market concepts undermines that rules and principles binding public and elected officials are considerably distinct from those applicable to market actors. Market(s) of corruption—a disputable concept (Cartier-Bresson 1995)—can be defined as parallel exchanges where scarce 'goods' are allocated at prices determined illegally, contrary to governmental regulations and affecting its public policies (i.e., 'black market'). Such definition may not even correspond to the mechanisms and concepts operating in a free market situation. The very designation of 'black,' i.e., obscure and sanctionable, runs counter to the 'freedom of choice' qualifying market economies.

1.1.3 Public-interest-centered definitions. In recent years, political scientists increasingly have felt that both these types of definition were narrowly conceptualized. On the one hand, market-centered definitions were useful in so far as one dealt with transaction corruption, but insufficient once manifestations referred to nonpecuniary social exchanges and their moral implications. On the other, there was an upsurge against the tendency to reduce corruption to public-office rules applicable to a limited number of practices/behaviors, most likely criminal. According to these authors, corruption is a deviant behavior or practice characterized essentially by the subjugation of public to private interests (Rogow and Lasswell 1963, Mény 1992). The classical concept of public interest is revived and argued vividly as a criterion not only useful, but also indispensable to illustrate the essence of corruption. The public interest invites men to overcome their selfishness, to confront their preferences with those of others, and to evaluate options with equal disinterest and impartiality.

Moral issues are taken into account. Friedrich wrote, 'Corruption, being in fact a decomposition of the body politic through moral decay, is a general category to include all kinds of practice which are believed … morally corrupt' Friedrich (1989). The immediate questions are 'whose morals?' determine 'what corruptions?' In order to avoid associating corruption as value system degeneration with the classical idea of a transcendental and pre-established set of mores, the concept is made tangible through the predominant public perceptions in society. Morality is regarded as a social construction and what is or is not corruption will depend on the observer's opinion. However, replacing 'public interest' by a more fluid and vague concept of 'public opinion' does not prove elucidating either. The usage of public opinion pertains to the conceptualization of corruption, but only in terms of its operationalization, in other words, as a soft criterion used to measure the nature and scope of corruption.

Critics insist that the public interest is a weak reference, since in most contexts there is no definition of what the concept stands for: the notion of public is difficult to ascertain, least to say, that interest is another jargon of pluralist theories of the State. The concept is a battled one and open to broad interpretations and for that reason tends to be discarded from comparative measurements. The notion of public interest—its values, perceptions, and laws—vary across societies and that has implications in terms of what manifestations of corruption are identified across cases. However, this should not constitute an obstacle to the explanation of why societies have different standards defining corrupt practices/behavior or why these standards change through time.

1.2 Operationalization

The plurality of definitions available, sometimes controversial, may become an obstacle to empirical research. An alternative is to operationalize the con-

cept with the utmost goal of enhancing broad-based comparisons. This is not an easy task as most measures do not 'travel' easily in space and time. Scott wrote, 'Corruption, we would all agree, involves a deviation from certain standards of behavior. The first question which arises is, What criteria shall we use to establish those standards?' Scott (1972). Empirical studies on corruption have too often relied on legal/formal criteria to qualify standards of corruption (Nye 1967, Scott 1972). These tend to be regarded as stable and accurate indicators of what are the standing standards of corruption at a given time slot and society. Yet, even legal standards are not monoliths. The concept of corruption as defined in most penal codes is no longer particularly distinct from other types of crimes, such as fraud, influence trafficking, peculate, extortion. There has been equally a tendency towards enlarging its definitional parameters in order to embrace a wider range of pervasive manifestations (e.g., the inclusion of nonpecuniary inducements, the distinction of passive and active initiatives, and licit or illicit outcomes).

Legal criteria are not a precise volume indicator either: most corrupt transactions are obscure and clandestine; and shifts in volume may be a product of greater or more efficient prosecution. By excluding public reaction from the conceptual framework of corruption one risks to fall into legal dichotomising (i.e., legal 'noncorrupt vs. illegal' corrupt). But not everything that is legal is approved morally by citizens (Gardiner 1992). A purely legal conceptualization would omit all corrupt behavior which does not necessarily imply a breach of law or of codes of conduct, but still involve 'a serious violation of the standards and expectations associated with a public role' (Friedrich 1966, Jos 1993).

Corruption is also about perceptions. It can be many things to many people and has been used incessantly as an offensive political weapon. Another aspect of public opinion condemnation is that of labeling a cluster of distinct practices/behaviors as corruption, independently of the standing legal standards. Greater public perception depends largely on 'how?' and 'what kind?' of manifestations has been made visible to the public. Public opinion is fluid and particularistic, susceptible of being politically mobilized. Hence, the understanding of the 'corruption of politics' passes through an attentive analysis of the 'politics of corruption' (Nelken and Levi 1996). For most times, public opinion is an insufficient criterion based upon unstable, vague, if not contradictory, standards which oscillate between diversified perceptions in society, but criticisms fall short of a flexible alternative to measure qualitative variations. The variety of social representations on corruption is a sign that there is no harmonious definition, but competing standards. There is no static definition, but a qualitative gradation in terms of public condemnation and there is no necessary concordance between social/cultural standards and the standing legal rules condemning corruption in society.

However, a purely public opinion-based conceptualization is not the solution either. In as much as public opinion is important to understand changes in ethico-juridical structure, the condemnation of corruption is not just a matter of perception. Public accusation goes beyond the allegations raised by prominent newspapers, the rhetoric of electoral campaigns, or that of fervent parliamentary debates, and condemnation can be translated into criminal prosecution.

Corruption cannot be defined exclusively by legal or public opinion criteria. Corruption as a deviant behavior/practice concerns both the breach of rules governing public office and the infringement of noncodified, widely accepted ethical norms (Gardiner 1992, Jos 1993). The concept has to be flexible enough to include both set of norms 'constituting a society's system of public order' and the way these two ethical components are being challenged continuously and revisited (Johnston 1996).

Heidenheimer's (1989) definition of black, gray, and white types of corruption in relation to a variation of an elite- and public-based standards attempts to bridge both criteria. His typology is innovative in so far it denotes a certain qualitative gradation of the phenomenon product of value change. Some practices/behaviors, (often) collusive and subject to prosecution, are regarded as severe violations of the legal and moral norms set in society (black corruption). In this case, standing legal standards are likely to be reinstated by competent authorities when infringement is exposed. When toleration mounts, coding certain corrupt practices/behaviors 'a way of life,' legal condemnation gradually loses its meaning (white corruption). Standards degenerate. Neither of these two situations will necessarily trigger a revision of standards. It is rather the 'grayness' of corruption that promotes the demand for reform in the system, because existing standards are no longer seen as operational by political elites and sectors of public opinion. The waves of reform and control that swept across most Western European countries by the late 1980s and early 1990s can only be understood in the light of a significant value discrepancy between ruling elites and masses (gray corruption).

2. *The Measurement of Corruption*

The measurement of corruption goes hand in hand with the observation of qualitative and quantitative variations in space and time. Is country 'A' more corrupt than country 'B'? Is there more corruption at the end of the twentieth century than in the 1980s? Was illegal party financing equally condemnable as political corruption across different pluralist democracies? Political scientists increasingly are concerned

to come about with a measurement of corruption as a pre-analytical step towards a more comprehensive, empirically based, comparative explanation of corruption.

Priority has been given to the measurement of levels of corruption, but this was not without its problems. Attempts at measuring corruption across countries with significantly different legal and moral norms have been criticized as an academic tool of stereotyping, which political actors and others, at the national or international levels, are just too willing to have at their disposal as an offensive (or defensive) labeling weapon. The problem of stereotyping emerges at the level of operationalization, but it also has to do with the parameters of comparison (small n/large N). How to include the greatest number of cases without losing consistency and comparability? Different countries are governed by different rules and norms, so the immediate problem is: whose standards should be taken as reference to comparison?

This brings back the problematic that surfaced earlier comparative works: how to avoid 'cultural relativism' without falling into 'cultural imperialism?' Taking a lower denominator—each country's rules governing office or national perceptions of the phenomenon—makes it difficult to envisage meaningful generalisations about corruption. Cultural specificities are to be taken seriously; yet, this has often permitted a degree of toleration towards some forms of corruption regarded as beneficial to the societies in question. Taking Western values as an higher denominator, which other countries may try to emulate, raises doubts about the validity of results attained, either because those standards are not yet embedded in developing societies or because such *alta vista* neglects different social/cultural realities.

Transparency International (TI), a non-governmental organisation (NGO) devoted exclusively to the study and combat of corruption worldwide, has developed a corruption perception index based on several surveys conducted in as many as 85 countries (cf. http://www.transparency.de). The TI's index is the first attempt to measure levels of corruption, but its reliance on public opinion poses serious limitations: (a) there is a problem of operationalization (the index is concerned only with transaction corruption, namely, bribery of foreign officials); (b) there is a problem of sample (it relies on an homogeneous sector of public opinion, i.e., international businessmen, financial journalists); (c) it reinforces (or creates) stereotyping. Despite undeniable methodological weaknesses, political scientists have not precluded its use as a starting point for further qualification and understanding of corruption.

Unfortunately, there have been few attempts at measuring qualitatively standards of corruption and establishing comparative frameworks of control measures implemented and their effectiveness. After all, corruption as a policy issue is part of a cumulative learning process of past control experiences, their successes, and failures. Timescale measurements of qualitative variations equally have been lagging. The understanding of why corruption emerges in a particular conjuncture leading to widespread condemnation and revision of standards, or inversely, why after periods of enforced political morality, ethical standards shade into oblivion, has been mainly a task of some political historians and public policy analysts (Woodiwiss 1988, Mény 1993).

3. *The Evolution of Theoretical Approaches*

3.1 *The Corruption of the 'Good Polity'*

For the founders of Western political thought, such as Plato, Aristotle, and Thucydides, corruption expressed the degeneration of right regimes, those who rule for the 'good of the whole,' into perverted ones, those who rule for 'the good of themselves' (i.e., tyranny, oligarchy, demagogy). Whereas the conceptual overlap between the broader institutional decay and corruption, *stricto sensu*, was explained in terms of behaviors, practices, and laws that debased from the 'common good,' little was said about the moral components of that intangible axiom. This tradition persisted throughout the development of Western political thought, from Aquinas to Rousseau, from Montesquieu to Burke, from the twentieth century philosophers of *décadence* (Aron, Malraux) to the contemporary theorists of democracy (Dahl, Sartori). Their conceptual weakness was that of not establishing empirically what standards defined political corruption, because that was secondary to their theoretical concern with the broader moral corruption.

This contributed largely to its unpopularity in earlier comparative works, because it 'sacrificed clarity to brevity, in so far as it leaves too implicit how or why behavior is deviant from which norms' (Heidenheimer et al. 1989). The decolonization processes in the aftermath of World War II brought a vast number of new entities to the world's political map, whose values of democracy emulated were not necessarily those upon which Western democracies had been historically founded. The moralist (or institutionalist) approach became an easy target by 'those whose conceptions are not based on Aristotelian ideal types' (Heidenheimer et al. 1989). With the autonomy of political science in the 1950s, the classical approach was gradually replaced by new political science approaches (functionalist, market, and systemic).

3.2 *Contemporary Political-science Approaches*

The attempt to locate studies about corruption according to schools of thought does not seek over-

simplification of the variety of methods and perspectives through which the complexity of corruption is made tangible. Typologizing aims at helping those who are strange to the subject or have come across its problematic in the course of their research, to be aware of their adhesion to each alternative available as well as the insufficiencies and partial judgements recurring from their own choice.

The specificity of each theoretical approach depends largely upon the definition chosen to interpret the phenomenon. Their evolution denotes a value change in the way the phenomenon has been identified and explained.

3.2.1 Functionalist approach. Viewing corruption as 'another form of political influence,' functionalism, during the 1960s, tolerated certain forms of corruption in so far these were held to enhance economic development and political integration. Cultural relativism added to this complacency by considering corruption to be inherent in specific cultures/societies, and ignoring it elsewhere.

The normative argument surrounding the degree of legitimacy of the authoritative allocation of values and goods to society was a question which functionalists avoided at all costs. Corruption thus concerned the same 'legitimate apparatus' in two different facets of political activity: 'Whereas party manifestos, general legislation, and policy declarations are the formal façade of the political structure, corruption stands in sharp contrast to these features as an informal political system in its own right' (Scott 1972). Here, one could identify a Machiavellian vision of politics. But whereas the Florentine thinker observed that the struggle, exercise, and maintenance of power opened the door to a number of strategies, common to both democratic and authoritarian regimes, which were not necessarily confined to the legal and ethical norms set in society, functionalists went further to actually claim that corruption had its positive effects to the political system, despite being an 'immoral thing.' Corruption, functionalists concluded, 'greased the wheels of the system' in countries where the administrative process was overloaded and overstretched and it helped to hold shaky systems together, by mobilizing voters into the democratic process through party patronage and clientelism (Leff 1964, Bayley 1966, Huntington 1968).

Today, it would be difficult to advocate the benefits of conventional forms of corruption, in countries where toleration of those practices furthered the expansion and institutionalization of corruption into other areas of public life and paved the collapse of the political system. Moreover, the belief that corruption in developing regions, such as Latin America, Asia, and Africa, promoted economic development, political participation, and administrative efficacy proved historically wrong. Functionalists had never accounted for the long-lasting negative effects of corruption.

3.2.2 Market approach. The market approach focuses essentially on the principal-agent-client (PAC) corrupt transactions taking place at the bureaucratic level, coupling positive economic theory with neo-liberal theories of the state (Rose-Ackerman 1978). Although PAC theorists criticized vividly the functionalist view on benefits of corruption for development, their approach also sought to evade moral issues by centering their utilitarian arguments on the rational choice of individuals to undertake corrupt transactions. Accordingly, corruption depended on two major determinants: the existing structures of opportunity and the costs/incentives involved. From a theoretical standpoint, the rational choice approach has underestimated personal ethical standards constraining the public official's 'choice' or willingness to engage in corruption. Certainly, individual standards of probity, what the Anglo-Saxons termed 'civil service spirit,' go beyond cost-benefit calculations and constitute an important element in any micro-interpretation of corruption. Its theoretical weakness, however, had to do more with a drawback of neoliberal theories of the State.

The Welfare State crisis and the collapse of socialist economies offered propitious ground for a conceptualization of corruption as an illegal tradeoff between public and private spheres. Corruption, it was argued, expanded where the State extensively had permeated the market sphere, directly, through interventionist policies and ownership, and indirectly, via 'obstructive' market regulation. The remedies advocated were too simplistic: if the reason for corruption was excessive State intervention and regulation over the market economy, the solution was, *ipse dixit*, to privatize and deregulate. By the late 1980s, however, PAC theorists were less prone to support the neoliberal assumption of 'less State, less corruption': privatization and deregulation processes taking place worldwide had created new corrupt incentives and opportunity structures. The contribution of political economists to the study of corruption did not preclude with the neoliberal theories of the State, nor public choice interpretations of the motivation for corrupt behavior. Current economic theory is re-examining the very concept of 'market of corruption' through an analysis of the networks of corruption unrepresentative of a market and by introducing nonrational elements to motivation (Cartier-Bresson 1995).

3.2.3 Systemic (or neoclassical) approach. Both these approaches have avoided an important conceptual aspect, namely, moral condemnation. They had fallen into a reductionist and mechanic vision of the

democratic process and ignored that democracy, other than being a set of procedures and institutions, is also a normative system with ultimate goals to be realized in society (Mény 1992). Current literature on democracy theory looks attentively at normative aspects and qualities, including its pathologies and the measures to prevent its degeneration. This is not because corruption is more frequent in democracies than in nondemocracies, but because its consequences seem to be more damaging to the basic principles of democracy: equality before the state apparatus, accountability and transparency of public decisions, and the legitimacy of political institutions.

The revival of the moralist approach goes together with the growing belief that the ethical foundations of democracy have degenerated during the past decades. Academic concern about the growth of corruption in the post-Cold War environment is associated closely with the processes of state collapse and democratic consolidation in Central and Eastern Europe (Holmes 1993) and a period of crisis faced by the model of liberal democracy—weakened political participation and solidarity, party and party system crisis, crisis of the State of Law, crisis of the Welfare State (Della Porta and Mény 1995).

Everywhere, corruption was no longer product of an occasional 'rotten apple,' but a systemic phenomenon often with greater success than the legitimate political system from which it draws its resources (Della Porta and Mény 1995). It no longer appeared to be an exception, but a norm: threatening democratic foundations, causing institutional crisis, destabilizing the global economy, helping 'organized crime' to breed from clandestinity to illicit government, fomenting public deception about political life, and undermining the idea of public good. Corruption celebrated the communion between power and economy: money increased the possibility to privileged access to power, and power allowed the possibility to enrich (Della Porta 1992).

Political scientists were invited to revise their definitions and to include normative concerns in their empirical account of corruption (Jos 1993). Politico-institutional crisis and reform were the key conjunctural features urging the need for a normative analysis of corruption and this was not detached from the world economic downturn of the early 1990s. 'What changed in the early 1990s was the public's readiness to tolerate political corruption' (Heywood 1997): if the economic boom of the 1980s had been propitious for complacent views about corruption, the decreasing 'feel-good' factor of the 1990s hastened perceptions and condemnation, if not only as a reaction to widening social disparities.

By the early 1990s, corruption was condemned widely at all levels of decision-making: local, national, regional, and international. The discrepancy between the legal/formal standards and those upheld by the society at large had grown wide (Johnston 1991, Mény 1996). Most democracies became engaged in a spiral-web of media exposure, scandal, political inquiries, and judicial prosecution. Governments, even those that until then considered corruption 'a problem affecting others,' reacted through the implementation of a series of control measures and devoted their efforts to the moralization of political life.

The growing concern about corruption by international governmental (the Council of Europe, the European Union (EU), the Organisation for Economic Co-operation and Development (OECD), the World Bank, and the International Monetary Fund (IMF)) and nongovernmental (the International Chamber of Commerce (ICC), some NGOs, and multinational corporations (MNCs)) entities was contemporary to other transnational issues, such as environmental degradation, human rights, fraud, money laundering, fiscal evasion, and organized crime. Although analytically distinct from these cross-border phenomena, the mechanisms and ways in which corruption takes place are often intertwined. Not surprisingly, bribery by MNCs linked to the establishment of petrol and chemical industries or infrastructural projects in developing countries have resulted in vast environmental degradation. Similarly, countries condemned internationally for human rights violations are also known for their predatory practices towards national and foreign investors. At the EU level, official reports have indicated that the growth of fraud against Community financial interests is related partly to the diversion of funds by criminal organizations, which have been used, *a posteriori*, for illegal political financing.

3.2.4 Corruption and its public policy dimension. Current political research is particularly concerned with the way corruption affects governmental ability and efficacy to deliver policy outputs, varying accordingly to the singular organisational and attitudinal characteristics of each country. In a few words, corruption runs counter to good governance.

Other than a moral issue, corruption is a public policy problem. Corruption grows where public ethics have degenerated, where there are no clear rules through which public business is carried out, and where public or private activities lack proper modes of regulation to guarantee due process and fairness. The changing nature of the State and the blurring of the public/private divide have been at the core of the problematic of corruption in recent years, alerting decision makers to the need to strengthen controls and revise standards in public life (Mény 1992, Della Porta 1992).

The complexity of modern decision-making process—different layers, actors, and mechanisms of political influence—added to the lack of transparency in which public decisions and procedures have been

carried out, permitted a privileged access to State resources and undermined public confidence in democratic government.

The costs of corruption to the public purse are unquantifiable. Besides being a burden to taxpayers, corruption consolidates inefficiency and foils value-for-money considerations. It inflates market prices for public services and goods, supplied directly or contracted out to market actors; it fosters clientelism at the cost of fair competition. It allows the uncompetitive to thrive in a context of political protection.

Policy-makers have tried, in many countries, to regulate and control the situations conducive to corruption: procurement policies, regulation of public utilities delivery, control of markets. Other forms of soft corruption (various types of conflict of interest, *pantouflage*, *cumul des mandats*, lobbying) have also been subject to tighter regulation.

At the international level, the United Nations (UN) incessantly has reported and condemned vividly corruption as a product of mismanagement and bad policy-making at all levels. International economic/financial organizations (the OECD, the IMF, the World Bank) equally have realized that their rehabilitation programs could not be accomplished solely through the recruitment of expert economists and that specific social, cultural, political, and institutional factors conditioning development had to be brought into account. Financial aid to underdeveloped economies, rather than contributing to development, was helping to sustain corrupt elites in power. The European Commission has insisted on good governance as a criterion to its preferential financial treatment and trading benefits with developing countries, and a guiding principle to enlargement/accession strategies.

The European Parliament has also taken a recriminatory position in regard to corruptive practices within EU institutions, more precisely, the Commission.

Cortical Activity: Differential Optical Imaging

Introduction

Primates are extraordinarily visual animals. Hence it is not surprising that we (as humans) prefer visual

representations of everything we try to understand. Whether in the form of text, images, or graphs, visual representations are an integral component of our efforts to comprehend. As a consequence, it is easy to understand the appeal of techniques for mapping activity in the brain. It is even easier to understand the appeal of optical imaging, which maps activity patterns directly by monitoring changes in reflected light.

The roots of optical imaging can be traced back at least 60 years, to the observations of Wilder Pennfield (1933) who noted minor changes in the appearance of exposed cortex during epileptic seizures. On account of associated vasospasms, the seizing regions looked alternately light and dark. Though such changes must be large indeed to be visible to the naked eye, they resemble smaller ones that accompany normal events. This wasn't recognized at the time—indeed these changes were deemed pathological. But even if it had been, the technologies needed for using them to map normal activity would not become available for many years.

A few years after Pennfield's initial observations, Kelin and Millikan found activity dependent changes in the optical properties of cytochromes. Hill and Keynes (1949) subsequently recorded the first activity dependent optical signals, in specially prepared nervous tissues. However, these and subsequent efforts soon were diverted by an emerging focus on single neurons. Hence, the possibility of using light to monitor slow changes in the activation of cortical tissue was neglected until Blasdel and Salama (1986) showed that slow, activity-driven changes in light reflectance can be used to visualize organizations that had intrigued neuroscientists for decades: the arrangement of ocular dominance and orientation slabs in the primary visual cortex. Though their initial observations have been replicated many times, using a variety of slightly modified procedures, the fundamental strategy stays the same. All rely on the small, activity driven reflectance changes resembling those noted by Pennfield, all try to drive these alternately between two extremes, and all try to map associated reflectance changes with some differential imaging technique.

1. *Primary Visual Cortex*

It is not an accident that the first comprehensive optical maps were obtained from the primary visual cortex of macaques—an area ripe for this kind of analysis, after decades of brilliant discoveries showing the importance of ocular dominance and orientation selectivity, and the likely organization of these properties in slabs (see Fig. 1). In addition, the primary visual cortex of macaque monkeys is particularly well suited to optical investigation since most of it is remarkably large and flat and, due to its location on top of the occipital lobe, conveniently accessible. It also was not an accident that this was first achieved by visual neuroscientists, since many of the problems with differential imaging resemble those in vision—problems whose solutions are most familiar to those thinking about them full-time.

In order to appreciate the nature of the problem at hand, it is important to understand a few aspects of primate area V1. Light from the outside world is refracted onto the retina, where it directly forms the first of several representations including one in a layer of ganglion cells, whose axons form the optic nerve and project centrally to the lateral geniculate nucleus (LGN). Neurons in six separate but retinotopically aligned layers of the LGN receive this information and project directly to V1. The thing to keep in mind, therefore, is that V1 is not the first two-dimensional representation of visual space, nor does it reflect retinotopic arrangements in any simple way. Instead, it reflects the cumulative consequences of successive transforms, each one of which modifies the representation of space in simple but important ways.

These modifications lie beyond the scope of this review. However, they can be summarized as a tendency to reduce some form of redundancy with each and every step. The consequence of a center-surround receptive field in the retina or LGN, for example, is to minimize responses to diffuse or gradually changing light. Light that doesn't change with distance is redundant and can be ignored. This makes it possible to concentrate on more important events, like those where light changes suddenly, associated with an edge.

The reduction in redundancy continues in the LGN and primary visual cortex (also known as the striate cortex, area 17, and V1), where redundant views from the two eyes are merged. Because the convergence is usually incomplete, there is a residual tendency for one eye to dominate in alternating 0.5 mm wide slabs. These are known as 'ocular dominance slabs' or 'ocular dominance columns' and are illustrated in Fig. 1a.

At the time information converges from both eyes to form a single binocular map, the cortex sees the emergence of a new response property—orientation selectivity—that is characterized by selective responses to particular orientations of edges. This property too can be characterized as a reduction in redundancy, since strings of discontinuous events that occur along a single axis in space can now be summarized by a single neuron. Like ocular dominance, this property is characterized by vertically aligned neurons, with those lying above one another responding only to similar orientations. What is particularly important about the vertical alignment of ocular dominance and orientation columns, in regard to optical imaging, is that their depth invariance makes it possible to ignore the depth of light penetration, which is difficult to de-

Figure 1
Organizational schemes for the representation of visual space, ocular dominance and orientation preference columns. (a) Monkey striate cortex occupies a region half the size of a credit card at the back of the animal's head; each hemisphere represents the contralateral hemifield. The representation is topographic (neighboring points in space are represented by neighboring points in cortex. However, it is also characterized by a regular arrangement of half millimeter wide ocular dominance slabs—shown here for the right hemisphere representation of left visual space—that interleave striped representations of the right and left eyes. A characteristic feature of ocular dominance columns in monkey striate cortex is that they intersect the boundary of this area at right angles (modified from LeVay et al. 1975 and from Hubel and Freeman 1977). (b) Hubel and Wiesel's results for electrode penetrations conducted perpendicular and parallel to the cortical surface. For perpendicular penetrations, the preferred orientation remains constant (except in layers 4a and 4c, where the selectivity for orientation is weak or absent). For lateral penetrations, the preferred orientation rotates continuously for distances of 0.5–1.0 mm. (c) Orthogonal stripe-like representation of orientation and ocular dominance in primary visual cortex, proposed by Hubel and Wiesel (1974). This model has four important components: 1) slab-shaped regions preferring one eye or one orientation project vertically between pia and white matter, 2) slabs representing the two eyes lie parallel to one another, 3) slabs representing different orientations lie parallel to one another, and 4) ocular dominance and orientation preference slabs intersect at right angles. These illustrations are re-drawn from those appearing in Hubel and Wiesel (1974, 1977)

termine. In spite of their clear importance, ocular dominance and orientation selectivity patterns had proven difficult to map.

2. *Differential Video Imaging*

A solution to this problem is provided by the small changes in reflectance—similar to those described by Pennfield (1933)—that accompany normal activity as well. Due to recent advances in the development of practical imaging technologies (e.g., cameras, image processors, computers, etc.) reflectance differences as small as 0.01 percent—approximately 500 times smaller than ones that can be seen by the unaided eye—can easily be seen (Blasdel 1992a, b). Accordingly, any area of cortex that can be exposed and activated physiologically, can be mapped with this technique.

Figure 2
Patterns mapped from the surface of primary visual cortex. (a) The appearance of 3 mm × 4 mm region of cortex under 540 nm light, where the blood vessels appear dark due to the strong absorption of this wavelength by hemoglobin. (b) The same region of cortex under near-infra red (720 nm) light—the wavelength at which optical maps are obtained—where blood vessels appear fainter due to weak absorption by hemoglobin. (c) Visualization of ocular dominance bands by stimulating right and left eyes on alternate trials and differentially imaging the small changes in reflectance that occur. Note the characteristic width of these bands and their tendency to intersect the border of cortex (represented by gray arrow) at right angles. (d) Differential images of orientation visualized by stimulating both eyes alternately with orthogonal orientations (in this case, vertical and horizontal) and differentially imaging the changes that emerge.
(e) Differential images of retinotopic space, obtained by stimulating complementary stripe like compartments on alternate trials and differentially imaging the changes. Due to the retinotopic organization of cortex, the stimulation of vertical stripes in space induces vertical bands (that run parallel to border, represented by arrow), while (f) The stimulation of horizontal stripes in spaces produces bands that intersect the V1 border at right angles

Though a number of procedures have been described for doing this, all entail minor variations of the same technique. All exploit small, activity-dependent changes that cause active cortex to reflect less light; all seek to modulate them between two extremes, and all seek to average responses to increase ratios of signal to noise. The specific mechanisms that couple reflectance to activity are controversial and likely to reflect different contributions at different wavelengths. Since shorter wavelengths (600 nm) are strongly absorbed by hemoglobin, signals obtained with them are dominated by vascular events: changes in blood volume and possibly even the oxygenation of hemoglobin. Since longer wavelengths (720 nm) are absorbed much less strongly by hemoglobin, signals monitored with them are freer from vascular events and more likely to reflect differences in scattering due to changes in ion concentration, water movement, and the volumes of active cells; they are also less pronounced (for a review, see McLoughlin and Blasdel 1998).

The first apparatus used for differentially imaging these changes relies on a low power microscope (Blasdel 1992a) that uses co-axial illumination to irradiate the cortex with monochromatic light (720 nm ± 20 nm). Reflected light is collected by an objective that relays it to an imaging device—usually a TV or CCD camera—that transduces it into a video signal that is digitized and recorded by an image processor that averages thousands of frames for each response to improve ratios of signal to noise.

The point of differential imaging is to see changes that are too small to be seen by themselves. This is especially true in the case of cortical responses, where the optical changes associated with orientation preference or ocular dominance may be a hundred times smaller than those associated with cortical activation alone. By stimulating the cortex twice, however, with stimuli that activate it to approximately the same degree, it is possible to modulate a single variable and visualize the small reflectance changes that develop in phase. In the case of ocular dominance patterns, for example, the responses to either eye alone may be huge. Yet because common mode changes to each eye are similar, a differential subtraction (i.e., images achieved during stimulation of one eye are subtracted

Figure 3
Differential images of orientation and ocular dominance from the same region of macaque V1. The horizontal axis in each frame corresponds to 4.4 mm. Each of the 8 images in (a–h) was obtained by differentially imaging responses to orthogonal edges, moving bilaterally at 1.5°/sec. Dark and light values reflect preferences for each of the two orientations, which are indicated by dark and light bars in the lower right hand corner, and which are rotated by 22.5° in successive frames—i.e., 0°–90°, 22.5°–112.5°, 45°–135°, 67.5°–157.5°, 90°–0°, 112.5°–22.5°, 135°–45°, and 157.5°–67.5° (from Blasdel 1992b). Note how similar these patterns look, even though actual positions of dark and light regions change. This is made clear by the relative location of an **'x'** appearing at the center of a 'Vertical' region in all frames. This coincides with a dark patch in (a), a light patch in (e), and intermediate locations in between. (i) Differential image of ocular dominance from same region. (j) By turning each of the images in (a–h) into vectors, to keep track of angle phase, it is possible to add them to achieve a field of orientation vectors that

Figure 4
Because orientation preferences change cyclically, they cannot be illustrated by gray levels. Hence, the orientation preferences (calculated from images in Figs. 3a–3h), are illustrated more easily by using opponent colors to represent orientations that are perpendicular. (a) This color-coded map contains the same information as Fig. 3j, but represents preferences for vertical and horizontal with green and red, preferences for left and right oblique with blue and yellow, and preferences for intermediate orientations with colors in between. (b) This shows the degree of selectivity in gray-scale: lighter regions correspond to longer lines in Fig. 3j, indicating greater selectivity for the indicated orientation in Fig. 3j, and (a), above. (c) Superposition of the short lines from Fig. 3j, which appear in white, on the color-coded representation from (a). (d) Iso-orientation contours (Fig. 3k), re-drawn over color-coded map

from images averaged during stimulation of the other) can remove these common mode events and reveal differences specific to the two eyes.

Once the cortex has been exposed (by removing the scalp, cranium, and overlying meninges) and immobilized by a thin plastic or glass plate, it is possible to see the surface of the cortex (Fig. 2a) and differentially image activity. While the dense covering of superficial blood vessels might seem to present a problem, they become virtually transparent at 720 nm.

indicate the degree of selectivity and the preferred orientation at each location. Though these usually are represented by color-coded maps, they also can be represented by short lines, whose lengths and orientations reflect selectivity and preferred orientations at corresponding locations. Note that the **'x'** from the images above appears in a field of vertical lines. (k) Iso-orientation contour map (derived from Obermayer and Blasdel 1993) by calculating contours along which the preferred angle (e.g., vertical) does not change and representing it by a white line superimposed over maps of orientation selectivity (grayscale) from the same region. The thin black lines represent ocular dominance borders for the same region, derived from (i). Important differences from expectations based on Hubel and Wiesel's (1974, 1977) work—see Fig. 1c—include: 1) Iso-orientation slabs (white lines) are limited to 0.5–1.0 mm in length, 2) Iso-orientation slabs converge at regular orientation *singularities* (indicated by white circle) in the centers of ocular dominance bands, 3) Iso-orientation slabs do intersect ocular dominance borders at right angles in *linear ones* (indicated by white square), which lie equidistant between singularities and where they appear particularly well aligned

Due to the weak absorption of 720 nm light by hemoglobin, the same blood vessels that dominate Fig. 2a become virtually transparent in Fig. 2b. This is the image seen by the camera imaging all responses that are compared.

Differential imaging works by comparing two images of the cortex (see Figs. 2c–2f) in slightly different states that under ideal circumstances differ with respect to only one variable. If done carefully, the resulting difference image reveals a pattern specific to the variable. By subtracting images of the cortex responding to the left eye from images of it responding to the right eye, for example, one obtains an image of ocular dominance columns, as illustrated in Fig. 2c. By subtracting images of the cortex responding to horizontal edges from images of it responding to vertical edges, one obtains a pattern associated with orientation selectivity, where dark and light regions represent selectivity for vertical and horizontal (Fig. 2d). Similarly, by differentially imaging responses to complementary parts of space, it is possible to visualize their cortical representations. The vertical stripes in Fig. 2e, for example, elicited bands running parallel to the V1/V2 border (which represents vertical), while horizontal stripes (Fig. 2f) induced bands that intersect the V1/V2 border at right angles.

Fig. 3 shows 8 differential images (a–h) of orientation, obtained by comparing responses to each of two perpendicular gratings, with the orientation of each pair rotated by 22.5° in successive frames. As one can see, the small 'x' placed at the center of a vertical iso-orientation band lies at the center of a dark patch in Fig. 3a, but moves gradually to the side in successive frames until it lies over a white patch in Fig. 3e. From the relative displacements of light and dark regions relative to this x, it is possible to see that these patterns depend *only* on the orientations of stimuli used to induce responses that are compared.

3. *Orientation Preference Patterns*

As one might note from the images in Fig. 3, the gray values at various locations reveal the degree to which each of the two opposed orientations (indicated in the lower right hand corner of each frame) was effective at driving responses. They do not indicate which orientation was optimal, however, since this information can only be inferred by comparing responses to many orientation pairs. Because this information appears distributed across *all* the images in Fig. 3a–3h, it is easiest to extract from all of them at once, by converting the pixel values in each image into vectors (which use phase to keep track of the angle used), that can be added to reveal the distribution of preferences and selectivities at all locations (see Blasdel 1992a for more details). The outputs of this operation are illustrated in Fig. 3j, where each short line indicates the degree of selectivity and preferred orientation, through its length and orientation. As one can see, some of these are quite short, indicating no selectivity at all; while many are quite long, indicating sequences of orientation preference that rotate gradually in swirls, from side to side. In order to estimate the shapes of orientation 'columns,' it is possible to calculate contours along which orientation preferences do not change. The resulting iso-orientation contours (Obermayer and Blasdel 1993), which resemble Hubel and Wiesel's (1974) iso-orientation slabs, are illustrated for the same region of cortex in Fig. 3k.

As one can see, this pattern differs from that expected (see Fig. 2c). Rather than appearing in long arrays of infinitely long columns, iso-orientation slabs appear limited to 0.5–1.0 mm in length and to sequences that are no more than 0.5–1.0 mm across. This wasn't known before, and has become apparent only on account of optically imaged patterns, with results from all laboratories showing approximately the same thing (see also T'so et al. 1990, Bartfeldt and Grinvald 1992). A particularly surprising phenomenon concerns orientation singularities that occur at regular intervals in the centers of ocular dominance columns where iso-orientation contours converge (Blasdel 1992b; Bonhoeffer and Grinvald 1993). One example appears highlighted by a white circle in Fig. 3k. These are the main events that disrupt iso-orientation contours, and prevent them from getting longer. Nevertheless, iso-orientation contours seem to congregate in equally regular linear zones that subtend 0.5–1.0 mm and predominate near ocular dominance borders. One example is outlined by a white rectangle in Fig. 3k. Within these zones, iso-orientation contours appear particularly well organized in linear arrays of slabs, more or less as Hubel and Wiesel (1974) predicted (see Fig. 1c). Note, that within these zones, iso-orientation slabs also have a striking tendency to cross ocular dominance borders at angles of approximately 90°—more or less as suggested by Hubel and Wiesel's model, in Fig. 1c.

From this relatively simple analysis of optical imaging maps, it is possible to conclude that orientation preferences organize according to one of *at least* two competing schemes—a linear one, confined to 0.5–1.0 mm patches, where orientation preferences change linearly along one axis while remaining constant along the other; and a discontinuous, circularly symmetric one, that entails continuous changes in preferred orientation around a point singularity. The linear scheme predominates in two-dimensional patches, 0.5–1.0 mm across, while the pinwheel singularities that disrupt them lie somewhere in between. Also, these results make it clear that within the linear zones iso-orientation contours and ocular dominance borders cross at right angles.

The true strength of optical imaging is apparent from the comparisons that it enables. Since it only takes a few minutes to obtain each pattern with a technique that appears to be relatively benign, it is

possible to collect many different types of response profile from the same cortical regions. This is what makes it possible to calculate maps of orientation preference, for example, where responses to many different orientations need to be compared. It also is what enables comparisons between ocular dominance and orientation maps from the same regions, allowing them to be related precisely for the first time. By comparing these with maps of retinotopic representation from the same region (see Figs. 2e, 2f) it is possible to obtain unprecedented insights into cortical organizations.

Cortical Development: Transplantation and Rewiring Studies

The mammalian neocortex, a folded sheet that in humans contains over 10 billion neurons, is the seat of the highest sensory, motor, and cognitive abilities. Cortical development involves the formation of many discrete areas that process different kinds of information uniquely. Individual areas are characterized by specific sets of inputs, processing networks, and outputs. The development of these features involves factors that are intrinsic to the tissue or are regulated by extrinsic or environmental influences. This article examines the relative roles of such influences, employing in particular evidence from experiments that have probed developmental mechanisms by transplanting cortical regions or by rewiring inputs to a part of the cortex.

1. Development of the Cortex

The principal method for studying mechanisms of development is to manipulate developmental processes. In general, it is not possible to separate intrinsic cleanly from extrinsic aspects of developmental programs of an organism: no gene acts independently of an environment, and the environment always acts on a scaffold. A classic paradigm in developmental biology for clarifying the role of the local environment in determining the features of a tissue is to translocate the tissue to a novel environment.

Transplanting one part of the mammalian cortex to another at different stages of development has been a valuable tool for determining whether or not unique features of a cortical area derive from intrinsic properties of the cortex, or are induced by new inputs in the host environment. A powerful recent method that complements transplantation studies is to route sensory inputs that normally drive one part of the cortex to another part. Thus, instead of altering the location of a target and preserving host inputs, the inputs to existing targets are altered. Together, these studies demonstrate that the features that make a cortical area unique are expressed progressively as development proceeds. Importantly, they show that electrical activity can have an instructive role during the development of cortical networks, so that specific spatial and temporal patterns of activity regulate specific patterns of connections between cortical neurons.

2. *Formation of Cortical Layers*

The adult mammalian neocortex consists of six layers. These are generated by a heterogeneous population of precursor cells that lie along the walls of the lateral ventricles very early in development. The time of neurogenesis in the ventricular zone regulates the final disposition of cells in individual layers. Cells which are born earlier form the deeper cortical layers, whereas later-born cells form the progressively more superficial layers. Transplantation experiments have shown that there is a progressive restriction of cell fate in the precursor population: Early progenitors are able to give rise to neurons which come to reside in any cortical layer, whereas later progenitors give rise only to neurons of more superficial layers.

One key set of experiments (McConnell and Kaznowski 1991) demonstrates that transplanting neurons from the ventricular zone of a donor animal at an age when layer 6 is being born, into a host in which layer 2/3 is being born, causes the donor cells to settle into either host-specific layer 2/3 or donor-specific layer 6, depending on the stage of the cell cycle at which donor cells are extracted. If donor cells are extracted prior to or during the phase of DNA synthesis, they are able to switch their fate and migrate to the layer that is being generated in the host (layer 2/3), due presumably to environmental cues in the host. If donor cells are extracted later in the cell cycle, their fate is sealed prior to transplantation and they settle into the layer determined in the donor (layer 6). The precise nature of extrinsic signals that determines or alters the laminar fate of newborn cells during a certain part of the cell cycle is unknown.

Events occurring at the ventricular zone can contribute in other ways to regional differences in cortical architecture. The dynamics of the cell cycle show regional variation. Most notably, the germinal zone of the primary visual cortex (V1) of primates, a region with twice the neuronal density of other areas, has a notably higher rate of cell production which is associated with changes in the parameters of the cell cycle. Thalamic afferents can exert a mitogenic effect on cortical progenitors, resulting in an increase in the number of cell divisions. Thus, thalamic inputs are one important source of extrinsic influences on cortical development, starting with the cell cycle and lamina formation.

3. *Formation of Cortical Areas*

There is considerable evidence suggesting that at least the initial broad parcellation of the cortex into discrete areas is regulated by molecular determinants that are intrinsic to the proliferative zone of the developing cortex. For example, evidence from transplantation and co-culture studies suggests that the initial expression of region-specific markers or phenotypes is not dependent on specific thalamic innervation. A number of genes are expressed differentially between cortical areas before thalamic afferents are believed to have invaded the cortical plate. Similarly, the expression of several genes can occur normally even in the absence of thalamocortical innervation. Finally, gradients of gene expression in the early cortex can regulate initial cortical parcellation, and such genes can also serve to attract appropriate sets of inputs from the thalamus, or direct appropriate outputs from the cortex (Rubenstein and Rakic 1999).

While the expression of genes and molecules may delineate broad areas of cortex at very early stages of development, subsequently thalamic afferents can influence the size and even the identity of specific areas (O'Leary et al. 1994). Transplants of extremely immature cortex—at embryonic day (E)12 in rats—from the limbic to the somatosensory cortex may take on inputs and express molecules characteristic of the host region rather than the region of origin. This ability is lost if the transplants are derived at a later developmental stage. Transplanting visual cortex into somatosensory cortex in rats causes the graft to accept inputs from the somatosensory thalamus and form 'barrels,' a characteristic of the rodent somatosensory cortex. Other work shows that the transplant needs to occur early, before E16, for the graft to form substantial connections with the somatosensory thalamus, and later grafts are already committed to form connections with the visual thalamus. With respect to output connections, occipital to frontal transplants at E12 can form projections to the spinal cord, a characteristic of the host cortex rather than the donor; however, by E14 that capacity has been lost and projections to the tectum, a characteristic of the region of origin, are formed instead. Interestingly, a similar age-dependent switch between E12 and E14 influences the corticocortical connections made by transplanted

perirhinal cortex into the parietal region. These findings indicate that there is an early time window during which the input and output connections of a cortical area may be sculpted by thalamic and local or regional signals to produce an area-specific phenotype. Thus, cortical areas arise by progressive specification of their region-specific phenotype from a multipotent phenotype (Levitt et al. 1997).

4. *Formation of Cortical Networks: Ocular Dominance and Orientation Columns in Visual Cortex*

The cortex differentiates progressively into layers, and as layer 4 appears in the cortical plate, thalamic innervation specifies the principal sensory areas. Concurrently, descending projections from the cortex innervate specific thalamic nuclei, primarily by the targeting of axons of layer 5 cells to principal and/or association nuclei, followed by the development of layer 6 projections to principal relay nuclei. Thus, a thalamocortical loop is set up very early in development, and the initial specification of cortical areas is fundamentally a specification of unique feedforward and feedback connections between thalamus and cortex. The development of intracortical circuitry follows thalamic innervation; considerable recent evidence, primarily from the visual cortex, demonstrates that a combination of intrinsic and extrinsic factors (such as electrical activity in thalamic inputs) is responsible for the formation and maintenance of specific thalamocortical and intracortical connections.

Ocular dominance columns—regions within layer 4 of V1 in higher mammals that receive input exclusively from one eye or the other via the lateral geniculate nucleus (LGN) of the visual thalamus—are paradigmatic of thalamocortical patterns that specify individual cortical areas. In primates they are present by birth, suggesting that visual experience is not required for their formation. Recent work suggests that they may also be set up before eye opening in ferrets, soon after geniculocortical axons innervate layer 4 (Crowley and Katz 2000), and similarly in cats. Surprisingly, they may not even require the presence of the eyes for their initial establishment. Monocular enucleation does not degrade these early columns immediately, and binocular lid suture does not reduce their development in cats for the first three weeks. One possibility is that ocular dominance columns are set up initially by the molecular matching of inputs from different layers of the LGN (each layer representing a given eye) with appropriate target regions in V1.

An alternative view is that ocular dominance columns are set up by activity-based rules of development. Thus, if inputs from one eye are correlated with each other and uncorrelated with inputs from the other eye, application of a Hebbian developmental rule for strengthening connections (and of a complementary rule for weakening connections), together with local excitation and long-range inhibition in the cortex, can lead to cortical stripes that resemble ocular dominance columns. Correlated inputs in the form of spontaneous waves of activity exist in the retinae prior to eye opening. In the LGN, the firing of neurons within a given eye-specific layer is well correlated, and uncorrelated with the firing of neurons in an adjacent layer which represents the other eye. Interestingly, ablation of the cortex abolishes these correlations, whereas ablation of inputs from the eyes has little effect. The pattern of electrical activity transferred to the cortex, therefore, appears to be regulated strongly by interactions between the thalamus and the cortex, and activity in the thalamocortical loop may be sufficient for eye-specific patterning. Significant support for the hypothesis that ocular dominance columns can arise, at least in principle, by activity-dependent sorting of inputs comes from the finding that eye-specific stripes form in the optic tectum of 'three-eyed' frogs forced to receive input from two eyes (Law and Constantine-Paton 1981). Whether or not ocular dominance columns in V1 require electrical activity to instruct their formation, there is convincing evidence that electrical activity is required to maintain them (Sherman and Spear 1982).

Orientation selectivity is a major emergent property in visual cortex that is created by aligned thalamic inputs whose activity is amplified by local intracortical connections. Orientation selectivity is present in V1 of primates at birth, and to a degree in cats and ferrets at or before the time of natural eye opening, although selectivity increases with visual experience (Chapman et al. 1999). Orientation-selective cells in visual cortex are linked by long-range horizontal intracortical connections in the superficial layers to form an orientation map. The adult pattern of clustered horizontal connections is present at birth in primates. In cats and ferrets, crude clusters appear just prior to eye opening, and are refined after the onset of vision; binocular deprivation prevents this refinement. The orientation map, revealed by optical imaging of intrinsic signals, develops in parallel with the development of orientation selectivity in single cells.

Monocular lid suture after orientation maps have already formed disrupts the map from the closed eye; reverse lid suture restores the map precisely. In addition, matching orientation maps for the two eyes develop even in cats raised under an alternating-suture paradigm, so that the two eyes never have common visual experience. Together, these studies indicate that the emergence of orientation-selective responses in single cells and the overall layout of the orientation map does not require patterned vision, although visual experience is necessary for orientation selectivity and maps to fully mature. However, blocking electrical activity in V1 reduces both the orientation tuning of single cells and the clustering of horizontal connections. Thus, spontaneous electrical activity in cortex or

in the thalamocortical loop is required for the initial establishment of local and long-range intracortical connections.

5. Patterned Electrical Activity and the Development of Cortical Networks

The vast majority of experiments on the influence of activity on visual cortical networks have involved manipulations such as lid suture or activity blockade that alter the *amount* of activity in the visual pathway. Relatively few experiments have examined the influence of the *pattern* of activity on cortical network development and maintenance; such manipulations include artificial strabismus, specific rearing paradigms, and rewiring of visual projections to the auditory pathway.

Strabismus refers to misalignment of the two eyes' optical axes, so that activity from corresponding retinal loci in the two eyes are no longer temporally correlated. Artificially induced strabismus causes neurons in V1 to become almost exclusively monocular, and ocular dominance columns to be more sharply delineated and have altered spacing compared to normal animals. Long-range horizontal connections within the superficial layers of V1 are also affected. Whereas in normal cats these connections cluster to link regions with similar orientation preference but do not align with ocular dominance columns, in strabismic cats the connections come to link columns with similar eye dominance and orientation preference (Schmidt et al. 1999). Thus, correlations in input activity are used to sharpen and organize ocular dominance columns, and to shape intracortical horizontal connections.

Rearing kittens in a visual environment consisting of alternating black and white stripes at specific orientations restricts pattern vision and appears to shift the orientation preference of cortical cells towards the experienced orientation. While a shift could be caused by a passive loss of responses to nonexperienced orientations, there is an expansion of cortical columns devoted to the experienced orientation (Sengpiel et al. 1999), indicating an instructive effect of patterned visual experience on orientation selectivity and the orientation map.

5.1 Rewiring the Cortex

A unique paradigm for investigating the role of patterned afferent activity in the development of cortical circuitry and function is experimentally to redirect afferents carrying information about one sensory modality to central targets and pathways that normally process a different sensory modality (Schneider 1973). Retinal axons can be induced to innervate the auditory thalamus in the ferret (Sur et al. 1988), a carnivore with a highly organized visual pathway and which is born at a very early stage in development. The routing of retinal projections to the auditory pathway can be induced at birth, allowing the probing of the role of patterned activity in the *establishment* (and not simply the *maintenance*) of cortical circuitry. Importantly, visual input is relayed from the auditory thalamus to the primary auditory cortex (A1) via thalamocortical projections whose physical identity is unchanged but which provide spatiotemporal patterns of electrical activity to the auditory cortex that are very different from normal (Fig. 1).

Visual driving leads to emergent responses in 'rewired' A1 that demonstrate the role of patterned activity in shaping cortical networks. An orderly two-dimensional retinotopic map develops in A1 of rewired ferrets, in cortex that normally maps a one-dimensional surface, the cochlea. The retinotopic map in rewired A1 arises despite widely dispersed and overlapping thalamocortical projections, suggesting that well-localized receptive fields and their orderly progression are created by correlation-based mechanisms that operate intracortically to select and strengthen a specific subset of synapses from a broader set available anatomically.

Visual cells in rewired A1 have orientation-tuning, direction-tuning, and velocity-tuning properties that are quantitatively indistinguishable from V1 cells, suggesting that similar mechanisms operate in the generation of receptive field properties in the two cortices. Orientation-tuned neurons in A1 are organized into an orientation map that resembles in important respects the map in V1 (Sharma et al. 2000). The differences between orientation maps in V1 and rewired A1 reflect differences in the underlying organization of superficial-layer long-range horizontal connections in these two cortices. In V1, horizontal connections are patchy, spatially periodic, and extend mediolaterally. In contrast, horizontal connections in normal A1 are more band-like in organization, show little spatial periodicity, and are anisotropic anteroposteriorly. Horizontal connections in rewired A1 show features that are intermediate between V1 and normal A1: The connections in rewired A1 form much smaller and more regular patches than in normal A1, though the patches are less tightly clustered and are larger in size than in V1. Thus, horizontal connections within the rewired cortex are significantly altered by visual input, but in a manner that appears to be constrained by intrinsic features of the auditory cortex.

Rewired ferrets also provide an opportunity for examining whether the behavioral role of a cortical area is set by intrinsic determinants or by the pattern of afferent activity during development. Behavioral experiments, supported by several kinds of control experiments, indicate that rewired ferrets interpret visual stimuli which activate the rewired projection as visual rather than as auditory (von Melchner et al.

Figure 1
Retinal inputs routed to the auditory thalamus in rewired ferrets drive the auditory cortex with visual activity without altering thalamocortical projections. **A:** Visual and auditory pathways in normal ferrets. The retina projects predominantly to the lateral geniculate nucleus (LGN) and superior colliculus. The LGN projects to the primary visual cortex. The medial geniculate nucleus (MGN) receives most of its subcortical afferents from the ipsilateral inferior colliculus, although afferent projections also arise from the contralateral inferior colliculus. The MGN projects to the primary auditory cortex. **B:** Visual pathways in rewired ferrets. Subcortical inputs to the MGN in one hemisphere are removed in early postnatal ferrets. This induces retinal axons to innervate the deafferented MGN. The MGN still projects to the primary auditory cortex, as in normal ferrets, but in rewired ferrets it relays visual rather than auditory inputs. This change in spatiotemporal patterns of input activity early in development has a profound effect on networks in auditory cortex, and on its function. Adapted from Angelucci et al. (2000)

2000). Thus, the function of a cortical area is dependent fundamentally on the spatiotemporal pattern of activity it receives during development. It is possible that all 'auditory' pathways central to the thalamus in the rewired hemisphere are turned 'visual,' including the cortex and downstream structures, with a concomitant respecification of their perceptual identity.

Cortical development involves a progressive shaping of the fate of the cortical epithelium into discrete cortical areas with specific inputs, outputs, and local networks. Developmental manipulations, which include, importantly, transplantation and rewiring studies, demonstrate a continual interplay of intrinsic and extrinsic factors at all stages of development—at the ventricular zone during the cell cycle, in the cortical plate during the parcellation of cortical areas, and within the cortex during the formation and maintenance of cortical networks. The nature of extrinsic signals varies with developmental time, and likely includes intercellular signals in the ventricular zone that influence the formation of layers, trophic or permissive electrical signals in early area formation, and instructive electrical signals in late network development, which persist into adulthood as substrates for learning and memory.

Cosmopolitanism

Cosmopolitanism is a western notion that epitomizes the need social agents have to conceive of a political and cultural entity, larger than their own homeland, that would encompass all human beings on a global scale. Cosmopolite in Ancient Greece meant citizen of the world. Cosmopolitanism presupposes a positive attitude towards difference, a desire to construct broad allegiances and equal and peaceful global communities of citizens who should be able to communicate across cultural and social boundaries forming a universalist solidarity. Its inclusive drive is most evident in moments of crisis of other modes of representing and ascribing membership to existing sociopolitical and cultural units. Much of the malaise and misunderstanding cosmopolitanism may provoke are related to its ambiguity, that is, its unique way of uniting difference and equality, an apparent paradox of wishing to reconcile universal values with a diversity of culturally and historically constructed subject positions.

The composition of the Greek term, *cosmopolis*, already indicates this unsolved tension: *cosmos*, a natural universal order, is related to *polis*, society's variable order. As a consequence, from the Greek democratic city-state to the global village, the idea of a cosmopolite has been haunted by questions such as *whose* world this is. Can homogeneous external expansionist forces coexist with heterogeneous localized ones? A truly cosmopolitan answer would imply a permanent interest in difference and the recognition that globals and locals depend on each other to exist.

Since its inception, cosmopolitanism has been a category marked by a need to negotiate with 'others' and has reflected tensions between local and supralocal realities, ethnocentric and relativist perspectives, and particularism and universalism. Historically, cosmopolitanism has mirrored the ideologies of different periods and modes of integration to larger, imperial or global, political entities. As a category mostly held by elites, it often means the sophistication that results from familiarity with what is different. It has become a metaphor for mobility, migrancy, sensitivity, and tolerance to otherness, independence from specific authorities, and transcultural and transnational realities and claims. Its opposing concepts have often indicated xenophobia, fixity, parochialism, restricted sovereignty, and allegiance to a motherland, or a nation-state.

1. *A Brief History*

The history of the relationships between local and supralocal conceptions is probably as old as humankind. A strong trend towards local reality, particularism, diversity, and context may oscillate, such as at the end of the Renaissance or during the Enlightenment, towards an emphasis on general formal timeless statements that pretend to be universal. Having its roots in Ancient Greece, cosmopolitanism has been variably present in western philosophical or political discussions.

The military conquests of Alexander the Great (356–323 BC) opened up the conditions for the existence of a 'world empire' that allegedly aimed at uniting East and West into an enlightened commonwealth. Greek became the *lingua franca* of the Hellenistic age (fourth to first century BC), a period that lasted until the establishment of Roman hegemony. Although cosmopolitanism was an issue for Greek philosophers before Stoicism, this school of philosophy established in Athens by 300 BC systematized cosmopolitan theories advancing visions such as that of a world city, an ideal state where everyone would be a citizen. Stoics were instrumental in criticizing Greek ethnocentrism towards barbarians and fostered a sense of brotherhood, a vision of humankind that was transmitted to Romans and predated Christianity's claims to universalism. From the Roman Empire through Medieval Europe cosmopolitanism passed on to different political and intellectual elites. The Christian church played a major role in the reproduction of cosmopolitan ideals and apparatuses by forming transcultural sacred imagined communities and diffusing Latin as the language of a transnational European power.

Some of the fundamental historical processes of long duration that strengthened cosmopolitanism were related to the establishment of modernity, itself a civilizatory cosmopolitan notion and force. The printed book, a new technology of communication developed in mid-fifteenth century, put into question parochialisms in time and space, performing a typical cosmopolitan operation: the enhancement of the consciousness of diversity and the construction of larger imagined communities. Sixteenth-century European expansion gave impulse to the world capitalist system through the incorporation of new territories and populations, and established global colonialism,

multiplying the number of images of and contact with exotic others. Science, technology, and reason began their path to hegemony in the construction of universalizing discourses. Market places and urban centers emerged with citizens that experienced new forms of individuality, etiquette, and public space aspiring to new secular ideologies and modes of Republican, democratic governments. The American (1776) and French (1789) Revolutions formally marked this cleavage in time. The Enlightenment and its Encyclopedia represented a climax of universalist ideals.

Impersonal, anonymous relations, mobility, and estrangement were to become the rule for proletarians and the bourgeois in metropolitan centers that were being transformed by an emergent industrial revolution. The time came for capital to intensify its global reach through the networks of new colonial and imperial cosmopolitan elites linked to the development of the nation-state as the dominant form of organizing the equation territory-culture-ideology-politics-state. Expansion of the nation-state had started with the Peace of Westphalia in 1648 and consolidated in the nineteenth century. This movement was to be completed only in the twentieth century with the last great wave of decolonization in the 1960s and 1970s. The notable growth of nationalism invigorated its counterpart, internationalism, especially in moments of crisis of the interstate system. After the two World Wars, organisms were inaugurated to regulate the world system and establish new forms of global governance and hegemony: the League of Nations (1920–1946); the United Nations (1945); the International Monetary Fund (IMF) and the World Bank (1944). These agencies are greatly responsible for the dissemination of transnational ideologies and initiatives.

In all these processes, many thinkers have played important roles. They held lay, religious, idealist, positivist, socialist, liberal, conservative, or revolutionary positions, clearly demonstrating the plasticity and efficacity of cosmopolitanism across political and theoretical persuasions. They thought of an international court and army (Abbe de Saint Pierre), a federation of nations and eternal peace (Kant), technological solutions for rationally organizing the planet (Saint-Simon, Goethe), global alliances against oppression (Marx), world government and state (H. G. Wells, Lippmann), world economic regulations (Keynes).

The need for cosmopolites to communicate with a myriad of others has been a crucial leitmotif from Leibniz (a universal system of characters) to Sapir (an international auxiliary language). This ancient quest for a 'debabelized' world, a peaceful community of communication constructed out of heteroglossia, has proved to be unviable given the highly complex ways language communities are reproduced. Moreover, the uneven distribution of power within the world system structures the role certain languages—Greek, Latin, and English, for instance—have played in the construction of cosmopolitan/transnational creoles, communities, and imaginaries, leaving little room for initiatives such as Esperanto.

2. *Anthropological and Sociological Considerations*

The sentiments cosmopolitanism evokes are not restricted to the western world. Human beings are always interested in knowing where people come from. The ability to locate oneself or others in geographical, cultural, and political terms depends on an array of classificatory categories that are culturally and historically constructed. These modes of representing membership to sociocultural and political units, modes that bind people to collectivies and territories, can be conceived as a continuum of concentric circles ranging from local, phenomenological immediacies, to more distant regional, national, international, and transnational levels of integration whose influence is variably present in the lives of social agents. Given the present nature of world system integration, all these levels are simultaneously present allowing for feelings of multiple belonging, generally conceptualized in terms of 'hybridity.' Participation on one level triggers certain forms of social representations and allegiances that are relational and circumstancial, and that define rigid or flexible identity boundaries and subject positions that in turn inform social cooperation or competition. A person can simultaneously hold allegiances to a neighborhood, a city, a region, a country, or a continent, or be a transmigrant in a world city or, yet, a global nomad, an employee of a transnational corporation. Much of the discussion on whether cosmopolitanism is possible or not rests on a disconsideration of the simultaneous presence of these forces of identity construction, which resonates with essentialist conceptions of identity. The existence of broad-based encompassing forms of integrating people and territory under the same political and symbolic umbrella does not mean the end of narrower ones. Otherwise, how could one explain the persistence of regional and ethnic separatism within nation-states? It should be clear, though, that while everyone is local, not everybody is global.

Many forces have made contemporary cosmopolitanism possible: individualism with its relative detachment from immediate, narrow solidarities; global expansion of economic and political systems by military, commercial, and religious means; development of transportation and communication technologies that have exacerbated time-space compression and, consequently, the circulation of people, information, and commodities on a planetary scale; growth of global cities and the heightening of cultural and ethnic heterogeneity they have brought; the empire of the mass media especially of global television

and the emergence of the information era with its worldwide virtual web; new political actors such as nongovernmental organizations that are fueled by transnational organizations and ideologies.

Two criticisms are commonly made against cosmopolitanism: one, that it is an elitist social representation; the other, that it is an impossible project. Arguments can be offered to counterbalance both these points. The intense global migratory movements of the last two centuries generated large numbers of uprooted people, complex urban and national ethnic segmentations, transnational networks, and diasporic cultures that, intermixed with the works of the mass media, created a popular cosmopolitanism, fueling processes and visions of globalization from below. It is thus necessary to explore the existence of several cosmopolitanisms. Popular cosmopolitanisms differ from corporate ones, which in turn differ from those of bourgeois tourists, business magnates, or international scholars. There is no doubt that exposure to difference and cultural diversity is increasing rapidly as is the number of transmigrants and differentiated groups, most often occupational ones, among whom allegiance to a nation-state is secondary. The efficacy of historical and sociological facts (such as the Atomic Bomb, satellite planetary integration, the global interconnection of stock markets, global consumer culture, the European Union) and of new universalist ideologies (such as environmentalism and the defense of human rights), together with the emergence of new political subjects and social movements, has further stimulated articulations and actions of a new transnational activism. For some, all this will result in the organization of a global civil society. In spite of the fact that these processes also generate relativist critiques in face of the unequal global distribution of power (the South/North divide in activism also draws a line of asymmetrical relationships and access to visibility and infrastructure), they engender a more concrete framework for cosmopolitanism than in any previous period. Extraterritoriality is another real challenge to legal systems firmly set on national legislations and jurisdictions in a world system where imperial powers or multinational military alliances operate.

3. Cosmopolitanism, Globalization, and Transnationalism

With the completion of the nation-state system in the 1970s, cosmopolitanism clearly meant transcending this entity. Nation-states were then viewed as a homogenizing force by an arising postmodern critique tired of the universalist metanarratives of the Enlightenment based on discursive matrices, such as progress, embodied by contemporary nation-states. French-inspired postmodernism hit mainstream academia, especially in the 1980s and 1990s, in the United States, favoring visions of global heterogeneity and multiculturalism. More than ever, the discussion on cosmopolitanism became intimately intertwined with debates on transnationalism. In the late 1980s, the end of 'really existing socialism' helped to propagate the image of a unified world, monopolized by a triumphant capitalism under the hegemony of powerful transnational corporations and financial capital. In the kingdom of flexible, postfordist capitalism, globalization turned into a mantra and much of the typical tensions inherent to cosmopolitanism as a notion were dramatized within the localist/globalist framework of analysis, sometimes regarded as antithetic polarities, othertimes as complimentary and articulated terms. Notions of transnational classes, cultures, and identities entered the horizon of the social sciences.

There are two major currents of interpretation and promotion of transnational cosmopolitanism. The first is dominated by transnational capitalists and associated elites that praise a borderless neoliberal world, that is, unrestricted access to domestic markets and natural and social resources, and the empowerment of global actors and agencies such as the World Bank, the IMF, and the World Trade Organization. The second is composed of intellectuals, some of them within academia (working mostly in the fields of anthropology, cultural studies, economics, geography, international relations, political science, and sociology), others in nongovernmental organizations, who are advancing visions of heterogeneity, heteroglossia, migrancy, cultural diversity, or empowerment of local actors, and claiming a need for global governance and a global civil society to regulate the power of transnational deterritorialized elites. In different ways, both sides feed on universalist ideologies such as development (with its promises of unlimited fortune and technological transcendence), republicanism, liberalism, socialism, environmentalism, and the defense of human rights. They are also strengthened by new transnational frameworks of cultural and political activity engendered by the new technologies of communication of late twentieth century. The latter have become a focus of explorations on global culture, on the emergence of new fragmented and flexible identities, electronic public spaces and interactions, cultural hybridty and cosmopolitan political communities. The Internet has brought about the possibility of a transnational imagined virtual community: a decentered cosmopolitan crowd, synchronized by cyberspace, interacting on real-time, and engaging in global commercial, cultural, and political exchanges.

Cosmopolitanism frequently is conflated with the imperial inclinations of a historical period; a fact that stresses its contradictory relationships with power. In the early twenty-first century, it will be criticized increasingly as a disguised form of Americanism or of serving transnational capital. Will the future see a

homogenizing global state or a heterogeneous planetary civil society? Be that as it may, one thing is certain, cosmopolitanism—the need to transcend received loyalties and attachments in favor of imagining distant unknown others, of constructing broader solidarities and global notions of citizenship—will continue to furnish, with its pacifist, egalitarian, utopian reverberations, a powerful ideological window into the future of a shrinking world.

Cost–Benefit Analysis

Cost–benefit analysis (CBA) is a method for assessing the economic efficiency of public policies through the systematic measurement of social costs and social benefits. When economic efficiency is the only relevant social goal, CBA provides an appropriate decision rule: choose the policy, or set of policies, that maximizes net social benefits. Although the conceptual foundations of CBA continue to be refined, most of the basic concepts were in place when it was explicitly introduced in the 1930s to evaluate water resource projects in the USA. Advances in empirical research methods, especially with respect to the measurement of the benefits of goods not traded in markets, have steadily expanded the plausible range of application of CBA.

1. Foundations of Cost–Benefit Analysis

CBA is concerned primarily with efficiency in the allocation of resources. As such, it follows directly from the body of neoclassical economic theory (or resource allocation theory). Yet whereas the main body of neoclassical theory deals with the nature of *private* decisions by households and firms, CBA focuses on *public* decisions. It sets forth the requirements for any public decision, or policy, to be efficient; that is, for the policy to contribute to an 'improvement' in the allocation of economic resources. CBA seeks to answer the question: will an alteration in the current pattern of resource allocation improve efficiency in the use of national resources? Insofar as CBA is directed at allocative efficiency, it can be viewed as an attempt to replicate for the public sector the decisions that would be made if private markets worked satisfactorily. In private markets, no explicit attention is given to social goals such as equity. Indeed, private markets tend to respond to actual demands and resource constraints, where demand is partly a reflection of the distribution of income, and economists do not generally regard private markets as operating unsatisfactorily simply because they fail to produce goods for people who cannot afford to pay for them. Similarly, the focus of cost–benefit analysis is on allocative efficiency, and implies that public sector decisions should be guided by these same demand (not desire) and resource cost considerations. It is presumed that if there are concerns about the acceptability of the income distribution that gives rise to the pattern of demands, or to the impact of the policy's benefits and costs on the income distribution, these concerns will be taken into account through other policies with explicitly redistributive goals.

As with the neoclassical theory that guides market analysis, CBA rests on the analytical underpinnings of modern welfare economics. Modern welfare economics shares the utilitarian presumption that aggregating the wellbeing (utilities) of the individuals who make up society is a valid measure of social wellbeing. CBA provides a basis for inferring changes in utilities, which are unobservable, from economic choices and outcomes, which are observable. These outcomes, especially if they are revealed in markets, express the value of changes in utilities in terms of a money metric. At one level, then, CBA can be thought of as the accounting protocol of welfare economics for measuring in terms of a money metric the changes in utilities caused by changes in public policy.

The principle of *Pareto efficiency* lies at the heart of welfare economics (see *Pareto, Vilfredo (1848–1923)*). An allocation of goods is Pareto-efficient if there exist no alternative allocations that make at least someone

better off without making anyone else worse off. The intuitive appeal of Pareto efficiency is obvious: one would have to be malevolent to oppose a reallocation that betters the situation of someone without harming anyone else.

Although the Pareto criterion seems unobjectionable as a basis for judging the relative desirability of public policies, it would be largely useless as the basis for choice because policies without some losers are extremely rare in the real world. This limitation of the Pareto criterion prompted efforts to develop a normative welfare criterion with more general applicability to actual decisions. A more serviceable criterion for CBA arose out of proposals by Nicholas Kaldor and J. R. Hicks: a change in the allocation of resources should be regarded as increasing welfare if either the Pareto criterion is met or the persons who have gained by the reallocation could compensate those who have been harmed by it so as to leave everyone at least as well off as they would have been without the reallocation. Any resource allocation that meets this criterion is said to be a 'potential Pareto improvement.' This criterion expands the set of situations and policies about which statements may be made as to whether economic welfare has been increased, decreased, or left unchanged.

In resting on this criterion, CBA becomes an accounting protocol that enables the analyst to determine whether a reallocation has the potential to be Pareto improving. As a decision rule, this criterion seeks the greatest potential Pareto improvement by choosing projects that maximize the excess of social benefits over social costs.

CBA gained a distinct identity in the 1930s as a formal technique for systematically measuring benefits and costs of flood control projects sponsored by the US federal government (for an overview, see Steiner 1974). As the scope of governments grew, and economists gained influence as policy analysts, the use of CBA expanded well beyond the evaluation of public works projects. In the USA, for example, Executive Order 12291 (February 17, 1981) requires that federal regulatory agencies subject proposed regulations with estimated costs of over $100 million to CBA. Continuing advances in empirical research methods further expand its range of application. Natural resource economists, for instance, use survey methods to estimate benefits necessary for applying CBA to environmental policies.

2. *Social Benefits and Costs: Concepts and Measurement*

2.1 *The With/Without Principle of Evaluation*

The evaluation of public projects in terms of the potential Pareto improvement principle requires that analysts determine if the value of the output in the economy *with* the proposed project would be greater than the value of the economy's output *without* the project. Note that this comparison must be made *ex ante* (based on the prediction of results). It therefore requires the prediction of the future under two scenarios: one with the project and one without it. This with/without principle is important for defining and measuring both social benefits and social costs.

Although CBA is forward looking, its application often requires analysts to draw on past experience as a basis for prediction. In such cases, the outcome of a similar policy previously implemented is observed but the counterfactual—what would have occurred without it—is not. Analysts must infer the counterfactual in order to make the with/without comparison. For example, in order to assess the social costs and benefits of an existing irrigation project, analysts must infer the value of crops and environmental quality that would have been produced without the project for comparison with those observed to occur with it. This *ex post* CBA (based on actual results) could then be used as an empirical basis for predicting the social costs and benefits for an *ex ante* CBA of a proposed irrigation project with similar features.

2.2 *A Comprehensive Framework: Standing*

Costs and benefits in CBA derive from the preferences of the individuals who make up society. But what defines society? And are all preferences legitimate? These questions have come to be known as issues of 'standing' (Whittington and MacRae 1986). Recognizing that the citizens of a country share a common constitution, which sets out values and rules for making collective choices, and participate in the same national economy, most analysts define society at the national level. The evaluation of social benefits andu social costs requires that the protocol for the analysis be a comprehensive one in which all of the adverse and beneficial effects of the policy are tabulated, regardless of who in the society is harmed or helped by them. It follows that all effects accruing to national citizens (or perhaps residents) be counted.

Comprehensively taking account of effects accruing to all those with standing means that CBA differs from financial analysis. Considering only the revenue flows to government agencies is generally inadequate because it does not take account of all the impacts of policies on citizens. It also means that analysts working for sub-national governments should resist pressures to ignore national costs and benefits that accrue outside of their jurisdictions. For example, a city may view a grant from the central government as only a benefit, while from the social perspective it involves an offsetting national cost.

An accounting that accepted all preferences as legitimate would be too broad. For example, most observers would not view the pleasure that psychopaths get from physically assaulting people as an

appropriate part of the utilitarian calculus. Where to draw the line between legitimate and illegitimate preferences, however, is sometimes difficult. One approach is to rely on the existing legal framework for guidance (Zerbe 1998), yet doing so assumes that existing laws are moral.

2.3 The Concept of Social Benefits: Willingness to Pay

The fundamental concept for guiding the measurement of social benefits is the aggregate *willingness to pay* of those with standing for the impacts of a policy. The analyst wishes to know the maximum amounts individuals would be willing to pay for policy impacts that they view as beneficial, and the minimum amounts individuals would be willing to accept as compensation for policy impacts that they view as harmful. In other words, the analyst would like to know how much each individual's wealth would have to be adjusted in conjunction with the policy change so that the individual's utility remained unchanged. The algebraic sum of these wealth adjustments for all individuals measures the social value of the impacts of the policy in terms of dollars. Although some theoretical caveats apply (Blackorby and Donaldson 1985), policies with larger positive sums have larger social benefits.

Note that the amounts that people are willing to pay to obtain a policy's impacts depends on their levels of wealth. For example, provision of a public good, such as improved environmental quality, may convey the same physical effect on all people. However, people with more wealth would be willing to pay more for this benefit than those who are poorer. An obvious implication of the dependence of individuals' willingness to pay on their levels of wealth is that the aggregate willingness of a society to pay for a policy impact depends on the distribution of wealth among its members. Thus, the social benefits used in CBA are contingent upon the particular distribution of wealth that exists in the society.

2.4 Categories of Social Benefits: Active and Passive Use

The impacts of public policies can be divided into two broad categories. In the first category are impacts that change observable behaviors of individuals. These behavioral changes are labeled 'active use.' For example, preserving a wilderness area may facilitate birdwatching, an observable behavior. Any such behavior provides at least the possibility of making an inference about willingness to pay through its observation.

Many policies also produce impacts that are valued by people without changing observable behaviors. The realization of these values is labeled 'passive use.' Analysts have found it useful to identify three distinct categories of passive use.

First, a policy may have an 'option value' (Weisbrod 1964). People may value a good because they anticipate the possibility of using it in the future. Only when they actually use it, if ever, will their behavior be observable. For example, a person may be willing to pay something now to preserve a national park in Alaska with the hope of visiting it someday. The person's circumstances, however, may never allow the visit to be made.

Second, a policy may have 'existence value' (Krutilla 1967). People may value a good even if they never anticipate actively using it. For example, a person may be willing to pay to preserve a wildlife habitat that would be completely closed to the public. One motivation for the willingness to pay may be a belief in the intrinsic value of the natural order. Another motivation may be altruism: a desire to make the good available either to the current generation, or to bequeath it to future generations.

Third, a policy may have a 'donor value' (Hochman and Rodgers 1969). People may be willing to pay something for a policy that distributes goods in a way they view as desirable. The motivation may be altruistic, say in providing more to those who otherwise would be consuming less. It may also be motivated by values of equality or fairness. The inclusion of donor values integrates individual preferences over the distribution of wealth into the efficiency framework, broadening it substantially from a normative perspective. While some studies have attempted to attach explicit weights to benefits and costs depending on the characteristics of who bears them, most analysts suggest an alternative approach—namely that the distributional consequences of a proposed resource reallocation be displayed as a supplement to the cost–benefit calculation based purely on efficiency. Such a display enables decision-makers to perceive fully the distributive implications of the proposals being discussed.

2.5 The Measurement of Social Benefits

How can willingness to pay be measured? It would be ideal if analysts could elicit willingness-to-pay amounts directly from individuals through structured conversations. If securing this information from all citizens were too costly or impossible, surveys of population samples could be used as the basis for estimating aggregate willingness to pay for the population. This approach, called 'contingent valuation,' is conceptually attractive because it potentially allows the analyst to elicit a willingness-to-pay amount for impacts that involve both active and passive use.

The use of contingent valuation to measure willingness to pay has become increasingly common, especially in the evaluation of environmental policies

(Bateman and Willis 2000). A blue ribbon panel convened by the US National Oceanic and Atmospheric Administration concluded that contingent valuation could be a reasonable basis for estimating passive use values in natural resource damage assessment (Arrow et al. 1993).

Nevertheless, the use of contingent valuation remains controversial. One source of concern is the cognitive demands that it places on respondents in terms of understanding the policy being valued. Unless respondents understand what is being valued, and believe their answers to be consequential in influencing the policy choice, they cannot be expected to give meaningful answers to serve as the basis for an inference about the willingness to pay of the entire population. Considerable research, mainly by environmental economists, is contributing to the craft of designing effective questionnaires for contingent valuation. Another source of concern is the fear that respondents will answer strategically in the sense of giving false answers that they believe will lead to a better outcome for themselves than would result from truthful answers. Both theory and evidence suggest that giving respondents referendum-type questions about public goods minimizes the dangers of strategic responses. That is, rather than directly asking a respondent to state her willingness to pay, she is given a random dollar amount and asked if she would vote for the policy if it would cost her that amount in higher taxes or increased costs for other goods. An estimate of mean or median willingness to pay for the sampled population can be inferred statistically from sample responses.

The conceptual and practical problems in conducting contingent valuations commonly lead analysts to estimate willingness-to-pay amounts through inferences from observation of the behavior of individuals, especially in markets. Demand analysis plays an especially important role in such estimation. A person's demand schedule for a good tells how much of a good the person wishes to purchase as a function of the price of the good, holding all other prices and the person's utility constant. The height of the demand schedule at each level of consumption gives the person's willingness to pay for an additional unit of consumption. The difference between the willingness to pay for this unit and the amount that the consumer actually pays is its 'consumer surplus.' Adding up the surpluses for each of the units consumed gives the total consumer surplus that accrues to the person from participation in the market or experiencing services produced by the public sector.

If a policy measure either satisfies a demand that has not been met, or changes the price of a good or service that a person is already consuming, the consumer surplus of the person will be changed. This change is the person's willingness to pay for the impact of the policy measure. (Graphically, the consumer surplus is the area under the demand schedule but above the market price from zero units to the number of units actually purchased.) If the good or service produced by the public sector is a private good, in that it does not generate external, or spillover, costs or benefits, then the market demand schedule for the good (that is, the horizontal sum of all the individuals' demand schedules) provides the basis for estimating changes in consumer surplus, and hence changes in the aggregate willingness to pay of individuals for the effects of the policy.

The market demand schedule must be estimated from observed price and quantity data. The standard econometric procedures result in the direct estimation not of the demand schedule described above, which holds the utilities of individuals constant (the Hicksian or compensated demand schedule), but of one that holds their incomes constant (the Marshallian or market demand schedule). Quite often these demand schedules are sufficiently similar so that measuring consumer surplus in terms of the market demand schedules provides good approximations of the aggregate of individuals' willingness-to-pay amounts (Willig 1976).

Estimation of willingness to pay is more difficult when policy impacts do not correspond to changes in markets for traded goods. For example, though most people would be willing to pay positive amounts for improvements in environmental quality, there is no market for this public good. People may convey information about their willingness to pay for changes in environmental quality, however, by their action in other markets. So, for instance, housing values may change to reflect changes in levels of noise pollution near airports, thereby providing a so-called 'shadow' price for quiet. In general, shadow prices refer to inferences of marginal social value when it is not revealed through market prices.

This approach is based on what is called the 'hedonic price model,' which provides a theoretical basis for statistically isolating the independent effects of the various characteristics of a product on price. It has been used extensively to estimate the benefits of air quality improvements and health risk reductions from wage and housing value variation. An important use of the hedonic price model in CBA has been to estimate the 'value of life,' defined as the amount that people are willing to pay for reductions in the risks of death that they face (see Viscusi 1993). Analysts can take advantage of prior research to find estimates of relevant shadow prices (Boardman et al. 1997). For example, a large number of studies conducted across a number of countries suggest that commuters value reductions in their travel times at between 40 and 50 percent of their after-tax wage rate (Waters 1996).

2.6 The Concept of Social Costs: Opportunity Costs

The implementation of policies usually requires the use of economic inputs that could be used to produce

other things. CBA uses the concept of 'opportunity cost' to value these particular policy impacts. The opportunity cost of an input is the value of the goods and services that the input would have produced in its best alternative use. This value is just the willingness to pay for these goods and services on the part of those who would have consumed them if they had been produced.

Opportunity cost may or may not correspond to the accounting cost of inputs used to implement policies. If purchasing the input in a competitive market does not alter the price in the market, then opportunity cost and accounting cost are identical. For example, buying books for a local reading project is unlikely to affect prices so that the purchase cost of the books represents their opportunity cost. If purchasing the input in a competitive market increases the market price, then opportunity cost will be less than the accounting cost based on the post-purchase price. For example, buying concrete for a dam in a local market may drive up the price of concrete, as the marginal costs of producing concrete increase. However, some of the payments at the higher price will be to more efficient suppliers with lower marginal costs. These payments in excess of marginal costs, called 'rents,' are simply transfers from the project budget to the efficient suppliers and therefore do not contribute to opportunity cost. The opportunity cost of inputs purchased in noncompetitive markets may be larger, smaller, or equal to their accounting cost. For example, the opportunity cost of the time of people compelled to serve on juries may be larger or smaller than the legally set payments they receive from the court.

2.7 *The Measurement of Social Costs*

The problems encountered in measuring social opportunity costs are very similar to those confronted in measuring social benefits. A commonly encountered problem in CBA is the measurement of the opportunity cost of unemployed labor. The conceptually correct measure is the value of the forgone leisure to each worker. The accounting cost of the project is certainly an overestimation of the opportunity cost of otherwise unemployed labor. Alternatively, zero is probably an underestimation of the opportunity cost. Rarely do analysts have enough information about the value of the forgone leisure to estimate the conceptually correct opportunity cost for unemployed labor so they usually use some fraction of accounting cost as an approximation (Haveman and Krutilla 1968).

Another commonly encountered problem in CBA is the appropriate measurement of the opportunity cost of government revenues. Standard practice is to treat a dollar of accounting cost raised through taxation as the equivalent of a dollar of opportunity cost. Raising revenue through taxes, however, usually involves inefficiencies, or 'deadweight losses,' that reduce social welfare. The amount by which the social cost of a dollar of tax revenue exceeds its nominal value is called its excess marginal burden. Expenditures funded by tax increases, and revenues allowing tax reductions, should be adjusted by the marginal excess burden of the relevant tax. A number of estimates of marginal excess burden have been made for various components of the US tax system (Jorgenson and Yun 1990).

An appropriate accounting of opportunity costs helps clarify when the inclusion of so-called secondary benefits is correct (Haveman and Weisbrod 1975). The primary benefits of a project derive from its direct effects. For example, the primary benefit of stocking a lake with game fish is to increase the supply of fishing days. The improved fishing might very well have secondary effects, such as the construction of a nearby hotel. It is usually incorrect to attribute any benefits to the secondary effects because they involve offsetting opportunity costs—the hotel requires resources that could have been used to build it elsewhere. Such secondary effects may involve benefits, however, if they use otherwise unemployed resources such as labor. In such cases, the benefits produced may not be fully offset by opportunity costs. A final point on opportunity cost: resources already expended have zero opportunity cost if they are no longer available for other uses. These previously expended resources are known as 'sunk costs.' Because it is forward looking, CBA ignores sunk costs.

3. *Timing of Costs and Benefits: Discounting*

The social benefits and costs generated by a public program often extend over long periods. Because waiting is costly, the amount that people value a dollar of benefits or costs in the future is less than if that value were obtained in the present. In an ideal economy, markets for lending and borrowing funds (also known as capital markets) balance the preferences of lenders who require a payment for giving up use of their funds (hence, delaying consumption) and the preferences of borrowers who invest in projects with future payoffs. In this situation, the market interest rate that is the outcome of this balancing serves as the basis for adjusting costs and benefits occurring in the future to make them commensurate with costs and benefits occurring in the present. This adjustment for time is called discounting. In particular, if $\mathbf{r}$ is the annual market interest rate, then a dollar of cost or benefit that will be realized after N years in the future would have a present value of $1/(1+\mathbf{r})^N$. Maximizing the present value of net benefits would maximize potential Pareto efficiency.

This simple solution results if capital markets are competitive and not restricted or distorted, for example because of taxes on savings (consumption) or on the returns from investment. When such distortions

exist, the solution becomes more complicated. Such taxes insert wedges between the marginal valuation of funds by lenders and borrowers. With such wedges, it is not clear which of the values is appropriate for discounting: the before-tax rate of return of borrowers who invest (the marginal rate of return on private investment), or the after-tax return faced by lenders (the marginal rate of pure time preference). Another distortion is general price inflation. Market interest rates reflect expectations about inflation. They correspond to projections of costs and benefits in inflated (nominal) dollars. When costs and benefits are projected in terms of current (real) dollars, typically the most convenient method, nominal discount rates must be converted to real discount rates.

Although some controversy remains, most analysts do seem to agree that the social discount rate should reflect the fact that both consumption and investment are foregone when the public sector uses resources. Thinking of the discounting problem in terms of shadow price of capital provides a way of taking account of these effects (Bradford 1975, Boardman and Greenberg 1998). It involves using the marginal rate of return on private investment to convert any foregone investment to the stream of future consumption that it would have produced. The consumption equivalents of foregone investment are then added to any foregone consumption to express all resource costs in terms of consumption, which can then be appropriately discounted using the marginal rate of social time preference.

4. *Accounting for Uncertainty*

As CBA involves prediction, it can rarely be done with certainty. The standard approach to dealing with uncertainty is to estimate expected net benefits. The first step is to convert the problem from one of uncertainty to one of risk by assuming a plausible distribution of benefits. The second step involves finding the expected value, basically the weighted average, over this distribution. Third, society is assumed to be risk-neutral, so that the expected values can be treated as commensurate with certain values. For example, a project with certain opportunity costs of \$15 million and a 20 percent chance of yielding \$5 million in benefits and an 80 percent chance of yielding \$20 million in benefits would have expected benefits of \$17 million and expected net benefits of \$2 million.

The calculation of expected net benefits, however, does not fully take account of individual preferences for risk. Individuals may not be willing to trade certain amounts for expected values of the same magnitude. In such cases, the appropriate measure of benefits is 'option price,' the individual's willingness to pay for the particular distribution of outcomes associated with a policy (Graham 1981). As individuals are generally risk averse, policies that reduce risk generally have option prices larger than expected benefits. The difference, 'option value,' is a premium individuals are willing to pay for the reduced risk. As option price can only be elicited through contingent valuation surveys, it is rarely estimated. Unfortunately, relatively little progress has been made in the theoretical determination of the magnitude or even sign of option value. For policies involving substantial risks, especially if the risks are social in the sense that everyone realizes the same outcome, the use of expected benefits may introduce substantial error into CBA. Even when the policy being evaluated is not inherently risky, analysts may be uncertain about their predictions of its costs and benefits. It is common, therefore, for analysts to test how sensitive their estimates of costs and benefits are to particular assumptions. This process, called 'sensitivity analysis,' typically involves changing the assumed values of a few key parameters to see how net benefits change.

5. *The Maximum Net Benefits Rule*

Assuming that all of the costs and benefits of a policy have been correctly measured, discounted, adjusted for uncertainty, and aggregated, positive net benefits indicate that the policy is potentially Pareto improving: the excess of benefits over costs would permit the policy to be implemented in conjunction with a set of compensatory transfers such that at least someone would be better off without anyone being worse off. Thus selecting policies on the basis of positive net benefits, the Kaldor-Hicks criterion discussed above, guarantees that adopted policies are potentially, but not necessarily actually, Pareto-improving.

The rule can be stated as follows: choose from among all possible policies those that offer the largest sum of net benefits. In the special case of mutually exclusive policies, the one with the largest net benefits should be selected. In the special case of completely independent policies, all those with positive net benefits should be selected. Note that this rule says nothing about a benefit–cost ratio, which is a common calculation made by CBA analysts. The use of a benefit–cost ratio criterion is appropriate only if the policies are independent of each other, in which case the set of projects with benefit–cost ratios greater than one corresponds to the rule of adopting policies with positive net benefits.

6. *Further Reading*

A number of textbook-length treatments of CBA are available for those wishing to explore it in much more depth (Boardman et al. 2001; Dinwiddy and Teal 1996, Zerbe and Divily 1994, Gramlich 1990, Sugden and Williams 1978).

Counsel, In-house

1. Introduction

In-house counsel are legally trained individuals who have responsibilities for some of the law jobs of the organizations employing them. Organizations having needs for legal services may resolve them either internally or with legally trained individuals whose services are purchased in the market. Organizations may chose to 'make' rather than 'buy' legal services, as they do in hiring in-house counsel. Hiring in-house counsel is an instance of organizations 'professionalizing' their workforce. Sociological research on in-house counsel has focused on in-house counsel being both organizational and professional actors.

2. Delimiting the Role of In-house Counsel

Many individuals with legal training work for organizations in other than a distinctly legal capacity. In most of the world, university legal study usually does not lead graduates into a career as a legal professional. These graduates take a facility in the law into whatever positions they assume. Others may leave a career in law to work for organizations in positions other than that of in-house counsel. In some countries, including the USA, individuals may combine being lawyers with careers as organizational actors.

In-house counsel do not differ from these other law-trained employees because they are primarily employed for their law training and practice experience. Corporate finance departments, for example, may employ many law graduates, some with significant careers as lawyers, to perform law work. These individuals, however, have not been considered to be in-house counsel. Although they perform legal work and are law graduates, they are responsible to the corporate finance department, not to the organization's general counsel. An organization's law department is the home of in-house counsel.

In-house counsel are responsible for only a limited part of the law jobs of an organization. Legal work is performed in organizations by other than in-house counsel. Executives, staff members, regulatory specialists, managers, and salespeople all may have degrees

and experience in law and be responsible for a number of law jobs. Other law jobs may be performed by individuals who do not have any formal legal training. They may negotiate, write, and sign contracts, or deal with banks and enter into loan agreements. Organizations may have such continuing relations with regulators that they develop specialized subunits, such as employment or environmental relations, with responsibilities for legal compliance and dispute resolution.

With in-house counsel, organizations delimit a distinctly legal capability, but in-house counsel's responsibilities are neither co-extensive with the organization's law jobs nor comprehensive of organizational law compliance. In-house counsel are employed lawyers who provide the organization with a professionally managed legal capability (Mackie 1989). Organizations vary greatly in how they manage in-house counsel. Depending on the legal regime and its professionalization project among other factors, in-house counsel differently attest to the organization's legal function.

3. *In-House Counsel as Organizational Actors*

In-house counsel vary in their work responsibilities. Some organizations make in-house counsel rather than buying their legal services across the market, in order to increase the economic and efficient meeting of recurrent predictable legal needs. Others may hire in-house counsel because of the firm-specific knowledge needed in providing legal services. Others may hire in-house counsel in imitation of other organizations. Yet others, risking reducing organizational flexibility, hire in-house counsel to increase the organization's coordination and control of legal services (Chayes and Chayes 1985).

The extent to which in-house counsel assume organizational responsibilities varies greatly. In-house counsel perform a staff function, but, either individually or organizationally, they also may command executive functions. Hiring in-house counsel attests to the jurisdictional claims of law graduates. In-house counsel may extend beyond fulfilling a staff function by making professional jurisdictional claims, for example, gain a voice in the choice of remedy for legal problems.

In the USA, in-house counsel make professional claims to organizational power. The rules of the legal profession require in-house counsel and legal departments to have access to the Board of Directors. Some in-house counsel secure these claims by emphasizing their skills in handling legal risk. Others do so through their unique and nontransferable skills. In gaining organizational responsibility, in-house counsel become managers of aspects of the organization's legal services.

Today, in the USA business sector, many in-house counsel are involved in compliance issues and strategic decisions that gain them access to the ultimate organizational decision makers. US corporate counsel have won the right to monitor and review many legal services produced internally or purchased across the market by the organization. Often, they are sought for their judgment about decisions where legal risks do not predominate (Rosen 1989).

In many economies, corporate in-house counsel are less frequently ceded executive responsibility (see e.g., Van Houtte 1999, Daly 1997). In most of the business world today, in-house corporate counsel resemble US corporate counsel of an earlier era. Although situations varied, depending on the trust and confidence particular in-house counsel attained, in-house counsel performed scrivener and secretarial tasks, carrying out decisions reached without their significant input (Rosen 1989). But even in economies where in-house counsel have few responsibilities, global corporations located there use in-house counsel as do modern US ones (Daly 1997).

Outside the business sector, in-house counsel for organizations—especially public interest organizations—face the possibility—and are cognizant of the attendant responsibilities—of performing executive tasks in the organizations or causes they take as clients (Sarat and Scheingold 1998).

Even where in-house counsel have executive power, they share control with others. As a matter of professional ethics, lawyers cede some forms of control to their client, the organization. Decisional authority over the scope and content of legal work, however, may be allocated within an organization by dynamics driven by other than the norms of the legal profession. Students of organizations may study inside counsel to gain information about organizational decision making, especially in regards to certain aspects of regulatory compliance.

4. *In-house Counsel as Professional Actors*

Professions whose professionalization projects stress autonomous employment as a hallmark of the profession—the 'liberal' professions—may denigrate employed lawyers for lacking professional independence. During the progressive era, in the USA, in-house counsel were called 'kept lawyers.' In the European Union, unlike self-employed lawyers, in-house counsel are not legally privileged to protect the confidentiality of their work product. In many civil law countries, a lawyer must resign from the bar before taking salaried employment. A 'heteronomously employed' legally trained individual who performs legal work may not be professionally respected as a 'lawyer.'

The law jobs performed by in-house counsel may be bought by contracting with external providers. In the marketplace, there are sellers of legal services in professional law firms, multi-disciplinary practices, and competing professions. In-house counsel compete with autonomously employed lawyers who compete with accounting-consulting firms, regulatory engin-

eering specialists, and business advisors of many sorts. In the USA, this competition has altered the distribution of deference within the legal profession, with independently employed lawyers no longer denigrating in-house counsel.

The substantive claim in the professional denigration of in-house counsel is their supposed lack of professional independence. Organizational control over the work of professionals, from a legal perspective, creates a potential conflict of interest. Although the control may better align legal services with the interest of the organization, it may cause conflicts with legal interests, sometimes crystallized in the personal and professional interests of in-house counsel. In-house counsel may experience conflicts of interest that will shape their professional judgments.

The professional independence of in-house counsel is relative to both that which can be bought in the market and the organizational role in-house counsel assume.

The independence of external providers of legal services is relative to the organization's abilities to control them. By increasing the organization's ability to monitor the legal services purchased, in-house counsel may decrease external providers' abilities to effect their independence. Sometimes, in-house counsel may demand that external providers be independent. Other times, their influence on whom and when to hire in the external market can decrease external providers' willingness to exert their independence. In-house counsel also decrease the abilities of external providers to be independent by inhibiting personal relations with organizational members or by limiting either the time frame in which the external providers respond or the problem posed. By retaining authority to select external providers, define the goals of their work and define the problem that is the subject of legal work, organizations control what legal services they purchase in the market, decreasing the professional independence of external providers (Kagan and Rosen 1985).

The independence of in-house counsel is also relative to the organizational roles they assume. First, in-house counsel may be delegated or may assume organizational decisional authority. In-house counsel vary in the extent to which they are assigned thick responsibility in their organizations. Second, organizations differ not only in their enacted cultures, but also in the extent to which they seek to gain the advantages of in-house counsel commitment by supporting job-enrichment schemes mirroring professional privileges. Third, in-house counsel differ not only in their professional orientations, but also in their abilities to draw on professional resources of independence. Fourth, in-house counsel differ in the human capital they bring to their jobs. In-house counsel may be trusted organizational actors, using that trust to exercise their professional independence. Fifth, organizations differ in their internal politics, so that in-house counsel may have opportunities to assert their independence by bargaining. And sixth, in-house counsel may be induced to assert their independence as the addressees of laws or as a result of threats of their own legal liability.

Legal professions differ in where and how they establish the lack of plasticity in professional work that is deemed to warrant the assertion of professional independence. During much of this century, there have been calls that in-house counsel serve as consciences of their organizations. In the US business sector, where in-house counsel have attained organizational power, this is no longer on the agenda. Nor on the agenda are limits on what information about the law in action in-house counsel may professionally provide. Students of professions may study inside counsel to gain information about the plasticity of the professional legal role.

In their work, in-house counsel attest to the law's legitimacy for the organizations they serve. In their work, in-house counsel apply professional knowledge. Inside counsel and their work create subjects for research for students of both organizations and professions.

Counseling and Psychotherapy: Ethnic and Cultural Differences

1. Introduction

Scholars and mental health professionals have argued that racial-cultural issues have been obstacles for those seeking help (Sue and Sue 1999). When counseling has been available, the focus has often been placed upon failures to create realistic understanding of members of racial-cultural groups in the United States, practitioners' unfamiliarity of historical, social, and political discrimination and oppression (Guthrie 1998), narrow professional cultures, and biased theoretical models (Carter 1995).

In many regards, scholars, educators, and practitioners have been focusing upon changing population demographics as a driving force necessitating multicultural inclusion. For example, the US Bureau of the Census data (1990) has shown significant increases in the number of Blacks, American Indians, Asian/Pacific Islanders, and Latinos. Between 1970 and 1990, the Latino population increased 145 percent, the Asian/Pacific Islander population by 375 percent with 22.3 million Latinos and 7.2 million Asian/Pacific Islanders now living in the USA. Currently one in three US Americans has been either born outside of the US or are members of visible racial-cultural groups. Given the present rate of immigration as well as fertility rates, researchers at the Bureau of Immigration have predicted by the year 2040 Whites will only comprise 62 percent of the total US population.

Recognizing the importance of meeting the needs for all seeking mental health services, scholars and educators have developed competency guidelines and ethical mandates for integrating multicultural perspectives into psychology research, practice, and training (American Psychological Association 1991, Sue et al. 1982, 1992, 1998), educational programs (Carter 1995, Ridley et al. 1994), and evaluation instruments (Pope-Davis and Dings 1995).

2. Culture

What is culture? Culture at its core understands human behavior through causes and effects *and/or* content and processes. While cultural content is focused on knowledge about learned and acquired beliefs, art, morals, customs, and habits, cultural processes attend to the process and perpetuation of pattern transmission. Thus, psychosocial cultural perspectives are socially transmitted attitudes and behaviors emerging from interpersonal interactions transmitted generationally, not through biological inheritance but by formal and informal methods of teaching and demonstration. Thus, culture can include historical dimensions emphasizing traditions, normative dimensions focusing upon unique and shared experiences, psychological dimensions including adjustment, learning and group behaviors, structural dimensions attending to the composition of and interrelated patterns in organizations and, genetic dimensions focusing on the origins of culture as interactive adaptive processes between groups and their environment. Broadly speaking, culture has bound groups of people by common explicit (e.g., tangible artifacts, clothing, food, festivals, and behaviors readily observed by outsiders) and/or implicit (e.g., intangible conscious and unconscious values), assumptions, attitudes, beliefs, and feelings and has endured over time and space. Additionally, while people may be identified with one or more groups, the intensity and resilience of belongingness can vary with the interaction of self-investment and degree of group acceptance.

How people's racial-cultural assumptions shape the way in which culture is embraced, rejected, and ignored has been described in Carter's (1995) classification system. In the *Universal* paradigm, shared similarities are affirmed as universal human experiences and differences as secondary intragroup variations. In the *Ubiquitous* paradigm, socially derived circumstances constitute cultural groups. From this perspective, people embrace one or more socially derived cultural group affiliations. Unlike the Universal paradigm, the Ubiquitous paradigm acknowledges and accentuates differences by promoting cultural sensitivity to increase people's awareness of variation. Influenced by anthropology, the *Traditional* paradigm equates culture with geography (e.g., country) and adaptive socialization (e.g., birth, upbringing). Since cultural membership circumscribes personality development by experiencing 'cultures' through exposure and cultural informants, culture is understood as personal circumstances superseded by the dominant culture. In the *Race-based* paradigm, culture is a function of transcending racialized experiences. Becoming aware of the effects of racism, oppression, and promoting racial identity development, culture is understood by how race and racism influence power and authority in the USA. In the fifth *Pan-National* paradigm, culture is constructed as how racial group affiliation and the distribution of power influence global issues.

2.1 Cultural Pluralism and the Tyranny of the Shoulds

Historically, group relations between White Anglo and all other racial-cultural groups in the USA have influenced psychological, social, and cultural adjustment for members of dominant (e.g., mainly White Anglo-Saxon) and subordinate cultural (e.g., visible racial-cultural) groups. For example, from the mid 1700s to the early 1880s, the melting pot concept

(Zangwill 1910) assumed all entering US inhabitants would willingly relinquish indigenous heritages and adopt existing White Anglo-Saxon cultural norms. From the late 1880s to the mid-1950s, this biologically blended melting pot became '*Americanized*' (Fairchild 1926). Through Americanization, the ideology of *cultural pluralism* or *cultural unity* advocated including visible racial-cultural groups into 'mainstream' American culture. Symbolic appreciation for diversity, especially from other civilizations beside White-European societies through congressional legislation and Supreme Court decisions in the 1960s and 1970s furthered the cultural pluralist movement. However, while White European immigrants were expected to assimilate dominant White Anglo-Saxon cultural norms, visible racial–cultural groups were still excluded and institutionally segregated.

Thus, cultural pluralism ideology was contradictory to the realities of the American 'melting pot.' While preserving cultural and social heritages as a means to creating a new society, economic, political, and educational separatism for visible racial-cultural groups was creating a 'tyranny of the shoulds'—idealized images and standards imposed upon visible racial-cultural people by the dominant society resulting in the suppression of the 'true self' (Horney 1950). Despite conformist trends throughout the nineteenth century, voices of dissent and the 'tyranny of the shoulds' was heard in the words of W.E.B. Dubois as:

> … a peculiar sensation, this double consciousness, this sense of always looking at one's self through the eyes of others, of measuring one's soul by the tape of the world that looks on in amused contempt and pity. One ever feels his two-ness – an American, a Negro; two souls, two thoughts, two unreconciled strivings; two warring ideals in one dark body, whose dogged strength alone keeps it from being torn asunder (1989, p. 3).

At some level, cultural pluralism may have enabled visible racial-cultural people to exist in threatening environments. However, the consequences of vigilance against repressive environments also created unnecessary personal and group self-doubt, alienation, and isolation from resources and support, thus limiting a person's ability to achieve their full potential.

2.2 Cultural Pluralism and Cross-cultural Psychology

While cross-cultural, diversity, multicultural, and cultural pluralism have been used interchangeably, these terms have generally referred to people who are members of visible racial-cultural groups (e.g., American Indians, Blacks, Asians, Latinos). Recognizing the health disparities of these visible racial-cultural groups, the cross-cultural psychology movement has been focused upon improving mental health services for members of these groups. Thus, cross-cultural psychology presumed that 'cross-cultural counseling problems were most likely to occur when there was a low degree of client–counselor assumed similarity… [where] the practitioner is…a member of the majority group and the client is a minority group member…[and] include[s]…counselor/therapist and client…minority individuals, but represent[ing] different minority groups ([B]lack-Hispanic, Asian-American-American Indian, (Sue et al. 1982, p. 47). By appreciating group differences, cross-cultural psychologists believed that understanding racial-cultural group specific knowledge (e.g., values, customs, communication patterns) would eliminate racial-cultural mental health disparities. For example, misunderstandings arising from cultural variations in values and language were suggested as antecedents to early psychotherapy terminations at rates greater than 50 percent compared to 30 percent for White clients (Sue and Sue 1999).

Recognizing the majority of mental health educators and practitioners are White, professional organizations developed guidelines endorsing cross-cultural culture-specific heritage education about specific visible racial-cultural groups (e.g., Blacks, American Indians, Asian and Pacific Islanders, Latinos) in hopes that sensitizing White practitioners to issues of '*culturally different*' people, practitioners would become more effective counselors (American Psychological Association 1991, Sue et al. 1982, 1992). For example, a plethora of information exists about group specific racial-cultural knowledge about self-expression, norms, family structures, and values for 'special populations' (e.g., restraint of emotions and hierarchical relationships for Asian American clients, extended family and religion for Latino and Black clients and harmony and cooperation among American Indians). (It should be noted that these categories have been recently expanded to include Whites, socioeconomic status, ethnicity, religion, gender, age, etc. and effects of institutional racism, classism, and sexism (Sue and Sue 1999).)

Thus, cross-cultural educational strategies have virtually used 'othered' focused (Sue and Sue 1999) or universal (Fischer et al. 1998, p. 561) perspectives when teaching about cultural issues. If cultural pluralism and cross-cultural psychology have been effective in equity and inclusion of underserved visible racial-cultural groups, why does racial-cultural separatism continue to exist?

Several reasons can account for this ongoing separatist phenomenon. Overall, cultural pluralism has not provided meaningful principles about psychological well-being. Beyond obvious axioms such as all humans have language, social systems, emotions, and values and cultural norms, identification of group understanding perceived specific racial-cultural groups by group comparisons has neglected existing within group variation. The results have been simplistic

caricatures about service delivery, cultural norms, and group homogeneity. Consequently, using a social constructivist approach, multicultural psychologists have begun developing more inclusive, affective, and intrapsychic approaches to applied mental health.

2.3 Moving From Cross-cultural to Multicultural Psychology

Understanding people from a multicultural perspective has meant simultaneously recognizing individual and group identities. From this perspective, culture accounts for internal and external personal and social realities by becoming distinct from biological and geographical heritage. In this regard, the importance of racial-cultural self-exploration of understanding explicit content knowledge and implicit affective processes has been most illustrative in the clinical bias literature where scholars have shown mental health professionals susceptibility to clinical bias (Oakes et al. 1994). Given issues of professional and personal bias, applied psychology and other mental health training programs have been remiss when addressing how personal assumptions influence professional development. Lacking has been a counselor-focused framework incorporating a multiculturally inclusive perspective. By challenging people's beliefs and assumptions about who they are as cultural people, mental health professionals can more realistically contextualize how social, historical, and political processes have influenced their personal and professional development

While the cross-cultural competencies (Sue et al. 1982) were expanded from 11 to 31 in 1992 (Sue et al. 1992), the 1998 multicultural competency guidelines (Sue et al. 1998) have taken a fundamental shift towards being more culturally inclusive by focusing upon issues of within group variation (e.g., counselor *and* client racial–cultural identity development into counseling relationships, interventions, and processes) and proposing greater latitude in defining professional roles and responsibilities. Here, multicultural unlike cross-cultural psychology has suggested mere intellectual understanding of visible racial-cultural groups norms does not meaningfully translate into adequate or sufficient counseling skills.

Thus, the movement from cross-cultural to multicultural psychology has involved a fundamental shift of cognitive learning about (e.g., between group differences) visible racial-cultural groups to an integrated cognitive-affective racial-cultural identity (within group/individual variation) orientation. Thus, clarifying ones' own racial and cultural identities, developing a sense of comfort and self-acceptance within a social, historical, and political framework, and respectfully relating and functioning with all racial-cultural groups have become essential prerequisites for developing multicultural competence (Carter 1995, Sue et al. 1998).

3. Multicultural Psychology and Racial-cultural Identity Development

People throughout time have been challenged to understand their sense of self and life experiences in unifying ways. As critical tools for cultural understanding, racial-cultural identity development models have been considered 'one of the most promising approaches to the field of multicultural counseling/therapy' (Sue and Sue 1999, p. 123). By incorporating sociopolitical contexts, racial identity theories have provided a structure of how to understand life experiences, perceptions, attitudes, and behaviors of one's own and other racial-cultural groups, identity formation and intra-group variation.

Diagnostically, racial-cultural identity models also have clinical utility by framing how individuals' experiences of counseling are influenced by their racial-cultural identity and not simply linked to presumed racial-cultural group affiliations (Carter 1995).

Racial-cultural identity attitude theories are dynamic identity models representing developmental ego differentiation and have existed for Blacks, other visible racial-cultural people (e.g., Asian, Latino, women), and Whites since the early 1970s (Sue and Sue 1999). Racial identity attitudes are the psychological consequences of racial socialization.

Whereas people are socialized in racialized environments, racial-cultural ego identity development is the psychological reaction to the benefits and consequences of racial-cultural social systems. Involving simultaneous perspectives of oneself in relation to members of dominant and subordinate groups, people with less developed racial-cultural ego identity statuses hold more simplistic and unexamined notions about race and race relations while greater differentiated racial-cultural ego identity statuses are based on more accurate and examined personal and group information and experiences. Thus, a person's presumed racial-cultural phenotype does not preclude racial-cultural orientation. Rather, a person's overall psychological self that has been validated, denied, or ignored influences the manner in which racial identity has been integrated into one's personality and psychological well-being. By exploring the psychological aspects of how feelings, thoughts, and behaviors people have about their own and other's race, a more realistic understanding of *who* a person rather than *what* a person is becomes possible.

3.1 Racial Identity Theory

Based upon internal racial identification levels, racial identity models have provided a framework for understanding intra-group socio-racial psychological perspectives. According to Black racial identity theory (and more broadly, People of Color Identity Theory), Black people develop from (a) overvaluing and idea-

lizing White cultural norms and internalizing negative stereotypes of Blacks (Preencounter); (b) feeling confusion as they try to understand their previously held beliefs of White superiority and Black inferiority (Encounter); (c) affirming 'Blackness' and denigrating 'Whiteness' by idealizing African cultural heritage and withdrawing from White society (Immersion); (d) accepting strengths and weaknesses of Black people and incorporating a more affirming and realistic Black identity (Emersion); (e) intellectually assessing and responding to Whites (internalization); and (f) integrating a positive Black identity while maintaining a balanced perspective of 'Whiteness' motivated by personal preferences rather than racial group self-denial (Integrative Awareness) (Carter 1995).

In White racial identity theory, identity development involves the abandonment of racism and the development of a non-racist White identity by moving from (a) being unaware of their own racial group and ignoring the race of others (Contact); (b) becoming aware of the saliency of Whiteness, feeling guilty over personal internal standards and societal norms about race and over-identifying with Blacks (Disintegration); (c) rejecting Blacks and over idealizing Whiteness (Reintegration); (d) intellectualizing rather than emotionally understanding race (Pseudo-Independence); (e) exploring biases and redefining Whiteness by trying to change Whites instead of Blacks (Immersion/Emersion); and (f) emotionally and intellectually internalizing a positive White identity through appreciation for and respect of racial differences and similarities (Autonomy) (Carter 1995).

Overall, for visible racial-cultural people, as members of less powerful sociocultural groups, the primary socioracial identity issue in developing racial-cultural identity means overcoming internalized negative stereotypes associated with their racial-cultural group affiliation. For Whites, as members of the dominant sociocultural group, racial-cultural identity development means overcoming entitled stereotyping, learning self-value and appreciation as a White person. Therefore, in efforts to serve as racial-cultural change agents, all people must seek and promote racial-cultural affirmation—the experience of having various facets of their racial-cultural identities validated for themselves and by others. Thus, the strength of racial-cultural identity models has relied upon their dynamic nature of understanding within group racial-cultural variation within a social, historical, and political context as well as their diagnostic value for informing counseling processes and outcomes.

Whether its socio-political forces vs. poor psychological functioning, racial-cultural issues are silent or powerful environmental and psychological realities in a person's development. By examining how racial-cultural issues influence psychological phenomenon, therapists can help clients discover how their racial–cultural ego identity forms a filter which thoughts, feelings, and behaviors organize perceptions and interpretations of thoughts, emotions, and psychological life. To this end, racial-cultural identity models provide a framework understanding personal racial-cultural intrapsychic phenomena with in and between people.

4. *Conclusions*

Since the 1970s, scholars, educators, and applied mental health professionals have become increasingly aware that for the needs of all clients to be met, multicultural psychology is a needed and essential change for the profession (American Psychological Association [APA] 1991). However, since the original cross-cultural counseling competencies position paper (Sue et al. 1982) to the latest multicultural competences (Sue et. al. 1998), educators' ambivalence towards programmatic multicultural education has continued through decreasing multicultural-related courses in counselor preparation programs (Hollis and Wantz 1994), lack of comprehensive training models (Ridley et al. 1994) and professionals who continue to perceive themselves as having limited multicultural counseling competence providing mental health services (Allison et al. 1994).

Since intellectual knowing does not necessarily translate into sufficient multicultural counseling competence, multicultural psychology in the twenty-first century must mean looking beyond the cross-cultural 'tyranny of shoulds' of cultural groups differences toward racial–cultural self-reflection. Since mental health professionals' worldviews are neither neutral or culture free, questions posed, studies designed, and results interpreted will be inherently influenced by their racial-cultural perspectives.

As Gordon (1999) so aptly states:

> I like to remind people who cannot recognize it that I am an African-American male, born in the United States in the 20th century, and that these things influence me and what I do. They influence the way I think about things. When I identify a problem, to investigate, I bring my African-American, 20th century, male person to bear on it. That person is likely to be somewhat different from some of my colleagues who do not share my particular background and identity.... each of us bring to our work may be different. Most important is that those perspectives may influence our respective findings as well as our interpretations – even though we may like to think of findings as being objective (p. 150).

Thus, cognitively and affectively understanding ones' own racial and cultural identities and developing a sense of comfort and self-acceptance are essential prerequisites for developing multicultural competence. Accordingly, cognitive-affective reflective learning of personal and social identities has been shown to be a powerful and effective method of developing multicultural counseling competence (Carter 1995).

For example, an ecological person-process training framework has been successful in allowing trainees to

gain multicultural counseling competence (Tomlinson-Clarke and Ota Wang 1999). Allowing examination of *who* a person is, this model has emphasized how intra-/intergroup processes influence personal and social racial-cultural identity development. Here, people have been conceptualized within interlocking dynamic systems of: personal individual interactions (microsystem); institutions directly influencing individuals (mesosystem); institutional policies (exosystem); and the overall zeitgeist (Tomlinson-Clarke and Ota Wang 1999).

Unfortunately, while everyone has potential to develop multicultural competence, sociocultural environments have often imposed barriers of *conformity*, *prejudice*, and *oppression*, limiting essential cognitive and racial-cultural flexibility. Moreover, to varying degrees, people have been overtly or covertly subjected to these obstructions. For example, in *conformity*—the prevalence of expected societal, institutional or self-imposed mythical ideals (e.g., White, blonde, blue-eyed people are smarter than those who have darker complexions) have often resulted in feelings of inferiority for those who do not fit these ideals and of superiority for those who do. Beyond limiting, these mythical ideals have also prevented others from recognizing the value of diversity. In *prejudice*—those who hold the power in society and in institutions have denied equity to people who are different from them by conveying messages of 'you can't be successful unless your phenotype, attitudes, and behaviors are similar to ours.' Because prejudice promotes group and cultural superiority, its destructive forces have artificially separated racial-cultural groups. And with *oppression*, this barrier has been socially and personally destructive due to mythical prescriptions for visible racial-cultural people to be *what they are not* while exploiting them for *being who they are* as means for keeping them from true full participation in society.

So how can social scientists nurture the development of multicultural psychology? A discipline hoping to understand, and value diversity must identify and eliminate overt and covert conformity, prejudice, and oppression in its institutions and members. Additionally, programmatic multicultural programs with goals of recognizing, respecting and learning from individual and cultural similarities and differences will combat the present day mythical social ideals and stereotypes resulting in the exploitation, coercion, and oppression of all people. While difficulties exist in eradicating xenophobia and notions of individual, group, and cultural superiority/inferiority, these obstacles will be outweighed by the ultimate rewards of all people having the opportunity to develop into their fullest personal, social, and racial-cultural potential. Thus, educators will need to continue developing training programs to incorporate cognitive/affective racial-cultural learning so counselors will be prepared to realistically work with inherent human variation. By clarifying ones' own racial and cultural identities and developing a self-acceptance, counselors will be able to respectfully and effectively work with all racial-cultural groups. Thus, the growth of multicultural psychology will depend on those who teach, research, and practice to continually develop themselves as racial-cultural people. Institutional support will provide the fertile ground necessary to do this work of moving beyond ignorance, tolerance, to meaningful understanding. Ultimately, the results will be a world where multicultural psychology is a lifestyle lending itself to an openness of understanding *who people are* rather than *what they are imagined to be*.

Counseling Psychology

This article is about the science and profession of counseling psychology. Key distinguishing features of counseling psychology are described, as are the main roles and work settings of counseling psychologists. In addition, basic areas of scientific inquiry are discussed.

Counseling psychology is a specialty field within the broader discipline of psychology. This specialty is related to, but also different from, several other psychology specialties that are often characterized by the term 'applied.' The psychology specialties to which counseling psychology is most closely related are clinical, community, school, and industrial/organizational psychology. Although each of these fields seeks to study and understand human behavior empirically, the fields also share the mission of applying scientific understandings to the solution of human problems and the betterment of peoples' lives. It is in this sense that they may be termed applied specialties.

As is the case with any field or specialty, counseling psychology originated from a broad matrix of social, economic, and psychological forces. Its beginnings may be traced to the early part of the twentieth century. However, the designation of counseling psychology as a specialty within the American Psychological Association (APA) first occurred in 1952. For historical analyses, the reader is referred to Gelso and Fretz (2000).

1. Counseling Psychology: Distinctiveness and Diversity

In this section, the features that make counseling psychology a unique specialty within psychology, as well as the breadth and diversity of this field, are described.

1.1 The Unifying Themes of Counseling Psychology

As a way of clarifying the features that make for its distinctiveness, Gelso and Fretz (2000) proposed five unifying themes of counseling psychology. These themes, which have received substantial endorsement in the field, are briefly described below. The themes are best viewed as central tendencies, for there is also great variability around each theme.

The first unifying theme is a focus on intact, as opposed to profoundly disturbed, personalities. In earlier days, counseling psychology was thought of as a field that focused only on 'normal' problems. Today, psychologists trained in this fieldwork with clients at all levels of disturbance. However, in comparison to other health service fields such as clinical psychology and psychiatry, counseling psychologists continue to work more with clients closer to the normal range, and to devote more time to issues of psychological health and wellness.

The second unifying theme is the focus on assets and strengths, regardless of clients' level of disturbance. Indeed, attention to strengths has been a hallmark of this specialty, and is most evident when counseling psychologists engage in preventive and developmental interventions, as opposed to remedial ones. Preventive and developmental interventions, rather than emphasizing emotional problems that have already emerged, seek to prevent problems and enhance growth. A few of the numerous examples of such interventions are enhancement treatments for couples who do well but want to improve further, career counseling for clients who want to understand fields that fit them best, and consultation with business organizations to help create healthy work environments.

The third unifying theme is emphasis on relatively brief interventions. Counseling psychologists engage in a wide range of interventions, for example, counseling, consultation, guidance. Also, many practitioners in this specialty conduct long-term psychotherapeutic treatments. However, a hallmark of the field has always been an emphasis on brevity. The use of the term 'counseling' is a reflection of this tendency, and currently popular brief therapies fit closely with such a counseling orientation. Generally, therapy lasting less than six months is seen as brief, although most counseling psychology interventions are of much briefer duration.

Emphasis on person–environment interactions is a fourth unifying theme. From its inception, counseling psychology has sought to balance the intrapsychic and the environmental, both in understanding development and in formulating interventions. Theories that have focused largely on intrapsychic explanations, such as psychoanalysis, have not had wide appeal. Current attention to the role of culture and multicultural issues is an example of counseling psychology's commitment to incorporating the role of situation and environment in understanding personality and development, and in providing effective interventions.

The final unifying theme, perhaps more than the others, reflects counseling psychology's distinctive-

ness. The field's emphasis on educational and career development and environments has often been seen as its most distinctive feature. Throughout its history, counseling psychologists have theorized about and empirically investigated issues around career choice, problems, interests, development, and interventions.

1.2 Fundamental Features of the Field

There are certain features of this field that, while not necessarily distinctive, are so fundamental as to require mention. First, counseling psychology is a doctoral level field in the USA in that the large majority of US psychologists who use the title counseling psychologist, and who join the Division of Counseling Psychology of APA, hold a doctoral degree. Second, since the specialty's beginnings, it has strongly endorsed the scientist-practitioner model of training, which dictates that doctoral programs seek to train students as scientific researchers as well as practitioners of counseling psychology.

A third fundamental feature of the field is its attention to issues of culture, multiculturalism, and diversity. Although all fields within psychology have begun to pay attention to diversity in terms of race/ethnicity, sexual orientation, gender, religious beliefs, and physical disability, counseling psychology has been at the forefront in these areas for many years. Attention to issues of diversity pertains to, for example, recruitment of doctoral students and faculty, empirical research and theory, and counseling practice. The fundamental emphasis on culture and diversity in the specialty is evidenced in chapters in the most recent edition of the *Handbook of Counseling Psychology* (Brown and Lent 2000) on the role of race and social class in development; gender, sexuality, and sexual orientation; gender issues in counseling; and models of multicultural counseling.

1.3 The Roles and Functions of Counseling Psychologists

Information on where counseling psychologists work and what they do is basic to understanding this specialty. Gelso and Fretz (2000) present data on job settings indicating that over half the counseling psychologists who were members of the Division of Counseling Psychology (DCP) of APA were employed in college and university settings, either in academic departments (35 percent) or counseling centers (17 percent). A major change in recent years has been the increased appeal of independent practice, with approximately 20 percent of DCP members claiming this as their primary job. Furthermore, since many counseling psychologists who are in independent practice do not join the DCP, the 20 percent figure is likely a significant underestimate.

The remainder of counseling psychologists are distributed across a wide range of job settings, including hospitals (e.g., general, psychiatric, Veterans Administration), clinics, government agencies, business and industry, and rehabilitation facilities. Surveys over several decades indicate that these job patterns have been generally quite consistent, except for the increase in independent practice since about the mid-1980s, and a decline in the numbers of counseling psychologists in Veterans Administration centers.

Regarding job activities, the most basic finding of all surveys is that counseling psychologists are involved in an extensive range of activities. A significant number devote at least some of their work time to counseling and psychotherapy (individual, group, couples, family); consultation; psychological testing, assessment, and evaluation; research and writing; teaching, training, and supervision; and administration (Gelso and Fretz 2000). At the same time, the activities performed by the greatest numbers for the greatest amount of time are counseling and psychotherapy.

2. Scientific Inquiry

The major areas of theory and research in counseling psychology reflect the above discussion. Below are described key scientific issues and topics in this field.

2.1 Methodological Considerations

A fundamental quality of science in counseling psychology since the late 1970s has been its emphasis on diversity of research methods and approaches (Heppner et al. 2000). As pointed to by most reviewers, beginning in the late 1970s, there has been an increasing press to incorporate research methods that go beyond the 'received view,' for example, quantitative-experimental research.

Within the context of this methodological pluralism, two notable patterns may be seen. First, stemming from postmodern thought that is evident in all scholarly disciplines, there has been a growing interest in the use of qualitative research approaches (Morrow and Smith 2000). Such approaches use verbal or even visual rather than quantitative data, gather data by observing and listening to what people do and say, and present results in the form of verbal descriptions and theories rather than statistics.

A second pattern actually moves in the opposite direction from qualitative research. That is, there has been a major increase in the use of highly sophisticated quantitative methods. Multivariate statistical methods now appear to be as common as univariate approaches. Especially prominent are techniques that seek to permit causal inferences from correlational data, for example, structural equation modeling.

2.2 Counseling and Therapy: Theory and Research

Regarding psychological interventions, counseling psychologists study essentially the same therapeutic process and outcome questions as do other applied counseling fields, for example, clinical psychology. After many years of outcome research, it is clear that, on the whole, therapy is effective; researchers now seek to discover what treatments are most effective when offered by what therapists for which clients experiencing what problems (Gelso and Fretz 2000).

Beyond this general statement, there are some therapy theories and topics that have been most influential in counseling psychology. Broadly speaking, cognitive-behavioral and experiential-humanistic theories of counseling have had the greatest impact (Heesacker 2000). As part of the strong cognitive-behavioral influence, theories such as Albert Ellis' rational-emotive behavior therapy (see *Behavior Psychotherapy: Rational and Emotive*), Aaron Beck's cognitive therapy (see *Cognitive Therapy*), and Albert Bandura's social cognitive theory (see *Social Cognitive Theory and Clinical Psychology*) have been particularly appealing to researchers and practitioners. Psychoanalytic theories have historically been less attractive to counseling psychologists, partly because these theories have conflicted with some of the major emphases of the field (e.g., strengths and assets, brevity, environmental influences). Fundamental paradigmatic changes in psychoanalysis in recent years, however, have made some of its theories (e.g., psychoanalytic self-psychology) more appealing (Gelso and Fassinger 1992). Social psychological conceptions have also had great appeal in recent decades. Theories such as social influence theory have been creatively extrapolated to counseling and therapy, and their propositions extensively investigated (Heesacker 2000).

2.3 Multicultural Counseling and Research

As noted, counseling psychologists have closely attended to diversity for many years. Since the early 1980s, however, there has been a mushrooming of theory and research on counseling and development as related to culture and diversity. The topic that has gathered the most scientific momentum is that of race and ethnicity in psychological development and treatment. This momentum is evidenced in the form of the high rate of articles on race, ethnicity, and culture in leading journals; major handbooks on the topic (e.g., Ponterotto et al. 1995); the creation of new journals; and the publication of texts and significant chapters. Although race and ethnicity are the most frequently studied topics under the umbrella of diversity, there are others. In recent years there has been a significant surge of research on gay, lesbian, and bisexual issues in counseling and development. The study of gender, which may be placed within the diversity category, has been central in counseling psychology for nearly three decades (Heppner et al. 2000).

2.4 Career Development and Intervention

Whereas the development of theory and research on diversity topics has increased at a dramatic pace in recent decades, the topic of career development and intervention has been a mainstay of counseling psychology since its inception. Many consider this the strongest and most empirically mature area within the specialty (Heppner et al. 2000). As part of this strength and maturity, robust theories of career development and choice guided theory and practice over many years (e.g., theories by Holland, Super, and Krumboltz). There exist a number of journals, handbooks, and texts aimed at studying and elaborating career development and intervention processes. In keeping with the diversity movement, recent decades have witnessed much attention to career development in the lives of marginalized people. The study of career development and intervention in womens' lives has been particularly prominent over many years.

2.5 Training in Practice and Science

The tandem topics of counselor training and researcher training are key areas of investigation. Of the two, counselor training and supervision has had the longer life. In particular, theory and research on the process and outcome of counselor supervision have been prominent since the late 1970s. Especially notable have been developmental models of counseling supervision, wherein therapists are theorized as developing in certain stages, and supervision approaches need to be matched to those stages (Stoltenberg et al. 1997). Regarding research training, theory and research have examined both person and research training environment factors that contribute to graduate students' and psychologists' interest in, sense of efficacy for, and production of research and science (Gelso and Lent 2000).

2.6 Healthy Functioning and Human Effectiveness

Research and theory in this general area are natural extensions of two key unifying themes described earlier: focus on intact personalities and attention to people's strengths. Although attention to positive qualities is a deep and widely shared part of the specialty, theory and research on the topic within counseling psychology had waned for a number of years, to the point that Gelso and Fassinger (1992)

viewed this area as counseling psychology's 'unfulfilled promise.' However, there has been an upsurge of scientific attention to well functioning. The study of positive constructs such as subjective well-being, career self-efficacy, and problem solving all fit this thrust. So, too, does the emerging examination by counseling psychologists of biopsychosocial factors that promote positive physical health (Hoffman and Driscoll 2000).

Counterculture

First, the word: 'counterculture' came into common usage largely as a result of the success of historian Theodore Roszak's bestseller, *The Making of a Counter Culture* (1969), a book about the movements of the 1960s. Earlier, J. Milton Yinger had used the term 'contraculture' in an article in *The American Sociological Review* (1960) concerned with distinctions among subcultures. But in a later comprehensive treatise, *Countercultures* (1982), Yinger yielded to the broad adoption of Roszak's usage.

Whether counter- or contra-, the prefix suggests opposition, and in the 1960s there were plenty of oppositional movements in Europe and the Americas against what was taken to be the dominant culture. That culture was conceived as a set of values—and practices which either (a) manifested those values (in which case the values were opposed as oppressive or repressive), or (b) contradicted them (in which case the practices were condemned as hypocrisy).

In either case, the oppositional movements, which ranged across the institutional landscape, emphasized 'liberation' from the constraints of dominant norms which were, more or less, enforced by authorities in each of the institutional domains. What had previously been regarded as 'deviance' from those conventional norms becomes countercultural when the deviants themselves begin to defend and celebrate their values and practices as wholesome, appropriate, desirable, or healthy, and seek to attract adherents.

Any ambiguity between counterculture as the word specifically designating the oppositional spirit of the 1960s, and its more general oppositional meaning, can be clarified by observing that the movements of the 1960s had predecessors to which they are historically linked. Similarly, one of the accomplishments of culture theory in recent decades has been to highlight the diversity of cultures (i.e., subcultures) contained within the notion of a national (or 'dominant') culture. Indeed, part of the dominance of a dominant culture is that *its* culture is taken to be *the* culture when, in fact, almost any group (e.g., ethnic, occupational, or age groups)—being sufficiently insulated from the dominant culture and/or interacting primarily or exclusively with its own members—may be expected to generate (or imperfectly sustain if already established) a set of values and practices—sometimes even an argot or lingo of its own—that defines its distinctive mode of life.

Seen in this context, countercultures are a subcategory of subculture, having a distinctively oppositional posture toward the dominant culture, unlike most other subcultures, which may differ from the dominant culture in several respects but are seldom essentially or overtly oppositional. The counterculture of the 1960s affirmed the Dionysian character of rock music and shared (among other things—an exhaustive listing is not practical) a taste for psychedelic drugs, consensual nonpossessive sex, emotional candor, colorful dress, ecstatic dance, racial equality, avant-garde esthetics, religious mysticism, and communal living. Along with their more politically militant comrades in the New Left, these counterculturalists

shared a distaste for the Vietnam war, bureaucracy, authority, impersonality, consumerism, careerism, corporate capitalism, some (though not all) technology, and 'suburban' blandness. Any such description has the status of what Max Weber called an 'ideal type': no specific counterculture group is likely to carry every one of these features—they characterize an 'ideal' counterculture.

The values and practices of this counterculture were of course regarded by many as outrageous. That the behavior was usually not actually illegal made it difficult to suppress, especially in societies that guaranteed civil liberties. Rather than violating statutes, some ostensibly common set of implicit rules and sense of propriety were being violated, propriety being one of the important dimensions of social life that culture defines. Countercultures are part of continuing effort to redefine that dimension.

Conceived as a kind of cultural radicalism, then, countercultures have a long tradition. Like all traditions, contemporary expressions of counterculture incorporate some (though not all) of its ancestral features and adds some new wrinkles of its own. Its ecstatic Dionysian character is continuous though any specific expression of it is inevitably affected by current conditions, for example the way in which certain forms of rock music, by appealing to its counterculture audience, is designed to offend others. The milieu of counterculture is evoked in Warren Beatty's film *Reds*, about the Russian revolution. In art it is evident in futurism, surrealism, dadaism, and abstract expressionism; it was there at the birth of cultural modernism in Vienna in the 1890s, and at the turn of the nineteenth century in Munich's then Bohemian district, Schwabing—whose denizens at that time regarded Paris as provincial. Some of it can be seen in the revolutions of 1848 and back beyond that to the Parisian Bohemia of the 1830s whose roots can be found in the cafes of Paris two generations earlier, before the French Revolution: that peculiar mix of populist and democratic, anarchic and communal sympathies combined with 'advanced' tastes in art and 'liberated' ideas about sex, drugs, and general lifestyles. Malcolm Cowley had evoked the tradition in his book *Exile's Return* (1934) about the experience of his 'lost generation' of friends in Europe in the 1920s. Yinger finds evidence of counterculture as early as the seventeenth century in the Ranters of that time.

Since the late nineteenth century, eruptions of counterculture have usually been attributed to 'generations'—usually to a 'younger' generation rebelling against some features of a status quo. While it is true that young people, frequently students, have been prominent partisans of counterculture movements, they have never been anywhere close to a majority of their age-cohort, but rather mostly well-born youth with more education than most of their contemporories. Still, like other group-elites they have often been successful in 'speaking for' their age group; majorities don't matter much in generational rhetoric. Moreover, in order to achieve any success in altering some of the values and practices of the dominant culture, counterculture youth require wider support from groups other than their age-mates. By themselves, 'generations' don't pass legislation, stop unpopular wars, decriminalize marijuana, destigmatize premarital sex, or even abolish the *in loco parentis* functions of college and university administrators.

To achieve such essentially political objectives, counterculture radicals must make common cause with political radicals, but the alliance is an uneasy one and often short-lived. The eventual disdain in the early nineteenth century between the Saint Simonians and Paris's literary Bohemians foreshadowed the mutual disdain between the 1960s counterculture and the New Left ('Heads' and 'Fists', respectively) after they broke apart around 1968. In the 1920s the cultural avant-garde of the Weimar Republic could find no political home; they were an embarrassment to the left-wing parties who feared alienating their culturally conservative working-class constituencies.

There are good structural reasons for the fragilities of the alliance between counterculturalists and political radicals. Counterculture objectives usually focus on matters like art, sex, manners, mores, and other lifestyle issues that involve mostly claims for private rights and liberties not usually requiring basic structural changes in the society. Political radicals, on the other hand, usually aim at achieving basic change in the structures of political power and the distribution of wealth. The different agendas (and therefore the constituencies) of these two versions of radical oppositional movements create tensions between them which are difficult to resolve. The natural constituencies of political radicals are the oppressed or disadvantaged classes with deep grievances and resentments against the privileged classes.

The constituencies of counterculture radicals are harder to designate: not the disadvantaged classes, not 'the people,' but small sectors of the high bourgeoisie, educated professionals, some students at elite universities, some sectors of contemporary culture industries (e.g., film, theater, advertising, fashion) seeking marketable innovation, and other hard-to-classify groups who patronize their efforts, partially adopt their style, ambivalently admire their 'wildness,' and otherwise aid and abet such swings in the fashions of culture.

Because most forms of counterculture are not major threats to the political and economic interests of ruling groups they are frequently (though far from always) tolerated by established powers. Bismarckian and Wilhelmine Germany tolerated a lot of youthful cultural radicalism. The same was true of Franz-Joseph's Austro-Hungarian Empire, and even, for a short time, of the Soviets. In the US, attacks on The National Endowment for the Arts and efforts to suppress the exhibition of 'indecent' or 'pornographic'

art in some museums at the end of the twentieth century succeeded only in dividing powerful elites. Countercultures, then, do not typically need political and economic transformations to achieve their moral and esthetic aims. What they do need are special audiences and publics, free spaces, tolerant ambiances and milieux which are either insulated against the larger political community, or functionally important to it—for example, in the way that colorful 'Latin Quarters' of cosmopolitan cities attract tourist business to them, are defended by active merchants' associations, and are therefore at least tolerated, if not wholly respectable, parts of their economies.

Counterfactual Reasoning: Public Policy Aspects

There is nothing new about counterfactual inference. Historians have been doing it for at least 2500 years. Thucydides invoked counterfactuals when he argued that had it not been for the far-sighted policies of Themistocles, the Persians would have defeated the Athenians at the battle of Salamis—an outcome that many, although not all, twentieth century observers believe might have nipped Western civilization in the bud (cf. Hanson 2002, Strauss 2002). Contemporary social scientists—from Max Weber ([1905] 1949) to Robert Fogel (1964)—have also long been aware of the pivotal role that counterfactuals play in scholarship on such diverse topics as the causes of economic growth and the diffusion of religious and philosophical ideas. Interestingly, though, some scholars have still sternly warned against 'what-might-have-been' questions. They claim that making sense of history is tough enough as it is—as it actually is—without worrying about how things might have worked out differently in this or that fictitious scenario (Carr 1961).

1. The Unavoidability of Counterfactual Reasoning

The ferocity of the critics is a bit unnerving. Moreover, they are certainly right that counterfactual inference is often dauntingly difficult. But they are wrong to say that one can avoid counterfactual reasoning at acceptable cost. And they are wrong that all counterfactuals are equally absurd because they are equally hypothetical (Fisher 1970). Analysts can avoid counterfactuals only if they eschew all causal inference from historical data and limit themselves to strictly noncausal narratives of what actually happened (no smuggling in causal claims under the guise of verbs such as 'influenced,' 'responded,' 'triggered,' 'precipitated,' and the like). Putting to the side the question of whether any coherent and compelling narrative can be noncausal, this prohibition would prevent observers from drawing exactly the sorts of lessons from history that scholars and policy makers regularly draw concerning such topical areas as the best ways to encourage economic growth, to preserve peace, and to cultivate democracy. Without counterfactual reasoning, how could observers know whether state intervention accelerated or retarded growth in a set of developing countries, whether deterrence policies prevented or provoked aggression, or whether the loan policies of international institutions such as the World Bank reduced the risk of financial contagion or increased the risk of moral hazard? In brief, counterfactual reasoning is a prerequisite to any form of learning from history. To paraphrase Robert Fogel's (1964) reply to the critics of counterfactual history in the 1960s, everyone does it and the alternative to an open counterfactual model is a concealed one.

This article surveys the diverse roles that counterfactual arguments play in policy analysis and in political debate. A useful place to begin is by clarifying what is meant by counterfactual reasoning. A reasonably precise philosophical definition is that counterfactuals are subjunctive conditionals in which the antecedent is known or presumed for purposes of argument to be false (Goodman 1983). As such, an enormous array of politically consequential arguments qualify as counterfactual. Consider the following rather representative sample of counterfactuals that have loomed large in recent policy controversies:

If Boris Yeltsin had followed the fiscal and monetary advice of the advocates of shock therapy policies in early 1992, Russian inflation in 1993 would have been a small fraction of what it was;

If the USA had not dropped atomic bombs on two Japanese cities in August 1945, the Japanese would still have surrendered roughly when they did;

If it were not for the affirmative action programs that have existed in the USA since the 1970s, the black middle class would have grown much more slowly than it did;

If Reagan had not adopted such a hard-line posture toward the USSR in the early 1980s, it is very unlikely that the USSR would have been as conciliatory as it was in the late 1980s;

If the liberal social welfare policies of the 1960s had not implicitly encouraged single parenthood, the percentage of out-of-wedlock births in the USA in the 1980s would have been much lower than it was.

2. Distinguishing Sound from Unsound Counterfactuals

What standards of evidence and proof might be used for judging the quality of the counterfactual arguments that underlie so many causal claims in policy debates? In a comprehensive review of the methodological and philosophical literature bearing on counterfactual inference, Tetlock and Belkin (1996) identify six classes of criteria for making such judgments. These are outlined below.

2.1 Clarity

Good counterfactual arguments should specify and circumscribe the independent and dependent variables (the hypothesized antecedent and consequent). This initial recommendation might strike readers as obvious. Like actual experiments, thought experiments should manipulate one cause at a time, thereby isolating pathways of influence. Although excellent advice in principle, implementing it is often deeply problematic. As Jervis (1997) documents, there is no way to hold 'all other things equal' when we perform thought experiments on social systems that are densely interconnected. To invoke the terminology of experimental design, the 'independent' variable in interconnected systems cannot be manipulated without creating ripple effects that alter the values taken on by other potential causes in the historical matrix, thereby creating 'confounding' variables that render the interpretation of the original thought experiment problematic. For example, if Boris Yeltsin had lived in a Russia in which he felt it was feasible to pursue shock therapy policies in 1992, there is a good case to be made that this hypothetical Russia differs from the actual Russia in a host of other ways (less corruption and reduced influence of special interests) that might also have been more conducive to better economic performance.

2.2 Logical Consistency or Cotenability

Good counterfactual arguments should specify the connecting principles that link the antecedent with the consequent with sufficient precision that it is possible to gauge whether those connecting principles are cotenable with the original antecedent. Every counterfactual claim represents a condensed or incomplete argument that requires connecting principles that sustain, but do not imply, the conditional assertion. When explicitly articulated, these connecting principles are often complex, even in the case of such deceptively simple counterfactuals as 'if the match had been struck, it would have lighted.' The connecting principles specify, within reasonable limits, everything else that would have to be true to sustain the counterfactual, including the necessary amount of friction generated by the contact of the match against the surface, the chemical composition of the match, the absence of water, and the presence of oxygen.

These usually invisible connecting principles are sometimes in direct tension with the historical antecedent that has been altered in the counterfactual. One example is Jon Elster's (1978) critique of Robert Fogel's (1964) counterfactual assertion that if the railroads had not existed, the American economy in the nineteenth century would have grown only slightly more slowly than it did. Elster did not show that Fogel was wrong but he did show that it is nonsensical to postulate as a supportive connecting principle the proposition that the internal combustion engine would have been invented earlier in a USA without railroads because that proposition presupposes a theory of technological innovation that undercuts the original antecedent. If we have a theory of innovation that permits the invention of cars 50 years earlier, why does it also permit blinding people to the potential of railroads? In a similar vein, some critics have taken to task John Mueller (1988)for his counterfactual claim that, even in the absence of nuclear weapons, the Cuban missile crisis would not have escalated into war. This is an even more straightforward violation of cotenability of antecedent and connecting principles. Why would the USSR go to all the trouble of placing conventionally armed intermediate-range missiles in Cuba? Why take so large a risk for so small an advantage?

Taken together, the previous two standards—the logical clarity and cotenability standards—are helpful for screening out ambiguous and oxymoronic counterfactuals. But they define a bare minimum for quality-control purposes. Additional, historical and theoretical standards are needed for winnowing out other forms of 'what-if' foolishness.

2.3 The Minimal Rewrite Rule

Good counterfactual arguments should specify antecedents that could possibly have been implemented given the political and economic constraints at work in the situation. As shall soon be evident, there are occasions when scholars and policy analysts want to override this rule. However, historians do frequently apply it and many policy makers sympathize. What is the point of wondering about the effects of a policy that never had the remotest chance of being implemented? There is indeed little point in doing so if one is interested solely in judging whether policy makers selected the best of the politically feasible options at that historical moment. But there is good reason for doing so if the goal is to delineate the conditions under which particular policy interventions are likely to have particular effects. For instance, political leaders in industrialized countries during the Great Depression

may have correctly surmised that they had little choice but to resort to protectionist policies. To suppose that they could have acted otherwise may be historically naive. But from the standpoint of drawing useful policy lessons for the future, it is important to assess to what degree the economic downturn of the 1930s was exacerbated by the proliferation of beggar-thy-neighbor tariffs that thwarted application of the logic of comparative advantage.

2.4 Theoretical Consistency

Compelling counterfactuals should rest on connecting principles that are consistent with well-established theoretical generalizations relevant to the hypothesized antecedent–consequent linkage. Otherwise, analysts cannot rule out counterfactuals that start from reasonable antecedents but end in far-fetched consequences by invoking preposterous principles of causality such as: 'If Oswald had not shot Kennedy, then someone else would have done so, because Kennedy was astrologically fated to die by assassination' or 'If North Korea had conquered South Korea in 1950, the economy of the South would have grown even more rapidly than it actually did because of the wisdom of the policy of self-sufficiency of the Great Leader Kim Il Sung.'

Ideally, all counterfactual inferences could be grounded in extensively validated scientific laws of the sort drawn upon in the match-lighting conditional. Occasionally, this is possible: Witness physicist Richard Feynmann's compelling thought experiment (with the assistance of a glass of ice water) that demonstrated the key role that cold-sensitive O-rings played in the explosion of the space shuttle Challenger in 1986 (Vaughan 1996). More often, however, policy analysts must rely on more fragile—and controversial—connecting principles drawn from the behavioral and social sciences.

2.5 Statistical Consistency

Compelling counterfactuals should rest on connecting principles that are consistent with well-established statistical generalizations bearing on the antecedent–consequent linkage. In many contexts, we rely not on theoretical laws but on statistical generalizations to fill in 'what would have happened if this rather than that event had occurred.' One obvious form such reasoning takes is reliance on base rates and patterns of co-variation. For instance, an observer might justify the counterfactual, 'If Bill Clinton had lost the presidential election of 1992, he would have been disappointed,' by observing in a two-by-two contingency table that when people fail to achieve a goal for which they have worked long and hard, the overwhelming majority experience disappointment, but when people do achieve their goals, there is markedly less disappointment. This discovery is hardly startling; statistical counterfactual arguments can, however, be made more controversial. Econometric modeling techniques can be used to reconstruct how the US economy might have performed if the invention of railroads had been delayed or whether slavery might have disappeared as a result of the operation of market forces (no Civil War necessary?). Or regression and time-series techniques might be used to infer how extensive out-of-wedlock births would have been in late twentieth century USA if welfare benefits had been lower or higher across states since the 1970s (inferences that rest on controversial but at least well-defined analytical assumptions).

2.6 Projectability

Good counterfactual arguments should lead to testable implications that help to make sense of antecedent–consequent links in other contexts. Theory evaluation and counterfactual evaluation are inextricably entangled. Sound counterfactuals require sound theories that provide the law-like generalizations that fill in the missing data points in our thought experiments. How can social scientists judge, however, whether these law-like generalizations are robust enough to support counterfactual inferences? Here Nelson Goodman's (1983) concept of projectability is helpful. Goodman draws a sharp distinction between coincidental generalizations that just happen to be true at a particular time and place (and are therefore unprojectable) and robustly law-like generalizations that hold up over a range of circumstances and permit projection into the past and future. An example of a merely coincidental generalization is 'All the coins in my pocket yesterday were silver.' Nothing follows from this observation—certainly not 'If this penny were in my pocket yesterday, it would be silver.' The counterfactual fails because 'if this penny were in my pocket yesterday,' the reader would simply assume that the original generalization—'all the coins in my pocket yesterday were silver' was false. By contrast, a robustly law-like generalization—such as that oxygen is a necessary but not sufficient condition for fire—inspires confidence when the reader moves either backward in time (if there had been no oxygen, the Great Fire of London would not have occurred) or forward in time (if we cut off any future fire's source of oxygen, the fire will expire).

Many social scientists view projectability as the acid test of scientific legitimacy. The same causal principles that allow observers to retrodict the past should make it possible to predict the future. Indeed, the strong Popperian form of this argument asserts that observers should take counterfactual claims seriously if and only if the law-like generalizations supporting the claims

yield falsifiable forecasts. This classic philosophical argument has resurfaced in the recent methodological advice of King et al. (1994), who urge scholars to search aggressively for the observable implications of their causal constructs by regularly asking themselves, 'If my argument is correct, what else should be true?' Counterfactuals that are devoid of testable implications in the actual world leave historical observers marooned in hypothetical worlds of their own subjective making. Projectability, from this vantage point, stands as the pre-eminent criterion for judging the value of counterfactual speculation.

3. *'Consciousness Raising'*

There are special classes of counterfactual arguments that thoughtful people may not want to subject to the conventional historical and social science tests—counterfactuals that are designed primarily to open otherwise closed minds. Tetlock and Belkin (1996) dub such arguments 'gadfly counterfactuals.' Here it is, however, worth noting the intense skepticism of many psychologists. They doubt the capacity of the human mind to escape its preconceptions when it undertakes mental simulations of possible worlds. It is just too easy for political partisans to conjure up answers to 'what-if' questions that reinforce their prejudices: what could be more natural than for liberals to fill in the missing counterfactual control conditions of history with ideologically consonant scenarios ('of course, subtract out the Reagan presidency and replace it with a two-term Carter presidency and a Mondale follow-up, and the USSR disintegrates pretty much in the same way it did') and for conservatives to reach the opposite counterfactual conclusion. Indeed, such beliefs are often held with such conviction that they feel factual, not counterfactual.

But there are also psychological reasons for suspecting that people are not always fated to be prisoners of their preconceptions (Tetlock 1998, 1999). Here it is worth dwelling on some intriguing parallels between the mental process of simulating what would have happened in possible worlds and that of constructing computer simulations of natural or social phenomena (Cederman 1997). Both the computer software and the mental wetware exercises require making explicit previously implicit and ill-thought-through assumptions. In the course of running these computer or mental simulations, one can in principle learn a great deal about hitherto concealed gaps and contradictions in one's knowledge. As Kahneman (1996) points out, mental simulations derive their persuasive force and power to surprise people by revealing unnoticed tensions between explicit, conscious beliefs and implicit, unconscious ones. In this sense, people discover aspects of their political belief systems in mental simulations that would otherwise have gone undiscovered. It is useful to distinguish three specific ways in which mental simulations can yield insights into one's own thought processes: by revealing double standards in moral judgment, contradictory causal beliefs, and the influence of unwanted biases such as certainty of hindsight.

3.1 *Counterfactual Morality Tales*

Mental simulations can compel people to acknowledge embarrassing inconsistencies in their application of moral rules. The paradigmatic example is the identity-substitution thought experiment that manipulates either the perpetrator or victim of a policy act and asks the audience to contemplate whether they had the same emotional reaction to what actually happened as they would have to various hypothetical events. For example, 'if Bosnians were bottle-nosed dolphins (or if Rwandans were white or if Chechnyans were Lithuanians …), the public never would have tolerated the slaughter of innocence so long.' Insofar as the audience detects a discrepancy in their reactions to the scenarios, and insofar as the audience firmly believes that the mentally manipulated cause should be irrelevant, the audience will deem the discovery of a differential emotional reaction to be a disturbing fact about themselves, that is, to be cognitively dissonant. Of course, not all political leaders fold when they are accused of moral inconsistency: The famously anti-Bolshevik Winston Churchill responded to those who probed how uncomfortable he felt about being aligned with Stalin in World War II by invoking a counterfactual argument of his own to the effect that if Hitler were to invade Hell, Churchill would find a way of making a favorable reference to the Devil in the House of Commons.

3.2 *Counterfactual Consistency Probes*

These mental simulations reveal contradictions between causal beliefs that may have previously coexisted within a belief system. The paradigmatic example is the syllogism that traces the logical implications of one set of beliefs to the point where the contradiction becomes undeniable. For example, 'if you really believe there is that much indeterminacy at the microlevel (factors that determine the outcome of battles, the success of firms, the policies of bureaucratic units of government), even invocations of the 'miracle of aggregation' do not allow you to argue for so strongly deterministic a position at the macrolevel (the outcomes of wars, the performance of economies, the political stands of governments).' Or, 'if you adopt an extreme structural-realist position that denies any significant role to domestic politics in shaping properties of the international system, then you would have to belief that even if the USSR had been a democracy in 1945, the Cold War would still have occurred.' In these cases, the thinker has the dissonance-reduction

options of changing one or both sets of beliefs, introducing new cognitions that neutralize the contradiction, or disengaging from the simulation exercise by simply ignoring the contradiction.

3.3 Counterfactual Exercises as Means of Stimulating the Imagination

Retrospective scenario generation is a form of mental stimulation in which the goal is to prevent premature cognitive closure induced by certainty of hindsight. Some scholars (e.g., Weber [1905] 1949) have long suspected, and cognitive psychologists have now demonstrated (e.g., Fischhoff 1975), that 'outcome knowledge' contaminates our understanding of the past. Once people learn the outcome of an event, they not only perceive that outcome as more likely *ex post* than they did *ex ante* (which might be defended as a rational Bayesian updating of subjective probabilities), they systematically misrecall their *ex ante* assessments as more consistent with that actual outcome than those assessments really were (the 'I-knew-it-all-along' effect).

Counterfactual thought exercises can check the 'creeping determinism' of certainty of hindsight. Asking people to think of how things could have worked out differently becomes a means of preventing the world that did occur from blocking our views of the worlds that might well have occurred if some antecedent condition had taken on a different value. Indeed, there is a 'debiasing' literature in experimental psychology that assesses the usefulness of encouraging people to imagine that the opposite outcome occurred. There is also a literature in literary studies on the concepts of sideshadowing, foreshadowing, and backshadowing in narratives that makes a strikingly similar normative point (for reviews, see Tetlock and Belkin 1996). Sideshadowing calls attention to what could have happened, thereby locating what did happen in the context of a range of possibilities that might, with equal or even greater likelihood, have taken place instead. Sideshadowing serves as a valuable check on foreshadowing (the tendency, in extreme form, to reduce all past events to harbingers of the future) and backshadowing (the even more insidious tendency to judge historical actors as though they too should have known what was to come).

4. Closing Remarks

The topic of counterfactual thought experiments in public policy leaves many social scientists feeling a bit uneasy, even defensive. To be blunt, it feels like epistemological slumming. There is, in the behavioral and social sciences, a prestige hierarchy of methods for drawing causal inferences. At the top of the pecking order is experimentation in which investigators can manipulate hypothesized causes and then either hold everything else constant (*ceteris paribus*) or randomize extraneous influences across treatment conditions. Experimental control of this sort is occasionally possible in the domain of public policy: There have been some well-known experimental attempts to assess the impact of various drug treatment programs and social welfare programs. By and large, however, experimentation is hopelessly impractical. We cannot rerun the tape of history to assess the causal impact of Gorbachev's policies of glasnost and perestroika or to assess the impact of Reagan's defense build-up or tax cuts.

Social scientists often resort to statistical control when experimentation is ethically or practically problematic. But statistical arguments invariably rest on counterfactual assumptions and are extraordinarily difficult to justify in many policy contexts. For example, what kind of regression or time series analysis will allow us to estimate the causal contribution of nuclear weapons to the 'long peace' between the USA and USSR between 1945 and 1991? There are too many confounding variables—a problem that can be alleviated but not eliminated through judicious selection of comparison cases and meticulous examination of decision-making protocols (Fearon 1991).

So where does this leave the field? Probably still feeling uneasy: Social scientists and policy analysts seem to be stuck with quite literally a third-rate method, i.e., counterfactual thought experimentation. The control groups exist—if 'exist' is the right word—only in the imaginations of the policy analysts who are left with the daunting task of trying to reconstruct how history would have unfolded if causal variables from the past had taken on different values from the ones that they actually did. The whole exercise starts to look hopelessly subjective, circular, and nonfalsifiable. What is to stop ideologues from simply inventing counterfactual outcomes that serve to justify their political biases and predilections? There appear to be large classes of policy questions for which experimental control is out of the question and statistical control is of limited usefulness (assuming that one can find suitable comparison cases and can reliably operationalize the key conceptual constructs). These questions are too important to ignore but apparently too difficult to answer in a fashion that transcends traditional ideological divisions.

Too often, the response to the dilemma is to embrace extreme solutions (Strassfeld 1992): either to reject all counterfactual arguments as fanciful suppositions, mere conjecture, and frivolous figments of policy analysts' imaginations or to assume confidently that we know exactly what would have happened if we'd gone down an alternative path, sometimes going so far as to project several steps deep into hypothetical causal sequences. The former response leads to futile efforts to exorcize all counterfactuals from historical inquiry; the latter response leads at best to error (we

ignore the compounding of subjective probabilities at our peril) and at worst to the full-scale politicization of counterfactual argumentation (as advocates claim *carte blanche* to write hypothetical histories that advance their ideological agenda).

This article has articulated a principled compromise between these extremes. On the one hand, it is necessary to acknowledge that counterfactual thought experiments inevitably play key roles in the causal arguments that animate many policy controversies. On the other hand, it is necessary to acknowledge that counterfactual thought experiments are often suffused with error and bias. But, that said, it is not appropriate to conclude that things are hopeless—that it is impossible to draw reasonable causal inferences from historical data when experimental and statistical control are not available. Rather, the preferred conclusion of this article is that disciplined use of counterfactuals—grounded in explicit standards of evidence and proof—can be enlightening in specific policy settings.

Counterfactual Reasoning, Qualitative: Philosophical Aspects

1. Supposition

To reason about an hypothesis counterfactually is to reason about what *would be true*, on the supposition that the hypothesis *were true*. Such reasoning is naturally expressed in the form of conditional sentences couched in the subjunctive mood, for example:

If this glass had been struck, then it would have shattered.

The implication is that, in fact, the glass was not struck and did not shatter; hence the term *counterfactual*, or contrary-to-fact, conditional. However the same kind of reasoning applies in situations where the truth–value of the antecedent is an open question, as for example in the open subjunctive conditional:

If this glass were struck, then it would shatter.

This suggests that the terms *subjunctive conditional* and *suppositional reasoning* might more appropriately delineate the topic. But since the term 'counterfactual' is well entrenched, it will suffice to stipulate that one may reason 'counterfactually' about hypotheses that turn out to be true.

The philosopher Frank Ramsey once remarked: 'If two people are arguing "If p will q" and are both in doubt as to p, they are adding p hypothetically to their stock of knowledge and arguing on that basis about q' (Ramsey 1990). Ramsey seems to have had open conditionals in mind, but the comment has been taken

by some to suggest a general pragmatic account of conditionals, that has become known as the Ramsey test: a subjunctive conditional is accepted in a belief state if and only if the consequent of the conditional is accepted when the belief state is adjusted so as to accommodate the hypothesis that the antecedent be true.

'Accommodating' the hypothesis must be more than just a matter of adding it to one's stock of beliefs, since to extend Ramsey's idea beyond the open case is to admit that the hypothesis may be inconsistent with one's prior beliefs. The 'adjustment' should, at the very least, leave the belief state consistent. But the adjustment might also reasonably allow for what Isaac Levi (1996) calls *inductive expansion*, the addition of further beliefs that are not entailed by the hypothesis.

This might suggest that the problem of counterfactual reasoning is one and the same as the problem of rational revision of belief. But there is a catch. Rational revision of belief is generally held to be subject to the following condition:

> Preservation: If the evidence to be accommodated is consistent with the prior belief state, then any proposition accepted in the prior belief state will still be accepted in the revised belief state.

Example: if you come to believe that Phar Lap won the 1930 Melbourne Cup, and this piece of information is consistent with everything you previously believed, then you should not respond by rejecting any of your old beliefs. Information is valuable and should not be discarded unnecessarily.

The catch is this: the Preservation condition and the Ramsey test are inconsistent with one another on pain of triviality. This result is known as Gärdenfors' theorem (Gärdenfors 1988, Sect. 7.4). It is closely related to the Lewis trivialization theorem described in the companion article.

The moral of Gärdenfors' theorem is that counterfactual reasoning has a logic of its own, distinct from the theory of the rational revision of belief. Supposition is not the same thing as belief revision. Entertaining the hypothesis A counterfactually is a matter of determining what one believes would be true, were A true. This must be distinguished from the different process of determining what one would believe to be true if one came to believe that A is true. Consider, for example, the difference between reasoning about what would have happened if Oswald *had not* killed Kennedy, and reasoning about what did actually happen if (surprise!) Oswald *did not* kill Kennedy.

2. *Imaging*

Revision is a matter of moving from a prior belief state to a revised belief state so as to accommodate input in the form of propositional evidence. Widely accepted criteria for the rational revision of belief have been developed by Alchourrón, Gärdenfors, and Makinson (Gärdenfors 1988). These criteria are usually referred to in the literature as the *AGM axioms*. Among them is the Preservation rule, along with the following natural conditions:

(a) The proposition to be accommodated must be accepted in the adjusted belief state.

(b) The adjusted belief state should be consistent if both the prior belief state and the proposition to be accommodated are consistent.

Gärdenfors' theorem tells us that supposition cannot satisfy all of the AGM axioms, since it is a method of belief adjustment that fails to satisfy Preservation. So what can be said about the logic of supposition?

Agents typically agree on some matters of belief and disagree on others. In general, given two agents, we may talk about the beliefs that they *share*. A shared belief is simply a proposition accepted by both agents. Those shared beliefs may themselves be thought of as forming a potential belief state; the strongest belief state compatible with what both agents believe. Now if you and I both adjust our beliefs in order to accommodate the same proposition there will be an adjustment to the beliefs that we share. How might the adjustment to our shared beliefs be determined? One simple answer to that question would be provided by the following principle:

> Composition: the adjustment to what is shared between belief states is what is shared by the adjustments to those belief states.

Call a method of belief adjustment that satisfies (a), (b), and the Composition principle an *imaging* method. The central result of the logic of supposition may now be stated: in the presence of conditions (a) and (b), the principle of Composition is equivalent to the Ramsey test condition. So, by the Gärdenfors theorem, AGM revision cannot be compositional. But supposition will be. Supposition—that is to say, counterfactual reasoning—is always a matter of imaging.

Example: it is a sunny day and Alice and Bob are driving to Versailles. They have been there twice before. They share the belief that it was raining on exactly one of those occasions. Alice believes it was raining on their first visit, but Bob believes it was raining the second time. Alice says: 'If it *had* rained the second time we were there, then since it rained the first time too, it would have been raining on both occasions.' Bob does not have to adjust his beliefs to entertain the hypothesis that Alice considers counterfactual; he thinks it is true. Cher is sitting in the back seat. She does not know whether Alice or Bob is correct, but she is tired of their argument. Cher thinks to herself, 'If Bob is right then if it had rained the first time they were there, it would have rained both times, but if Alice is right, then it would have still have been fine the second time.' Cher concludes, 'So, if it *had* rained the first time they were there it might have

rained the second time and it might have been fine the second time.' But Cher also thinks, 'If it *did* rain the first time they were there, then Alice is right and it was fine on their second visit.' Cher's belief state consists of the beliefs shared by Alice and Bob. When Cher supposes that it rained the first time, the suppositional state is obtained by counterfactual adjustment of the shared beliefs, which by Composition is the state that consists of those beliefs common to the states obtained after Alice and Bob make that supposition separately. This suppositional state is distinct from the revised belief state that Cher would be in if she were to learn that it is Alice who is remembering events correctly.

This section concludes with a demonstration of the close connection between counterfactual supposition as imaging and the Stalnaker–Lewis semantics for the subjunctive conditional described in the companion article.

Consider the subjunctive conditional: 'If this glass were struck, then it would shatter.' By the Ramsey test, I accept this conditional when my supposing that the glass be struck leads to my concluding that the glass would shatter. Since supposition goes by imaging, this means that the image of my belief state on the hypothesis that the glass be struck entails that the glass shatter. But imaging is compositional, so taking any more detailed account of the way things might be that is consistent with what I believe, and forming the image of that on the hypothesis that the glass be struck, must also result in a state that entails that the glass shatters. This remains true for the most detailed accounts of all, which might as well be called 'possible worlds.' To accept the conditional is to believe that the actual world is such that its image on the hypothesis that the glass be struck entails that the glass shatters. Call those worlds compatible with the image of the actual world on the antecedent the *closest* worlds at which the antecedent is true. Then to accept the conditional is to believe that all the closest worlds at which its antecedent is true are worlds at which its consequent is true. The conditional whose acceptance conditions are given by the imaging Ramsey test is revealed as none other than the Stalnaker–Lewis conditional.

3. *Subjunctivity*

The role of subjunctivity in nonconditional contexts is illuminated from a rather different angle by attempts to correct the expressive limitations of conventional formal languages. Crossley and Humberstone (1977) observe that one sense of the three-way ambiguous sentence:

It is possible for every red thing to be shiny

cannot be rendered in the standard language of modal logic. The possibility operator may be positioned inside or outside the scope of the universal quantifier, but neither formulation captures that third sense whose expression seems to require recourse to the logic of *actually*:

It is possible for everything *that is actually red* to be shiny.

If the modal operator 'possibly' functions like an existential quantifier over possible worlds, allowing us to roam freely over the domain in search of a world at which the embedded sentence is true, then 'actually' functions to *switch off* that operator temporarily. In the example just given, it forces us to return to our own world when it comes to determining what the relevant red things are. Humberstone (1982) remarks that 'actually' may be viewed as an *inhibitor*: a sentential operator that shields whatever is within its scope from the influence of other external operators.

Thus 'actually' has a function that is the exact opposite of the kind of semantic role Castañeda (1967) ascribes to subjunctivity. As Humberstone puts it, expressive inadequacies like the above are overcome in languages in which the subjunctive mood functions to *switch on* or to *activate* an otherwise dormant external operator. So, to adapt an example of Quine (1956), the ambiguity of the English sentence:

I am looking for a dog that talks

is resolved in Spanish via the indicative/subjunctive distinction. 'Busco un perro que habla' ('*habla*' indicative) means that there is a particular dog I am looking for that just happens to talk. 'Busco un perro que hable' ('*hable*' subjunctive) suggests that I do not have any particular dog in mind, any talking dog will do. The subjunctive element activates the 'looking for' operator at that point in the sentence, signaling that the dog's talking is to be understood as part of the content of my seeking. In Spanish (at least) desire contexts are among those naturally activated by the subjunctive.

4. *Desire*

DAB: To desire something is to believe it desirable.

An argument similar to the proof of the Gärdenfors theorem establishes that DAB also conflicts with Preservation (Collins 1988). But DAB is the simplest form that a cognitivist theory of motivation might take. So if cognitivism is not to be ruled out on purely logical grounds, 'desirability' must be interpreted suppositionally. Thus: a possibility is believed desirable just in case the supposition that the possibility be true leads to the conclusion that ones desires would be satisfied. Similarly, the expected desirability of an option is a belief-weighted average of the desirabilities of more specific ways the option might be realized. A *suppositional decision theory* obtains the expected desirability of an option by imaging on the supposition that the option be chosen. But this is none other than the *causal decision theory* (described in 'Newcomb's problem'). There is an argument for causal decision

theory that bypasses the usual discussions of Newcomb's problem.

Counterfactual Reasoning, Quantitative: Philosophical Aspects

This article should be read in conjunction with its companion (see *Counterfactual Reasoning, Qualitative: Philosophical Aspects*). Here, after a general introduction and historical overview, we emphasize the role of counterfactual reasoning within the quantitative frameworks of probability theory, decision theory, and game theory.

1. Counterfactuals

Counterfactuals are a species of conditionals. They are propositions or sentences, expressed by or equivalent to subjunctive conditionals of the form 'if it were the case that A, then it would be the case that B,' or 'if it had been the case that A, then it would have been the case that B'; A is called the *antecedent*, and B the *consequent*. Counterfactual reasoning typically involves the entertaining of hypothetical states of affairs: the antecedent is believed or presumed to be false, or contrary-to-the-fact, but its truth is imagined or supposed. Counterfactual reasoning is thus a form of *modal* reasoning, kindred to reasoning about necessity or possibility, and in constrast to reasoning about the way things actually are.

The philosophical study of conditionals goes back at least as far as the Stoics of ancient Greece, although their systems of logic apparently did not accord the counterfactual any emphasis. The rise in interest in counterfactuals has been a rather recent phenomenon, as it started to become clear to philosophers that counterfactuals are implicated in a host of other important concepts—laws of nature, confirmation, causation, scientific explanation, knowledge, perception, dispositions, free action, etc. The significance of counterfactuals has also become increasingly appreciated in the social sciences—by psychologists (e.g., in understanding emotions such as regret), by historians (e.g., in studying the incremental contribution by some commodity to economic growth), in the law (e.g., in apportioning responsibility), etc. However, a widely agreed upon analysis of counterfactuals has proved elusive. The so-called *problem of counterfactuals*, raised notably by Chisholm and by Goodman in the 1940s, is that of providing adequate (in particular, noncircular) truth conditions for the counterfactual.

Let '$A \Box\!\!\rightarrow B$' denote a counterfactual with antecedent A and consequent B. Fixing the truth value of A and B clearly does not fix the truth value of $A \Box\!\!\rightarrow B$. For example, 'if I were to drop this fragile glass, it would break' is true, 'if I were to drop this fragile glass, it would turn into a hamster' is false, yet the antecedents ('I drop this fragile glass') and consequents ('the glass breaks,' 'the glass turns into a hamster') are all false. This rules out as an adequate analysis the material conditional $A \supset B$ (defined to be equivalent to 'not-A or B'), which is automatically true when A is false. According to *metalinguistic* approaches, $A \Box\!\!\rightarrow B$ is true if and only if A, together with suitable further premises (on one version, stating appropriate laws of nature and initial conditions), implies B. Mackie takes counterfactuals to be themselves elliptical presentations of such arguments, and thus lacking truth values altogether. The advent of possible worlds semantics for modal logics in the 1960s gave new direction to the analysis of counterfactuals. Truth conditions for them are proposed in classic works by Stalnaker (1968) and Lewis (1973).

Stalnaker motivates his account by Ramsey's recipe for counterfactual reasoning ('Ramsey's test'): First, add the antecedent (hypothetically) to your stock of beliefs; second, make the minimal adjustments required in the rest of your beliefs to maintain consistency; finally consider whether or not you then believe the consequent. Stalnaker's truth conditions are intended to apply generally to conditionals of the form 'if A, then B,' which Stalnaker denotes '$A > B$,' pragmatics distinguishing between indicative conditionals and counterfactuals. He assumes that for each world w there is an ordering of worlds according

to their similarity, or 'closeness,' to w. Call a world at which A is true an *A-world*; the proposition A is regarded as the set of A-worlds. His guiding idea is that $A > B$ is true at a world w if and only if B is true at the closest A-world to w.

Lewis rejects Stalnaker's assumption that, for any given w and A, there is exactly one closest A-world to w. His truth conditions take as primitive the notion of comparative closeness of worlds: $A \Box\!\!\rightarrow B$ is true at w if and only if some AB-world is closer to w than any $A\bar{B}$-world. For both Stalnaker and Lewis, the counterfactual is vacuously true if the antecedent is impossible.

2. *Probabilities of Counterfactuals*

One important line of research considers counterfactuals within the quantitative framework of probability theory. In particular, there has been much interest in the connection between *probabilities of conditionals* (of which counterfactuals are an important class) and *conditional probabilities*. Let P be your subjective probability function, so that $\mathrm{P}(A \Box\!\!\rightarrow B)$ is your degree of belief in $A \Box\!\!\rightarrow B$. There are various reasons (linguistic intuitions, considerations stemming from Ramsey's test, etc.) for thinking that counterfactual reasoning is, or should be, subject to the following constraint: (*) $\mathrm{P}(A \Box\!\!\rightarrow B) = \mathrm{P}(B|A)$ for all A, B in the domain of P such that $\mathrm{P}(A) > 0$.

Stalnaker proposed a version of this identity, which can be shown to vindicate his truth conditions above, and to vitiate Lewis's. In response, Lewis (most famously in 1976) proved a number of 'triviality results': under certain assumptions, the only classes of probability functions that can sustain (*) consist solely of members that take at most four values, and that are thus trivial. Since then, a number of authors have strengthened these results (see Eells and Skyrms 1994 for a collection of relevant articles).

Nonetheless, an identity somewhat in the spirit of (*) does hold for the Stalnaker conditional. Start with probability function P. Among other things, P assigns probabilities to individual worlds. Define a new probability function P_A as follows: for each world w, P_A shifts the probability that P assigns to w to the closest A-world to w. P_A is said to be derived from P by *imaging* on A. Some authors model counterfactual reasoning by imaging (eschewing conditional probabilities as in (*)). Lewis (1976) shows that there is an intimate connection between the Stalnaker conditional and imaging: $\mathrm{P}(A > B) = \mathrm{P}_A(B)$ (for all P, A and B). The exploration of tenable variants of (*) is likely to continue to be a lively area of research.

3. *Counterfactual Reasoning in Decision Theory*

The distinction between probabilities of conditionals and conditional probabilities is important for decision theory, a normative theory of how one's beliefs and desires in tandem determine what one should do. Such a theory typically combines an agent's utility function u and probability function P to give a figure of merit for each possible action, called the *expectation* or *desirability* of that action. Let $S_1, S_2, \ldots, S_n$ be a partition of possible states of the world. *Evidential decision theory*, as presented by Jeffrey (1966), measures the choiceworthiness of action A by a conditional probability-weighted average of the utilities of its possible outcomes (the conjunctions A and S_i):

$$\mathbf{V}(A) = \sum_i u(A \& S_i)\mathrm{P}(S_i|A) \qquad (1)$$

It thus prescribes that an agent acts so as to maximize $\mathbf{V}$. Various authors believe that evidential decision theory gives incorrect verdicts in Newcomb problem cases, in which an action is thought to be evidence for the obtaining of a given state, without in any way causing that state (see *Newcomb's problem*). This has led to the development of rival versions of decision theory, sharing the name *causal decision theory*, that replace the 'evidential' conditional probability weights with weights that are supposed to capture the agent's degrees of belief about the causal efficacy of the action in bringing about each possible state of affairs. Gibbard and Harper (1981), following Stalnaker, use probabilities of counterfactuals as the weights

$$\mathbf{U}(A) = \sum_i u(A \& S_i)\mathrm{P}(A \Box\!\!\rightarrow S_i) \qquad (2)$$

They then advocate the maximization of $\mathbf{U}$. Proponents of causal decision theory believe that it agrees with evidential decision theory in unproblematic cases, and that it delivers intuitively correct answers in Newcomb problem cases.

4. *Counterfactual Reasoning in Game Theory*

Counterfactual reasoning can play a crucial role in the rational deliberation of two or more agents strategically playing against each other, their pay-offs depending on what they all do—the province of *game theory*. Paralleling the distinction we found in decision theory, Stalnaker (1996) distinguishes two sorts of counterfactual reasoning, *causal* and *epistemic* (the latter could also be called *evidential*). In the former, agents reason about what would happen if they or others were to act in ways that they know or believe to be nonactual. In the latter, they consider how their own or others' beliefs would change if they were to learn things that they expect not to learn, for example, contrary to what is standardly taken to be common knowledge (and thus regarded as certain) by all the players, an irrational choice is hypothetically made. Indeed, such (epistemic) counterfactual reasoning leads naturally to some important refinements of Nash equilibrium, such as Selten's subgame perfect and ('trembling hand') perfect equilibrium (see *Game Theory*).

Various models have been proposed of how an agent's beliefs are disposed to change in the face of unexpected actions by others, and the consequences of such dispositions for rational action—see, for example, Bicchieri (1988) (for extensive form games) and Stalnaker (1996) (for normal form games). Closely related is Shin's (1989) theory of equilibrium in normal-form games. He gives a counterfactual-based account of rationality—a rational agent never acts in such a way that he would have done better had he acted differently—and proves that his account is equivalent, under certain assumptions, to those that employ game theory's standard solution concepts of Nash equilibrium and correlated equilibrium. Skyrms (1998) integrates the themes that we have discussed in this and the previous two sections. He gives a probabilistic theory of subjunctive conditionals that finds its inspiration in (*), with 'assertability value' replacing the 'P' on the left-hand side, and expectation of conditional chance replacing the right-hand side. He then uses this theory to give a unified treatment of counterfactual reasoning in individual decision theory, and in normal form and extensive form games.

Finally, in what might be taken as an indicator of a future trend in this field, more and more sophisticated probabilistic models are being developed for the representation of conditional beliefs in games. The economists Battigalli and Siniscalchi (1998), for example, construct a space of infinite hierarchies of conditional probability systems in which one can represent any statement about the players' dispositions to hold (arbitrarily high-order) beliefs regarding the other players.

Courtroom Consultation: Psychology

This article is written from a US perspective. A domain now about three decades old, 'psychology and courtroom consultation' involves applying psychological theory and techniques in order to assist litigants present maximally effective trial presentations to juries that are as sympathetic as possible to litigants' claims. Also called 'trial consultation,' 'litigation consultation,' 'jury (de)selection,' and 'jury science,' the field grew dramatically toward the close of the twentieth century along several dimensions, including number of practitioners, scope of activities, level of public recognition, and debate over its ethical and legal legitimacy.

1. Historical Context

The first well-publicized instance of social scientists serving as jury consultants was the trial of Philip Berrigan and seven other defendants charged with criminal conspiracy involving numerous anti-Vietnam War activities. Faced with defending their clients, known as the 'Harrisburg Seven,' in the conservative community the federal government had chosen for the trial, the defense attorneys asked a group of social scientists, headed by Jay Schulman, a Columbia University sociologist, to help select a favorable jury from a largely unfavorable community. Using special public opinion surveys, the team interviewed hundreds of citizens to determine what background characteristics were correlated with pro-prosecution and pro-defense attitudes. They then used these empirical relationships as the basis for recommending which prospective jurors the defense attorneys should 'strike' from the panel. The trial ended in a hung jury (the vote was 10–2 for acquittal). Based on this outcome and several other highly visible trials throughout the 1970s in which politically liberal defendants relied on social scientists for jury selection advice and were found not guilty, trial consulting blossomed into a cottage industry.

In the first decade of psychology and courtroom consultation, consultants typically worked for poor defendants or socially unpopular individuals charged with political crimes. Their work was often done *pro bono*, and after the death penalty was approved by the Supreme Court in 1976, a particular focus of what was then called 'jury selection' was on defendants charged with capital crimes. Capital litigation proved to be a major training ground for jury consultants in part because the jury selection process (known as *voir dire*) is expanded in the typical death-penalty trial and in part because juror attitudes tend to correlate more strongly with beliefs about penalties than with assessment of evidence. As jury consultation became better known, its application spread to civil trials and to litigants with greater financial means. A landmark was MCI's antitrust suit against ATT in 1980, in which the MCI plaintiff team relied heavily upon jury consultant recommendations and won a nearly two billion dollar judgment.

By the 1990s, what had begun as a largely volunteer activity born from social consciousness and intellectual curiosity had become a large commercial enterprise associated with trials carrying enormous financial stakes. Jury consultants were credited with major roles in several trials involving the wealthy and the privileged, including O. J. Simpson, William Kennedy Smith, Imelda Marcos, and a host of large corporations. Consultants such as Jo-Ellan Dimitrius and Donald Vinson received a level of media attention normally reserved only for celebrities. Some consulting firms now employ scores of doctoral-level researchers and consultants and generate millions of dollars in fees annually. Formed in 1982, the American Society of Trial Consultants is the field's main professional organization; it has published a *Code of Professional Standards* that is a statement of aspirational practices rather than an enforceable set of regulations. On-line trial consulting was introduced in the 1990s; one service impanels 'cyberjuries' to listen to evidence and render mock decisions that can be analyzed by consultants and trial attorneys (Strier 1999).

2. *Techniques of Psychology and Courtroom Consultation*

Courtroom consultation is not limited to weeding out unfavorable prospects from juries although that goal has received inordinate attention in popularized accounts. Recognizing that jurors' demographic and personality characteristics usually do not correlate strongly with group verdicts in general, litigation consultants have turned their focus to studying intensively the dynamics and issues of each specific case (Vinson and Anthony 1985). Therefore, courtroom consultation applies many techniques to the detailed analysis of the individual case and considers how the main issues in that case will be evaluated by different types of jurors. Among the techniques employed by trial consultants, the following five are the most important:

2.1 *Public Opinion Surveys*

Consultants conduct public opinion surveys, usually by telephone, to measure the attitudes and beliefs of residents in communities from which jurors subsequently will be drawn. These surveys yield empirical profiles of favorable and unfavorable jurors, which are then used to guide the exercise of *peremptory challenges*, the mechanism by which attorneys arbitrarily deselect a certain number of individuals from serving on a jury. Although demographic and personality characteristics tend to show modest-at-best correlations with case-relevant beliefs, life experiences (e.g., personal victimizations, individual litigation history), attitudes about social issues, and general values can be fairly robust predictors of verdict tendencies and therefore are the focus of many surveys.

2.2 *Focus Groups and Mock Juries*

A favored tool is the pretrial focus group or *mock jury* in which the consultant arranges for a jury-sized group to evaluate an abbreviated,'dress rehearsal' version of the upcoming trial, including opening statements, evidence, and closing arguments. The focus group then discusses the evidence and makes individual and group decisions as the consultant observes the process. These simulations allow the consultant to pre-test several dimensions of the upcoming trial—impact of attorney styles, coherence of the theory of the case, clarity of exhibits, and persuasiveness of the overall presentation—before a group of people selected to resemble the real jury. Focus groups are sometimes repeated more than once before a trial, giving the litigation team the opportunity to gauge the effects of variations that were suggested from initial iterations of this methodology. In a few complex, lengthy trials, consultants have impaneled a mock jury to listen to the case simultaneously as it unfolds before the real jury, providing day-by-day data on how the trial is being perceived and enabling suggestions for mid-course corrections and adjustments.

2.3 *Pretrial Investigations; In-court Observations; Post-trial Interviews*

Consultants use several techniques to gather information about individual jurors. Pretrial investigations of jurors' backgrounds or interviews with key informants who know specific jurors are employed, but both methods have two drawbacks—resentment over what jurors perceive as an invasion of privacy and

limitations in the reliability and validity of informant data.

Consultants emphasize the in-court observation of prospective jurors as a basis for their advice on exercising peremptory challenges. A key element in this strategy is to evaluate prospects' answers to questions that have been crafted carefully to reveal their beliefs, biases, and preferences. In addition to the content of the answer, the nonverbal cues associated with jurors' responses reveal attitudes as well. For example, aloofness toward one type of person coupled with deference toward another may suggest authoritarianism, a juror quality generally not favorable for criminal defendants. Another technique is to conduct post-trial interviews with the jury to assess the validity of the consultant's decisions and to learn how the jury evaluated the trial. This method is not always available because some judges prohibit such interviews.

2.4 *Modification of Attorney Style; Enhancement of Voir Dire; Preparation of Witnesses*

In addition to studying and predicting juror behavior, litigation consultants often attempt to modify aspects of litigant behavior or influence the litigation process itself. In both instances, the purpose is to use psychological knowledge or techniques to gain an edge over the opposing litigant. For example, consultants can teach attorneys how to ask questions of prospective jurors so they are comfortable revealing their true feelings about sensitive topics of crime, race, justice, and punishment. Open-ended questions, often prefaced by a self-disclosure by the attorney, are effective in this regard as are those active-listening techniques used by contemporary psychotherapists. Similarly, consultants often recommend how *voir dire* can be conducted so that the maximum amount of candid information can be obtained from prospective jurors without biasing other members of the panel. Creating special questionnaires to be completed by prospective jurors prior to trial is a prime example. Another strategy is to seek permission to question jurors one at a time on key issues rather than to interrogate them as a group. Whether any of these innovations is used in a given trial is a matter over which the trial judge has almost total discretion so the consultant's role is simply to suggest that the attorney request the judge to allow them.

Most controversial among these techniques is witness preparation. Some consultants help prepare witnesses for their testimony with the intention of assisting them make as effective a presentation of the facts as possible. Other consultants are reluctant to prepare witnesses because of ethical concerns about the possibility of unintentionally encouraging or suggesting changes in the 'facts' to which a witness will testify. In general, most consultants believe that interventions aimed at 'how' the facts are presented or at the 'style' of testimony are acceptable.

2.5 *Development of a Case Theme*

Essential to the success of litigation consulting is the development of a case theme to which prospective jurors will be sympathetic. The modern trial has been likened to a morality play in which an audience of jurors writes the final scene (Nietzel et al. 1998). The first task is to deselect from this audience people whose personal characteristics and experiences might make them unfavorable 'playwrights.' Second, armed with the knowledge gleaned from public-opinion surveys and mock juries, the consultant will attempt to develop a case theme that promotes the plot lines and final resolution most favorable to the consultant's 'side.' This theme will then be reinforced in every way possible. Through the selection of *voir dire* topics, the framing of an opening statement, the structure of evidence presentations, and the building of a closing argument, the consultant will help the attorney repeatedly stress the most salient psychological factors of the case.

Jurors tend to form a narrative or private story that summarizes trial evidence into a coherent, emotionally and cognitively compelling account (Pennington and Hastie 1988). To the extent that a consultant helps an advocate present evidence that advances a captivating narrative, that advocate should improve the chances of a favorable verdict. For example, in the sentencing phase of capital trials, defendants strive for narratives that emphasize personal mitigators of culpability—e.g., youthfulness, psychological disturbance, a history of abuse, and deeply-felt remorse. Conversely, prosecutors fashion stories that emphasize the brutality of the crime, the loss suffered by the victim's family, and the deterrent value of capital punishment. The side that promotes the most convincing narrative enhances its chances of jurors finishing the script with the moral resolution it desires.

3. *Effectiveness of Psychological Courtroom Consultation*

The effectiveness of psychological courtroom consultation is disputed. Its initial successes in the political trials of the 1970s lent it an aura of potency that was exaggerated by the fact that political conspiracy charges are difficult to prove before juries of any kind. An additional confound is that attorneys who make the extra effort to employ trial consultants might also be more diligent in preparing other facets of their cases than attorneys who forego litigation consulting services. In fact, little empirical research evaluating the effectiveness of litigation consulting has been published, and what is available is plagued by questionable methodology (Cutler 1990; Strier 1999), including an over-reliance on mock jury studies. Consequently, it is still not certain whether and to what extent 'scientific jury selection' surpasses the effectiveness of traditional selection strategies. However, Horowitz (1980) did

compare scientific jury selection to traditional attorney methods in four simulated criminal trials. Neither approach was superior across all trials. Psychological consultation was more effective when there were clear-cut relationships between personality and demographic variables and jurors' votes, but when these relationships were weak, consultants' accuracy did not surpass the conventional wisdom of practicing attorneys.

One common claim is that jury consultants are unlikely to exert significant effects because the weak relationships between individual juror characteristics and verdicts would vitiate almost any empirical selection strategy (Saks 1976). In cases where the evidence is about equally persuasive for both sides, or where the trial issues provoke strong attitudes, individual juror characteristics have been shown to exert small to moderate influences (Hastie et al. 1983, Moran and Comfort 1982, Penrod 1990) that provides an opportunity for consultants to have an impact. Further, even when a collection of individual difference variables account for only a small amount of verdict variance, this relationship can still translate into trial outcomes that are of substantial practical importance.

One study of defense-team psychological consultants examined 35 jury verdicts in capital trials (Nietzel and Dillehay 1986). Juries recommended the death sentence in 61 percent of verdicts in trials where no consultants were employed compared to 33 percent of verdicts in trials with jury consultants, producing an effect size of 0.26. Because the cases differed on several variables besides the use of consultants, it is not possible to conclude that the effect was due to consultants, but the results are consistent with claims that consultation might be effective in cases in which juror attitudes are important, as they are likely to be when a jury must choose between life and death.

4. *Ethical and Legal Criticisms*

As the practice of psychology and courtroom consultation expanded, so too have legal and ethical objections to it. Critics have condemned these techniques as 'jury rigging' or 'jury tampering' and claim that they undermine the fairness of trials and the public's confidence in jury verdicts (Adler 1994). Another objection is that courtroom consultants have become affordable only by wealthy individuals or large corporations, producing a fundamental disadvantage for poor or even average-income litigants.

Fueled by these criticisms as well as by outrage over what have appeared to be miscarriages of justice in a few trials where consultants played a major role, public concern about litigation consultation has led to several suggested reforms. The following proposals are the most common (Strier 1999): (a) a complete ban on courtroom consultation; (b) a restriction of *voir dire* such that only limited questioning by the judge rather than the attorneys is permitted; (c) a curtailment of peremptory challenges so that there is less opportunity to remove jurors perceived as unfavorable; (d) a requirement that survey data or other information developed by a trial consultant be shared with the opposing litigant; (e) a prohibition against pretrial investigations of prospective jurors; (f) a requirement that litigants disclose publically their use of consultants; and (g) a suggestion that courtroom consultation be regulated through professional licensure and practice standards.

Few, if any, of these 'reforms' have been implemented, at least in the US, nor is it clear that they would be beneficial or yield fairer justice. The American system of justice is fundamentally adversarial in nature; each litigant is expected to present its case as zealously as possible, within the confines of the law, with the goal of persuading the jury to return a verdict favorable to that litigant. Attorneys on both sides of a case are expected to use every legal means available to woo the jury, present evidence, offer arguments, and counter the opponent in order to win the dispute. The objection that courtroom consultation gives one side an advantage ignores the fact that one side almost always has advantages—a better attorney, more persuasive expert witnesses, more skilled investigators. To single out courtroom consultation, *voir dire*, or peremptory challenges for special curtailments is a slippery slope premised on the faulty notion that each side in a trial can be 'required' to be equal. It is also important to remember that consultants cannot 'stack' juries in their favor; they can only prune juries of individuals they believe are unfavorable. The ability to eliminate jurors perceived as biased through the skillful use of peremptory challenges might be worth preserving, particularly if it enhances the general perception of trial fairness.

Courts and Adjudication

1. Introduction

Adjudication is a type of dispute resolution that relies on an independent, third-party facilitator (Eckoff 1965, Shapiro 1981). Such triadic relationships range from a mutual acquaintance who may serve as a go-between to help conflicting friends, to a powerful state which imposes a resolution on warring neighbors. Within the legal context there are three distinct types of dispute resolution triads: the mediator, the arbiter, and the judge. While all are engaged as third-party resolvers of disputes, they represent a continuum along which the freedom of the parties to the dispute is progressively limited. A mediator will facilitate communication between conflicting parties and perhaps propose a solution, but the parties themselves must agree to this solution. In contrast, an arbiter is a third-party decision-maker, selected and granted authority by the parties to impose a binding resolution.

Judges presiding over proceedings in courts share much in common with mediators and arbiters. All three are independent and strive to bring about a resolution of the dispute that will be perceived to be fair. But adjudication is distinguished from both mediation and arbitration in several ways. Judges are externally appointed by the state and parties have no or very little control over who is selected to hear their dispute. Judges impose authoritative outcomes, but unlike arbiters, judges are expected to render their decisions according to pre-established norms. Furthermore, unlike mediation, adjudication does not require the consent of the parties either to participate or to resolve the disputes. Indeed, typically adjudication is triggered by the action of one party against the other. In some cases, for instance in criminal proceedings, a public prosecutor acting on behalf of the state initiates a proceeding not only against the will of the accused but without the consent of the victim.

Because their proceedings do not require the consent of all parties, courts face a crisis of legitimacy. As a consequence, courts must find substitutes for consent. These substitutes can be understood as a set of principles (Cappalletti 1989). The more important of these are the principle of party participation, the principle of the rule of law, the principle of impartiality, and the principle of independence. Indeed these principles have come to be understood as the defining characteristics of courts. The principle of party participation assures that those likely to be affected by a court's decision have an opportunity to make arguments and offer proofs in their behalf, but it also requires that the court respond with reasoned arguments to these concerns (Fuller 1981). This principle may help account for the propensity of courts almost everywhere to encourage settlements in lieu of full-fledged trials and to value confessions of guilt or acknowledgements of liability. Although such practices have the obvious benefit of reducing the costs and risks of trial, they also provide–even if only symbolically–the active consent of the defendant to the process. The principle of the rule of law prohibits judges from making *ad hoc* decisions; it requires them to render decisions according to pre-existing norms, the rules of the game which both parties have used (or are free to use) to organize their expectations and to arrange their affairs. Both party participation and the rule of law can be understood as approximations for consent. Participation provides parties with a voice and requires that their concerns be addressed; the rule of law presumes a shared set of norms or at least a set of rules under which all the parties operate. As we shall see, the rule of law is not a necessary condition for judicial independence, though it is closely associated with the notion of judicial independence.

The principle of impartiality requires that judges have no interest in the outcome and no reason to favor one party over the other. This is usually achieved through the nature of the office; full-time judges, whose compensation is not dependent upon the outcome of the controversy, do not have any personal interest in the outcome of the controversy or ties to the parties of the dispute.

The related principle of judicial independence holds that the judge is not only independent of one or the other of the parties, but is also independent of other influences as well; the judge's full fidelity is to the rule of law. This poses an obvious and important challenge and may be the most difficult of the principles to implement. At times those not party to a dispute, such as an industry or trade association, may have an interest in pressing for a particular outcome in a case or for a particular interpretation of a rule. More challenging still is that, as officials of the state, judges may be under pressure to adhere to political concerns rather than to the rule of law. Indeed, these two concerns are not always clear and separate. Almost everyone would agree that judicial independence is likely to be jeopardized if political authorities dismiss or force the resignation of judges with whom they disagree or if courts routinely uphold edicts of the

regime that have not been duly enacted. A more subtle problem of judicial independence arises when the state enacts new laws, resists interpretative approaches of the judges, removes issues from the jurisdiction of courts, and seeks to influence judicial selection.

Similarly the issue of independence arises when judges make policy. Typically judges make policy when they confront new situations not covered by existing doctrine or when existing doctrine contradicts deeply held personal or widely supported social norms. In such situations, courts may continue to apply outmoded norms. However, courts might alternatively create new doctrine through any of several institutional devices, such as the use of fictions (Fuller 1967), reliance on metaphors, and reasoning by analogy (Levi 1961), or treat vague and open-ended provisions in constitutions or statutes as grants of authority authorizing them to make new law (Feeley and Rubin 1998). In any of these situations, judges can be criticized for abandoning the rule of law and hence for compromising their independence. Yet judges who insist on following outmoded or restrictive laws also run the risk of being criticized for failing to act independently and for being subservient to an unpopular regime or a new regime. Independence surely means more than freedom to apply a narrowly-prescribed process of interpretation.

No one seriously argues that the modern state lacks authority to enact a wide variety of laws (though constitutional safeguards, conceptions of individual rights, and the like may severely constrain what the state may do and how it must enact laws). Still, the rule of law requires that laws be duly enacted, and publicized. At a minimum an independent judiciary is one which honors and upholds these procedural limits on state power. Still, governments, particularly new regimes following major political realignments or revolutions, may exert strong pressures on the judiciary to fall in line with the 'spirit' of the new regime. The new regime may be impatient with the slow pace of change through the rule of law or may react to what it perceives as a conservative judiciary wedded to the old order; it might exert pressure upon the judiciary to look at things in a new way. Such pressures can take any number of forms, including requesting judicial resignations, altering the procedures for judicial selection and advancement, selecting new judges whose views are aligned with those of the new regime, demoting judges deemed to be recalcitrant, or simply ignoring judicial actions that are deemed unacceptable. This is more difficult in democratic regimes since they are all more or less committed to respecting judicial independence.

Thus it would be a mistake to treat the issue of judicial independence as a problem faced only by authoritarian or totalitarian regimes. In modern states everywhere, judges are governmental officials. In democracies, both the law and the constitution are understood to be products of popular will. Courts everywhere are likely to be affected by, shaped by, and at times in conflict with larger governmental processes in ways that raise issues about the independence of the judiciary. Indeed, since much of the legitimacy of modern government is closely tied to a belief in majoritarian principles and to the rule of law, conflicts between government and courts are all but guaranteed in all sorts of political regimes. This complex relation between law and government, adjudication and politics, and courts and governmental regimes is addressed in the sections below.

2. *Judicial Independence*

The quest for judicial independence in common law and civil law systems has taken quite different forms, though the differences may be due less to the particular legal forms than to the political systems in which they are situated. With the rise of absolutist states in early modern Europe and continuing well into the twentieth century, the judiciary was strongly integrated into the machinery of government and courts were well-known as arms of the ruling regimes. With the rise of support for constitutional democracy in Europe, reformers sought to institutionalize the principles of the rule of law and judicial independence. One of the main objectives of constitutionalism is 'to limit the arbitrary exercise of power and make it legally accountable' (Sartori 1987). Although the rule of law is embraced in all constitutional systems, it has taken quite different forms. In countries with traditions of strong states (which historically have drawn their judiciaries into the service of the state), judicial independence has been pursued by integrating the judiciary into the structure of the civil service, by developing comprehensive codes of law, so that laws are understood as bureaucratic-like rules, and by characterizing judges as technical experts. Judges are free to pursue their duties, but within these severe constraints. This conception of the separation of powers and judicial independence assumes the primacy of the legislature; the legislature represents popular will, and courts play a subordinate although independent role in finding facts and applying rules. Thus in strong states, judicial independence is purchased at the price of a narrow conception of the judicial role.

One can see this in the judiciaries of countries with a civil law tradition, where law is understood as a set of technical rules and judges are considered to be technicians (Merryman 1985). And one can see it in some authoritarian states, where judges have sought to protect themselves by defining their roles narrowly and by insisting on strict interpretations of the law. But where the law involves politically salient issues—such as labor relations or economic regulations—governments everywhere are likely to remove jurisdiction from ordinary courts and establish specialized tribunals more directly responsive to political

controls to deal with disputes. Thus in all countries, a large group of disputes between citizens and the state do not fall under the jurisdiction of independent courts but are assigned to specially created administrative tribunals that are more responsive to governmental direction. Similarly, issues of constitutional interpretation and judicial review, i.e., the power of courts to declare actions of other branches of government unconstitutional, have generally been removed from ordinary courts and assigned to more politically responsive bodies. As a result, many disputes between citizens and the state do not fall under the jurisdiction of ordinary courts, but are instead assigned to special administrative tribunals responsive to governmental direction. Thus, in disputes between individuals which are not likely to raise political controversy, judicial independence is protected, but where issues which may be politically charged, a more politically responsive judicial institution has been established. In a variation on this theme, Damaska has argued that, in regimes with a tradition of a strong or activist state, courts are designed and expected to implement government policy (1977).

In common law countries with traditions of weak states, judicial independence has been protected in a quite different way. Ironically, such common law political systems tend to foster 'strong' courts. Under the common law, the judiciary—and indeed, the entire legal system—has been understood as something distinct and separate from the state. The idea of the rule of law incorporates more than the belief in constitutionalism (i.e., that government officials are constrained by and must act within the law). Rather, it envisions a legal system in which law itself is separate from and independent of government. In these countries the independence of law is protected not so much through a careful civil service-style judiciary and minutely crafted legal codes, but through a robust legal profession and with close associations with the judiciary. Although here too judges are officials of the state, they are also regarded as an integral part of civil society and are closely associated with an autonomous legal profession (Halliday and Karpik 1998). Constitutionalism and the rule of law are understood not only as procedural constraints on the government; they are external limits on the state as well. Under such a system, courts are also likely to have judicial review. Ironically, this conception of the limited state produces a strong judiciary and an expansive notion of judicial independence (Damaska 1986).

It is important to underscore some of the salient differences produced by these two conceptions of courts and of judicial independence. On the European continent, independence is secured by subordinating the role of judges to the democratic principle—the will of the people expressed through parliament—and by insisting upon detailed codes so that judges have no need to make law but only to apply it. Typically this is reinforced by a career judiciary whose initial selection and subsequent promotions are based on seniority or merit. In contrast, common law systems entrust substantial law-making powers to the courts, since the law itself is conceived as something independent of the state and politics. Although there is an admitted political feature to judicial selection, judges are recruited from senior members of the bar, continue to maintain close ties to the bar, and are not dependent upon political authorities for support. Countries elsewhere have often adopted a hybrid of American-like and Continental institutions, though in all but former British colonies, the result has been much closer to civil law than common law style structures.

The differences between civil law and common law systems are familiar to anyone with some exposure to comparative law. Yet these differences only identify central tendencies; legal systems are too varied and too complex to be divided into any such neat categories. For instance in continental systems, even the most comprehensive code is not likely to anticipate all problems that may come within its scope; as a result a judge may have to make law to fill in the gaps. Similarly, law-making in modern common law countries is no longer primarily judge-made; modern law everywhere is increasingly statutory and administrative. Moreover, since the late twentieth century, the independence of civil law judges has been strengthened. In many countries, the government no longer controls judicial careers and judges have begun to play a more active role in law-making.

Furthermore, judicial independence—of either variety outlined above—is much more likely to occur in regimes with competitive political parties. Almost everywhere, one-party or predominant-party states have constrained the independence of the judiciary and sought to use it for their own political purposes. Conversely, countries with competitive parties which alternate in controlling the government or where political parties are weak (e.g., Italy and Israel in the late twentieth century) are more likely to have independent judiciaries. Although all political victors may be tempted to convert the judiciary for their own use, those knowing that they may hold office only temporarily may resist the temptation in order not to jeopardize their long-term interests. Recognizing the harm that each party could impose on the others, parties in competitive political systems all have an incentive to maintain an independent judiciary (Landes and Posner 1975).

3. *The Business and Organization of Courts*

The popular image of trial courts is that they try cases and resolve conflicts. But a careful examination of the process of adjudication reveals a more complex picture. The vast majority of all cases disposed of by courts—perhaps as many as 98 percent— are resolved by the parties themselves, without a full-dress trial.

Indeed, in many cases, there is not even any real controversy. In civil cases, court filings are often treated as signals to the opposing party that the other person is serious about pursuing his or her grievance. This is often enough to precipitate serious negotiations and resolution of the legal conflict. Similarly, in criminal cases in both civil law and common law countries, most matters are disposed of without sustained judicial involvement, through unilateral prosecutorial decisions to drop charges, plea negotiations, or simply pleas of guilty. Indeed, in many countries, vast numbers of lesser criminal cases are disposed of through the mail without even a single court appearance by the accused (Feeley 1979, Felstiner 1979). In many of these situations, some combination of the prospects of the cost, time, and embarrassment of a trial is enough to encourage the parties to negotiate a settlement in the shadow of the courthouse (Mnookin and Kornhauser 1979). In such situations, the court may have been actively involved in the preliminary stages of the conflict and may even have handed down important pretrial rulings dealing with the scope of discovery, the admissibility of evidence, and the like. Such rulings provide cues to the participants as to the likely outcome of their case and thus precipitate negotiations and settlement rather than a prolonged trial process. In such cases, although the court did not formally resolve the conflict, it did nevertheless play an important role in its resolution.

The reasons for negotiations in the shadow of the law are fairly obvious. Filing a case often provides each party with the first opportunity to determine the strength of the opposition. This experience leads weak plaintiffs to drop their cases or to try to settle, and weak defendants to admit liability quickly or to settle. Cases that continue to trial are likely to be close cases in which both parties believe that they stand a good chance of winning. Economists have formalized this model, hypothesizing that, all things being equal, defendants would win (or lose) just as often as plaintiffs in full-fledged trials (Priest and Klein 1984). Although uncertainty, changes in legal rules, and the degree to which an initiated case is controlled by the court can affect this dynamic, in the long run a stable equilibrium should prevail.

At the outset of this article, we noted that one of the problems of adjudication, in contrast to mediation and arbitration, is that the parties neither resolve their own dispute nor select the third-party decision-maker and that this can generate an aura of illegitimacy around the judicial process. If true, this may account for the ubiquitous tendency for parties to settle in the shadow of the courthouse and for courts to foster settlement (Shapiro 1981). Despite this, the tiny fraction of cases that go to full-dress trial provides the public with its perception of the nature of courts and adjudication.

There are still other types of adjudication which for all practical purposes do not involve any real disputes at all. In these situations, rather than adjudicate a controversy, the court simply ratifies or oversees a legal transaction that has been made elsewhere, and often hears no contested issues. Thus for instance, in many countries, trial courts are required to certify divorces, even if they are no-fault. Similarly, trial courts are often required to certify changes of name, uncontested child custody arrangements, conveyances of property, probate and bankruptcy proceedings, and to oversee a host of administrative matters. Many of these actions should be understood more as notary-like activities than as adjudication.

In both civil and common law systems, trial courts are divided into two levels: lower courts which handle minor issues and upper-level courts which are reserved for a handful of more important matters. Although a substantially higher proportion of cases are resolved without formal or full-fledged trial in the lower courts, most issues reaching upper level courts are resolved through negotiations or uncontested proceedings as well. Indeed, when all negotiated settlements and uncontested proceedings at both levels of courts are considered together, one finds that only a tiny portion of cases in trial courts of any sort are resolved through full-fledged adjudication (Trubek et al. 1983). One should however bear in mind that adjudication is a process that involves several steps. A party to a case may vigorously contest a pretrial ruling over, for example, the admissibility of evidence. Depending on the outcome of this ruling, it may then decide to drop the case or to admit liability. Although disposition is formally recorded as a dropped case or a negotiated settlement, this outcome was in fact the result of an adjudicated decision. This is not at all uncommon. For instance, in the United States, many so-called plea bargains in criminal cases take place only after a vigorously contested probable cause hearing or a hearing on a motion to suppress evidence. As trial procedures have become more complex over the past two centuries, much of the most important adjudication has come to take place in the pretrial process.

All modern judicial systems provide for some system of appeals. The scope of reasons for appealing a case varies widely in different legal systems, but it is safe to say that a primary purpose of appellate courts is to listen to those who lost at trial and those who claim that the trial court made a mistake. In some legal systems, an appellate court is restricted to consider only claims that the trial court erred in interpreting the law; if it finds an error, it must overturn the trial court's verdict or remand the case to the trial court for further consideration. In other systems, the appellate court can act like a trial court, reconsidering facts not properly considered at the original trial or examining additional facts brought to light since the trial. Whatever their precise duties, appellate courts provide losing parties with an opportunity to ask another court to review the decisions of the trial court and to correct its errors. But in addition to correcting errors,

appellate courts provide the judicial system with a way of overseeing and supervising the activities of lower courts. Appellate courts provide the political regime with a way of checking the independent powers of a highly decentralized system of trial courts. That is, by securing appellate court judges sympathetic to its aims, the ruling regime can gain some assurances that trial courts will act within bounds of toleration. This is an additional reason why civil law systems—that is active, policy-implementing states—tend to have more appeals (Damaska 1977).

4. Conclusion

Adjudication is a triadic structure, involving two disputants and a judge who is charged with imposing a solution on the parties. The process is inherently unstable; the losing party is likely to feel that the judge sided with the other party. In modern societies, where judges are government officials and the state is often a party in a case, the problem of judicial legitimacy can be considerable. Courts have responded to this inherent instability in two ways. They have fostered judicial independence through the formalism of the rule of law ('Don't blame me, blame the law!') and they encourage negotiations in which the contesting parties reach settlement on their own accord. As we have seen, judicial independence can take quite different forms; in civil law countries, it has led to judges being perceived and perceiving themselves as highly circumscribed civil servants 'applying the rules' made elsewhere. In other countries, perhaps most notably some common law countries, judicial independence means primarily judicial autonomy from the state.

In all countries, however, courts tend to encourage parties to arrive at consensual or negotiated outcomes so that they do not have to impose a solution upon the parties. A cursory look at judicial statistics around the world reveals that courts are fairly successful at this. The overwhelming bulk of all cases, of all types, are resolved short of full-fledged adjudication. However, such figures should not be interpreted to mean that the courts are irrelevant or play only a small role in this process. Legal claims are often resolved in the shadow of the courthouse and against looming alternative of a full-fledged trial. Furthermore, they are often settled only after a court has issued a preliminary ruling that has signaled its view of issues and hence a possible outcome.

Craft Production, Anthropology of

The familiar definition of 'craft' as a skill in making something, usually by hand, is essentially that used in anthropology. Political economists have distinguished between craftsmen who make things for use or sale to the consumer, and manufacture where things are made for merchants/capitalists to sell. Manufacture often involves several stages of production, either in the processing of raw materials (e.g., thread into cloth; weaving; dyeing) or of components (parts of a watch each made by a specialist craftsman; parts of a car). Before the industrial revolution the stages of manufacturing were coordinated and controlled by merchants or by the state, who had the necessary capital. While today manufacture refers to making things by machines, the literal meaning is 'hand-made' (from Latin *manus*, 'hand' and *facere*, *factum*, to make). Pre-industrial manufacture involved coordinating the stages of handcraft production, and was widespread in some societies with complex economies (India, China, medieval Europe). Production of goods by hand today is often coordinated by middlemen (see below). Thus it is useful to include in craft production both the making of goods by skilled craftsmen, and the coordinated manufacture of handcrafted goods.

1. Craft Specialization, the Division of Labor, and Commodization

The division of labor by gender and age has been basic in human societies from the simplest hunter-gatherers through pastoralism, simple and more complex forms of agriculture, to urban societies up until the industrial revolution, and remains important today. In small-scale societies where all adult men and women practice the same craft skills, these tend to be carried out as part of the domestic economy. Kin roles are also economic roles. In this 'domestic mode of production' (Sahlins 1972), craft products are made for both use and exchange. Craft skills are learned from older same-sex kin in the course of assisting with craft production. The developmental cycle of the domestic group reproduces the unit of craft production.

As societies become larger and more complex, emerging urban centers can support craftsmen who specialize in a single product (iron knives, silk cloth, pottery for cooking). Repeatedly we find that specialized production is associated with refinements in technology. With a specialist division of labor, craft products become commodities as they are exchanged for other commodities or enter the market. Hart writes that the central feature of increasing economic complexity is the integration of the division of labor in a nexus of commodity production and exchange; and that there is a tendency towards the progressive incorporation of ever more aspects of social life as commodities. 'The commodity is human labor embodied in a good or service offered to society rather than be consumed by its producer. As such, commodisation may be defined as the progressive abstraction of social labor' (Hart 1982).

As the nexus of production and exchange becomes more elaborate, new patterns of the division of labor appear. This pattern can be seen in the independent towns of medieval Europe and the Mediterranean. In Europe in the Middle Ages, textile production for an expanding market became organized as manufacture, first in specialist guild workshops, and then in rural cottage industry which took two forms. Cottage-craftsmen and women raised or bought the raw materials which they spun and wove into cloth, and sold locally to merchant buyers. The cottage-craftsmen owned raw materials, tools, and the finished cloth, planned their own work, and dealt directly with the market, although vulnerable to its fluctuations. In the other form of cottage industry, merchant manufacturers supplied the thread, often the loom, and owned the finished cloth. Weavers were paid for their work, in effect selling their labors as cottage-laborers. Rural cottage craft production organized by merchant capital is an example of what has been termed 'proto-industrialization.' With the harnessing of water- and then steam-power the invention of machines to replace handcrafts skills became possible. Such machines brought workers into factories, but the organization of components of production in manufacturing remained in many ways the same (machines now did the work of spinning, warping, weaving, finishing, dyeing) (Goody 1982).

Clearly, the industrial revolution has radically changed the conditions of craft production. It is no longer central to the production and exchange of commodities in industrial societies. Further, Western manufactured goods and industrial production have become integral to the economies of developing countries. Yet a number of niches of craft production remain. Social anthropology, grounded in participant observation, has addressed the topic of craft production during the twentieth century in several ways.

2. Theoretical Frameworks of the Anthropology of Craft Production

2.1 Material Culture and Folklore

The nineteenth century excitement with evolution was shared by anthropology, and carried over into the twentieth century with the Folklore school in which the study of material culture was central, especially in the United States and the Scandinavian countries. The focus was on detailed description and mapping of material culture, with a view of preserving a record of rapidly disappearing 'early' forms of society. Where craft production was treated it was within this framework.

2.2 Ethnographies in Social Anthropology

The ethnographies of this tradition took as problematic the social structure and functional integration of societies studied. Ethnographic accounts treat religion, kinship, economics, and political dynamics as all important and related. However social anthropologists differed in the weighting given to each domain, as did the societies they studied. Significantly, those ethnographers who treat craft production as a significant feature tend to have worked in relatively complex societies. Among them, Nadel's account of the kingdom of Nupe (Nigeria) is pre-eminent for its detailed accounts of a number of craft industries, and the way these relate to the Nupe court. Each craft is discussed in terms of the access to raw materials, technical processes, the organization of the division of labor within the workshop, authority and transmission of skills among craftsmen, design and fashions as these relate to consumer demand, and patronage by nobles and the court where this is relevant. Some crafts are 'open' in the sense that any man can learn by assisting a skilled worker (weaving, bead making); others are 'closed,' restricted to members of certain kin groups (blacksmiths, brass smiths). Craft skills are learned in informal apprenticeship. Closed crafts restrict apprenticeship to kin; this also serves to keep ritual and secrete knowledge within the craft kindered (Nadel 1942). Miner's account of craft production in Timbuctoo in the same period is less detailed, but closely parallels that for Nupe (Miner 1965 [1953]). Slave production of food stuffs and cotton was important, particularly in northern Nigeria, but does not appear to have been organized for craft production. However rural industry of the cottage craftsman kind in weaving and dyeing is documented around the city of Kano where certain villages were famous as centers of dyeing. The town of Daboya played a similar role as a center of dyeing in the precolonial textile industry of northern Ghana. (See also chapters by Pokrant and by Goody, in Goody 1982.)

2.3 Marxist Studies of Craft Production

With its focus on modes of production, Marxist theory offers social anthropology a framework for the study of craft production. A mode of production consists of the productive forces (natural, material, and technical) and the social relations of production. Most work in this area is by French anthropologists, exemplified by an English collection of papers by French neo-Marxists (Seddon 1978). The goal of this volume is to lay the groundwork for 'a truly scientific study of society … which will lead to the discovery of laws that underlie the development of … social and economic formations … (and) identify the relations of production characteristics of pre-capitalist formations' (Seddon 1978, p. ix). There are chapters about self-sustaining agricultural societies, the peasant mode of production, the Asian mode of production, and an African mode of production. Based on detailed ethnography, most are rich and insightful discussions of the relations between economic and political factors, several foregrounding kinship in new ways; this is especially true of those in the section based on fieldwork in Africa. However, perhaps because their goal is the identification of general laws, craft production is not a focus of description or analysis.

Following the Seddon volume a number of anthropologists have written ethnographic studies of craft production from a Marxist perspective. Three can be noted briefly: Kahn's *Minangkabau Social Formations* (1980) is a study of village blacksmiths in Sumatra. He describes in detail technology, organization, and marketing—treating relations of production within the workshop, the pattern of learning craft skills, relations between blacksmiths, external influences such as imported materials, and tools. The analysis is set in the context of Minangkabau matriliny, a subsistence agriculture based on rice, and economic policies of colonial overlordship. Based on individual or small workshop production for a local market or to traders, this is petty commodity production.

The next example is a study of Scottish Hebridean Island weavers of Harris tweed. Ennew (1982) traces the development of this industry from the first sales of Harris tweed in 1881. From the beginning it was based on cottage-laborer production, with merchants supplying the wool, dyes, and often the loom, and deducting the cost from payment for the finished cloth. Demands from the external market (London, overseas markets) led first to the introduction of a wider, foot-powered loom, then to removal of warping to the spinning mills in order to control quality and patterns. 'From the moment of wool-purchase the production process of Harris Tweed is entirely in the control of mill-owning capital, except for the slight loss of control during the outworking [weaving] phase' (Ennew 1982, pp.189–90).

Very different relations of production characterize the manufacture of carved hardwood furniture in

Hong Kong. In the factory which Cooper joined as an apprentice wood carver, identical sets of tables were carved for tourists and export. He speaks of the proletarianization of the industry. Workers were paid daily at an hourly rate; the factory products were standardized, carvers producing endless legs and tops for tables, with no involvement with design or contact with customers. However he does feel that seven months as a factory carver gave him insight into the Maoist distinction between manual labor and mental labor, into proletarian culture as well as ideology (Cooper, in Coy 1989).

It seems that craft production is incorporated in several modes of production: petty commodity, cottage laborer, and even as proletarian labor.

2.4 The Rebirth of Material Culture Studies: The Cultural Meanings of Commodities

Material culture has again become a central concern for anthropology, but now the focus is on the cultural and personal meanings of things as commodities. Objects serve to objectify cultural meanings in individual experience; individual identities are constructed through the consumption of commodities. Indeed it has been argued that the study of consumption and commodities represent a major transformation in the discipline of anthropology and may come to replace kinship as the core of anthropology. Appadurai, in his Introduction to *The Social Life of Things: Commodities in Cultural Perspective* (1986) reviews economic theories which focus on the production of commodities and argues, following Douglas and Isherwood, that the interesting questions are rather about why and how people consume goods. The factors that drive consumption (the 'demand' of classical economics) are to be found in socially and historically shaped cultural meanings—in the political economy of the social life of things. The Introduction concludes: 'Ever since Marx and the early political economists, there has not been much mystery about the relationship between politics and production. We are now in a better position to demystify the demand side of economic life' (Appadurai 1986, p. 58). Given this perspective it is not surprising that among these anthropologists the few who are interested in production deplore the scarcity of relevant studies (but see chapters by Spooner and Bayly in Appadurai 1986).

2.5 Learning and Apprenticeship in Craft Production

The learning of craft skills has consistently been central to craft production itself—with the domestic mode of craft production in simple societies, in apprenticeships in craft workshops, and again in the domestic mode of cottage industry production. Craft production is labor intensive, and the work of unskilled children and youths frees craftsmen to concentrate on more complex skilled tasks, assembly of components, and organization of both production and distribution to consumers. A Vygotskian view sees learning as based on working alongside an adept: observing, assisting with very simple task elements, gradually taking over responsibility for these elements while continuing to observe, and then assisting with more complex tasks. This model corresponds closely to the learning of weaving by fostered apprentices in the Daboya textile industry (Goody, in Goody 1982). It also appears to fit accounts of domestic craft production by blacksmiths (Nadel 1942, Kahn 1980, Coy 1989); it is consistent with formal apprenticeship as in industrial wood carvers (Cooper, in Coy 1989) and Japanese folk potters (Singleton, in Coy 1989). The contributors to Coy's edited volume on *Apprenticeship* (1989) are all anthropologists who did fieldwork while themselves apprenticed, and several learned handcrafts. Their work supports the view that in craft production the learner is central to the production process—by providing unskilled labor in labor-intensive production; by systematically enforced subordinate status which legitimizes labor demands and supports the expert's control of synchronizing elements of production; and by embodying the social reproduction of craft skills and knowledge.

3. Trajectories of Craft Production in a Global Economy

Before industrialization, virtually all artifacts—for daily use, exchange, luxuries—and the tools for making these, were the products of craft skills. With the industrial revolution, craft manufacture ('hand making') of most commodities has been replaced by machine production in factories. Yet today craft production still occurs in the many niches left by industrialization, sometimes in surprising places.

There are many craft production niches in both industrial and developing societies; this is an open set. The conditions under which handcraft production has advantages (of cost, of detail work, of skilled knowledge) are varied, and change in response to both local and global factors. Social anthropologists have studied craft production in some of these niches; other awaits research. Contemporary anthropology is responding to the complexity of globalization and postmodern skepticism of both theory and observation with a proliferation of particular interests. While none of the major current themes focuses on production, there are good individual studies in several of these niches. It is only possible here to sketch these briefly.

3.1 Niches of Contemporary Craft Production in 'Developing' Societies

3.1.1 Artisan/craft production for local use in developing societies. In partially industrialized third world

societies many commodities for local use are made by individual craftsmen and workshops, and in small factories, using handcraft tools and techniques. In Bolivia, tinsmiths make pails and basins, blacksmiths make farm implements and locks, others make kerosene lanterns, dancing masks, clothing, shoes, etc. (Buechler, in Coy 1989). The largest single example must be the Indian Khadi cottage industry making handspun, hand woven cloth. Beginning in the ideology of self-sufficiency with which Gandhi led the movement for independence, this continues to be centrally organized. As with other attempts to make household craft production economically viable alongside industrial production, partially mechanized processes have been introduced to support handcraft skills (e.g., multiple-spindle spinning jennies are wired to electricity by villagers, Bayly, in Appadurai 1986).

3.1.2 Artisan/craft production in developing countries for the global market. There are two links to this market, tourists buying locally, and international buyers for stores in industrialized countries. The two are related, since tourists want to buy similar craft products on returning home, and consumers of craft producers in industrialized countries look for them as tourists. Social anthropologists have recently become interested in tourism. Among the studies which treat craft production are several in Graburn's *Ethnic and tourist arts* (1976); see especially the chapters by Graburn (on Inuit soapstone carving), Kent (Puebio and Navajo weaving in the American Southwest), and Salvador (on Mola applique blouses made by Cuna Indians).

Handwoven and hand-printed textiles have for centuries been among India's most successful export industries. In the twentieth century some firms concentrating on garment manufacture attempted to secure advantages of efficiency and control through factory production. However, there is a pattern of reverting to commissioning both weaving and making up of garments from smaller units—cottage weavers and small workshops. Swallow's study of one such company finds that in a volatile export market the costs of factory production (maintaining plant and machinery, labor troubles) remain higher than those of cottage craftsmen and cottage laborers managed by intermediate capitalist merchants, under conditions of population pressure and lack of alternative unemployment (Swallow, in Goody 1982).

An increasingly common pattern is merchant or factory production of crafts sold locally to Western buyers for retail in industrial countries. Best studied is the production and marketing of luxury goods such as oriental rugs/carpets (see Spooner in Appadurai 1986) and carved hardwood furniture (Cooper 1980). Less elaborate, cheaper craft products (simple jewelry, pottery, glass, textiles) are made by cottage craftsmen, cottage laborers, or in workshops for sale to wholesale buyers who market them in bulk to retailers at trade fairs in industrialized countries. These are finally sold to consumers in Western gift shops, department stores, and clothing stores (buyer, personal communication). Although this mode of craft production for final sale in the commodity-rich markets of the West probably far exceeds in volume that of luxury goods, it seems as yet not to have been studied by anthropologists.

3.1.3 Development aid and craft production. International development agencies, nongovernmental organizations (NGOs), and national government agencies have seen craft production as a potential focus for income-generating projects, usually for women. This may mean building on existing craft skills; often crafts judged as marketable are unfamiliar locally, and have to be taught. Project effort is directed towards teaching skills, securing access to materials and tools, and marketing. The development of some form of local cooperative structure is often integral to the project. Although anthropologists often participate, little published material is available on such projects, except in the form of reports and evaluations.

3.2 Niches of Craft Production in Industrialized Societies

3.2.1 Outwork and workshop handcrafts in industrial societies. In industrialized societies craftsmen—here usually craftswomen—continue to work at home at piecework rates on a number of crafts: sewing on industrial machines (owned or rented), knitting (often by machine), and the making of small cheap goods like Christmas crackers. This modern cottage industry is cheaper for manufacturers for the familiar reasons: low rates of pay; a dependent labor force lacking employment alternatives; no need to maintain plant or machines; flexibility of labor force which is only given work when demand is high. Some manufacturers, particularly in textiles, bring craftspeople into workshops where sewing and knitting machines are provided and supervision is possible, making changes in design easier.

3.2.2 Production of folk crafts for the national market. The 'Arts and Crafts movement' associated with William Morris in England in the second half of the nineteenth century had counterparts in the United States, and later Japan. This movement reacted to industrial production by romanticizing craft production, seeing it as preserving old techniques and a classical vision of beauty expressed in individual hand skills. In order to manufacture craft products

so as to make them accessible to an enlightened market, Morris taught himself to weave, embroider, print textiles, make tied carpets, make glazed tiles, and block print designs used for wallpaper. Apprenticeship was initially rejected, since they were seeking a pure re-creation of the essence of each craft. Although it was Morris' dream to make craft products cheaply so all could afford them, the cost of production with skilled labor and costly materials meant they were always luxury goods.

This vision survived. It subsequently led to handcraft manufacturers using traditional patterns and materials but of relatively modest cost: of textiles (Harris tweed), pottery (exemplified by the craft of Bernard Leach), and in the United States of Quaker furniture. In Japan it was reflected in the deliberate creation of a word of 'folkcraft' (*mingei*) after discussions among artists and philosophers (including Bernard Leach), and the establishing of a national museum of folkcraft which worked especially with traditional potters to develop aesthetic and practical adaptations of old forms. This folk pottery was made in traditional rural workshops, and became commercially popular. In his study of several rural Japanese pottery-making communities, Singleton found that high demand led in some to an opening of apprenticeship to outsiders, with a decline in the authority of the master (Singleton, in Coy 1989).

3.2.3 Persistence of customized craft production. Factory production for mass consumption has become the major source of commodities in industrialized societies. Customised handcraft production continues alongside this, especially of men's clothing, women's fashions, shoes, and jewelry. Women's fashions have become international, with a few famous designers in Paris, Rome, New York, and Tokyo holding annual shows which set the latest fashion. At the luxury end of this mode of production the craftsmen designs a prototype made in his workshop; this may be commissioned by a customer, offered for sale through a show, or in exclusive shops. Successful designs may be copied in other workshops for sale in select stores; such as garment with a 'designer label' is still considered exclusive. A few designs are more widely copied and sold through chains of stores to the public. This 'trickle-down' of fashions through dressmakers' workshops has always linked dress to social mobility. Lace, from the sixteenth to the nineteenth centuries, moved from courts to town gentry to village bonnets. Maher describes this for Turin in the early twentieth century, where seamstresses copied the dresses made for customers to wear themselves—thus passing socially as ladies (Maher 1987). Customized craft production also continues to be important, for instance in fine furniture, jewelry, pottery, and textiles. These are sold in specialist shops, and increasingly in shops alongside replicas of museum holdings. Their makers are coming to be known as designer craftsmen,' and also as 'artist craftsmen.' There is a debate, as with some of the ethnic crafts, as to whether this is 'art' or 'craft.'

3.2.4 Individual craft production for pleasure in using craft skill. The anthropological preoccupation with conceptualization of identity in terms of commodities has displaced earlier anthropological interest in occupational and personal identity based on skilled craftsmanship. Yet there is a resurgence of popular interest in learning craft skills like sewing, knitting, embroidery, lace-making, weaving, pottery, jewelry-making, etc. A number of indices reflect this enthusiasm: where they used to be learned from kin or in apprenticeship, such crafts are now taught in community centers and in summer workshops; practitioners form associations concerned with style and pattern, access to tools and materials, teaching and examining craft skills; there are magazines and books devoted to patterns and techniques; practitioners hold exhibitions of their work. The main motivation seems to be development and exercise of individual handcraft skills. Products are used by the maker or given as gifts. While occasionally a seamstress, weaver, or potter becomes skilled enough to sell skills or products on the market, for most commodization is not a factor. Indeed, individual craft production may be seen as the separation of craft skills from the market.

Creationism, Evolutionism, and Antievolutionism

1. Creationism, Evolution, and Antievolutionism

1.1 Creationism

Broadly defined, *creationism* refers to the idea that a supernatural agent or agents created the universe, living things, and/or human beings. To Leibnitz's question, 'Why is there something rather than nothing?' most human societies answer with creation stories, wherein gods, culture heroes, or other powerful forces bring about the Universe from nothing, or modify some existing matter to produce the Earth and living things. More narrowly defined, in North America, creationism has come to connote the theological doctrine of special creationism, a particular kind of creationism in which God created the Universe—galaxies, stars, the solar system, Earth, living things, humans—all in a brief time in its present form. 'Young Earth creationism' is the most frequently encountered form of special creationism; its proponents believe that the creation event took place during six 24-hour days, a relatively short time ago (within 10,000 years). This reflects a literal interpretation of Genesis, the first book of the Bible, and although most common in Christianity, special creationism is part of the theology (but thought not to be a central part) of the other Middle Eastern monotheisms, Judaism and Islam.

1.2 Evolution

Evolution is a scientific view of the Universe as having reached its present form gradually over time. Evolution, then, is ultimately about history: galaxies, stars, the planet Earth, and living things are different today from what they were in the past; there has been change through time. Biological evolution, a subset of this larger view of change through time, is the theory that living things have descended with modification from common ancestors. As with all biological entities, human beings have a shared common ancestry with other living things; our closest nonhuman relatives are the living apes. The ape/human common ancestor shared common ancestors with monkeys and other primates, other mammals, and then (more distantly) with reptiles, amphibians, fish, and invertebrates. Biological evolution affirms a genealogical relationship of species through time. It thus contrasts sharply with special creationism, which requires that all living things be created in their present forms, rather than having descended with modification from common ancestors.

Religious views other than special creationism may be, and often are, compatible with evolution. Theistic evolution, the doctrine that God worked purposefully through natural law to bring about the Universe via evolution, is part of the accepted theology of the Catholic Church, mainline Protestant Christian churches, and Reformed and Orthodox Judaism. It is also acceptable in some interpretations of the Koran. In these theologies, Genesis is not interpreted literally, and the separate creation of 'kinds' of living things is not important. The focus is on God as Creator, rather than *how* God created.

1.3 Antievolutionism

Although evolution is widely accepted within the scientific community, evolution has come under attack in North America, and in a growing number of other countries, by holders of certain religious views. In North America, the controversy plays primarily in the arena of precollege public-school education, although antievolutionism is not uncommonly expressed in informal science education centers such as National Parks, museums, zoos, and science centers.

Young-Earth Protestant Christians following a biblical literalist religious tradition form the core of the antievolutionism movement, but in the USA at least, antievolutionism extends beyond biblical literalists to include some mainline Christians. These nonliteralist Christian antievolutionists are uneasy about evolution because it appears to them to have serious existential consequences (Pennock 1999). They reject theistic evolution in favor of special creationism because they believe that if humans evolved through the same process that brought about oak trees and salamanders, then we would be less special in the eyes of God. Being less special to God implies to them that there is no special purpose for human beings, and thus

that human life has no more meaning than that of any other creature on the planet.

For life to be a purposeless and meaningless —, and God to be at best impersonal, rather than directly concerned about and accessible to individuals, — is unacceptable. Forced to choose between creationism and existential fulfillment on the one hand, and existential emptiness and evolution on the other, they reject evolution. Other Christian traditions resolve these issues in a variety of ways, finding no theological problem with God's working through natural law to produce humans, but still sustaining the Universe and interacting with humans in a meaningful way.

It can fairly be said that antievolutionism does not flow from scientific weaknesses in evolutionary data and theory, but from religious or philosophical objections. This is illustrated by recent secular 'postmodernist' critiques of evolution, which focus on alleged negative implications for society of Darwinian evolution (evolution through Darwin's mechanism of natural selection). Much as did members of the progressivist movement at the beginning of the twentieth century, postmodernist antievolutionists criticize Darwinism as the source of racism, sexism, exploitation of workers, and other social evils. Ironically, conservative Christians criticize evolution for being the source of Marxism, while leftist postmodernists criticize evolution for being the source of 'nature red in tooth and claw' capitalism!

2. *History*

Antievolutionism has been most successful in the United States, for historical as well as cultural reasons. The United States was settled in part by religious dissidents, whose churches were strongly congregational rather than hierarchical in structure. The period since the early 1800s has seen the origin of a variety of unique American Christian theological traditions, and although many (Shakers, Millerites) have passed into history, some have continued into the twenty-first century (Mormons, Christian Scientists, Seventh Day Adventists). Decentralization also characterizes the American educational tradition, because isolated settlements were forced to create their own schools, hire their own teachers, and develop their own curricula. The United States has never had a national curriculum in science, or in any other field, and curricula may vary considerably from district to district even within a single state. Evolution may or may not be taught in a given school district, even if it is required in the district's curriculum. Teachers often omit evolution from instruction because it is controversial in their communities.

A major historical influence on American antievolutionism was the development during the second decade of the twentieth century of fundamentalism, a uniquely American Protestant religious tradition. Written between 1910 and 1915, the 12 pamphlets known as 'The Fundamentals' laid out a back-to-basics Protestant theology that relied heavily on the inerrancy of the Bible. Emerging during the unsettled social and political conditions preceding World War I, fundamentalism's comforting tenets were accepted rapidly by large numbers of Americans. Biblical literalism, however, had not been part of British Anglican, or continental Lutheran or Catholic traditions, and fundamentalism remained an American phenomenon.

By the beginning of the twentieth century, the theory of evolution had become widely accepted by scientists both in Great Britain and in the USA (Moore, 1979). In Great Britain, the Anglican church adjusted relatively quickly to evolution, accepting within a few decades of the publication of Darwin's *On the Origin of Species* that God created through the process of evolution. Textbooks in the USA at that time routinely discussed evolution as the organizing principle of biology. But the rise of fundamentalism was to change that, because evolution contradicted a literal interpretation of Genesis. Because Darwinism was associated in the public mind with *social* Darwinism, Christian social progressives such as William Jennings Bryan opposed it as they sought to ban child labor, improve the lot of workers, provide for women's rights, and promote other progressive causes. By the early 1920s, efforts were being made in many states to ban outright the teaching of evolution.

2.1 *Banning Evolution*

Although between 1921 and 1929 antievolution legislation was introduced into 37 states, only five states passed such laws: Oklahoma, Tennessee, Florida, Mississippi, and Arkansas. Tennessee's law was challenged by a high-school teacher named John Scopes, which culminated in the famous Scopes trial of 1925. Scopes lost, and the Tennessee law remained on the books for over 40 years.

Even though during the Scopes Trial the popular press pilloried the creationist view as old-fashioned and ignorant, antievolutionism did not go out of favor. In fact, the Mississippi and Arkansas antievolution laws were passed *after* the Scopes trial. The coverage of evolution in textbooks declined sharply after the Scopes trial, until by the mid-1930s, hardly any textbooks included the topic. Antievolutionism remained triumphant until the late 1950s, when the Soviet Union's launch of the first orbiting satellite, Sputnik, caused the federal government to reexamine its science policy and to begin a major science education reform movement. This movement included the production of textbooks written by scientists and master teachers rather than in-house writers in publishing companies.

The federally-funded Biological Sciences Curriculum Study (BSCS) cited evolution as an organizing principle in its textbooks, and soon commercial publishers followed suit. By the late 1960s, evolution was once again prominent in high-school textbooks. In 1968, antievolution laws such as the Tennessee law under which Scopes had been tried were overthrown by the Supreme Court in *Epperson vs. Arkansas*.

2.2 Creation Science

The resurgence of evolution in textbooks caused an antievolutionary backlash. A strategy developed: if creationism could be presented as an alternative scientific view, then it would deserve a place in the curriculum. 'Creation science' first appeared in developed form in 1961 in *The Genesis Flood* by John Whitcomb and Henry R. Morris, in which the authors argued that modern geological features could be explained by Noah's flood. Its mix of theology and science characterized future creation science efforts, and Morris became the foremost proponent of creation science in the latter part of the twentieth century.

Creation science is associated closely with 'young Earth creationism,' in which the six days of Genesis took place about 10,000 years ago. Most creation science literature focuses upon supposed flaws in evolution, the reasoning being that evidence against evolution is evidence for creationism.

In 1972, Henry Morris and others founded the Institute for Creation Research in San Diego, CA, as an antievolution ministry. It remains the flagship antievolution ministry, but there are other national organizations such as Answers in Genesis, the Bible-Science Association (recently renamed Creation Moments, Inc.), and several regional and local ministries that also promote the young Earth creationist views of Henry Morris. A sizable corpus of antievolutionary material consisting of books, videos, compact discs, filmstrips, tape recordings, posters, and curricula is publicly available from these organizations.

By the late 1970s, creationists instituted a movement to propose 'equal time' legislation in state legislatures, requiring that if evolution were taught, creation science would also have to be taught. At least 23 states had equal-time legislation introduced, and two states passed these bills: first Arkansas and then Louisiana. Although both laws were challenged in the courts, only the Louisiana decision reached the Supreme Court, which ruled in 1987 in *Edwards vs. Aguillard* that equal-time laws violate the First Amendment of the US Constitution, which requires that public institutions be religiously neutral. Creationism, being inherently a religious view, cannot be advocated in the public schools; thus laws promoting equal time for creationism are unconstitutional. Efforts to pass such legislation largely ceased, and school districts around the country that had required the teaching of creation science quietly changed their regulations.

2.3 Neocreationism

Although public-school teaching of creation science itself has been ruled unconstitutional, antievolutionism continues in the United States. More recent antievolutionary strategies avoid reference to any form of the root word 'creation' and go directly to trying to discourage the teaching of evolution without banning it directly. Whereas in the 1980s and early 1990s, school districts and teachers were exhorted to 'teach evolution and teach creation science to balance it out,' now antievolutionists encourage them to 'teach evolution and the "evidence against evolution" to balance it out.' In some districts, teachers are required to read a disclaimer that evolution is 'only a theory' to students before teaching the subject, and in fact, 'only a theory' disclaimer stickers have been placed in textbooks in Alabama and in several school districts around the country.

During the mid-1990s, a movement to 'teach evolution and "intelligent design theory" to balance it out' appeared and began to spread. 'Intelligent design theory' is a restatement of William Paley's 1802 argument from design, an apology for the existence of God. Paley argued that because complex, intricate structures such as the vertebrate eye could not have occurred naturally, they must have been created specially by God. Intelligent design creationists update Paley by claiming that the structure of DNA or functions of the cell are 'too complex' to have been brought about by the alleged 'random' process of natural selection.

3. International Antievolutionism

Antievolutionism has been strongest in the United States, but there are movements in several other countries as well. American creation science materials have been circulated in Canada, Australia, and New Zealand, and as translations into languages other than English have become available, into dozens of other countries including Korea, the Philippines, Turkey, the nations of Europe, and in the former Soviet Union. Antievolutionism has not taken root in Europe, probably because secular culture predominates there, but in the current disarray in which Russia and other former components of the Soviet Union find themselves, antievolutionism is increasing in proportion to the increase of adherents to conservative Christian sects.

International antievolutionism is largely the result of activities of American conservative Protestant Christian missionaries. The withdrawal of official

Catholic approval for 'liberation theology' has caused many in Central and South America to search for a religious alternative to Catholicism, and Protestant missionaries have stepped up their proselytizing efforts in this part of the world. Missionaries distribute antievolution materials as well as more traditional tracts. In Russia, Protestant missionaries have long been teachers of English, and with the breakdown of the central government's oversight (and the increase in interest in religion since the dissolution of the Soviet Union), antievolution materials have proliferated. The Institute for Creation Research has cultivated antievolutionists in Russia as well as many other nations, in order to spread creation science as well as biblical literalist Christianity.

Of interest is the growth of non-Christian antievolutionism, as seen in a small but vocal movement in Islamic Turkey, as well as in Israel from ultra-Orthodox Jews. In both cases, the literal interpretation of Genesis is foundational to the opposition to the teaching of evolution in schools. Of the two, the Turkish movement is more organized, and uses translations of American creation science materials. In fact, ICR employees have made several trips to Turkey to cultivate the antievolution movement, apparently without promoting Christian conversion.

One of the stranger chapters in modern antievolutionism is the development of a form of creationism based on Hinduism. A Krishna Consciousness organization in the United States, the Baktividanta Institute, contends that modern evolutionary science is not true. But instead of substituting creation science, Institute personnel argue for the literal truth of the Hindu Vedas. According to these religious scriptures, the world and living things have come and gone according to a series of cycles, and we are currently the midst of one. Humans were created 350 million years ago, and did not evolve only within the last few million years. Ironically, in a movie shown on American television during the 1990s ('Mysterious Origins of Man'), antievolution creation science arguments were used, but stripped of their biblical references, and also of their young-earth references. Like creation science, 'Krishna creationism' claims that modern scientists are in a conspiracy to hide the 'truth' of the lack of scientific support for evolution from the public.

4. *The Future*

Will antievolutionism increase or decrease over time? The future of social movements is always difficult to predict, but no predictions are possible without an understanding of the roots and motivations of such movements. Clearly, the foundation of antievolutionism is the concern (if not fear) that religious views will be proven untrue, or at least require major modification. This is most apparent with biblical literalists, who tie salvation to the literal truth of the book of Revelations, and tie Revelations to the literal truth of Genesis. But, as mentioned earlier, nonliteralist Christians may also be uneasy about evolution if evolution is seen to imply or require that only natural processes could be involved in the production of the Universe—that God is completely removed from Creation. Beliefs about such existential issues will be very influential in either the increase or decrease of antievolutionism.

Antievolutionism is correlated with conservative religious belief. Although sacred texts such as the Bible have been interpreted as making claims about the natural world, as science has grown and proven its worth, most varieties of Judaism and Christianity have gradually ceased to attempt to explain the natural world through revelation.

Even though there are religious traditions within which evolution is not acceptable, it is probable that theological change will continue. There are only a handful of Christians who believe that the Bible incorporates geocentrism, and perhaps on some future day, all Christians will look back on the era of religious opposition to evolution much as they do upon Galileo's conflict with the Church of his time: as an example of the gradual replacement of theological statements about the natural world with scientific data and theory.

Not surprisingly, polls show high acceptance of evolution in nations where religious belief is low. In a world of nonbelievers, one would find little antievolutionism. But faith does not seem to be on the decline. Secularism is more common in economically developed nations than in less developed countries. The United States, in fact, is atypical among developed countries for its high percentage of individuals who profess belief in God. But even with increased prosperity among developing nations, one would be unwise to predict a linear increase in secularism. Adherence to religion waxes and wanes through time, depending on a network of factors affecting the social and economic environment.

In Russia under the communists, for example, there was reportedly a very low level of religious adherence. Of course, there were reduced opportunities to practice religion in a state where religion was actively discouraged. But with the collapse of the communist system and government, more churches and synagogues are opening in Russia and more people are attending services at the start of the twenty-first century than for decades previously. Reportedly, the Chinese communist government has not been successful in fully stamping out religious adherence. It would be premature indeed to generalize the secularization seen in developed nations in Europe to other nations: traditional religious beliefs are very resilient.

So a decrease in support for antievolutionism is most likely to occur, if it occurs, because of changes in current religious views now hostile to evolution, rather than because of large numbers of people's abandoning

religion. Antievolutionism may in fact *increase* in the future, if there is increased adherence to traditions requiring the literal interpretation of sacred texts (the Bible, the Koran, the Torah, the Vedas, and perhaps others).

Antievolutionism is also related to the public understanding of science: people who understand evolution as a scientific idea that explains natural phenomena rather than as an inherently antireligious idea are less likely to reject it. Thus, if there is improvement in the public understanding of science, antievolutionism may decrease. An improvement in science education in countries in which antievolutionism is established or growing may reduce its effect.

Creativity and Cognition

Cognitive theories of creativity focus on the intellectual structures and processes that lead to insights, solutions, and ideas that are original and useful. Creative work may involve more than cognition, but certain cognitive processes may be necessary for virtually all creativity. Moreover, some of the extracognitive contributions to creative behavior (e.g., the motivation to identify and develop a creative idea) depend on cognition. With this in mind it is not surprising that many theories of creativity focus on cognitive processes. These describe creative thinking and problem solving in terms of divergent thinking, analogical thinking, metacognition (especially strategy), lateral thinking, associative thinking, or simply as a special kind of information organization and reorganization. This article briefly describes the various cognitive underpinnings of creative thinking. It also describes the major issues and questions, including the one already mentioned about the interdependence of cognition and motivation.

1. Information Processing and Perception

In the most general terms cognition involves the storage and processing of information. Often information processing is described with three stores (or memory banks) and three transfer processes. The first store is the sensory buffer, which hold raw information which has not yet been recognized or interpreted. Next is the short-term memory (STM), and last the long-term memory (LTM). Attention is the processes by which information is transferred from the sensory buffer to short-term memory. Rehearsal (in various forms) transfers information from STM to LTM. Retrieval transfers information back to STM from the LTM.

Different theories of creative cognition focus on different components or stages of thought. Creative cognition may occur very early in the process. Creative persons are, for example, often somewhat sensitive; sensitivity is one of the 'core characteristics' that personality researchers have found in many creative samples. This sensitivity may lead individuals to certain experiences, or more accurately, make them notice subtle stimuli and associations which others will overlook. In this sense sensitivity can dramatically influence the perceptual process in such a way as to make creative thinking more likely.

In strict cognitive terms, perception occurs when sensory information (based on experience and the environment) is interpreted. Perception always involves an interpretation of information; and as the example above suggests, interpretations are often significantly influenced by the individual's background, expectations, and personality. Creative persons may very well have certain perceptual and interpretive tendencies which lead them to original interpretations of experience. Other components of the cognitive process are also tied to creative thinking.

Attention, for example, plays an important role. This is because information is not processed unless the individual attends to it. By attending to information, we focus our limited cognitive resources, selecting some information and ignoring other information. Creative cognition may benefit from such selections. It is not, however, a matter of being especially focused. In fact, there are reports of creative persons having 'wide attention deployment strategies.' This means that they attend to a wider range of information and are not as selective as less creative persons. They probably have more information available to them at any one time, and more diverse information as well. Another way of describing this tendency is as 'defocused attention.' Again the idea is that there is less

selectivity and a broader range of available information. A broad range of associations may also result; the information may be environmental and experiential, or it may be internal and drawn from memory.

2. *Memory, Information, and Expertise*

The various memory stores hold information. Information in turn is frequently required of creative cognition. Some creative achievements, for example, require expertise, which can be loosely defined in terms of information or knowledge. Referring back to the model of cognition used earlier in this article, knowledge is information stored in long-term memory. Expertise is usually domain-specific; the individual has expertise within one field or another. It takes time to develop, though some fields take less time than others. Physics represents a highly technical field and expertise in that field requires years of effort; musical creativity often appears much earlier precisely because there is less technical information required.

An efficient memory, containing a great deal of information, does not always facilitate creative cognition. Information, knowledge, and expertise can benefit the individual but sometimes actually inhibit creative thinking. Sometimes expertise leads the individual to make assumptions, and assumptions minimize the mindful thought that is typically required for original problem solving. Expertise also often provides the individual with routines; but here again these can preclude the flexible perspective and questioning attitude that more often support creative thinking. The trick is to be well-informed but at the same time to avoid assumption and fixed routine.

3. *Metacognition*

Routine and assumption are easy to avoid. They follow naturally from expertise, and they often allow the individual to behave in an efficient manner. They will not inhibit creative cognition if they are used mindfully. This means that individuals must monitor their thinking and know when they are indeed relying on assumptions and routines. When original thinking is desired, assumptions should be questioned and routines broken.

Such mindful use of assumption and routine is relatively easy. This is because individuals develop metacognitive skills early in adolescence. Metacognition is thinking about thinking, or cognition about cognition. It is used whenever individuals reflect on their own cognition. It is especially useful for the kind of monitoring mentioned just above, and even more so for the direction and guidance of one's own thinking. Metacognition allows the individual to be strategic and tactical, as well as mindful.

A number of tactics are particularly useful for creative thinking. Some of these are metaphorical, such as the tactic for 'lateral thinking,' which asks individuals to 'dig elsewhere, not deeper.' Other tactics are more direct and quite simple, including two given above: 'question assumptions' and 'avoid routine' (when original thinking is desired). If the individual is having difficulty with a particular problem, for instance, he or she might ask, 'am I making inappropriate assumptions?' Other tactics include working backwards on a problem (begin with the objective and then consider what state must immediate precede it, and what must precede that, and so on) or changing one's perspective. Original ideas very frequently result from a change of perspective, whether it results from discussion with other people, travel, a change in the way the problem is represented, or from time away (incubation).

Consider the Wright brothers. They were extremely tactical in their work. They broke the large problem of flight down into small problems, for example (power, control, weight). They used analogies and looked to nature (studying birds during flight). They collected data by writing to many other persons working on the problems of flight and by experimenting. They even build a wind-tunnel in their bike shop! These same tactics—breaking a large problem into smaller ones, using analogies, collecting more information—can be used with many of our own day-to-day problems to facilitate the finding of original solutions.

4. *Associative Theory and Divergent Thinking*

Something more should be said about less mindful (cognitive rather than metacognitive) contributions to creative cognition. There are, for example, theories describing creative thinking as associative. Clearly, individuals often follow chains of thought, associating one experience or idea to a related one. That second idea or experience may in turn lead to a third idea, which then leads to a fourth, and so on.

In one associative theory creative insights result from long ideational chains. In this view the first associations are the most obvious (black is associated with white; dog is associated with cat). Creative insights, on the other hand, tend to be 'remote associates.' They are further along the associative chain. Research suggests that individuals differ in associative tendencies. Creative persons, for example, move quickly to remote associations. In theory, each of us can tactically and strategically postpone quick judgments, incubate (take one's time), and try to allow long chains of ideas and associations. In simplest terms the tactics would be 'take your time; don't rush; don't accept the first solution that comes to mind.'

Associative theory was used in the development of the Remote Associates Test, known as the RAT

(Mednick 1962. In the RAT, three words are given (e.g., blood, river, money) and the examinee is asked to find a common associate. Validation studies have offered only marginal support for the RAT, perhaps because of a potential verbal bias, but this does not imply that the theory which led to the RAT is invalid.

Associative theory was also used when tests of divergent thinking were developed in the 1950s (e.g., Guilford 1950, 1968). These tests also allow individuals to follow associative paths but they are less biased by verbal ability and scored for original ideas rather than correct associations. Correct associations, like those on the RAT, may result from 'convergent thinking' rather than 'divergent thinking.'

Divergent thinking is probably used any time an individual is faced with an open-ended task. On tests of divergent thinking, open-ended tasks include requests like, 'name as many round things as you can think of,' or 'how are a potato and carrot alike?' Clearly these questions do not have one correct or conventional answer. The examinee can generate a large number of ideas, all of which are fitting to the task at hand. Some are likely to be original and even creative. Thus, from this perspective, creative cognition is operationalized as divergent thinking.

Divergent thinking is further operationalized in terms of the individual's 'ideational fluency,' 'ideational originality,' and 'ideational flexibility.' Ideational fluency is defined in terms of the individual's productivity. The fluent individual will produce a large number of ideas. Originality is defined in terms of unusualness or uniqueness. The original individual will produce ideas that are unusual in the sense that other people do not think of the same things. Flexibility is defined in terms of variety. The flexible person produces varied ideas, ideas which tap a range of categories or cross diverse themes.

The inflexible person will respond to the task 'name things which are round' with 'tennis ball, basketball, baseball, softball, volleyball, golf ball, soccer ball,' and so on, while a flexible person will respond to the same question with something like 'eyeball, pea, Venus, golf ball, atoms, peaches,' and so on. Fluency is the most commonly recognized feature of divergent thinking, in part because it is predictive of originality and flexibility; but originality and flexibility are very important as well. Originality is, after all, the most widely accepted dimension of creativity. Creative things are always original. Flexibility is important in part because varied ideation may make it easier to find original solutions and insights. Also, flexibility seems to preclude the 'functional fixity' which keeps some people in intellectual ruts.

Empirical investigations have provided stronger evidence of validity for tests of divergent thinking than they have for the RAT, though the actual validity coefficients are only moderate. Still, no one claims that all creative thinking requires divergent thinking. Divergent thinking can lead to original ideas, but divergent thinking is not synonymous with creative thinking.

5. *Issues Concerning Creative Cognition*

One of the issues in this area of study concerns the relationship of creative cognition with problem-solving skill. There are theorists who believe that all creativity is a kind of problem solving. There are others who argue that problem solving and creativity are frequently independent. Problem solving may be creative, but sometimes is not. Support for this second view was mentioned above, with the distinction of divergent and convergent thinking. Sometimes problem solving requires one correct answer; this is convergent rather than divergent thinking, with little or no room for originality. The debate concerning the relationship of creativity and problem solving has been reviewed by Runco (1994).

The arts are unambiguously creative and typically seem to rely more on self-expression than problem solving. Then again, it is easy to see that artists are often solving problems. They may be expressing the problem in the content of the art, or exploring alternatives, or they may be experimenting with technique and solving problems of communication.

Better support for the independence of problem solving and creativity is provided by examples of 'problem finding.' Problem finding is the general term for effort that precedes problem solving. Long ago Wallas (1926) suggested that the creative process requires 'preparation,' along with 'incubation,' 'illumination,' and 'verification.' The preparation stage of this process may involve identifying a problem to solve, or the definition of a problem that allows original solutions to be found. Apparently there are notable individual differences in problem-finding tendencies, and persons who devote more attention to carefully defining problems are often more creative than other persons. It may even be the case that creative solutions are only possible when there is a original problem. Problem finding does seem to be distinct from problem solving, and it seems to play a role in many creative efforts. It is best not to equate creative thinking with problem solving.

Another issue involves the relationship of cognition proper with extracognitive influences on creative thinking. Creative efforts are, for example, often tied to intrinsic motivation. The creative person is not reacting to incentives, rewards, or other extrinsic motives but is instead driven by a personal need to understand or solve a problem. The issue reflects the priority of cognition and motivation. It has been suggested that the former depends on the latter because we don't think about what we don't care about. It has also been suggested that the latter depends on the former because we don't care about things we can't understand.

Creative cognition probably involves both motivation and cognition *per se*. In the model of the creative process presented by Runco and Chand (1995), a primary tier of cognitive components includes problem finding, ideation, and evaluation skills, with a secondary tier of important influences including motivation (both intrinsic and extrinsic) and information (both factual and procedural, or tactical). Although some parts of creative cognition are in fact more cognitive than others, realistically, extracognitive influences, and their interaction with the cognitive components, need to be recognized.

6. *Conclusions*

Creative thinking includes some basic cognitive processes, including perception, attention, and memory. Creative cognition involves perceptual processes when a creative insight is a direct result of the individual's original interpretation of experiences or associations. Creative cognition may reflect attentional selections when the individual benefits from the recognition of experiences and associations that can be used for original ideation. Creative thinking can depend on memory and the storage of information as well. Some creative achievements actually depend on expertise and require years (to master the knowledge which is required by a field). Recall what was said above, however, about expertise occasionally working against creative insights by leading to routine and assumption. Other basic processes are involved in associative and divergent thinking. In addition to these basic processes, creative cognition may be metacognitive and tactical. In this sense we can exert a degree of control over our own thinking and direct our cognition to the generation of original and useful ideas, insights, and solutions. We can think creatively.

Creativity and Innovation in Organizations, Management of

At the root of the development of our species from our primitive beginnings to the recent stunning advances in technology, communication, and social complexity, have been creativity and innovation—the development and implementation of ideas for improved processes, products, or procedures (Drazin and Schoonhoven 1996). In this article the factors that influence individuals, groups, and whole organizations to be creative and innovative in their work, are described. The range of research in the social sciences on this topic is enormous partly because of the positive connotations and practical benefits associated with innovation.

However, the notion that creativity and innovation are easy, positive, opportunistic processes is inappropriate. Conflict is a common characteristic of innovation, observable principally in resistance to change. Innovation by definition represents a threat to the status quo, so for a group or organization to implement innovation successfully, its members must manage conflict with the attendant emotional pain and difficulty, overcome resistance to change, and persist in ensuring the successful implementation of their innovative proposal. And innovations do not always have beneficial outcomes. An innovation is often a mistake after the event. Moreover, even creativity appears to be a consequence of hard work or as Csikszentmihalyi and Sawyer (1995, p. 331) suggest '… 99 per cent perspiration and 1 percent inspiration.'

To make sense of this domain of social science research without recourse to complex academic definitions it is useful to distinguish between creativity and innovation implementation. Creativity can be seen as the development of new ideas, while innovation implementation is the application of those new ideas in practice. Using this distinction between creativity and innovation implementation it becomes clearer that creativity is more a characteristic of individuals, while innovation implementation tends to be accomplished by groups, organizations, or societies. Indeed, there is evidence that people are most creative when they work alone.

Creativity requires individuals with creative characteristics, who feel free from threat and pressure, and

work in a supportive environment. Innovation requires diversity, integration, external challenge or demand, and practical support for innovation.

1. Individual Innovation

1.1 Individual Characteristics

The innovation process begins with the creativity of individuals, so the generation of a new idea is a cognitive process, located within individuals, albeit fostered by interaction processes, for example, in teams (Mumford and Gustafson 1988). Thus, first and foremost, innovative individuals are both creative and innovative (i.e., they don't just have creative ideas, they also try to implement them). These are people who have a preference for thinking in novel ways; who think globally instead of locally (distinguishing the wood from the trees); and who have intellectual abilities that include synthetic abilities (to see problems in new ways and escape the bounds of conventional thinking), analytic abilities to recognize which ideas are worth pursuing, and the practical contextual abilities to persuade others of the value of their ideas (Sternberg and Lubart 1996).

To be innovative and creative also requires sufficient knowledge of the field to be able to move it forward, while not being so conceptually trapped in it as to be unable to conceive of alternative courses (Mumford and Gustafson 1988). A legislative thinking style is required, or a preference for thinking in novel ways of one's own choosing. It also helps to be able to think globally as well as locally, and to be able to recognize which questions are important and which are not (Sternberg and Lubart 1996).

People who are confident of their abilities are more likely to innovate in the workplace. Researchers have found that confidence and motivation to develop knowledge and skills predicted innovation following job change. Innovative people also tend to be self-disciplined in matters concerning work, with a high degree of drive and motivation, and a concern with achieving excellence (Mumford and Gustafson 1988). This perseverance against social pressures presumably reduces the dangers of premature abandonment. Minority influence theory in social psychology suggests that this perseverance acts to bring about change in the views of majorities, and is a necessary behavioral style among innovators (see Nemeth 1986).

Tolerance of ambiguity, widely associated with creativity, enables individuals to avoid the problems of following only mental ruts, and increases the chances of unusual responses and the discovery of novelty (Barron and Harrington 1981).

Innovative people tend to be self-directed, enjoying and requiring freedom in their work (Mumford and Gustafson 1988). They have a high need for freedom, control, and discretion in the workplace and appear to find bureaucratic limitations or the exercise of control by managers frustrating. Such people need clear work objectives along with high autonomy to perform well in work.

1.2 Work Environments

Creative cognitions occur when individuals feel free from pressure, safe, and positive (Claxton 1997). Experimental manipulations of stress levels in experiments have shown that higher levels of stress lead to greater reliance on habitual solutions. Moreover, psychological threats to face or identity are also associated with more rigid thinking, and time pressure increases rigidity of thinking on work-related tasks such as selection decisions. Speculation (a critical creative process) makes people in work settings feel vulnerable because they often tend to experience their workplaces as unsafe. Questioning the person who comes up with an idea too closely, joking about the proposal (even in a light way), or simply ignoring the proposal, can lead to the person feeling defensive.

The characteristics of work tasks also impact upon people's creativity. Oldham and Cummings (1996) found that the following five job characteristics predicted levels of individual innovation at work: skill variety and challenge, task identity, task significance, autonomy task feedback.

Skill variety refers to the degree to which a job requires different activities in order for the work to be carried out and the degree to which the range of skills and talents of the person working within the role is used. Thus a nurse working with the elderly in their homes may need to use the professional skills of dressing wounds, listening, counseling, being empathic, and appraising the supports and dangers in the person's home.

Task identity is the degree to which the job represents a whole piece of work. It is not simply adding a rubber band to the packaging of a product, but being involved in the manufacture of the product throughout the process, or at least in a meaningful part of the process.

Significance of the task in terms of its impact upon other people within the organization, or in the world at large, has an influence on creativity. Monitoring the effectiveness of an organization's debt collection is less significant than addressing the well-being of elderly people in rural settings, and may therefore evoke less creativity.

Autonomy refers to the freedom, independence, and discretion for the people performing tasks, in determining how to do their work and when to do it. Their level of autonomy directly determines the extent to which people are creative and innovative in their work.

When people receive feedback on their performance they are more likely to become aware of the 'performance gaps.' Consequently they are more attuned

to the need to initiate new ways of working in order to fill the gaps. Of course this also implies that they have clear job objectives.

While some theories of creativity and flow suggest that creative work is primarily sustained by intrinsic motivation (Amabile 1988), emerging research evidence suggests that extrinsic rewards can complement intrinsic motivation. Rewards appear to be counterproductive only if they serve to displace attention from the task toward the reward. Despite much popular belief to the contrary, there is considerable evidence that extrinsic rewards encourage both creativity and innovation implementation.

Human beings minimize effort in their activities and therefore some external stimulus is necessary to prompt the extra effort required to innovate. Andrews (1979) found that moderate time pressure was generally associated with higher creativity amongst R and D scientists. Many studies have shown that work demands explained more of the variance in innovation than any other work role factor. Necessity may well be the mother of invention.

Job security is a positive predictor of innovation. People on short-term contracts are much less likely to innovate than those with longer tenure. At the same time, however, job tenure is often a negative predictor. In other words, the longer people are in their jobs, the less likely they are to innovate. Paradoxically, organizational tenure seems to be a positive predictor. Research suggests that job insecurity reduces the motivation to innovate. However, the longer people stay in the same job within the organization the less they innovate.

1.3 Work Group or Team Innovation

Group or team innovation occurs when a diverse group (in terms of task relevant knowledge, skills and abilities) experiences both high external demands and high levels of internal integration and psychosocial safety (and this may largely be determined by the knowledge skills and abilities members have for working in teams). Put succinctly, creativity requires safety, while innovation implementation requires high demands (whether in the form of threat or large reward). Groups will be creative primarily when their task is sufficiently interesting, motivating, and challenging and when the group's internal environment or processes are experienced as safe. Diversity is necessary to ensure there is sufficient difference and richness of input to encourage creative and innovative outputs (Mumford and Gustafson 1988).

Research on climates for innovation in teams has revealed the importance of shared objectives in teams, high levels of participation (information-sharing, shared influence over decision making and interaction), an orientation to excellent task performance, and support for innovation.

West and Anderson (1996) also found that these team climate factors predicted levels of innovativeness over a six-month period, in top management teams in 27 hospitals—innovation was monitored via tape recordings of team meetings, interviews with team members, and study of the minutes of team meetings (see also the seminal UNESCO studies reported in Andrews 1979). Moreover the proportion of innovators in the team (members scoring high on a measure of innovativeness) predicted the radicalness (changes to status quo) of innovations they introduced into the hospitals.

Of course, one of the implications is that organizations need to encourage teams by focusing not just on productivity, but also on creativity and innovation as important performance outcomes. Research examining the climate of UK university departments over an eight-year period showed that external ratings of performance, based on quantitative measures of scientific productivity and excellence, led members of those departments to report an increase in the perceived effectiveness of those departments. But they also reported that their departments became more formalized (more rules and regulations) while levels of participation in decision making and support for innovation declined. These are precisely the conditions under which innovation and creativity will also decline.

A key indicator of innovation in work groups is reflexivity. Team reflexivity is the extent to which team members collectively reflect upon the team's objectives, strategies, and processes as well as their wider organizations, and adapt them accordingly. There are three central elements to reflexivity: reflection, planning, and action or adaptation:

(a) Reflection consists of attention, awareness, monitoring, and evaluation of the object of reflection.

(b) High reflexivity exists when team planning is characterized by greater detail, inclusiveness of potential problems, hierarchical ordering of plans, and long-range as well as short-range planning. The greater the details of implementation intentions or plans, the greater the likelihood that they will manifest in innovation.

(c) Action refers to goal-directed behaviors relevant to achieving the desired changes in team objectives, strategies, processes, organizations, or environments.

As a consequence of reflexivity, the team's reality is continually renegotiated during team interaction. Understandings negotiated in one exchange between team members may be drawn upon in a variety of ways in order to inform subsequent discussions and offer the possibility of helpful and creative transformations in meanings as well as the development of shared mental models.

Leadership is also important to team performance and creativity. For example, research reveals that chief executive officers' ages, flexibility, and perseverance are all positively related to the adoption of tech-

nological innovation in their organizations. How the leader manages team meetings can influence group processes—directive chairs inhibit teams from achieving shared mental models and inhibit innovation by restricting the multiplicity of interactions in free-flowing teams. Recent theories of leadership depict two dominant styles: transformational and transactional. Transactional leaders focus on transactions, exchanges, contingent rewards and punishments to change team members' behavior. Transformational leaders influence group members by encouraging them to transform their views of themselves and their work. They rely on charisma and the ability to conjure inspiring visions of the future. Evidence suggests that it is transformational leaders who have most influence on consensus decision-making processes, and thereby innovation.

Dissent is a potential stimulus for group innovation when it occurs in a cooperative context. Minority influence theory provides an understanding of how dissent and minority influence intragroup processes lead to creativity and innovation (Nemeth and Owens 1996). It implies that individuals in small groups can bring about change in the views of the majority through being consistent and persistent. It suggests that minorities and dissenting views in organizations should be tolerated, and also encouraged, in order to develop seedbeds for innovation and creativity. By drawing upon this area of theory and research, powerful conceptual insights into innovation implementation strategies can be developed.

2. Organizational Innovation

2.1 Organizational Climate

Organizations create an ethos or atmosphere within which creativity is either nurtured and blooms in innovation, or is starved of support. Psychological research has revealed that supportive and challenging environments are likely to sustain high levels of creativity (Mumford and Gustafson 1988), especially those that encourage risk taking and idea generation (Kanter 1983). Employees frequently have ideas for improving their workplaces, work functioning, processes, products, or services. Where climates are characterized by distrust, lack of communication, personal antipathies, limited individual autonomy, and unclear goals, the implementation of these ideas is inhibited (Amabile 1988).

2.2 Organizational Structure

The greater the complexity and more differentiated the organization (in terms of departments, groupings, etc.) the easier it is to cross boundaries and the greater the number of sources from which innovation can spring. Yet, as organizations become more complex, senior managers tend to increase formalization and control systems and this constrains innovation (Kanter 1983, Van de Ven et al. 1989).

Companies operating in uncertain environments will require flexible, decentralized, and informal work practices (organic rather than mechanistic forms of organizing) in order to respond effectively through innovation. Collaborative idea development across an organization is often cited as a precondition for organizational innovation (Kanter 1983, Zaltman et al. 1973). There is support for the notion that high centralization is a negative predictor of innovation (Burns and Stalker 1961), and Lawrence and Lorsch's (1967) case studies showed that tightly coupled interdepartmental relationships fostered new product development in organizations. However, research also suggests that centralization may also be necessary to ensure innovation implementation. Zaltman et al. (1973) call this the innovation dilemma. Decentralization at local level is necessary for creative ideas to be developed but centralization may be required for the effective implementation of those ideas in the wider organization. The failure of many organizations to innovate may be a consequence of a failure to recognize this inherent tension.

The resolution of the dilemma may be team-based organizations. Teams provide the sources for ideas (especially cross-functional teams) while the team-based organization also offers simultaneously centralized and distributed decision-making structures that enable successful innovation. Indeed, the extent of team-based working in organizations appears to be a good predictor of innovation.

2.3 Organizational Size and Age

Large organizations have difficulty changing their forms to fit changing environments. Yet organizational size has been a positive predictor of both technological and administrative innovations. Innovative agility is more a characteristic of smaller organizations (Rogers 1983). Size may be a surrogate measure of several dimensions associated with innovation such as resources and economies of scale. However, in large organizations, decentralization and specialization are not sufficient to ensure innovation. Integration across groups, departments, specialisms, is also necessary for communication and sharing of disseminated knowledge, and this requires some centralization or else the sophisticated development of team-based structures. More recent research, examining all 35 US firms that produced microprocessors between 1971 and 1989, showed that smaller organizations were more likely to be the sources of innovation.

The longer human social organizations endure, the more embedded become their norms and the more resilient to change become their traditions. Consequently, mature organizations will have more difficulty innovating and adapting. Evidence from both UK and

US studies suggests that younger organizations (years since start up) are likely to innovate in products, production technology, production processes, work organization, and people management.

2.4 *Market Environment and Uncertainty*

Low market share predicts higher levels of product innovation while environmental uncertainly predicts administrative innovation (innovation in work organization and people management systems). These findings point to the importance of external threat or demand in stimulating innovation in organizations.

2.5 *Management of Quality*

The philosophy of continuous improvement embodies a central commitment to innovation. A wide variety of methods and techniques are deployed by total quality management (TQM) adherents, including improvements in product and manufacturing design, upgraded technology, responsibility for quality at the point of production, statistical process control, and the development of a production culture based on continuous improvement in both products and processes. The more sophisticated and pervasive the management of quality, the more innovative organizations tend to be.

2.6 *Support for Innovation*

Organizations must provide appropriate resources for creative efforts and encourage independent action in order to facilitate the implementation of the creative ideas of those who work within them. There are generally positive and strong correlations between R and D expenditure in organizations and innovation.

Companies use a wide range of schemes to support innovation, and the need for such practical schemes to stimulate, support, and ensure the implementation of innovation is clear. Many organizations include a commitment to innovation in their philosophies, but the practical realization of their commitments is poor. The tendencies to inertia in organizations and resistance to change require clear, practical, and effective strategies to promote innovation.

A central contextual factor for encouraging innovation is reward for innovation implementation. Outcomes like money, fringe benefits, public recognition, and preferred work assignments are likely to lead to innovation implementation.

2.7 *Networks and Alliances*

Increasingly researchers are examining the relationships between organizations (e.g., between suppliers and customers and in joint ventures) and this research suggests that such alliances are an important source of innovation. However, mergers, acquisitions, and divestitures by organizations are associated with lower levels of innovation, probably because managers divert attention and resources away from innovation in order to manage structural changes.

3. *Conclusions*

Findings across a range of levels and sectors make it clear that innovation only occurs where there is strong practical and cultural support for efforts to introduce new and improved products and procedures. At the same time, opportunities to develop and implement skills in the workplace and to innovate are central to the satisfaction of people at work (Nicholson and West 1988), while innovation is vital to the effectiveness of organizations in highly demanding and competitive environments.

Creativity Training

Creativity training focuses on the enhancement of creative potentials and performances. The training may be short- or long-term. It may involve explicit instructions or be less direct (e.g., simply suggesting that individuals appreciate originality and look to maximize it in their daily lives). Creativity is multifaceted (Runco and Albert in press), and enhancement efforts tend to focus on one component of what has been described as the creativity syndrome, or complex. Creativity often results from particular cognitive operations and processes, for example, but these are not used unless the individual is motivated to use them. In that sense, creativity is an affective, as well as cognitive phenomenon (Runco and Richards 1997). Particular personality traits, such as openness to experience, may also be involved in creative work, and many individuals studying creativity now assume that there are social, interpersonal, and contextual influences as well. This article first describes the issue of enhancement, and then reviews the cognitive, affective, and contextual training targets and concerns.

1. *Training as the Enhancement of Potential*

In the present context, 'enhancement' is best viewed as the fulfillment of potential. Such fulfillment may be intentional and systematic, as is the case in most experimental investigations of the topic and in those educational programs that attend to creativity. Enhancement also occurs in relatively unsystematic ways, as is the case in families or organizations which appreciate creativity but do not explicitly target original behaviors (Basadur 1994).

Defining enhancement as the fulfillment of potential allows all increases in creativity—systematic and unintentional, short- and long-term—to be recognized. It also circumvents the controversy over the nature and nurture of creativity. This is because most human potentials are both genetic and experiential, with experience (in the present context, the experience that leads to enhancement) working within genetic boundaries. Biologists refer to the 'range of reaction,' with the range genetically determined and the reaction within that range determined by the individual's experience. In this light, the enhancement of creativity merely fulfils an individual's genetic potential. Some will have more of that potential than others; not everyone can be Mozart or Einstein. Everyone can, however, fulfil his or her potential for original and creative expression. Given the importance of creativity for personal growth and social and technological evolution, we should consider carefully how best to fulfil the relevant potentials.

2. *Enhancement of Cognitive Components of Creativity*

There are various cognitive theories of creativity. Some involve basic process, such as memory and information processing, and some focus on higher-order thought, including problem solving, metaphor, and divergent thinking. Metacognitive processes are frequently involved in cognitive theories of creativity. This is because they refer to strategic and intentional operations, and creative work is often both of those. Many creative persons focus on doing what has not been done before, for example, or on stretching and extending ideas, approaches, or work into entirely new directions. They intentionally, and often strategically, target creative results.

As a matter of fact, given the intentionality assumed by all strategic and metacognitive efforts, it is likely that a count of all systematic enhancement efforts would show that the majority attempt to improve thinking by providing tactics. Table 1 presents a list of some common tactics.

Note that many of the tactics in Table 1 are interrelated. Many of them, for instance, involve some sort of change in perspective. This is true of points (a)–(h), (l), (m), (r), (t), (w), (x), and (z)—and the benefit of several others may follow from a shift in perspective. New perspectives break mental sets and routines, and thereby minimize the chances of fixity. Original ideas often result.

Several of the tactics focus on originality. This is because originality is necessary, though not sufficient, for creativity. Consider points (i), (j), and (t)–(v). Keep in mind, however, that original insights are not always creative. Some original insights are unusual, novel, or unique precisely because they are worthless or inappropriate. Creativity involves more than orig-

Table 1
Example tactics to improve creative thinking

(a) Change your perspective.
(b) Work backwards, from the end of the problem (the solution) to the beginning.
(c) Turn the problem upside down.
(d) Question your assumptions.
(e) Get another opinion. Talk to someone from another field, or with a different perspective.
(f) Incubate. Put the problem aside for a while.
(g) Think like a kid. (What would your younger brother say?)
(h) Break the problem into small parts.
(i) Try new combinations.
(j) Explore new connections.
(k) Let your mind wander. Trust your intuition.
(l) Be playful, foolish, uninhibited.
(m) Use trial and error, especially the latter—and then learn from those mistakes.
(n) Gather more data.
(o) Think big! Think small! 'Honey I shrunk the kids!'
(p) Find an analogy (The Wright brothers did it; they looked to birds!).
(q) Look to nature.
(r) Visualize. Try 'the mind's eye.'
(s) Change the medium. (Draw a picture. Make up a song about that problem.)
(t) Explore the bizarre.
(u) Be a 'contrarian.' Walt Disney was one—that's how we got Mickey Mouse.
(v) Bend the rules! Dr. Seuss made up how many new words?
(w) Focus on quantity for a while. A high-quality idea may find a way out, eventually.
(x) Borrow an idea and then make it better.
(y) Ask questions. Ask: why? how? why not? what if?
(z) Change the problem.

inality. Truly creative insights are original and somehow fitting or useful (Runco and Charles 1993).

One final note about the list of tactics given in Table 1. Some of them involve a problem, and others focus on a solution. It has been said that creative ideas require creative problems. Sometimes redefining the problem guarantees an original solution. With this in mind, it is not surprising that some tactics lead the individual to change the problem or its representation.

3. *Problem Solving and Finding*

There is a larger issue: namely that of the relationship of creativity with problem solving (and problem finding). Many definitions of creativity presume that it is a kind of problem solving. The alternative is that problem solving is sometimes creative, but that creativity may be involved when an individual has the need or urge for self-expression. In this alternative view, creative thinking and problem solving are sometimes unrelated; creative skills may be used for more than problem solving.

Tactics such as those listed above (and there are many others) are often included in the various systematic programs which are designed to enhance creativity. Synectics, for example, encourages the use of analogical thinking. It is easy to see the power of analogical thinking in inventions such as the steam engine (a tea kettle), Velcro (clingy burrs), and the airplane (birds, to whom the Wright brothers looked many times). Here again there is an alternative, which in this case is that some creative thinking uses analogical reasoning, and some does not.

There are many programs for enhancing creativity, in addition to synectics (see Meador et al. 1999). There is the Odyssey of the Mind, for example, Future Problem Solving, and Creative Problem Solving (CPS). The last of these is probably the best known. It relies heavily on *brainstorming*. When brainstorming, the quantity of ideas is targeted by a group; quality is de-emphasized. Judgment and evaluation are postponed, and 'piggybacking' (extending ideas given by others, stretching a line of reasoning) is encouraged. Empirical research on brainstorming suggests that it is only modestly effective (Rickarts and deCock in press). In fact, if an organization really needs a large number of ideas, they may be better off having individuals work alone. Brainstorming may be good for team building, but it does not seem to work as well as individual problemsolving. Too often, individuals in brainstorming groups loaf ('social loafing') and assume that others will do enough work to get the job done.

4. *Information Processing*

Enhancement efforts occasionally focus on basic facets of information processing. These efforts usually sug-

gest changes in information transfer and say little about information storage (memory). Sometimes enhancement is expected to result when an individual stops treating information as factual in the static sense. This is another way of saying that the individual questions assumptions and changes his or her perspective. Information is mindfully examined and perhaps even altered, rather than merely transferred without question.

Other times, enhancement is expected when the individual is simply better informed, or at least has the most relevant data. Good information is very important for many creative solutions. It is, however, a matter of quality more than quantity. In fact, individuals can apparently have too much information! When this occurs, there is a kind of expertise that typically leads the expert to more assumptions and a reliance on routines (Rubenson and Runco 1995). These preclude mindful and spontaneous thinking. Creative thinking thus often requires an optimal amount of information; more is not always better. Perhaps it would be most appropriate to conclude that enhancement is most likely when the individual is informed but, in addition, avoids the assumptions and routines that may preclude original thinking.

5. *Motivation*

The best enhancement efforts communicate the value of creative solutions and ideas, in addition to simply showing how the individual or organization can be more original. They demonstrate why and how, as well.

This brings us to the motivational and attitudinal components of creativity. Many enhancement efforts attempt to change attitudes about creative work and assume that improved attitudes will motivate the person or organization to utilize the strategies that have also a part of the enhancement. Attitudinal changes may be necessary because people will need to expend effort to change their ways. They will need to break routines, to question assumptions, to take risks.

They may also assume that creative persons are eccentric, or even difficult to work with (because they do things their own way); and in this light, one of the critical attitudes targeted in enhancement efforts is tolerance (Richards in press). People in organizations wishing to increase innovation and creativity must tolerate independence, risks, and perhaps a lack of structure. Educators must tolerate divergence in the thinking of the students; and this is especially difficult, because so much of the educational curriculum (and assessment tradition) is convergent. Tests, for example, are most objective when there is one correct answer, rather than originality.

It can be very difficult to motivate an individual to do creative work. If that individual is already motivated, it may be a matter of supplying tactics, direction, or resources. But if the individual is not motivated, or motivated to work in other ways (e.g., 'satisficing,' or just getting the job done), the motivation to do creative work may be difficult to arouse. This is because creative efforts are typically intrinsically, rather than extrinsically, motivated. Extrinsic motivation may result from pay, reward, incentive, or the like—contingencies and promises made by others. Intrinsic motivation, on the other hand, comes from within. It is personal and independent of contingencies and promises. Moreover, extrinsic factors can undermine intrinsic motivation. For this reason, the creativity that results from intrinsic motivation to solve a problem or express oneself can be lost if it is not respected and if an effort is not made to reinforce or redirect it. This can make enhancement very difficult. It means that enhancement usually requires that demonstrations and the like deal with impersonal examples. They may need to leave the application of the tactic by the individual to his or her own life to that individual.

6. *Environmental and Interpersonal Factors*

The need to respect intrinsic motivation and the need for tolerance in educational settings or organizations implies that there are interpersonal and contextual influences on creativity. Indeed, enhancement may result from the manipulation of context and interpersonal processes as much as from direct and explicit training.

In general terms, creativity is supported by environments which allow autonomy and which provide the resources and respect necessary for the individual to maintain independence of thought (Rickards and deCock in press, Rubenson and Runco 1995). Tolerance for autonomous and diverse work styles and interests may be necessary, and individuals may need time. Deadlines and imposed schedules can constrain thinking. Admittedly, there are individual differences. Some famous creative persons have claimed that they work best under pressure (e.g., with some competition).

Importantly, creative results are often unexpected. They are, after all, original, and original results may be at best loosely associated with previous efforts. But the unexpected nature of creative insights means that there is a risk. Hence, a tolerance of risk, on the part of the individual and those working with the individual, is often necessary.

7. *Conclusions*

Enhancement may involve explicit instructions (e.g., 'think of things no one else will,' 'find an analogy in

nature'), or it may result from a particular environment, context, and interpersonal stance. Enhancement efforts may focus on the cognitive, metacognitive, motivational, or attitudinal facets of the creative process. The cognitive facets may be the easiest to target (e.g., by suggesting tactics) and the motivational the most difficult. The most effective enhancement will take most or all facets of the creative process into account.

Educators or managers may recognize the need for enhancement efforts. They may investigate the programs which are designed to maximize creative efforts, or they may take it upon themselves to create a stimulating environment and provide the respect, resources, and tolerance that will allow creative thinking. Enhancement is, however, probably most effective over the long run. Short-term programs may be effective, but they may fail to generalize and may not be maintained for very long. Creativity is the most likely when enhancement is supported over a long period of time. In this sense parents may be in the position to best enhance creative thinking. They can model creativity, provide opportunities for original problem solving and self-expression, and appropriately appreciate autonomy and risk taking—and they can do so for an extended period of time. If the benefits of enhanced creativity are recognized on a larger scale, by society as a whole, enhancement is virtually assured. If that occurs, parents, educators, managers, and supervisors will all tolerate, appreciate, and support enhanced creative thinking.

Creolization: Sociocultural Aspects

The concept of creolization, so called by analogy with the creolization of languages, has been used in anthropology to refer to the process of social change that takes place in societies characterized by rapid social flux, and where cultural influences from various origins are integrated into a new system of meaning locally produced. Cultural creolization is found particularly in urban centers in association with sustained cultural contact, more typically produced within the hegemonical conditions of colonization, of World system influences, and of globalization.

1. The Origin of the Concept

The concept of 'creolization' is borrowed from linguistics, where it refers (a) to a process of transformation of a pidgin language into the main language (and often, into the mother tongue) of a new linguistic community, and (b) to the creation of a creole language out of different languages (at least two) without an intermediate pidgin state (see *Pidgin and Creole Languages*). It is this second meaning that has been borrowed by anthropology, but as this process is rather rarer than the preceding one, it would have been more accurate to use the term of pidginization (formation of a pidgin language) to refer to the cultural phenomena that are now described with the concept of creolization (Jourdan 1987, McKellin 1991). A pidgin or a creole develops as a response to communication pressures, in situations of intense cultural contact, and incorporates features from languages available to the pidgin/creole makers: the new language is distinct from the languages that have shaped it, yet has retained sufficient features of them, that their origin can sometimes be traced and identified. Theories of pidgin and creole genesis are highly debated in creole studies, yet scholars agree that the characteristics of pidgin and creole languages include the speed with

which they form and develop; the sociological conditions that have shaped them, most typically, colonization; and an almost instantaneous creativity.

2. Creolization and Anthropology

Despite the epistemological difficulties inherent to the borrowing of theories and analytical models across disciplines, the concept of creolization seems to have captured the imagination of some scholars as a way of talking about and analyzing rapid cultural change associated with contact between societies of different ideological and technological orientation. The fact that the label 'creolization' was retained, rather than the more technically appropriate 'pidginization' is linked to two factors: first, the word 'creole' already existed in anthropology to refer to the people and plantation societies of the Caribbeans and the Indian Ocean, typically characterized by a high degree of cultural diversity and intense contact, but nevertheless full-fledged cultural formations, most often sustained by creole languages. Second, for a long time pidginization has been thought of as a process of linguistic impoverishment, whereas creolization was always associated with linguistic enrichment and elaboration. Using the former label could have been seen as a pejorative and inadequate label to describe a process of cultural creativity where 'loss' had no place. In this case, the metaphorical power of creolization won over the more technically correct pidginization. The earlier examples of such usage appear in the works of Drummond (1980), and Hannerz (1987). In parallel, French linguists and anthropologists working in West Africa and in the Pacific have introduced the concept of *créolité* to talk about the creole-like features of the societies where they work (Mannessy 1987), of 'creolicity' to talk about the socioeconomic and ideological conditions fostering the development of creolized societies (Jourdan 1985) and of cultural *métissage* (Amselle 1990).

In anthropology, creolization has been used in two different ways. First, as a metaphor capturing elusive processes of integration of new cultural forms, a synonym of hybridization associated with globalization. Second, as an analytical model for the study of social change directly mapped onto the linguistic model of creolization–pidginization described above. In all cases, creolization is used to refer to social change. An example, yet not representative of all types and domains of creolization, would be a Solomon Island business man sending printed invitations to the Catholic wedding of his daughter in the biggest hotel of the city of Honiara, but who would make sure to collect the bridewealth from the family of the groom, and would subsequently redistribute it to his kin.

Used as a metaphor, the meaning of creolization remains very akin to that of hybridization and creates the same type of conceptual ambiguities: is it the process or is it the results of structural modification or reorganization? The image that there is something that gets mixed with something else to produce yet another thing (e.g., the new form of marriage in Honiara), is inherent to the metaphor. As such, it is an interesting shortcut into the description of phenomena not easily definable, but which seem to be clearly associated with the complexification of social relationships. Used only as a metaphor, creolization (and hybridity) fail to explain how what is happening warrants the usage of this new term rather than intersystem (Drummond 1980), syncretism (see *Syncretism*), or métissage, those other concepts central to a study of social change that focuses on the in-between. Creolization, in that sense, is used to refer to a recombination of structures, practices and meanings: a case of 'new meanings in old shells' or 'old meanings in new shells.' In as much as they focus on the dynamic intermixing and restructuring of meanings, both concepts are similar. Both capture the image of the in-between, of the neither/nor, of flux and vanishing boundaries, but focus on the result.

A stronger reading of the concept of creolization, closest to the way the concept is used in linguistics, proposes ways of identifying the cultural logic which provides answers to the following questions: What changes and what does not, and under which conditions? What is the nature and the pace of the change? If culture is practice, how does change affect the practice of identity? If culture is text, is every aspect of culture affected in the same manner and to the same extent? If culture is grammar, are there parameters and constraints for change? What makes the change acceptable? This version of creolization rests on a set of assumptions: (a) that moral–existential aspects of culture can be differentiated from instrumental aspects; (b) that the latter change at a faster pace than the former; (c) that, with regards to the pace of change, they can be compared with the syntax and lexicon of a language respectively. In situations of creolization, local instrumental aspects of culture are often replaced, along with their attending symbols and meanings, with those from another source. The moral–existential aspects of culture are now sustained by new symbols, and may be given slightly different meanings, but will still be perceived as essential to the group's definition of identity. The bridewealth payment mentioned above is essential to the father's standing in one of his networks (here his lineage) and justifies his traveling back to the home village to collect it. All participants in the transaction agree that the meaning of such bridewealth is now very different from what it used to be, and that the amount is inflated. Yet bridewealth has to be paid, even against the wishes of the parish priest, because this form of exchange is essential to the integration of lineages, and therefore to the father's identity as a member of the group. As with any form of social process, creolization rests on people's agency and ability to engage the

world, and is associated with a reconfiguration of self and of the practice of identity. Undoubtedly, there is a distinct advantage in identifying the processes that lead to a redefinition of people's practice of identity, even if, initially, this identification may start with an analysis of the features and elements that are being transferred across cultures, with or without attendant localization.

3. *Essentialism*

Contra critics have argued that creolization theory is essentialist because it presupposes the existence of pristine cultures that will subsequently join, mix, overlap, and be reshaped; proponents of creolization reject this notion, and point to culture as a locus of permanent change, made even more spectacular at particular times in the history of societies. They also point to the shortcomings of a conception of culture as a bounded pristine entity.

If creolization were an essentialist theory, the concept of cultural loss would be integral to its definition. Yet, it is not, for the simple reason that talking about loss in connection with social change implies a move away from the ideal, but unreal, pristine state of tradition. Loss belongs to a theoretical framework in which cultures are seen as essential wholes, neatly bounded self-reproducing structures, impervious to the passage of time and deriving legitimacy from a primal pristine state. Cultures are not less authentic because they are creolizing. The new cultural practices, and the new cultural forms, that have emerged out of the creolization process are not any more authentic or spurious than the ones they are derived from, or more spurious or authentic than societies that have changed in other ways. They simply exist. What is revealed by the creolization concept is the endless negotiation of meaning that takes place when groups and individuals engage in social relations within societies. The pace and scope of these cultural negotiations are more important in situations of rapid social change. The strength of creolization theory is that it points to (or foregrounds) elements that are not easily captured by other models: heterogeneity rather than homogeneity, process rather than stasis, fragmentation rather than integration, multiple rather than singular identities, and above all at the domain of culture as contested ground rather than public space.

4. *The World System and Globalization*

Typically, but not exclusively (see Hannerz 1996) the creolization concept has been applied to the analysis of social change in the so called Third and Fourth World societies, in colonial and postcolonial situations. Colonial, postcolonial and hegemonical contact relations are particular in the type and speed of the sociocultural change they provoke and are best suited to be studied with the paradigm of creolization that holds the speed of change as a defining element. Critics have argued that the quasi-exclusive application of creolization theory to these societies disempowers them and reinforces the *fait accompli* of colonization by strengthening stereotypes. The argument is usually framed in relation to the World System theory and to the concepts of core and periphery. There may be a reason for this affinity: the very sociocultural formations and ideologies that have fostered the development of creole languages have reappeared under a new guise, that of the World System, economic and cultural, which creates even more pressures for change in these societies than anywhere else at the same moment. These types of contact-induced ideological and experiential pressures resemble the superstrate and substrate influences at work in the formation of creole languages in that they juxtapose and confront practices and meanings that are produced by different social systems and ideologies. This raises the question of the relationship of creolization to globalization. Creolization shares with globalization an increase in available modes of social organization and cultural representation (Pieterse 1995), both offer more options. Both are associated with more culture and not less, even if, on the surface, things look different. But with globalization residing in a movement of ideas, as much as in people's engagement with new sets of ideologies and practices, one could identity, as Hannerz does in Stockholm (1996), creolizing formations in nontypical creolization sites.

5. *Urbanization*

It is in cities that creolization is the most obvious, if only because of the rate and scope of change. As cultural market places, cities are the loci of very fast sociocultural mutations that lead some observers to talk of deculturation, and not only of adaptation to an urban way of life. Creolization is neither. When full-fledged towns and cities develop over mere 40 years, as is the case in many parts of the Third World, in places where there is no local tradition of urbanization, for instance, it requires on the part of urbanites a reassessment of the parameters of their identity (as with the father's behavior at the time of his daughter's wedding) and subsequent engagement in new types of social relations of the type and scale that is not found in other forms of sociocultural change. What is typical of cities is the ebullition of cultural creativity. Only a close study of the superstrate and substrate influences could reveal why, despite the onslaught of a generic cultural and economic World System (the superstrate) onto local traditions (the substrate), the cultural formations of urban Nigeria (Hannerz 1987) Solomon Islands (Jourdan 1985), and Guyana (Drummond 1980) are similar in very many ways, and yet very different from

one another. This begs the question of the specificity of creolized societies: are they any different from other types of societies, given the fact that all societies are changing, and that many contemporary non-Third World societies have, at some point in their history, lived in situations of colonization, invasion or hegemony? May be they are, if only because of the speed and the depth of change that characterize them, and give the impression of a permanent flux. The lifespan of creolization is also a subject of debate: is creolization a transitional period in the life of societies, at particular moments of their history, or is it a permanent state of affairs? One has to ask whether anthropology will be better served by using creolization as a universal synonym for fast cultural change associated with globalization, or whether the concept is not more useful when applied to some social contexts of change and not to others.

Crime and Class

Does social class affect criminal behavior? If so, why has the relationship been so difficult to document in self-report crime surveys? If not, why are prisoners drawn almost exclusively from the ranks of the poor? These questions are important for stratification researchers as well as those studying law, criminology, and deviance. Criminologists are interested in class because it is a fundamental indicator of social position. If crime is related to social class, then social structural factors such as inequality, poverty, and labor markets are likely to be important causes of crime. If not, criminologists must look to factors that may cut more evenly across class lines, such as individual pathology or dysfunctional family processes. Stratification researchers are becoming interested in crime for analogous reasons. Individual-level evidence suggests that crime and the societal reaction to crime can disrupt individual attainment (Hagan 1993), while macro level studies show that crime and punishment may alter unemployment rates and economic performance (Western and Beckett 1999). This article first reviews empirical generalizations about class and crime, and the conceptual and methodological tools used to interpret them. It then outlines recent theoretical and empirical developments and diverse research strategies to further elaborate the relationship, concluding that the relation between criminal behavior and social class is likely to be reciprocal or endogenous.

1. Measurement

1.1 Measurement of Crime

The relationship observed between crime and class is sensitive to the measurement of each concept. There are three primary sources of crime data: the offenders, the official enforcement agencies, and the victims. Self-report studies, typically based on samples of high-school students, generally report very weak relationships between social class and delinquency (Tittle et al. 1978). However, social class is a strong and significant predictor of official law violation, as measured by arrest and punishment, all over the world (Braithwaite 1981). Surveys of prison inmates show that they are educationally and economically disadvantaged relative to the general population. Prior to their most recent arrest, only two-thirds of inmates in the USA had completed high-school, one-third were not employed, and less than half reported annual income greater than $10,000 (US Department of Justice 1993). The relation between social class and criminal victimization depends on the type of crime under consideration. In 1998, in the USA, the violent victimization rate among households reporting annual income greater than $35,000 was only half the violent victimization rate of households earning less than $7,500. For property crimes such as theft, however, the highest victimization rate occurs among households earning $50,000 or more per year (US Department of Justice 1999).

It has proven difficult to reconcile the conflicting pictures of the class–crime relationship provided by self-report, official, and victimization data. Some argue that the discrepancy arises because self-reports generally capture a different domain of behavior than official data. When self-reports are compared with police records, the results show high rates of congru-

ence for white, in-school youths, but less agreement for black males with an official history of delinquency (Hindelang et al. 1981). Some attribute these discrepancies to under-reporting by black males, while others point to race biases in arrest records that overstate the arrests of blacks relative to whites. Most agree that greater police attention to lower-class areas exacerbates class (and race) discrepancies in self-report and official data.

The nonsignificance of class in self-report surveys may also be a product of the compressed frequency and severity range of offending typically recorded in self-report surveys (Elliott and Ageton 1980). In support of the argument that self-reports and official data tap different domains of criminal behavior, some investigations find that middle-class and upper-class delinquency is less serious than delinquency by less advantaged youth. Nevertheless, the strong negative relation between social class and official delinquency and the far smaller class differences in self-report delinquency are well-founded empirical generalizations.

Any discussion of class and criminal behavior would be incomplete without noting that social class is one of the defining characteristics of white-collar crime, or 'crime committed by a person of respectability and high social status in the course of his occupation' (Sutherland 1983, p. 7). By definition, this conceptualization assumes that some degree of power and influence is necessary to commit crimes such as bank embezzlement or insider trading. Because the structure of opportunity to commit such crimes is bound up with social position, however, it is difficult to identify meaningful comparison groups to determine whether white-collar, occupational, or corporate criminals are any more or less deviant than the general population.

Finally, most self-report studies have been conducted on youth, often in school settings. Unfortunately, we know comparatively little about the class distribution of self-reported adult offending in the general population. Class differences in the longitudinal sequence or criminal careers of individual offenders have rarely been explored, although lower-class offenders may have higher crime frequency and participation rates, earlier ages of onset, and longer career durations (Janson and Wikström 1995). With the aforementioned caveats regarding occupational and adult offending, however, the results of self-report studies are generally consistent, reporting weak negative relations between social class and crime. Much of the remaining variation among these studies can be attributed to differences in the conceptualization and measurement of social class.

1.2 Measurement of Class

The effects of social class on self-reported crime depend on whether researchers use gradational or relational class measures. Researchers using continuous gradational measures, such as socioeconomic status (SES), generally find little association between SES and crime. Investigations that operationalize class as a relational measure, based on Marxian ownership or Weberian authority generally report somewhat stronger associations (Brownfield 1986) (see *Class and Law*). One problem with many class indicators, however, is that they omit the most disadvantaged individuals and families—the underclass or surplus population. Theories of crime such as Merton's (1938) anomie model point to the importance of sustained poverty and limited opportunity within a cultural context of common success symbols. Along these lines, some research suggests that parental unemployment is a positive predictor of self-reported delinquency (Farnworth et al. 1994).

Most of the research considered so far actually considers social class origins rather than the social positions or interests of the offenders themselves (Stark 1979). In part, this is because the peak age of offending for many crimes occurs in the mid-to-late-teens, preceding the transition to full-time employment in many societies. To the extent that the social class positions of adolescents have been considered in the delinquency literature, schools are generally the primary (if not exclusive) setting. Nevertheless, many adolescents and young adults have established independent class positions outside the educational arena, particularly those who have left home and school. Research on homeless youth that assesses class in terms of unemployment, hunger, and lack of shelter, reports strong 'foreground' class effects on street crime (Hagan and McCarthy 1997).

In summary, the strongest relations between social class and crime have been observed in studies that use relational rather than gradational class measures. In fact, the most important class distinction is likely between the most disadvantaged and everybody else. Though some specifications of the 'underclass' concept blur the distinction between class and criminal behavior by including law violation (in the form of violence, drug use, or other crime) among its many manifestations, such tautological reasoning is unnecessary to establish the relationship. Sustained parental unemployment in an individual's background or more immediate and extreme material deprivation places persons at greater risk of offending.

2. Sampling, Units of Analysis, and Analytic Approaches

2.1 Sampling

As the preceding discussion suggests, class effects on criminal behavior are unlikely to be observed unless the research methodology ensures an adequate rep-

resentation of extremely disadvantaged respondents and a meaningful comparison group. 'Street criminology' differs from 'school criminology' (Hagan and McCarthy 1997) in both theoretical and analytic orientation. In particular, each approach implies a different domain of criminal behavior and a correspondingly different sampling strategy. Student samples can yield elegant tests of theory among nationally representative samples, although results may not generalize to more extreme law violation. Street samples are more difficult to obtain, in part because complete sampling frames are rarely available. Nevertheless, the latter approach is best suited to identifying respondents from truly disadvantaged class origins and more marginalized current class positions.

2.2 Units of Analysis

Studies conducted at the aggregate rather than the individual level of analysis have generally shown stronger relationships between social class and crime. Housing costs affect the population composition of a neighborhood, which, in turn, influences the distribution of social groups with differential risks for offending (Janson and Wikström 1995). At the community level, the studies of Shaw and McKay (1942) showing delinquency rates in Chicago by neighborhood economic status remain among the most powerful statements in this line of research. At least part of the individual-level discrepancy between self-reported and official crime and delinquency is thus explained by greater police attention to lower-class areas (Sampson 1986).

Emerging multilevel methods are beginning to shed light on the intervening mechanism connecting class with neighborhood crime rates. Research merging individual-level data with neighborhood characteristics shows that the effect of poverty and unemployment rates on violent crime is mediated in large part by 'collective efficacy,' or a community's capacity for informal social control and mutual trust (Sampson et al. 1997). Finally, national-level research on class structure and crime suggests that inequality (Braithwaite 1979), state welfare spending (Messner and Rosenfeld 1997), and unemployment (Archer and Gartner 1984) bear some relation to official crime rates.

2.3 Qualitative and Quantitative Analytic Approaches

Many qualitative researchers take the association between class and crime for granted, focusing their efforts on gangs or individuals in extremely marginalized circumstances. Increasingly, however, such work also includes a comparative dimension. Mercer Sullivan (1989) for example, shows how early criminal behavior can disrupt adolescent education and employment, which in turn increases adult criminal behavior. By examining cliques of boys from similar class positions but different neighborhoods and ethnicities, Sullivan identifies contingencies such as local job networks and illegal markets that mediate the relation between class origins and crime. Other ethnographic work illustrates how street crime is woven into the everyday lives of some individuals and neighborhoods (Venkatesh 1997), identifying the critical turning points in their criminal histories. Because such insights are difficult to glean from the quantitative analysis of survey data, several prominent quantitative criminologists have added a qualitative element to their investigations (Hagan and McCarthy 1997, Sampson and Laub 1993).

3. Promising Avenues for Research

3.1 Reciprocal Relations

The reciprocal relationship between attainment and deviance that Sullivan (1989) noted among disadvantaged adolescents has been explored in a number of important quantitative studies. Analyzing a cohort of London boys born in the 1950s, Hagan (1993) finds that adolescent criminal 'embeddedness,' measured by delinquent activities, friends, and parental criminal convictions, has a strong effect on unemployment in young adulthood. Similarly, in a sample of American delinquent and non delinquent boys born in the 1920s, Sampson and Laub (1993) report that early juvenile incarceration decreases later job stability, which, in turn, exacerbates adult criminal behavior. Thus, social class and crime are likely to be reciprocally determined.

The type and severity of offending however, remains important in determining crime effects on class. Substance use and minor delinquency have little effect on the life outcomes of a predominantly middle-class sample, partly because they are likely to receive numerous 'second chances' (Jessor et al. 1993). Similarly, Hagan (1991) finds that identifying with a subculture of delinquency reduced occupational attainment among working-class boys, but identifying with a 'party subculture' had a small positive effect on attainment among non-working-class boys. In such cases, the type and severity of offending determine the sign as well as the magnitude of the effects of crime on social position.

3.2 Elaborating the Relationship

Criminological researchers have elaborated the relationship between class and crime by specifying and

testing interactions between social class and other factors and by seeking the intervening factors that interpret the relation. With regard to interaction, the relationship between social class and crime may be conditional on background characteristics, such as race, sex, or other characteristics. Power-control theory, for example, posits that social class interacts with gender to affect common delinquency, receiving mixed empirical support (Hagan et al. 1987) (see *Crime and Gender*; *Crime and Ethnicity (Including Race)*).

Regarding intervening factors, Wright et al. report both positive and negative social-psychological paths connecting socioeconomic status and delinquency, characterizing the relationship as 'causation but not correlation' (1999, p. 179). High SES increases delinquency by increasing risk taking and social power and by decreasing conventional values, but reduces delinquency by diminishing alienation and economic strain, and increasing aspirations (Wright et al. 1999). Other research suggests that class effects on crime and deviance are largely mediated by family factors and school performance (Hagan and McCarthy 1997).

Even if the bivariate relationship between class and crime is close to zero, as some self-report research suggests, further research on interactions is necessary to explain how we get to zero—to specify the positive and negative paths linking social class and criminal behavior. Where the bivariate relationship between class and crime is stronger, as in studies using parental unemployment or official crime data, further research is needed to identify the catalysts that transfer class origins into criminal outcomes.

3.3 Cross-national and Comparative Work

A great deal of the research discussed above has been conducted on English-speaking samples, such as Hagan's work on British (1993) and Canadian (1991) data, the Wright et al. (1999) piece on New Zealanders, and the many American studies reviewed by Tittle et al. (1978). Nevertheless, Braithwaite's comprehensive international review suggests that patterns observed in these nations are replicated across the world with a 'degree of consistency which is unusual in social science' (1981, p. 38). To date, however, few truly cross-national or comparative efforts have been undertaken. Most studies have taken nation states as the level of analysis, identifying the structural-level correlates of homicide rates (e.g., Archer and Gartner 1984). One individual-level effort, comparing working-class males in London and Stockholm, found remarkable similarity in the criminal career patterns of the two groups (Farrington and Wikström 1994).

It is difficult to locate the comparable samples and indicators necessary to test the stability of individual-level class effects across national contexts. Nevertheless, such research will be necessary to generalize knowledge of class and crime and to begin to disentangle the relation between social structure and criminal behavior in varying cultural settings.

4. Taking Stock

The concepts of class and crime are fundamental to understanding social position and social order and disorder. Not surprisingly, their relationship is complex and multifaceted. Social class is a strong predictor of official law violation by all measures and a weaker but consistent predictor of self-reported law violation by gradational measures. Researchers are elaborating the relationship by specifying the interactions and the intervening mechanisms connecting class and crime. In particular, it has become increasingly clear that criminal behavior and social class are likely to be reciprocally related throughout the life course.

C. Uggen

Crime and Delinquency, Prevention of

Juvenile delinquency and crime are legal definitions rather than specific behavioral or psychiatric syndromes. Since common law is based on theological law, society has historically responded to juvenile delinquency and crime based on moral and religious beliefs regarding the age at which juveniles are criminally responsible rather than from scientific knowledge regarding the developmental course of delinquency and crime. Historically, the age at which children are criminally responsible has been subject to much debate and has varied significantly both within and between nations (Rutter et al. 1998). Moreover, this debate and variability has led to ongoing tension within society and its institutions between a focus on punishment or treatment and rehabilitation. However, since the early 1970s scientists and interventionists in the fields of criminology, sociology, and psychology, who have focused on the prevention of juvenile delinquency and crime, have made significant methodological and theoretical progress. This progress has included identifying specific antecedents and mediators and their developmental sequencing, and the development of precise interventions (see Stoff et al. 1997). Society and its institutions will need to use this accumulated scientific knowledge as the foundation for developing policy and interventions that are intended to prevent delinquency and crime.

1. Historical Background in the Prevention of Delinquency and Crime

Since the rise of delinquency as a social problem during the industrial revolution, the prevention of delinquency and crime has had a history of swinging between two philosophical poles: punishment and rehabilitation (Bernard 1993). Advocates of punishment have relied on the intellectual power of classical theory, whereas advocates of rehabilitation have relied on learning and attachment theories. Classical theory and its criminological offspring, social control and strain theory (Gottfredson and Hirschi 1990), posits that individuals are responsible for their own behavior and are motivated by cognitive appraisals of the potential costs and benefits of delinquent or criminal acts. Attachment and learning theories and their most recent progeny, social interactional or social developmental theory (Patterson et al. 1992), posit that the probability of performing a delinquent or criminal act is highly related to a child's history of reinforcement for certain behaviors within a family and early associations with negative peers. That is, complex but observable reinforcement contingences are responsible for the initiation and then maintenance of chronic antisocial behavior.

Currently, social control theory appears to be most influential among the public and politicians both in the USA and in other Western countries (Howell 1997, Rutter et al. 1998). However, in the scientific literature social developmental theory appears to have more empirical support. Policy and intervention implications of a reliance on social control theory (i.e., harsher punishments such as training schools, juvenile jails, reprimanding juveniles into adult courts and jails,

mandatory sentencing, etc.) have been shown to be neither in the best financial interests of society nor to have reduced rates of juvenile delinquency and crime. Whereas, recent cost–benefit analyses of interventions based on social developmental theories suggest cost effectiveness, particularly in the long run (Howell 1997). Therefore, there has been a re-emergence of social developmental theoretical models of delinquency and crime. These models emphasize the importance of interactional contingencies operating within family, peer groups, schools, neighborhoods, and communities in the development and maintenance of antisocial behavior (e.g., Patterson et al. 1992) versus theoretical models of delinquency and crime based on economic opportunity (e.g., Gottfredson and Hirschi 1990).

2. *The Problem of Chronic Offenders*

Recent research has shown that a small percentage of children with antisocial behavior, including those who are arrested as juveniles, account for a large proportion (50–75 percent) of juvenile crime (Huizinga et al. 1995). Researchers have also found similar percentages in adult samples. Because this smaller proportion of criminals accounts for a large percentage of crime, it has been suggested that communities often waste their limited resources on noncareer juvenile delinquents who are unlikely to commit further offenses. By the time these noncareer criminals are arrested and/or targeted for intervention, they are often at the end of their short offending span. However, it is also argued that intervention may be easier and more likely to work with the non-chronic group. Some researchers have also suggested that the youth in the chronic group account for a disproportionate share of mental and physical health problems, divorce, domestic violence, and drug and alcohol problems in their age cohorts.

It has become clear that it is rare for a persistently delinquent youth to become a chronic offender without moving through an increasingly well-validated developmental sequence (i.e., early childhood noncompliance, antisocial or aggressive behavior in childhood including covert antisocial behavior, and early arrest, Stoff et al. 1997, Chap. 20). For example, Patterson and his colleagues at the Oregon Social Learning Center have developed two models, an early-onset and a late-onset model, that may account for differences between life-course persistent and transient offenders. In the Oregon Youth Study sample Patterson found that boys with the highest rates of antisocial acts in childhood are at the greatest risk of being arrested before the age of 14. In addition, Huizinga et al. (1995) reported that from 39–62 percent of chronic violent offenders self-report committing their first act of violence at or before age 9. Patterson has also found early arrest (before age 14) is associated with the increased probability of being a chronic offender and, in turn, being a chronic offender is positively correlated with both violent offending and being arrested as an adult (Howell 1997, Rutter et al. 1998).

3. *Prediction and Stability of Antisocial Behavior*

Since the early 1970s there has been increasing agreement among researchers that, to a great extent, externalizing conduct disorders in childhood precede chronic delinquency (Patterson et al. 1992), and chronic delinquency precedes serious and violent juvenile crime and adult criminality (Loeber and Farrington 1998). In addition, there is impressive international evidence that antisocial behavior, including criminal behavior, is relatively stable across stages of the life course (Rutter et al. 1998). The stability of delinquent behavior is particularly strong when antisocial behavior begins early in the life course. Researchers have also found that the development of childhood antisocial behavior and juvenile delinquency leading to adult criminality is multiply determined and involves the convergence of many risk factors (Howell 1997, Loeber and Farrington 1998, Patterson et al. 1992, Rutter et al. 1998). However, recent strides have been made in identifying specific risk factors for the initiation and maintenance of antisocial behavior and perhaps most important the developmental sequencing of their influences.

4. *Developmental Sequencing*

Several well-designed prospective longitudinal studies (e.g., Huizinga et al. 1995, Patterson et al. 1992) have shown that levels of common parenting practices starting early in a child's life and continuing through adolescence are associated with the reduced probability of delinquent behavior. These parenting practices include appropriate discipline (e.g., application of mildly aversive consequences for problem behaviors, structuring, reinforcement of prosocial behaviors, and lack of abusive tactics such as humiliation and hitting), supervision (e.g., monitoring children's behavior and peer affiliations in school and community environments), and developing a positive relationship with a child (e.g., having reasonable levels of positive reinforcement for prosocial behavior, involvement in positive leisure activities). These longitudinal studies along with other recent research (Dishion et al. 1999) have shown that delinquent peers become a significant factor in the development and maintenance of delinquency, and this effect is most significant during adolescence.

In addition, researchers have found an array of complex individual, psychosocial, and society-wide influences that are related to externalizing behavior

problems, offending rates, and a variety of antisocial and delinquent behaviors. These influences include genetic influences, obstetric complications, cognitive abilities, temperament, peer relationships, biased cognitive processing, autonomic reactivity, serotonin metabolism, teenage parenting, large family size, broken homes, abuse and neglect, coercion and hostility, ineffective parenting and supervision, peer groups, poverty and social disadvantage, mass media, school effects, and accessibility of guns and drugs (Rutter et al. 1998, Stoff et al. 1997). Although most of these influences have been shown to have robust associations with delinquent behavior, their individual influences on rates of delinquency are often small (i.e., often accounting for less than 10 percent of the variance in delinquency and crime).

What is significant about the individual influences is that most have been shown to increase in importance as they accumulate for any one child. Longitudinal research also suggests that individual influences are most important if they interact negatively with parent, peer, school, and community relationships. Contingent interactions (many of which have been shown to be bidirectional, Patterson 1982) that occur in these settings have been implicated in the emergence and subsequent maintenance of chronic childhood antisocial behavior, delinquency, and crime. For example, recent research strongly suggests that parent–child interaction patterns starting in early childhood that take place in the context of typical parenting tasks are associated with positive and negative child development outcomes (Patterson et al.1992). It has also been hypothesized that biological and genetic variables play a role in the development of problematic parent–child interaction patterns (Rutter et al. 1998). That is, infants with difficult temperaments and/or hyperactivity are harder to parent, and when matched with low-skilled parents, they have been shown to have more negative developmental outcomes such as higher levels of noncompliance and parental rejection. It is also interesting that, studies by Werner (1989) and others have shown that difficult infants raised by reasonably skilled parents are not at particular risk for negative developmental outcomes.

Many of the individual contextual influences that have been historically associated with rates of delinquency and crime (e.g., poverty, high crime neighborhoods, parental antisocial behavior and psychopathology), in large part, have been shown to be mediated to children through their disruptive effect on parenting practices and family functioning (e.g., parental depressed mood, poor parental discipline, marital conflict) (e.g., Patterson et al. 1992, Sampson and Laub 1994). Some theorists even postulate that economic downturns increase both the number of difficult-to-raise infants (because of increases in infant health problems) and the number of low-skilled parents (through the complex effects of transitions and mobility). These low-skilled parents then drift into disorganized neighborhoods (where rents and costs are lower) and where there are high crime rates and low levels of social support that create further isolation and stress (Sampson 1992). Patterson has suggested that further research on the relationship between economic downturns and density of difficult-to-raise infants and low-skilled parents may solve an embarrassing problem for most current theories of delinquency: that these theories have been unable to account for significant variance in societal rates of juvenile offending.

5. *Prevention and Intervention*

The outcome of three decades of intense research has been a general agreement that prevention of delinquency and crime needs to involve multiple components that target multiple risk factors, and that no single-component intervention will have enough strength to alter the course of seriously antisocial or delinquent behavior. Because many of the early risk factors directly or indirectly involve parent–child interactions, early prevention efforts are increasingly targeting parenting and other contextual variables that indirectly or directly affect parenting. As the children age, their interactions with adults and peers in schools, neighborhoods, and the larger community also become important in the further development and maintenance of antisocial and delinquent behavior (Stoff et al. 1997, Chap. 20). Therefore, all serious current prevention and intervention models for antisocial and delinquent behavior target multiple variables (e.g., family interactions, school success, peer group affiliations, social support, graduated sanctions) in multiple settings (e.g., home, school, neighborhoods, and communities) (Loeber and Farrington 1998).

5.1 *Gender*

International research has shown that young males commit a higher proportion (up to 80 percent) of officially reported juvenile crime. This ratio is somewhat lower when self-report data is used to document criminal acts. It is also known that these ratios are falling at the end of the twentieth century and the disparity between male and female delinquency was less than a third of what it was even 40 years before (Rutter et al. 1998). There is argument about why there is an increase in officially reported and self-reported female antisocial behavior (see Stoff et al. 1997). Regardless of why increases in female antisocial behavior are being reported, the long-term detrimental effects of such behaviors are well-documented (Sampson and Laub 1994). In particular, female antisocial behavior, especially delinquency, has been linked to the development of later psychiatric, educational, and

employment/occupational problems, substance abuse, early pregnancy, the selection of antisocial partners, early marriage, and early death.

However, because developmental research in the area of delinquency and crime has primarily involved boys (particularly prospective longitudinal studies), very little is currently known about the development of juvenile offending and criminality in female populations. The existing literature, however, does suggest that there are different effects for parenting, sibling, and peer relations on antisocial behavior in boys and girls. It also shows that the developmental histories of delinquent boys and girls differ in other respects such as levels of abuse, neglect, and trauma (Stoff et al. 1997, Chap. 46). Researchers also have proposed that the same predictors and mechanisms may not explain these gender variations. Further, even though females contribute proportionally less than males to delinquency and crime rates, some theorists believe it is critically important to increase the study of girls. Not only are antisocial or delinquent young women at grave risk for a plethora of negative developmental outcomes, they also may play a key role in the intergenerational transmission of criminality through pairing with antisocial boys, early pregnancy, and low parenting skills (Rutter et al. 1998).

6. *Future Directions*

Continued use of multiple measures and multiple methods within passive and experimental longitudinal studies will further identify malleable variables and validated intervention technologies at all levels of delinquency and crime prevention (i.e., primary, secondary, and tertiary) (Loeber and Farrington 1998). Studies will also focus on the further development and validation of gender-specific predictive and prevention models. These models will likely lead to the development of screening criteria that can identify the small percentage of youths who account for the most delinquency and crime and those youths most likely to be involved in the transgenerational transfer of delinquency and crime. These improved screening measures will reduce to acceptable levels the current high false-positive rates associated with previous attempts to develop screening tools for early identification of children at risk of persistent delinquency and crime. However, until this scientific task is accomplished, results from programmatic longitudinal research using causal modeling suggests that targeting children and families who have both biological and socioenvironmental risk factors will be most cost effective. Although the Gluecks and their colleagues argued for this approach many years ago (Glueck and Glueck 1972), accomplishing it appears possible at the beginning of the twenty-first century, given recent improvements in measurement theory, research design and analysis, and intervention technology.

In addition, future theoretical and methodological advances will include an increase in research on the interaction between biological/genetic variables and social environments (both naturally occurring and therapeutically designed) and the results of this interaction on antisocial developmental trajectories and rates of delinquency and crime (Stoff et al. 1997). Also, empirically validated prevention interventions targeting delinquency and crime will be developed for all ages and levels of seriousness. Furthermore, any intervention used by society will be seen as potentially a preventive intervention if it has a positive effect on the developmental trajectory of antisocial behavior once it has begun (Stoff et al. 1997, Chap. 32). Finally, long-term solutions to the problem of delinquency and crime will lie in the scientifically informed cost–benefit balance between prevention, rehabilitation, and graduated sanctions (Howell 1997, Loeber and Farrington 1998, Rutter et al. 1998).

Crime and Ethnicity (Including Race)

This article explores research regarding race, ethnicity, and crime. It focuses on the disproportionately high incidence of racial and ethnic minorities caught up in the justice systems of Western countries and on the reasons behind these disparities.

1. Race, Ethnicity, and Crime and the Limitations on Research

The term 'race' once referred to the 'major biological divisions of mankind' (Caucasoid, Negroid, and Mongoloid), as characterized by skin color, hair texture, and other physical features (Walker et al. 1996). This notion has fallen into disrepute for lack of scientific validation. Race is now recognized as a social construct used by groups seeking to delineate themselves from others. Ethnicity is a similar concept that principally refers to the countries from which an individual's heritage can be traced (e.g., 'Hispanic' refers to those with Spanish ancestry), although it is also associated with language, religion, cultural practices, and self-perception. The meanings of these terms continue to be debated, and usage is not consistent internationally. In Germany, for instance, the term *Ausländer* (foreigner) includes ethnic and racial differences in its vague and elastic scope. In England and Wales, researchers consider Blacks to be ethnic minorities, but offenses against them are sometimes referred to as being 'racially' motivated.

Crime typically is defined as 'a social harm that the law makes punishable' (Garner 1999). Examples of crime range from white-collar crimes and organized crime, to murder and hate crimes. This article will focus on conduct often referred to as 'street crime' (also known in the US as Index Crime: murder and nonnegligent manslaughter, forcible rape, robbery, burglary, aggravated assault, larceny-theft, motor vehicle theft, and arson), because current records provide the best data for analysis of variation in offending and victimization by race and ethnicity.

Analysis is constrained by the difficulty in obtaining reliable crime statistics. Such data are collected regularly in Western countries; however, even where crime data is available, the race and ethnicity of victims or offenders are rarely recorded. Only the US officially records and publishes data regarding an individual's race beginning at arrest and continuing to incarceration, and even there data has reliability problems (see the subsection entitled *The Quality of Criminal Justice Data on Race and Ethnicity*, in Walker et al. 1996). Lawmakers in many countries have chosen not to record racial and ethnic identification data for ethical reasons. Though the reluctance of Europeans to compile data regarding the ethnicity of offenders and victims is hardly surprising, given the legacy of Nazi Germany, the decision to forgo collection is equally problematic. Comparing existing data cross-nationally can be difficult because each country has different laws and processes, research traditions, and immigration histories, but these concerns are not insurmountable.

1.1 Racial and Ethnic Disproportion in Justice Systems

Tonry (1997) notes that 'members of *some* disadvantaged minority groups in every Western country are disproportionately likely to be arrested, convicted, and imprisoned for violent, property, and drug crimes.' Whether or not this is a more universal phenomenon is as yet unknown, as research has largely been limited to English-speaking and European countries. Regardless, what is now known is disturbing enough. Racial disparities in arrest and incarceration have historically been of particular concern to researchers in the US, and it is with that data that this investigation begins.

Table 1
Proportion of arrestees for FBI index crimes by racial category (percent of general population in parenthesis)

	Whites	Blacks	American Indian or Alaska Native	Asian or Pacific Islander
1976	72.3% (88.3)	25.3% (11.5)	1.4% (n.a.)	0.09% (n.a.)(a)
1986	71.3% (84.7)	27% (12.2)	1.0% (b)	0.7%
1996	66.9% (82.8)	30.7% (12.6)	1.3% (c)	1.2%

Source: Bureau of Justice Statistics: Source book of Criminal Justice Statistics: 1978, 1987, and 1997
(a) Chinese and Japanese only (b) Other racial categories comprised 3.1 percent in 1986 (c) Other racial categories comprised 4.5 percent in 1996

The Federal Bureau of Investigation (FBI) has collected crime data since 1930 and annually produces the Uniform Crime Report (UCR). The UCR details arrest data for four racial groups (White, Black, Native American, and Asian), but it does *not* include ethnicity. These data are necessarily incomplete, as they only reflect crimes reported to the police, yet they reveal the stubborn stability of racial disproportion in US arrestees for Index crimes (Table 1).

Clearly, White Americans are the most numerous arrestees, but African Americans are arrested at rates that greatly exceed their representation in the population (about 12 percent). Though the data in Table 1 are aggregated, the racial disparity holds in each Index crime category. In 1996, African Americans were arrested at a rate disproportionate to their representation in the general population ranging from 1.9 times for arson to 4.6 times for robbery.

Research indicates racial and ethnic disparities in US jail and prison populations as well. In 1990, 14 percent of jail inmates were Hispanics, who composed only 9 percent of the general population. More notable is the fact that in 1992, 27 percent of federal prison inmates were Hispanic. US jail and prison data revealed that in 1990, 47 and 51 percent of each population was African American, respectively; the percentage of African American prison inmates has exhibited an upward trend since the 1920s. In 1997, 1,083 of every 100,000 American Indians were in jail—the highest rate for any race.

The US is not alone in exhibiting racial and ethnic disparity in arrests and imprisonment. Australian records, for example, indicate disparity in the arrest of Aborigines—considered a racial minority in that country. Aborigines were almost 8 times more likely to be arrested than non-Aborigines in 1990; the rate increased to 9.2 by 1994. Additional data show that Aboriginal juveniles particularly are likely to be arrested or detained. Data from 1993 reveal ethnic or racial disparities in the prisons of England, Wales, and Canada. Blacks (people of West Indian, Guyanese, and African origin) represented 11 percent of the male English and Welsh prison population, while comprising only 1.8 percent of the young adult males in the general population. Aggregating across all Canadian provinces, researchers found that in 1993–1994, when about 3.7 percent of the Canadian general population was Aboriginal, Aborigines composed 17 percent of provincial prison admittees. Blacks are also overrepresented. Data from Ontario correctional facilities reveal a prison admission rate of 705 per 100,000 for whites, 1,992 per 100,000 for Aboriginals, and 3,686 per 100,000 for Blacks.

Notably, while *some* minorities are overrepresented in various criminal justice systems, others are underrepresented, either in the aggregate or in arrest rates for specific offenses. In England, the rates of imprisonment among Indians, Pakistanis, and Bangladeshis are generally *lower* than that of whites, despite their generally poorer economic position. Likewise, a 1992 profile of US prison populations showed that Asians were underrepresented. Asians comprised 3 percent of the general population, yet they made up only about half of one percent of state inmates and just over 1 percent of federal inmates.

Thus, minorities are over and underrepresented in Western justice systems—usually the former. Why?

3. *Reasons for Racial and Ethnic Disproportion in Justice Systems*

The debate concerning minority overrepresentation in justice system processing has largely centered around two questions. Are racial and ethnic disparities the result of discrimination by criminal justice system actors? Or are they the result of disproportionate offending? Current research strongly suggests that racial and ethnic disproportionate representation in international justice systems results from both factors.

3.1 *Evidence of Discrimination*

The evidence does *not* suggest that bias is systematic: it does not afflict Western justice systems at all levels, in all cases, and at all times. Rather, it suggests that in certain cases, places, and times, minorities are more likely than majority members to face discrimination in interactions with justice system components. Four arenas evidencing bias are worth discussing briefly: 'Neutral' processes, police practices, drug law enforcement, and the death penalty.

3.1.1 'Neutral' processes. Research has confirmed that two practices, designed to be 'race neutral' in implementation, operate to the disadvantage of minorities on a regular basis: pretrial detention, and plea-bargaining. Though it seems logical to hold before trial those most likely to flee, international scholars have discovered that the characteristics associated with flight risk are more likely to be present in the minority population than in the majority, which results in racial disparities in pretrial detention. Similarly, minorities are less likely to plead guilty. Research indicates that this tendency is shaped by and contributes to the beliefs many minorities have about justice system bias.

3.1.2 Police practices. The first experience many minorities have with the criminal justice system comes through contact with the police (see *Policing*). The police function entails vast enforcement discretion, so the possibility of abuse of authority is ever-present. In the countries in which minorities are

overrepresented in the justice system, there is also minority dissatisfaction with police practices. Reports of brutality and unnecessary stops, searches, and arrests fuel these views. In a 1994 US study, 47 percent of African Americans surveyed reported having been harassed by police, while only 10 percent of Whites reported harassment. Researchers in Maryland found that African Americans were the subject of 77 percent of vehicle searches conducted by state troopers in 1995; no contraband was found in 67 percent of the cases. Similarly, the police forces of Glasgow, London, Ottawa, and Toronto are among those who have come under scrutiny recently.

It is possible that police practices impacting primarily minorities also affect the opinions of the police held by the majority population. In a survey conducted in 1981 and 1990 in 20 countries, only a minority of *all* citizens polled, ranging from a high of about 40 percent in Britain to a low nearing 5 percent in Argentina, expressed 'a great deal' of confidence in their nation's police; in all but four of these countries the percentage had *declined* by 1990.

3.1.3 Drug law enforcement. Since the 1980s, the problem of race, ethnicity, and crime in the US and elsewhere has been driven by drug laws and policies that have resulted in the rapid rise in the incarceration rate of minorities. The increase in the Black prison population in the US, England, and Wales is obviously tied to drug law violations. In these countries minorities tend to be convicted of relatively low-level drug offenses at rates much higher than those of the majority of individuals. Scholars have concluded that the stark racial disparities in arrests and incarceration resulting from drug law enforcement are difficult to justify given the small gains in crime control from these policies (Tonry 1995, Meares 1998).

3.1.4 The death penalty. This issue is of particular concern to scholars in the US, as it is the only Western democracy still imposing this sentence. Examination of sentencing practices indicates that the *victim*'s race, not the offender's, most often determines whether or not the defendant will receive the death penalty. Those who murder Whites are more likely to receive the death penalty than those who murder Blacks. African American defendants charged with murdering Whites are most likely to receive the ultimate sanction.

Despite this evidence, the US Supreme Court has refused to void the death penalty, finding in *McCleskey v. Kemp* (1987) that defendants must demonstrate, in addition to discriminatory effect, that the prosecutor's decision to pursue the death penalty in a particular case was the result of racial animus. Today, US death rows are still predominantly minority. Not one death row defendant has yet been able to demonstrate the evidentiary requirements stipulated by *McCleskey* (see *Death Penalty*).

Figure 1
Annual average rate of violent victimization by race of victim, 1992–96. Source: Bureau of Justice Statistics, *American Indians and Crime*. Washington, DC: USGPO, 1999.

3.2 Evidence from Victimization Studies

To determine the extent of discrimination in international justice systems, some scholars have looked to victimization surveys, reasoning that if arrest data matches victimization reports, the racial disparities evidenced in arrests could be explained by disproportionate offending rather than by bias.

Among Western countries, only the US, England, Canada, and The Netherlands conduct long-term national victimization studies. US data shows that minorities fall victim to violent crime at a rate that exceeds their representation in the population (Fig. 1). US data also shows that violent crime is largely an intraracial event. From 1976 to 1996, 94 percent of cases involving Black murder victims involved a Black offender. The corresponding percentage was 85.6 for Whites.

The victimization data largely points away from invidiously or blatantly discriminatory targeting of offenders by the justice system. Instead, the data suggests that differential rates of offending by racial and ethnic groups contribute a great deal to the disparity in the US justice system. Hindelang's (1978) classic study shows significant correspondence between the distribution of the perceived race of offenders from victimization survey results and the distribution of arrestees by race from official statistics. While there are well-documented limitations to this approach, existing research has prompted Tonry (1997) to conclude that 'in countries in which research has been conducted on the causes of racial and ethnic disparities in imprisonment, group differences in offending, not invidious bias, appear to be the principle cause.'

4. Why do Minorities Disproportionately Offend?

Minority groups overrepresented in justice systems tend to be economically and socially disadvantaged, especially compared to the majority. In many cases this is the result of historical discrimination, or is tied to the group's recent immigration to their new national home. Often racial and ethnic minority groups are segregated geographically from other groups. *Social disorganization theory* postulates that the geographical concentration of poverty, along with factors such as joblessness and family disruption, negatively impacts the ability of community-level institutions to mediate crime (Shaw et al. 1929, Sampson 1989). This theory helps to explain why some disproportionately minority areas—especially urban ones—exhibit high crime rates. But it does not explain why particular individuals do or do not engage in crime. It is primarily for this reason that attempts to incorporate the notion of 'rotten social background' as a legal excuse for crime commission have been unsuccessful.

Other explanations for minority involvement in the criminal justice system emphasize power and social relationships over economic disadvantage. *Conflict theory* suggests that discriminatory justice practices are simply another expression of the disproportionate power distribution in society. The dominant group can and does use available means to maintain its grip on power (Liska 1992). *Cultural conflict theory* maintains that heterogeneous societies tend toward disparate values and are thus more vulnerable to crime (Sellin 1938). This theory suggests that some minority groups, for various reasons, do not accept majority values, increasing the likelihood of criminal behavior. Finally, *social strain theory* sees increased criminality as one of several responses to the tension inherent in a society in which many lack the means to obtain dominant goals in the generally agreed upon manner (Merton 1957). Rebellion and retreatism (e.g., through drug use) are among the other reactions to this type of societal stress. While each of these theories has certain merits, none does a particularly good job of explaining why some disadvantaged minorities are disproportionately *underrepresented* in criminal justice systems.

5. Conclusion

Racial and ethnic disparities apparent in Western justice systems will increase rather than decrease, at least in the short term, as a result of increasing rates of immigration to Western countries by racial and ethnic minorities and the worldwide trend toward urbanization. This problem is not confined to the Western countries emphasized here. One need only consider the social landscape of South Africa (and the ongoing conflict between Israel and the Palestinian Liberation Organization) to see this. The main impediment to exploration of these issues worldwide is the profound lack of data. Thus, the challenge of promulgating useful crime policy without unnecessarily impacting racial and ethnic minorities will continue to be considerable without good data to help determine the scope and substance of the problem.

Crime and Gender

One of the most consistent and strong findings in criminology is that females commit much less crime and juvenile delinquency than males. This gender gap in law-violation is found using data on arrests, convictions, self-reported crime, and victims' reports about offenders. It also appears to exist across nations and over time.

Yet, until the 1980s, gender differences in crime received scant attention. In the 1970s, feminist critiques of criminology called attention to the neglect of females (e.g., Smart 1976). Since that time, there has been a trend toward taking more seriously the issue of female offending and the gender gap in crime and delinquency.

This article summarizes the research on gender and crime that has been conducted since these critiques. It first identifies some of the major issues that have emerged in this research, and identifies three typical approaches to the study of gender and crime. It then discusses key findings and arguments in research taking each of these approaches. Note that space limitations restrict the scope of this essay to research on the causes of gender differences in offending; it does not address the literatures on gender and victimization, or gender and criminal justice processing. For a review of this literature, see Kruttschnitt (1996).

1. *Approaches to Studying Gender, Crime, and Delinquency*

A major issue in research on gender and offending centers on the level of analysis. One line of research focuses on the *macro-level* of analysis, emphasizing patterns of crime over time and space, and seeking to explain these as the outcomes of broad social patterns. Specifically, this line of research examines changes in the gender gap in crime over time, and reports some convergence between female and male crime rates since the 1950s and 1960s in various nations, including England and Wales, Canada, and the United States (Box and Hale 1983, Fox and Hartnagel 1979, Steffensmeier 1993). At some times during this period, the increase in female crime rates has exceeded the increase in male rates; at other times, male crime rates have declined more than have female rates. Both of these patterns have resulted in some narrowing of the gender gap in crime, although male offending exceeds female offending throughout the period. This pattern holds for most types of serious crime, except murder (Heimer 2000); however, it is more pronounced during some periods for certain property crimes, such as larceny and fraud (Steffensmeier 1993). Almost all existing research on changes in the gender gap uses annual arrest or conviction rates, aggregated to the national level. The typical explanations offered for the changes include women's liberation and economic circumstances.

Another line of research on gender differences in offending uses individual-level data and proposes *social–psychological* explanations. This research typically is based on quantitative data from self-report surveys administered to large samples. These surveys show that males are more likely than females to commit minor, as well as serious, law violations. However, the gender gap is most pronounced for the most serious offenses (see Smith and Visher 1980). Individual-level research has focused on how social–psychological factors—such as family processes, beliefs, and attitudes—contribute to the gender gap in law-violation.

A second major issue in the study of gender and crime is the type of methodology employed. Whereas the two lines of research discussed above rely mostly on *quantitative* methods, a third line of research uses *qualitative* methods, such as the analysis of open-ended interviews and ethnographic techniques. This research most often focuses on either male or female offenders, and thus addresses differences in crime among groups of females or groups of males rather than the comparison of offending across gender.

The remainder of this essay briefly reviews the three lines of research identified above. It then, discusses attempts to bridge the macro- and individual-levels of analysis. Finally, it suggests that fruitful avenues for future research are continuing to bridge levels of analysis, and moving toward greater synthesis of quantitative and qualitative research findings.

2. *Research on the Narrowing of the Gender Gap Over Time*

Research on the narrowing of the gender gap in crime rates over time proposes three explanations—women's liberation, economic marginalization, and the decline in chivalry. The *liberation hypothesis* argues that women's crime rates increased during the 1960s and 1970s because women gained increased economic and social independence from men. One variant proposes that a convergence in gender roles led to a convergence in the gender gap in all types of crime (Adler and Adler 1975). Another variant proposes that women's increased labor-force participation created new opportunities for crime in the workplace (Simon 1975). Both variants have been criticized for assuming that labor-force participation and improved economic

conditions increase crime by females, whereas these conditions reduce crime by males (Chesney-Lind 1997). Moreover, the narrowing of the gender gap is most pronounced for crimes that are consistent with women's preliberation roles—including larceny (theft), fraud, and forgery (see Steffensmeier 1993). Perhaps not surprisingly, therefore, empirical research provides little evidence that women's labor-force participation increases their crime (e.g., Box and Hale 1983; for review, see Steffensmeier and Allan 1996).

Consequently, contemporary studies often focus on the *economic marginalization hypothesis*, which proposes that the increased financial hardship of women relative to men has contributed to the narrowing gender gap in crime (Box 1987, Steffensmeier 1993). Very few studies have assessed this hypothesis empirically, and existing studies use restricted measures of economic marginalization. A review of these studies argues that future research needs to address the interplay between the specific elements of women's poverty that affect their crime rates, including increasing rates of single motherhood, persistent gender inequality in wages, and changes in social welfare policies (Heimer 2000).

A third explanation of the narrowing of the gender gap in crime is the *decline of chivalry hypothesis*, which proposes that the observed changes are due in part to changing attitudes among law enforcement personnel. Specifically, the gender gap in arrest rates reflects the chivalry of law enforcement personnel toward women (e.g., hesitation to arrest women), and the narrowing of the gap reflects a decline in this attitude over the years (Steffensmeier 1993). Empirical evidence suggests that the decline of chivalry likely has had some effect on changes in the gender gap in crime, although economic factors are at least as important (Box and Hale 1983, Steffensmeier and Allan 1996). However, there remains debate over the veracity of the chivalry hypothesis, with some researchers arguing that females are treated more harshly than males for some types of offenses (Chesney-Lind 1997).

3. *Qualitative Research on Women's Offending*

Consistent with the economic marginalization hypothesis, most ethnographic and qualitative studies of women's crime highlight structural disadvantages. These studies typically focus on women offenders only and do not address directly the gender gap in offending. Instead, they conduct an in-depth analysis of the factors that are associated with chronic offending among women. As a group, these studies suggest that poverty, unemployment, and single motherhood combine to create conditions of extreme economic hardship, which in turn are associated with events and conditions of women's lives that increase the chances of a life of crime (Miller 1986, Carlen 1988, Daly 1994, Maher 1997, Baskin and Sommers 1998). For instance, several studies emphasize the connections between abuse during childhood, economic hardships, and criminal careers among women (Daly 1994, Maher 1997). Other studies show how living in a marginalized community facilitates entry into criminal networks and peer groups, which play an important role in initiating women into lives of crime and sustaining these lifestyles in the future (Miller 1986, Baskin and Sommers 1998). Finally, several studies suggest that turning to crime is a rational attempt to support children and other family members when confronted with severe economic hardship (e.g., Miller 1986, Carlen 1988). These studies offer rich insight into the social world of female chronic offenders and, as we note in Sect. 5, open the door for the development of theories that can address macro-level as well as social–psychological processes.

4. *Self-Report Research on Gender and Juvenile Delinquency*

Most research based on self-report surveys focuses on juvenile delinquency, especially common and less serious forms of delinquency. The emphasis is on understanding the social–psychological mechanisms that contribute to the gender gap in delinquency. Recent research on these mechanisms suggests that the gender gap reflects both gender differences in *exposure* to factors that make law violation more likely, as well as gender differences in the *impact* of these factors.
