Ecological Fallacy, Statistics of

Researchers are said to commit the 'ecological fallacy' when they make untested inferences about individual-level relationships from aggregate data. That practice is called a fallacy because it is based on the problematic assumption that relationships that hold at one level of aggregation also hold at another level of aggregation. Researchers are subject to the ecological fallacy in virtually all the social and behavioral sciences, from history (where individual-level data often are unavailable) to criminology (where, for example, a positive relationship between poverty rate and crime rate across cities might be interpreted as evidence that poor people commit more crime) to epidemiology (where preliminary studies might correlate cancer rates across regions with other regional characteristics to decide what sorts of expensive individual-level data to collect).

This article cites examples of the ecological fallacy, explains why inference across levels of aggregation is sometimes unavoidable in social science research, and overviews solutions that have been proposed for alleviating the problem. Because individual-level data are not available for studying many issues of concern to social and behavioral scientists, the article emphasizes the theoretical conditions under which individual-level and aggregate-level relationships are the same.

1. An Example

One important contemporary example involves the relationship between race and voting behavior in the United States. The assumption is that voters have a propensity to vote for someone of their own race: whites are more likely to vote for a white candidate, blacks for a black candidate, and so on. If there is a propensity for intraracial voting, candidates are handicapped in political districts where their race is different from that of the majority of the voters. A probable outcome is that members of minority races will be under-represented in governing bodies because of their minority status in almost all political districts. One proposed solution is to use race as an explicit criterion for determining political districts, with the goal of drawing district boundaries in such a way that blacks and other minorities are in the majority in some of the election districts.

This issue poses the classic ecological fallacy problem for researchers because use of the secret ballot rules out the best source of data on how individuals actually voted. To make sound policy decisions about the use of race as a criterion for drawing up political districts, policy makers should know the strength of intrarace vote propensity, yet individual-level data typically are not available for estimating that propensity. Voting data come in aggregated form, by precincts. Hence researchers often must rely on correlations for voting data aggregated to the precinct level. In an election pitting a white candidate against a black candidate, for example,

researchers might attempt to use the correlation between a precinct's percentage of white voters and the percentage of votes for the white candidate to draw inferences about the propensity of whites to vote for white candidates.

Those inferences are problematic because relationships at the precinct level need not equal relationships at the individual level. Even the direction of the relationship can be different for individuals and aggregates. The 1968 US Presidential election provides a real-world example. In that election, George Wallace, a third-party candidate who was known primarily for his segregationist position as Governor of Alabama, captured about 10 percent of the national vote. What is relevant here is that in the South he tended to receive a higher percentage of the vote in congressional districts with higher percentages of blacks (the correlation across districts in the South was $r = 0.55$ (Firebaugh 1978)). Because no one believes that blacks were more inclined than other racial groups to vote for George Wallace, this is a compelling example of the danger of using aggregate data to draw inferences about the behavior of individuals.

Why was there a positive correlation between percent black and vote for Wallace in the 1968 election? The answer is that whites in heavily black districts were more likely to vote for Wallace than were whites in districts with fewer blacks. In other words, in this election the effect of one's race on one's voting behavior was affected by one's racial context—an example of a contextual effect (see *Contextual Studies: Methodology*). Subsequently this article shows that relationships differ at the individual and aggregate levels when such contextual effects are present.

2. *The Impact of the Ecological Fallacy on Research Practices*

Although the term ecological fallacy is most often associated with W. S. Robinson, Robinson does not use the term in his classic 1950 article. Instead he uses the term 'ecological correlation,' and he states that his analysis 'provides a definite answer as to whether ecological correlations can validly be used as substitutes for individual correlations. They cannot' (Robinson 1950, p. 357). Robinson uses illiteracy data from the 1930 US census to show the discrepancy between ecological correlations and individual correlations. The correlation between percent black and percent illiterate is $r = 0.77$ across States and $r = 0.95$ across nine larger geographic divisions of the USA. The size of those ecological correlations stands in stark contrast to the size of the individual-level relationship between race (black vs. others) and illiteracy ($r = 0.20$). As a second example, Robinson notes that the ecological correlation of percent foreign-born and percent illiterate across States is large and negative ($r = -0.53$), suggesting that the foreign-born are substantially less likely to be illiterate. Yet the foreign-born actually are more likely to be illiterate, as shown by the positive correlation at the individual level ($r = 0.12$).

Whereas Robinson focused on the danger of using aggregate data to draw conclusions about the behavior of individual people, the ecological fallacy problem in fact applies to inferences across levels of aggregation in general. Individuals need not be people. The terms individual level and aggregate level as used here refer to relative levels of aggregation. To illustrate, the term 'individual' could refer to a single church congregation within a population of congregations. The ecological fallacy problem would arise if a researcher tried to use data on racial diversity and attendance growth rates across church denominations (collections of congregations) to draw conclusions about the effect of racial diversity on local church growth. Because parishioners attend a local congregation, it is racial diversity at the local level, not at the denomination level, that is the natural focus here. One could of course survey local congregations in this instance, but the survey would ask questions about a collective (a congregation) rather than about a person.

It would be difficult to overstate the impact Robinson's article has had on social science research during the second half of the twentieth century. The use of ecological correlations to study individual-level relationships had been commonplace before Robinson's article, and the article sharply curtailed that practice. The article also served to motivate the development of survey research. If aggregate data are not adequate to study individuals, then social scientists need data on individuals. One efficient way to gather data on individuals is to ask them questions. So in this way Robinson's message about the need for individual-level data to study individuals no doubt played a role in the amassing of the large survey data sets that have become standard fare in social science research in the twenty-first century.

It is sometimes difficult or impossible to collect survey data to overcome the ecological fallacy problem, however, for two main reasons. First, individuals might be hard to reach. The extreme case of this occurs in historical research, where the pertinent individuals are dead. For this reason, historical research is especially plagued by the ecological fallacy problem (geography is another discipline especially affected, since geographic research is often based on spatial units). Aggregate data often are the only data available to historians, and it is not possible to go back in time to collect data to determine who voted for the Nazis, for example. Second, individuals might be reachable, but the needed information is sensitive. To protect the privacy of individuals, government agencies in some instances aggregate individual-level data before releasing the data to researchers (see *Aggregation:*

Methodology). But aggregation in turn creates the risk that researchers using the aggregate data might commit the ecological fallacy.

3. *Mitigating the Ecological Fallacy Problem*

No expert disputes Robinson's claim that aggregate-level relationships very often differ markedly from individual-level relationships, but a very active literature since Robinson takes issue with his strict prohibition against the use of aggregate data to study individual-level relationships. Necessity motivates this literature: Given the unavailability of individual-level data for many issues of interest in the social and behavioral sciences, the Robinson prohibition would rule out research in some areas of compelling interest, as illustrated by the earlier example of race and voting behavior.

Writing shortly after the Robinson broadside, Goodman (1953, 1959) observed that aggregation tends to affect correlation coefficients (r) more than it does regression slopes and that, under certain statistical conditions, aggregate-level and individual-level slopes are the same. The challenge has been to translate Goodman's statistical conditions into broadly applicable substantive terms that researchers can use. That challenge has resulted in extensive literatures on the ecological fallacy in sociology, geography, economics, political science, and history. One prominent approach seeks to spell out the conditions under which aggregate-level coefficients provide unbiased estimates of individual-level parameters. A second approach seeks to use a method-of-bounds to derive estimates of individual-level effects. This article concludes by briefly overviewing the two approaches.

3.1 *Equivalence Conditions for Aggregate-level and Individual-level Parameters*

Since the Robinson and Goodman articles in the 1950s, much of the methodological work on the ecological fallacy has been devoted to spelling out the conditions under which aggregate-level coefficients provide unbiased estimates of individual-level relationships. Following Goodman's lead, this work focuses on regression slopes, since the bias tends to be smaller for slopes than for correlation coefficients. Hannan and Burstein (1974) consider the effects of the variable by which the data are grouped (e.g., precincts, schools, States). For the bivariate case, they show that aggregate data yield unbiased estimates of individual-level relationships when the grouping variable is either (a) uncorrelated with the independent variable or (b) uncorrelated with the dependent variable, with the independent variable controlled for. Applied to the example of race and voting behavior, the precinct-level data provide unbiased estimates of individual-level voting behavior when precinct is unrelated to race, or precinct is unrelated to voting behavior, controlling for race. The first condition is improbable, since neighborhoods in the USA tend to be highly segregated by race. The second condition (voting behavior is unrelated to precinct, race controlled for) means that one's propensity to vote for a same-race candidate is unaffected by the racial makeup of one's precinct. Thus whites in majority-black precincts are as likely to vote for the white candidate as whites in majority-white precincts, blacks in majority-white precincts are as likely to vote for the black candidate as blacks in majority-black precincts, and so on. Unless Americans of all races are remarkably oblivious to their social contexts, this assumption is unlikely to hold.

Firebaugh (1978) subsumes the Hannan–Burstein conditions under a single rule. The rule states that the aggregate-level regression slope provides an unbiased estimate of the corresponding individual-level effect of X on Y if and only if aggregated X (denoted $\bar{X}$ since aggregated X is usually a type of mean) is unrelated to Y, controlling for individual-level X. For example, using precinct-level data to estimate the effect of one's race on one's vote will yield a biased estimate of that effect unless the racial context of precincts is unrelated to one's vote. Firebaugh shows that the $\bar{X}$-rule generalizes to the multivariate case where a researcher wants to estimate the effect of more than one independent variable.

Firebaugh's $\bar{X}$-rule suggests one solution to the ecological fallacy problem: eliminate $\bar{X}$ effects. To eliminate $\bar{X}$ effects, researchers must determine why $\bar{X}$ might have an effect on Y beyond the effect of individual X, and then add variables to try to remove the effect. Using the voting example to illustrate: the first step is to ask why it is that the racial composition of one's precinct might be related to one's vote, independent of one's race. The most likely answer is that minorities in largely white precincts differ from minorities in largely nonwhite precincts on a host of factors, *other than race*, that are related to voting—characteristics such as income, education, and home ownership. These non-racial characteristics of the precincts should be entered into the aggregate-level equation as control variables. Here the logic of control is the conventional logic used in nonexperimental analysis: Regressors are included (average income in the precinct, average education level, percent homeowners, etc.) in an attempt to use the least-squares method to 'equate' the precincts on those properties. If the method is successful, the aggregate-level slope for race will reflect the effect of race for voters who live in precincts that are otherwise equivalent—that is, the aggregate-level slope will reflect the effect of race itself on vote.

3.2 *Bounding Individual-level Parameters*

The $\bar{X}$ -rule is not a foolproof solution to the ecological fallacy problem since there is no way (with aggregate

data only) to test the assumption that $\bar{X}$ effects have been eliminated. So methodologists continue to work on the problem. One line of work gains leverage on the problem by applying the insight that marginal frequencies bound the cell frequencies in a contingency table (Duncan and Davis 1953). For example, in a precinct where 500 whites and 100 nonwhites collectively cast 450 votes for candidate A, the number of nonwhites voting for candidate A is bounded by 0 and 100 and the number of whites voting for candidate A is bounded by 350 and 450.

A book by King (1997) entitled *A Solution to the Ecological Inference Problem* combines the bounding principle of contingency tables with probabilistic statistical methods to fashion a sequential procedure for estimating individual-level coefficients and their confidence intervals. In essence the method begins with the deterministic information provided by the bounds for each of the aggregates (e.g., precincts) and then applies likelihood methods to narrow probabilistically within those bounds. A public-domain computer program provides estimates, visual depictions, and diagnostic tests. King's method is the most ambitious attempt to date to provide a general solution to the ecological fallacy problem. Ultimately, the worth of a tool is proven in use, and the most telling test of King's method and its successors will come as researchers apply them.

Ecological Imperialism

Ecological imperialism refers to the environmental aspects of the political domination of territorial areas and subjugated peoples. It is concerned with the consequences to imperialism of environmental conditions and processes. Ecological imperialism has been central to the geographical expansion and historical rule of empires, most notably those of Europe in the sixteenth to twentieth centuries, and to their present-day environmental legacies (Crosby 1986). The term also has been applied to the environmental dimension of economic and political domination of poorer countries by global superpowers and institutions (MacKenzie 1990).

Ecological imperialism includes: (a) the geographical introduction of non-native organisms such as disease pathogens, crops, and livestock and, during recent years, the transfer of toxic waste, nuclear contaminants, and other hazardous materials; (b) the ecological interaction of the introduced organisms and materials with human activities that incur environmental changes, often degradation; (c) the environmental role of imperial institutions, historically often those belonging to colonialism; (d) the work of the environmental sciences in the context of imperialism, in some cases for the goal of conservation; and (e) the use and ideas of the environment by persons and groups that resist the rule of empire.

Geographical introduction of nonnative organisms is a facet of ecological imperialism that is based on the dynamics of biogeography or the distribution of plants and animals. The spread of non-native organisms, or 'colonizers,' was a concomitant of the European empires (Crosby 1986). Introduced organisms were brought both by accident and by design. Disease organisms resulted in massive epidemics and mortality among non-Europeans. Mortality due to pathogens that were introduced in imperial exploration and colonialism of the Europeans resulted in the deaths of 25–50 million American Indians, whose immunities did not include such Old World diseases as smallpox, measles, typhus, and influenza (Denevan 1992). Another avenue of ecological imperialism was the introduction of crops, food plants, and livestock. Ecological ease of the transfer of major economic organisms—such as wheat, pigs, cattle, and sheep—was a key to success of the European empires in expanding their rule over the 'Neo-Europes' of temperate North and South America, southern Africa, New Zealand, and Australia (Crosby 1986, Gade 1999). Not least, the ecological colonization of invasive weeds and animal vermin, such as nettles and black rats, actively undermined the living habits, resource use, and production systems and social organization of the subjects of European imperialism.

The impacts of ecological imperialism are influenced by human ecosystems, that is, the ecological inter-

actions among people and their biotic and abiotic surroundings in a given place (i.e., human and cultural ecology). Common interactions are associated with cultivation, land and resource use, and other sorts of environment-related activities that have occurred in the expansion and rule of empires. Dynamics of human ecosystems determined the actual impacts of introduced diseases, crops and livestock, and weeds and vermin. Often these effects were set amid general environmental degradation, such as worsened soil erosion and fertility loss, deterioration of water supplies, and the decline of vegetation resources due to overgrazing and extensive clearing. Some human ecosystems allied to ecological imperialism are thought to have been consonant with environmental conservation. The colonial wheat and livestock-raising customs of the Spanish Empire, for example, may have been environmentally sound in certain places in Mexico (Turner and Butzer 1992, Sluyter 1999).

Ecological imperialism involves the power of particular institutions and social groups, which is a focus of the perspectives of environmental history and political ecology (Grove 1996, Mackenzie 1990). Imperial institutions typically governed the ownership or allocation and use of arable resources such as farmland and irrigation. Also, protection was common under colonial conservation institutions. Conservation policies and resource control were aimed at soil protection and irrigation works as well as nonarable resources such as forests, grazing and rangelands, and game reserves. The motivation for colonial conservation included the use and appropriation of resources for business and the needs of the imperial state; the interests of states and rulers in limiting or localizing degradation; and cultural concerns symbolized by images of Eden and Paradise. Some imperial conservation has been deeply influenced by the concerns and agendas of modern science. For example, the colonial scientists in the employ of European empires in India, southern Africa, and on oceanic islands (e.g., Mauritius, St. Helena, Barbados) were driven by the fear of resource scarcity. This concern in the context of ecological imperialism, or 'Green Imperialism,' contributed to the birth of modern environmentalism (Grove 1996).

Ecological imperialism is also concerned with the resistance and opposition to authoritarian rule. Imperial subjects have both reacted against imposed environmental restrictions and created ecological customs as part of political alternatives. Colonial subjects in Africa, India, and Asia drew on their customs of a moral or affective economy in protesting or refusing to comply with conservation policies involving soil protection, game reserves, and water diversions (Neumann 1998). Slaves and colonial Indians in North and Latin America created customs of food plant use and production with environmental capabilities that enabled their resistance against the administrative fiats of European colonialism (Carney 2001, Zimmerer 1996). These investigations are a broadening of the study of ecological imperialism that extends beyond either moral outrage with denunciation or mere justification and prescription.

Ecological Inference

In nineteenth century Europe, suicide rates were higher in countries that were more heavily Protestant, the inference being that suicide was promoted by the social conditions of Protestantism (Durkheim 1897); also see Neeleman and Lewis (1999). According to Carroll (1975), death rates from breast cancer are higher in countries where fat is a larger component of the diet, the idea being that fat intake causes breast cancer. These are 'ecological inferences,' that is, inferences about individual behavior drawn from data about aggregates.

To continue with Durkheim, the Protestant countries were different from the Catholic countries in many ways besides religion (the problem of 'confounding'). Moreover, his data do not tie individual suicides to any particular religious faith. Confounding must be dealt with in any observational study. But the second problem—that exposure and response are measured only for aggregates rather than for individuals—is specific to ecological studies. If there is no confounding, the expected difference between effects for groups and effects for individuals is 'aggregation bias'; in general, the difference is partly attributable to confounding and partly to aggregation bias.

The ecological fallacy consists of thinking that relationships observed for groups necessarily hold for individuals: if countries with more Protestants have higher suicide rates, then Protestants must be more likely to commit suicide; if countries with more fat in the diet have higher rates of breast cancer, then women who eat fatty foods must be more likely to get breast cancer. These inferences may be correct, but are only weakly supported by the aggregate data.

Ecological studies in epidemiology yielded important insights for Snow (1855), Finlay (1881), Goldberger (Terris 1964), and Dean (1938) among others. However, it is all too easy to draw incorrect conclusions from aggregate data. Greenland and Robins (1994) review the issues. For one example, recent studies of individual-level data cast serious doubt on the link between breast cancer and fat intake (Holmes et al. 1999). Another well-known example, on the sources of popular support for the Nazi party pre-war Germany, is discussed by Lohmoller et al. (1985)

1. Ecological Correlation

Robinson (1950) discusses ecological inference, stressing the difference between ecological correlations and individual correlations. One striking example is the relationship between nativity and literacy. For each of the 48 states in the US of 1930, Robinson computes two numbers: the percentage of the population who are foreign-born, and the percentage who are literate. (The base for each percentage is the number of residents of the state who are 10 or older; data are from the Census of 1930.) The correlation between the 48 pairs of numbers is 0.53. This is an 'ecological' correlation, because the unit of analysis is not an individual person but a group of people—the residents of a state. The ecological correlation suggests a positive association between foreign birth and literacy: the foreign-born are more likely to be literate (in American English) than the native-born. In reality, the association is negative: the correlation computed at the individual level is -0.11. The ecological correlation gives the wrong inference. The sign of the correlation is positive because the foreign-born tend to live in states where the native-born are relatively literate.

Figure 1
For each state, the horizontal axis shows the fraction of the population aged 25 and over that is foreign-born; the vertical axis shows the fraction having high incomes. The regression line is also shown

The example can be replicated using data from the March 1995 Current Population Survey, restricted to persons age 25 and over. Literacy is not reported, but incomes are. Say that a person has 'high' income if family income in 1994 was $50,000 or more. Figure 1 shows for each of the 50 states the fraction of persons who are foreign-born, and the fraction of persons who have high incomes. The regression line is shown too. The ecological correlation (across the 50 areas) is 0.52, suggesting that the foreign-born have higher incomes on the whole than the native-born. The truth is the opposite. About 35 percent of the native-born have high incomes, compared to 28 percent for the foreign-born. The correlation at the individual level is -0.05. In Fig. 1, there is no state where the fraction of foreign-born approaches 1. However, the same sort of reversal can occur even with a full spectrum of x-values. The issue is the disaggregation, not the range of the data.

2. Ecological Regression

Under certain restrictive assumptions, individual behavior can be inferred from aggregate data using a technique called 'ecological regression.' The unit of analysis in the regression is a group of people, typically defined by geography (as in Fig. 1). The technique has been widely used in voting rights litigation in the US. For discussion from various perspectives, see Dogan and Rokkan (1969), Freedman et al. (1991), Grofman and Davidson (1992), Achen and Shively (1995), and Cho (1998).

It may, for instance, be desired to estimate the support for a particular candidate among Hispanics and non-Hispanics. For each precinct in an electoral contest, suppose we know the fraction x of voters who are Hispanic; we also know the fraction y of votes obtained by the candidate of interest. We would not know the fraction of Hispanic voters who voted for the candidate, due to the secrecy of the ballot.

A regression equation can be fitted to the data:

$$y_i = a + bx_i + \varepsilon_i \tag{1}$$

In Eqn. (1), the subscript i indexes precincts; x_i is the fraction of voters in precinct i who are Hispanic; y_i is the fraction of votes cast in that precinct for the candidate of interest. (More exactly, y_i is the number of votes for that candidate, divided by the number of voters.) The precinct-level disturbance terms ε_i would typically be assumed to be independent and identically distributed with mean 0, although this is seldom made explicit.

The parameters a and b in Eqn. (1) can be estimated by ordinary least squares; call the estimates $\hat{a}$ and $\hat{b}$, respectively. Then $\hat{a}$ would be interpreted as the fraction of non-Hispanic voters who supported the candidate in question: after all, $\hat{a}$ is the height of the regression line at $x = 0$, corresponding to precincts with no Hispanic voters. Likewise, $\hat{a}+\hat{b}$ (the height of the regression line at $x = 1$) would be interpreted as the fraction of Hispanic voters who supported the candidate.

The data are available for groups defined by area of residence; the inference is to groups defined by ethnicity. The statistical logic connecting the inference to the data rests on the 'constancy assumption,' that voting preferences within ethnic groups do not systematically depend on the ethnic makeup of the area of the residence (Goodman 1953, 1959). In Fig. 1, the regression equation is $y = 0.29 + 0.56x$, leading to the inference that 30 percent of the native-born have high incomes, compared to $29 + 56 = 85$ percent of the foreign-born. In reality, as noted above, the percentages are 35 and 28 percent. The ecological inference is in error, because the constancy assumption fails: the incomes of the native-born increase systematically with fraction of foreign-born in the state. Immigration to the US tends to concentrate in richer states—California, Hawaii, and New York rather than Kentucky, Tennessee, and West Virginia.

3. *The Method of Bounds*

In 1995 in the state of Washington, 8 percent of the population was foreign born, while 34 percent had high incomes. These are known. Let p be the fraction of the foreign-born who had high incomes, and let q be the corresponding fraction for the native-born. Investigators making ecological inferences would typically not know the fractions p and q. The two unknowns satisfy an equation:

$$0.08p + (1 - 0.08)q = 0.34 \tag{2}$$

We have one equation with two unknowns: that is the whole problem of ecological inference. However, Eqn. (2) does contain some information, because $q = (0.34 - 0.08p)/(1 - 0.08)$. Since p is bounded between 0 and 1, it follows that q is bounded below by $(0.34 - 0.08)/(1 - 0.08) \doteq 0.26$. Similarly, the upper bound is $0.34/0.92 = 0.37$. This is 'the method of bounds' (Duncan and Davis 1953). Such bounds can be computed for each study area, and then aggregated. However, in typical applications, the bounds are too broad to be informative (also see Goodman 1959).

4. *Ecological Regression with Random Coefficients*

Models with random coefficients have been used to make ecological inferences. By way of illustration, we consider a model for nativity and income. Index the study areas by i. As before, let x_i be the fraction of the population in area i that is foreign born, and y_i the fraction with high incomes. These fractions are known, as is the total population n_i of area i. Let p_i be the fraction of the foreign-born with high incomes, and let q_i be the corresponding fraction for the native-born, so

$$y_i = p_i x_i + q_i(1 - x_i) \tag{3}$$

The problem is to make inferences about p_i and q_i. To solve such problems, King (1997) assumes the pairs (p_i, q_i) to be independent and identically distributed across the study areas. This is his version of the constancy assumption: the statistical behavior of a demographic group is not allowed to depend on area of residence. The parent distribution is taken to be bivariate normal, conditioned to lie in the unit square so that p_i and q_i are both between 0 and 1. The five parameters of this parent normal distribution can be estimated from the data by maximum likelihood, and estimates $(\hat{p}_i, \hat{q}_i)$ can be derived from Eqn. (3). Rates for each demographic group can then be estimated by addition over areas, as $\sum_i n_i \hat{p}_i / \sum_i n_i x_i$ and $\sum_i n_i \hat{q}_i / \sum_i n_i (1 - x_i)$, respectively. More complex models have also been developed.

To show the force of the constancy assumption, we can use the 'neighborhood model' which assumes that behavior is determined by geography not demography. Then $\hat{p}_i = \hat{q}_i = y_i$ for each study area i. (In our example of nativity and income, if 33 percent of the residents of a particular study area have high incomes,

this percentage applies equally to the foreign-born and the native-born in that area.) The neighborhood model turns the constancy assumption on its head. In a variety of test applications where all the data are available, the neighborhood model gives more accurate estimates for demographic groups than ecological regression or random-coefficients models. In some contexts, of course, the neighborhood model proves deficient (Achen and Shively 1995). If the data are incomplete so estimation is needed, it will be unclear which model if any is giving the right answers. The track record to date favors the neighborhood model (Freedman et al. 1991, 1998). For another perspective see Schuessler (1999).

5. *Summary and Conclusions*

Aggregate data are often easier to obtain than data on individuals, and may offer valuable clues about individual behavior. Ecological inferences will therefore continue to be made. The problems of confounding and aggregation bias, however, are unlikely to be resolved in the proximate future.

Ecology and Health

1. *Ecology and Health*

The term 'ecology' pertains broadly to the interrelations between organisms and their environments (Hawley 1950). From its early roots in biology, the ecological paradigm has evolved within several disciplines (e.g., sociology, psychology, economics, and public health) to provide a general framework for understanding people's transactions with their physical and sociocultural surroundings (e.g., Barker 1968, Bronfenbrenner 1979, Park et al. 1925). The field of ecology and health examines the direct and interactive effects of conditions in the physical and sociocultural environment on the physiological, emotional, and social well-being of individuals and groups (cf., Duhl 1996, Moos 1979, Stokols 1996). Ecological analyses provide more integrative and comprehensive explanations for the joint influence of biogenetic, psychological, behavioral, sociocultural, and physical environmental factors on human well-being, than do narrowly-gauged biomedical, behavioral, and environmental theories.

2. Emergence of Ecological Perspectives on Health and Illness

The emergence of an ecological paradigm for understanding the determinants of health and illness in human populations can be traced to research developments in several scientific fields. During the 1920s and 1930s, a series of correlational analyses were conducted by researchers in the Chicago School of human ecology, and revealed systematic associations between community rates of illness and crime, and physical and social conditions of the urban environment including poor-quality housing and high population densities within residences and neighborhoods (cf., Faris and Dunham 1939, Park et al. 1925). These correlational studies in the fields of human ecology and sociology suggested a strong link between conditions of the urban environment and residents' health, but did not provide an integrative theoretical account of the causal pathways connecting those variables.

An important theoretical analysis of the links between the social environment and illness etiology was provided by John Cassel in the field of public health. Cassel's (1964) conceptualization of *social epidemiology* signaled a shift from 'germ-theory' accounts of health and illness (focusing on the health-impairing effects of specific pathogens once they invaded a human 'host'), toward a more ecologically-oriented, contextual perspective emphasizing the effects of one's social environment (e.g., work overload, sources of interpersonal stress) on immune functioning and host resistance to pathogenic agents. Cassel's formulation of social epidemiology during the 1960s and his hypotheses concerning the impact of social and cultural factors on human health have been corroborated empirically in subsequent studies linking job strain, social isolation, and interpersonal stress to a variety of illness conditions and premature death (cf., Berkman and Syme 1979, Karasek and Theorell 1990, Marmot et al. 1997).

Publication of the *US Surgeon General's Reports* in 1964 and 1979, documenting the deleterious effects of smoking on health, prompted the rapid growth of health promotion and disease prevention research during the 1980s (cf., US Public Health Service 1979). Much of the early research in this field was rooted in the concepts and methods of health education, and focused largely on behavioral change strategies aimed at fostering healthier lifestyles and health habits among individuals (cf., Belloc and Breslow 1972). Targeted efforts to enhance individuals' health behaviors have led to reduced use of tobacco products among adults, lower rates of alcohol-related automobile deaths, moderate gains in the proportion of adults exercising regularly and eating less fatty diets, and reduced employee health costs at the worksite (cf., McGinnis and Lee 1995, Pelletier 1996). At the same time, however, certain health risks, such as exposure to community violence, substance abuse, and lack of medical insurance, remain segmented in hard-to-reach 'pockets of heightened prevalence' (Fisher 1995)—especially among low-income and minority groups in the population (cf., Adler et al. 1994).

Growing recognition of the limitations associated with behavioral change programs has prompted a paradigm shift in the health promotion field, away from individually-focused interventions toward more comprehensive, ecological formulations that address interdependencies among socioeconomic, political, environmental, organizational, biological, and psychological determinants of health and illness (cf., Kickbush 1989, Winett et al. 1989). An explicit emphasis on ecological strategies of health promotion is evident in the design and implementation of broader-gauged community interventions aimed at reducing handgun violence, smoking prevalence, teen pregnancy, and HIV infection in recent years (cf., Breslow and Johnson 1993, Schneider Jamner and Stokols 2000). A common feature of these programs is that they incorporate multiple levels of analysis and intervention components—including political action, legislative reform, media advocacy, as well as behavioral change and environmental enhancement efforts—to address key contextual factors that substantially influence individual and population health.

One other major development that has prompted greater interest in ecology and health in recent years is the discovery of adverse global environmental changes—for instance, the depletion of atmospheric ozone and the trend toward global warming—which have the capacity to elevate population morbidity and mortality rates at worldwide as well as regional and national levels (cf., Stern et al. 1992). Potential health impacts of these global changes include elevated skin cancer rates resulting from ozone depletion and individuals' heightened exposure to ultraviolet rays; and the food shortages, nutritional ailments, and respiratory illnesses associated with global warming (cf., Leaf 1989). The discovery of these global environmental threats to population health has prompted greater international collaboration in the development of ecologically-oriented health promotion programs through the World Health Organization's Healthy Cities Program (cf., Duhl 1996).

3. Core Principles of Ecology and Health Research

Research on ecology and health encompasses several disciplines, including medicine, public health, urban planning, environmental design, public policy, and the behavioral and social sciences. The scientific contours of this research are not easily delimited, due to the interdisciplinary scope of the field (cf., Stokols 2000). The unique concerns of ecology and health can be better understood in terms of the overarching con-

ceptual principles that underlie this field, than by searching for a clearly defined body of research organized around this topic. The core principles underlying ecology and health research are drawn largely from programmatic statements about the 'New Public Health' and the conceptual and methodological assumptions of systems theory and social ecology (cf., Duhl 1996).

3.1 Intellectual Antecedents: Systems Theory and the Ecological Paradigm

The 'New Public Health' outlined in the Ottawa Charter for Health Promotion (1986) called for the development of comprehensive, ecologically-oriented approaches to the study and prevention of disease (cf., Kickbush 1989). For instance, the Ottawa Charter gave explicit attention to social causes of illness, as well as the physical-environmental health threats that exist in many communities. Subsequent analyses of ecology and health extended these programmatic ideas by providing a set of conceptual and methodological principles derived largely from systems and ecological theories, for organizing and evaluating community-based health promotion programs (cf., Green and Ottoson 1999).

The field of ecology and health incorporates a number of concepts derived from systems theory (e.g., interdependence, homeostasis, negative feedback, deviation amplification; cf., Emery and Trist 1972, Maruyama 1963) to understand the interrelations among people and their environments. Systems analyses suggest that the healthfulness of particular settings and the well-being of their participants are jointly influenced by multiple facets of the physical environment (e.g., geography, architecture, technology) and the social environment (e.g., culture, economics, politics). The health status of individuals and groups is also influenced by personal attributes such as genetic heritage, psychological dispositions, and behavioral patterns. From the vantage point of systems theory, efforts to promote well-being should be based on an understanding of the relationships among diverse environmental and personal factors, rather than on analyses that focus exclusively on environmental, biological, or behavioral factors (cf., Moos 1979).

3.1.1 Research findings from ecological analyses of health. The direct and interactive effects of environmental and personal attributes on health have been observed in several lines of research. For example, a substantial body of research highlights the ways in which poverty, inequality of income distribution, and minority status jointly undermine the health of individuals and vulnerable subgroups in the population (cf., Adler et al. 1994, Bullard 1990, Kaplan et al. 1996). Other studies indicate that neighborhood socioeconomic status (percent of households in a geographic area receiving public assistance) is associated with poorer self-reports of health, above and beyond individual socioeconomic status (Malmstrom et al. 1999, Robert 1998). Interactive effects of environmental and behavioral risk factors are exemplified by the findings that environmental exposure to asbestos exacerbates chronic smokers' risks of developing lung cancer (Grunberg 1991), and that an individual's disposition toward exerting internal control over his/her environment buffers the potentially negative effects of low education and income on health status (Lachman and Weaver 1998).

Systems theory also posits that people–environment transactions are characterized by cycles of mutual influence, whereby the physical and social features of settings directly affect occupants' health and, concurrently, the participants in settings modify the healthfulness of their surroundings through their individual and collective actions (or, alternatively, adopt an increasingly passive stance toward their environment). For example, individuals' routine exposure to community violence in some low-income neighborhoods can provoke feelings of disempowerment, helplessness, and depression, which in turn diminish their efforts to adopt health promotive practices related to physical activity and dietary change (cf., Sanders-Phillips 2000). Similarly, the well-being of elderly individuals depends on the degree of fit between their functional abilities, on the one hand, and environmental constraints on their daily activities, on the other. Either or both of these elements can be modified to promote higher levels of person–environment fit (cf., Lawton 1999).

Ecologically-oriented studies of health also incorporate certain conceptual and methodological principles drawn from the field of social ecology. For instance, ecological theory highlights the multidimensional nature of human environments. Environmental settings can be characterized in terms of their physical and social components, their objective (actual) or subjective (perceived) qualities, and their scale or immediacy to individuals and groups (proximal vs. distal). Moreover, the participants in environmental settings can be studied at varying levels ranging from individuals, small groups and organizations, to larger communities and populations. Rather than focusing solely on individuals or aggregates, the social ecological perspective incorporates multiple levels of analysis and diverse methodologies (e.g., medical exams, questionnaires, behavioral observations, environmental recordings, epidemiologic analyses) for assessing the healthfulness of settings and the well-being of individuals and groups.

Social ecological analyses conceptualize human environments as complex systems in which local settings and organizations are nested within more complex and remote regions. Accordingly, efforts to promote human well-being must take into account the

interdependencies that exist among immediate and more distant environments. The occupational health and safety of workplaces at the local level, for example, are directly influenced by state and national ordinances aimed at protecting environmental quality and public health (cf., Stokols 1992).

Another core theme of ecological theory is that physiological, emotional, and social well-being are influenced by the multiple, interrelated settings that comprise *the daily activity systems* of individuals and groups (cf., Michelson 1985). Bronfenbrenner's (1979) ecological model of human development highlights the joint influence of people's families, school, work, and recreational settings on their health and developmental outcomes. Rather than focusing exclusively on person–environment transactions that occur within single settings (*microsystems*, such as home or work environment), Bronfenbrenner's research emphasizes the ways in which functional linkages between two or more settings (i.e., the *mesosystem*, the *exosystem*, and the *macrosystem*) influence developmental processes and outcomes. Mesosystem units are comprised of two or more environmental settings (e.g., family and occupational environments) in which the individual is directly involved (e.g., a parent employed outside the home). Exosystems include an environment in which the developing person is directly involved (e.g., a child in his or her home environment) and one or more other settings in which that person does not participate directly (e.g., the workplaces of the child's parents); but that, nonetheless, affect his or her development and well-being (e.g., stressful experiences at work that impair the quality of parents' interactions with their children at home). Finally, the macrosystem level of analysis encompasses the belief systems, social norms, and institutions of the culture as a whole.

The joint influence of multiple life settings on individuals' health has been observed in several studies. Children's exposure to environmental stressors (such as high levels of spatial density and noise) in their home and elementary school environments, for instance, was associated with both additive and interactive effects of those conditions on their physiological health (e.g., systolic and diastolic blood pressure) and academic achievement (cf., Cohen et al. 1986). In other studies, employees' perceived lack of flexibility in work hours for scheduling children's doctor visits was associated with their underutilization of employer-provided family health benefits (Fielding et al. 1994). Health outcomes associated with the work–family mesosystem have also been documented through studies of the adverse impacts of 'work–family conflict,' as well as the positive effects of spousal support in buffering work-related stressors (cf., O'Neil and Greenberger 1994).

The research findings noted above suggest the value of studying human health from an ecological systems perspective. By considering the joint influence of multiple life settings on individuals' well-being, a broader understanding of how personal and situational factors contribute to health status can be achieved, than by focusing more narrowly on environmental conditions within single settings.

4. *Directions and Challenges of Ecology and Health Research*

The broad conceptual scope of ecology and health research is both an asset and a limitation. On the one hand, the breadth of ecological analyses affords a more comprehensive understanding of the multiple determinants of well-being. For instance, major political, economic, and environmental determinants of health that were neglected in earlier behavioral and medical studies have been targeted in more recent ecological analyses. On the other hand, so many disciplines and levels of analysis are combined in ecological research that it is difficult to achieve parsimonious explanations of health phenomena. Thus, an important challenge facing the field of ecology and health is to develop criteria for identifying the most influential determinants of wellness at particular levels of analysis (intrapersonal, social, organizational, institutional, community, global) and to give greatest priority to these high-leverage variables when designing scientific studies and community health promotion programs (see *Health Education and Health Promotion*).

4.1 *Developing High-leverage Strategies for Effective Health Promotion*

Examples of high-leverage variables and health promotion strategies include: (a) the implementation of strategic corporate and public policies that can enhance population health on a broad scale (e.g., California's Proposition 99 which imposed a $0.25 tax on each pack of cigarettes sold and thereby reduced statewide levels of smoking prevalence (cf. Breslow and Johnson 1993); (b) the modification of 'other-directed' health behaviors enacted by corporate and public decision-makers whose actions directly influence health outcomes among large numbers of their employees and constituents; cf., Stokols (1996); (c) the identification of key life settings (e.g., a stressful commute between home and work, or poorly designed work facilities) that can be modified to reduce behavioral risk factors (e.g., smoking, substance abuse, injurious work routines) associated with poor health; (d) the implementation of defensible space design guidelines to reduce the incidence of violence and crime in urban neighborhoods (cf. Newman 1972); and (e) the development of internet-based 'telewellness' programs designed to enhance health awareness and well-being among large segments of the population (cf., Stokols 1999).

4.1.1 Targeting vulnerable subgroups in health promotion programs. An important direction for future ecological research is to incorporate the above leveraging strategies into the design of community health promotion programs aimed at improving the well-being of impoverished and underrepresented groups. Certain illness risk factors, including environmental racism, exposure to community violence, and lack of medical insurance, have proven to be highly resistant to earlier and more traditional health promotion programs (cf., Bullard 1990, Fisher 1995). These interrelated community problems, borne disproportionately by low-income minority groups in the population, are highly complex and will be reversed only through the design and implementation of strategically leveraged, multilevel intervention programs (Winett et al. 1989)—example, the multisectoral Healthy Cities Programs sponsored by the World Health Organization (cf., Duhl 1996).

5. Conclusions

The field of ecology and health, which grew rapidly during the 1980s and 1990s, highlights the importance of developing integrative, broad-gauged strategies for promoting human wellness. As proponents of ecological analyses have noted aptly, improvements in individuals' health practices 'usually require some combination of educational, organizational, economic, and environmental interventions in support of change in both behavior and conditions of living' (Green et al. 1997, p. 125). The principles of systems theory and social ecology outlined earlier provide a useful framework for establishing more integrative and effective approaches to wellness promotion in the coming decades.

D. Stokols

Ecology, Cultural

The central interest of cultural ecology is the mutual relations of people and the environment (of places and resources) they occupy and use. Julian Steward coined the term in 1937, to distinguish it from biological, human, and social concepts of ecology. Steward defined it as:

> the study of the processes by which a society adapts to its environment. Its principal problem is to determine whether these adaptations institute internal social transformations or evolutionary change. It analyzes these adaptations, however, in conjunction with other processes of change. Its method requires examination of the interaction of societies with one another and with the natural environment (Steward 1968).

Cultural ecology, an inquiry dominated by geographers and anthropologists, has sought to make a place for environment in understanding and explaining the human condition (i.e., culture alone cannot explain culture or cultural change). It studies the significance of environment and the interactions humans have with it, with influences going in both directions: humankind's role in modifying the earth, and the environment's influences on human nature and culture. There is the undoubted fact that humans use the world around them and solve questions about how to make the material world meet human needs and wants. Adaptation of and to the material world is a great intellectual accomplishment of humankind.

Steward wrote the essay on cultural ecology for the 1968 edition of the *International Encyclopedia of the Social Sciences*. This article, after summarizing the main purposes and methods of cultural ecology in the early 1960s, traces the development of the field through the subsequent four decades. The purpose of the article is to illustrate the kinds of questions asked in cultural ecology and the way they are answered. Examples have been chosen for their illustrative power.

1. Major Themes in Cultural Ecology

The most important preoccupation in cultural ecologic research, particularly when done by anthropologists, has been with cultural adaptation. According to Steward, one studied (a) the connections between an environment and the technology people use to exploit it, (b) the patterns of behavior that result when particular technologies are used, and (c) the effects, if any, these have on other cultural patterns (Steward 1955). The resulting changes set in motion by cultural adjustments to environmental conditions constituted, in Steward's phrase, a process of multilinear cultural evolution (the idea being that there are significant, but

not universal, regularities in cultural evolution, that lead to parallel form, function, and sequence in quite disparate, unrelated cultures). Although complex, this approach is essentially a functionalist one, which argues that there are predictable relations between a given set of environment/technology relations and the evolution of other aspects of culture–social institutions and individual personality and behavior.

This theme of adaptive dynamics has been further developed by Gregory Knapp in *Andean Ecology* (1991). An associated theme, studied by Fredric Barth (1956), was economic specialization by different groups, with mutually beneficial reciprocal relationships. The resulting regions of specialization he termed econiches.

Works cited in this article which do not, because of space limitations, appear in the bibliography, can be found in one, or more, of the following four review essays in cultural ecology: Bassett and Zimmerer 2001, Butzer 1989, Grossman 1977, and Porter 1978. For reviews of cultural ecology by anthropologists, see Hardesty 1979, Moran 1990, Netting 1977, and Vayda and McCay 1975.

The second most important theme in cultural ecology can be called agricultural stability and change, an intersecting set of topics including population pressure and agricultural intensification (Boserup 1965, Netting 1968); carrying capacity (Allan 1949, Carniero 1956, Sahlins 1958); agricultural involution (Geertz 1963); environmental cognition and systems of indigenous knowledge (Porter 1965); systems analysis (Von Bertalanffy 1959); and energetics (Rappaport 1968). Two perspectives, synchronic, which focuses on contemporary conditions, and diachronic, which has a deep cultural historical, even archeological, basis, have been evident in much cultural ecological study (Butzer 1964, 1989, Denevan 1966). Agroecology, the study of field systems, crop management through habitat modification, and fertility management, has been a major interest of cultural ecologists, a good part of which has been archeological in nature—relict fields, terraces, irrigation systems, etc. (Denevan 1972, Doolittle 1988, Turner 1983, Dunning and Beach 1994).

Other themes and concepts that figured in cultural ecology by the mid-1960s include environmental risks and hazards (White 1961, Kates 1962); the behavioral environment (Kirk 1963) and environmental perception (Saarinen 1966); and medical ecology (May 1958, Hunter 1974, and reviewed by Pyle 1976, and Earickson et al. 1989).

2. Methods

The methods of the cultural ecologist are essentially those of the ethnographer—careful observation and recording of the ideas and material practices of the people whose culture is being studied, as well as participant observation and recording of life histories. The difference lies, perhaps, in the emphasis placed on the biophysical world the people use. Whereas the ethnographer pays great attention to kinship, law, language, origin myths, and religious beliefs and practices, the cultural ecologist devotes comparable attention to knowledge and beliefs regarding plants, soils, seasons, terrain, agriculture, livestock, and other aspects of the environment the people use. Another difference may lie in the degree to which cultural ecologists collect and carefully measure highly detailed data relating to resource use and the environment, and seek to understand the meaning of complex interrelationships among the data. An example is Eric Waddell's work in *The Mound Builders* (1972), in which relationships of sweet potato varieties, mound size, cold air drainage, size of soil aggregates after tillage, elevation of gardens, and frost hazards are considered.

Among cultural ecology's methods is an anthropological/ethnographic use of an approach associated with the linguist Pike (1966); namely, a focus on the internal, emic world of contextualized meanings of terms, in contrast to any universal, etic, or standardized manner of uttering a term (derived from phonemic vs. phonetic). The cultural ecologist also uses western science to the extent possible and when appropriate to the task at hand, whether it be carbon-14 dating methods, measurement of energy-water budget variables, or analysis of satellite imagery. The use of western science methods was strongly endorsed in the 1970s by such cultural ecologists as Karl Butzer (1982) and Harold Brookfield (1968). One further precept is that the cultural ecologist should be historical to the extent possible. A sensitivity to historical aspects and change through time helps ensure that analysis avoids freezing cultural groups into an ahistorical ethnographic present, an approach that permits them ethnography but denies them history.

Cultural ecology's use of the emic approach as a method and research framework frequently emerges through a common sense evaluation of how to do field work, and has been independently invented by field researchers any number of times. For example, the soils of the Pokot of western Kenya can be described using Western science—the US Soil Conservation Service's Comprehensive Classification System, but it would have no meaning for Pokot farmers, who have their own well-developed system of soil names with associated characteristics, typical locations, and uses. Since Pokot behavior is informed by their names for and understanding of soils, one learns much by using their classification (Porter and Sheppard 1998).

3. Scale and Location

The scale of cultural ecological studies reflects the intense nature of the research that produces it. Most cultural ecological study concerns small areas and

Figure 1
The bulk of the research shown in this figure has been done by these scholars: for *Papua New Guinea*—Harold Brookfield, Paula Brown, William Clarke, Lawrence Grossman, Paul Sillitoe, Andrew Vayda, and Eric Waddell; for *Africa*—William Adams, William Allan, Thomas Bassett, Simon Batterbury, Frank Bernard, David Brokensha, Karl Butzer, David Campbell, Judith Carney, Claudia Carr, Francis Conant, James Delehanty, Ton Dietz, Tom Downing, Neville andRada Dyson-Hudson, Robert Ford, John Galaty, Abe Goldman, Walter Goldschmidt, Leslie Gray, Philip Gulliver, John Hunter, Douglas Johnson, Robert Kates, Cindi Katz, C. Gregory Knight, Richard Lee, Peter Little, Gordon Matzke, Jacques May, Michael Mortimore, Robert Netting, Roderick Neumann, James Newman, Symmes Oliver, Philip Porter, Paul Richards, Bernard Riley, Dianne Rocheleau, Abdi Samatar, Richard Schroeder, Earl Scott, Thayer Scudder, Frederick Simoons, Derrick Thom, Mary Tiffen, Colin Trapnell, Matthew Turner, Donald Vermeer, Michael Watts, Gene Wilken, Edgar Winans, and Ben Wisner; for *Latin America and the Caribbean*—David Aagesen, Sheryl Beach, Anthony Bebbington, James Blaut, Karl Butzer, Robert Carniero, Oliver Coomes, William Denevan, William Doolittle, Nicholas Dunning, Arturo Escobar, Kent Flannery, Lawrence Grossman, Susanna Hecht, Anne Kirkby, Gregory Knapp, Diana Liverman, Kent Mathewson, Emilio Moran, Bernard Nietschmann, Ben Orlove, Eugene Parker, Campbell Pennington, Andrew Sluyter, Julian Steward, B. L. Turner, II, James and Connie Weil, Thomas Whitmore, Gene Wilken, and Karl Zimmerer, and for *South and Southeast Asia*—Nigel Allen, Jacques Barrau, Fredrik Barth, Piers Blaikie, Clifford Geertz, Harold Conklin, Roy Ellen, Charles Frake, Martin Lewis, Melinda Meade, John Metz, Haripryia Rangan, Paul Robbins, Marshall Sahlins, Stan Stevens, and Andrew Vayda

small groups of people—a village, a community, a valley. By judicious use of synedoche and caveat, the cultural ecologist may claim that the findings for the smaller group represent the larger culture. Indeed, following Brookfield's early lead (1962), cultural ecologists commonly work at multiple scales: the individual, the household, the community, the culture (and its territory) overall, as well as the culture in larger settings—national, international, and with reference to global political economy.

The 'third world' location of most cultural ecological research is illustrated in Fig. 1. It is based on a large bibliography on cultural ecology, collected over the years, plus searches, by title and subject, of several library databases (anthropology and geobase) using the linked key words cultural ecology. The search generated over 700 books and articles, either with the term cultural ecology in the title, or classified under the subject heading cultural ecology. The geographic locations of as many of these works as could be determined (over 550) were plotted on the map. The resulting pattern (an approximation) emphasizes the tropical and subtropical, colonial location of the bulk of the research. An exception is the work that has been done among native American Indian groups in the US and Canada. There are significant clusters in Papua New Guinea (where much early work originated), Africa, the Caribbean and Latin America (especially

Mayan, Andean, and Amazonian), and Himalayan south Asia.

The cultures that have been studied by cultural ecologists have tended to be preliterate, agrarian, and part of the former colonized world. The goal of the cultural ecologist has been to understand and convey the life-world and life-ways of indigenous cultures. It has sought to give a voice to the knowledges, beliefs, and values of indigenous peoples. Cultural ecology, therefore, constitutes, in the language of contemporary social sciences, a discourse. Its effects have been muted, since other discourses in the social sciences and in policy arenas are dominant. This may be changing, however, as witness the World Bank's recent focus on social capital and forms of reciprocity and community that tap local knowledge.

4. *Cultural Ecology 1960–2000*

Much happened in cultural ecological research in the final four decades of the twentieth century. The remaining discussion is divided into three sections: the evolution of cultural systems, the study of livelihood and environment, and recent critiques of cultural ecology.

4.1 *The Evolution of Cultural Systems*

People appraise the potentialities and constraints of their surroundings in different ways: (a) in the way they organize space (settlement patterns, field dispersal, use of different ecological zones), (b) in their use of local resources (irrigation, crop varieties, medicinal plants), (c) in the organization of internal relations (family, clan, age-set, bridewealth, neighbors, ritual and ceremony), and (d) in the way they connect with larger social and economic forces—local and national governments and the global economy (labor migrancy, remittances, production and sale of cash crops, contract farming, adoption of new technologies). Changes in circumstances in any of these domains can affect any of the other domains and occasion cultural change.

As an illustration of efforts to demonstrate how cultures evolve in response to changes in environmental/technological circumstances, consider the work of Walter Goldschmidt and co-workers in the Culture and Ecology in East Africa Project (1965). The central hypothesis of this project was that a major change in livelihood (say from livestock keeping to farming) would require changes in the nature and inter-relationships of social institutions and people, and at a deeper level, changes in the attitudes and personality characteristics of individuals. With a change in livelihood, social institutions and the repertoire of techniques must be refashioned or abandoned and replaced by new ones to meet changed circumstances.

The project centered on pastoralism, with farming used as its foil. Four cultural groups in east Africa (Sebei, Pokot, Wakamba, and Wahehe) were chosen because in each there was a group whose members were predominantly pastoralists and another whose members were predominantly farmers. It was hypothesized that the Sebei, for example, were 'originally' pastoralists, but over a period of generations, after some of their members took up farming on the higher potential parts of Mount Elgon in Uganda, growing bananas, maize, and coffee as a cash crop, their social institutions adapted to the requisites of horticulture. In the process they transformed a lightly peopled montane forest environment into one of dense human settlement.

First, the reader should envisage the dramatic contrast in settlement pattern between the farming and pastoral communities Goldschmidt studied. In the farming area the population density was 343 people/sq. km (888 people/sq. mile), a landscape of nearly continuous banana groves, which shaded coffee trees. Among the pastoralists, who grew some maize and finger millet, the population density was seven people/sq. km (19 people/sq. mile), with large open tracts of unpeopled grazing land, a sparse *Acacia* savanna.

Goldschmidt, in *Culture and Behavior of the Sebei* (1976), documented numerous ways in which institutions that were important for pastoralists, changed under a regime of cultivation. For example: the *pororyet*, a military organization based on age grades and designed for offensive action and rapid movement in open country, became among the farmers a resident militia of a fixed territory and made up of men of all ages; the *misisi*, a 'first fruits' thanksgiving harvest ritual, based on a carefully defined list of kin, was transformed into the *mukutanek* (sharing), a ritual beer party to which one invited neighbors, not kin. Its purpose came to be maintenance of good relations with neighbors. The *chomi ntarastit*, an oathing ceremony originally used to settle interclan disputes among the pastoralists, became a ceremony in which adult male residents of the farming community swore to abide by laws intended to preserve peace and public order; the *chichomnko lekok*, a ceremony among pastoralists performed between half-brothers, when they were toddlers, to ensure that there would be peace between them, was used by adults among the farmers to resolve tension and disputes over land and inheritance; age grades and male and female circumcision ceremonies became less formal and in certain instances were abandoned altogether in the shift from pastoral to farming livelihoods; the *tokapsoi* and the *toka che kichenkochi korket*, terms that refer, respectively, to a man's cattle and those that have been anointed and smeared for a wife, and over which she

has control (but which pass to her sons upon her death), were applied to farmed fields.

Edgerton, in *The Individual in Cultural Adaptation* (1971), explored the inner worlds of beliefs, attitudes, and personality of the Sebei and members of the other three cultures. His purpose was to see how pastoralists and farmers differed. He interviewed samples of about 30 adult men and 30 adult women in the pastoral and farming communities of the four cultures, administering a rich variety of test instruments. Although there were greater within-culture similarities than between cultures (i.e., 'culture' explained more than 'ecology'), there were 31 categories of difference between the people of the eight Culture and Ecology communities that were statistically significant. Some of these differences were attributable clearly to farming or herding. He discussed the various attributes along a continuum with herding at one pole and farming at the other. Five attributes were found close to the pastoral pole: affection, direct aggression, divination, independence, and self-control. Nearly as central in importance were adultery, sexuality, guilt-shame, depression, and respect for authority. In contrast, the attitude closest to the farming pole was disrespect for authority, but the following attributes were also characteristic of farmers: anxiety, conflict avoidance, emotional constraint, hatred, impulsive aggression, and indirect action. As one considers the requirements of a settled, sedentary life, and life in a community where one cannot easily escape the proximity of neighbors, in contrast to the demands of a life managing livestock, where one must be flexible in meeting the daily, unremitting needs of animals for water, graze, browse, salt, and safety, one can see ways in which the attributes emphasized in each lifeway make sense. In the broadest terms: 'Farmers must create institutions for the preservation of peaceable relationships, ... [P]astoralists must create ideals that bind together persons who need to preserve a sense of community in the face of the fact that they are forced by economic circumstances to operate as individualists' (Edgerton 1971).

The foregoing illustration of Steward's project to 'study the processes by which society adapts [or maladapts] to its environment,' could be expanded by the citation of many other scholars.

4.2 The Study of Livelihood and Environment

The core of this theme is the nexus of population and resources, from which many subsidiary questions flow—limits to growth, the carrying capacity of the earth, agricultural intensification, soil erosion and environmental degradation, destruction of forest lands, with associated species extinctions and loss of biodiversity, problems of the global commons (oceans, atmosphere, lakes, forest habitat, and coastlines). Key events in the study of livelihood systems were: (a) Harold Brookfield's 1964 article in *Economic Geography*, which argued the urgent need to include the interior dynamics of culture—that which lay in the beliefs, values, and attitudes of people, as well as their social institutions; (b) the appearance in 1965 of Ester Boserup's *The Conditions of Agricultural Growth* (to which we return); (c) Roy Rappaport's influential (1968) *Pigs for the Ancestors*, which illustrated systems theory, energetics, and homeostasis and feedback in ecological systems; (d) Robert Netting's (1968) classic work on the Kofyar, as well as his influential monograph, *Cultural Ecology* (1977); (e) two studies of disruptions in subsistence systems brought about by commercial activities: Bernard Nietschmann (1973), on the Miskito Indians of Nicaragua, and Lawrence Grossman (1984), on the highlands of Papua New Guinea; and (f) the publication of Piers Blaikie and Harold Brookfield's *Land Degradation and Society* (1987). Blaikie and Brookfield emphasized the importance of using a nested set of scales for research, in order to show how decisions and policies at national and international levels affecting land ownership, commodity pricing, development assistance, etc., had impacts on people at local levels. They showed how poor farmers were marginalized, both literally and figuratively, and were unable in their struggle to eke out a living (and despite their better instincts) to avoid degrading the environments they were forced to use.

Boserup's book challenged the classic argument of Thomas Malthus (that population can increase geometrically while agricultural productivity could only increase arithmetically). Her argument was that through slow sustained pressure of population on resources, people improved agricultural output. She focused on the means by which this was done: (a) the mobilization of labor, and (b) the tools appropriate to the vegetation managed by cultivators at the end of each fallow. She placed land on a continuum of use (forest fallow, bush fallow, short fallow, continuous cultivation) and examined a suite of expectations about the tools, the role of livestock, land ownership, and social and infractructural institutions and attitudes associated with different stages in land use intensification. Her work, supported by that of William Allan, whose *The African Husbandman* appeared the same year, transformed thinking in cultural ecology in many fruitful ways. Despite cogent critiques of her work, for neglecting capitalism, market relations, and the state, evidence of the impact and acceptance of her ideas is the now widespread use of the adjective Boserupian.

Environmental change induced by human action has also been an important theme in cultural ecology (Turner 1990). Some of it has speculated on population dynamics of past civilizations—Mayan, Incan, Egyptian (Denevan 1976, Butzer 1976). In contemporary terms it involves the inventorying of land use and land quality and subsequent tracking of changes in the geosphere and biosphere. These questions require a

'big-science' approach and involve the cooperation of different disciplines and international organizations. Among themes in this topic are land use change, climate change, pollution, and loss of plant diversity, farmland, and wilderness. Cultural ecologists contribute to some aspects of this inquiry.

4.3 Recent Critiques of Cultural Ecology

Cultural ecology as practiced in an earlier period ran four interrelated risks: (a) that of assuming equilibrium and balance in the society studied, (b) ethnographic presentism, i.e., failing to give adequate attention to history and change in the society, (c) use of an agreeable, internal, circular functionalism in explanation, and (d) failure to incorporate influences external to the group being studied. Given these potential flaws, scholars sometimes found cultural ecology inadequate and incomplete as a research paradigm and modified or added to the approach (Porter 1978). Although one might argue for an earlier beginning of the radical critique of cultural ecology (Brookfield and Kirkby 1974), one seminal event was the publication of Michael Watts' *Silent Violence: Food, Famine and Peasantry in Northern Nigeria* (1983). This book brought political economy, Marxian analysis of global capitalism, and the state more fully into the work of cultural ecologists. Watts in his writing and teaching has influenced a succeeding generation of cultural ecologists, many of whom prefer the term political ecology to describe their work. Political ecology has been a growth center of cultural ecology ever since, indeed, with efforts to go beyond political ecology to new, more effective approaches. An example is *Liberation Ecologies* edited by Peet and Watts (1996). The book argues for a single, all encompassing, poststructuralist, social science based on the discursive perspective and methods of critical theory as used in analysis in literature, the arts, and humanities. Both political ecology and cultural ecology are, they argue, inadequately theorized, and not sufficiently political. The various authors of *Liberation Ecologies* call for a reconceptualization of virtually everything: nature, environment, the state, class, gender, ethnicity, community, region, and identity. The central concern is with power relations and the contestations they generate at all scales, from the household (between wife and husband) to the state and the global economy. *Liberation Ecologies*, though full of stimulating ideas, does not, however, provide a unified alternative to political ecology, since its authors disagree on many questions.

Another critique of cultural ecology has been made by Karl Zimmerer (1994) in an article titled 'Human geography and the "new ecology": the prospect and promise of integration,' which proposes adoption of uncertainty principles and chaos theory in cultural ecological analysis, abandoning the underlying assumptions of homeostasis and ecological balance that characterized earlier work.

Among significant themes that have been developed are feminist political ecology (Carney 1993, Rocheleau et al. 1996, Schroeder 1999); the political ecology of protected areas (Neumann 1998, Stevens 1999, Nietschmann 1997); the political ecology of social movements (Bebbington 1996, Rangan 1996); and the theme of sustainability and global change (Chambers 1997, Turner 1990).

Although it has been critical of cultural ecology, political ecology should not be seen as an offshoot of cultural ecology. It is, rather, an enlarging of cultural ecology's domain of inquiry and the conscious incorporation of effects originating outside the ecological setting. Much early cultural ecological work was microscale and tended to study ensembles of things occurring at a place (site characteristics) as well as situational characteristics within the study area. Political ecology extended the scale of inquiry to include the global economy, intrusions of the state, markets, and other external influences.

Not all cultural ecologists accept the reconfiguration of cultural ecology as political ecology, and feel that with the addition of Marxian analysis and postmodern concerns over relations of power, knowledge, and resources, there has been a corresponding narrowing of inquiry and loss of the healthy eclecticism that has characterized cultural ecology, as well as moving it away from cooperation with the more positivist environmental sciences—ecology, paleoecology, and global change science (Turner 1997).

Cultural ecology remains a lively field of inquiry, asking questions that will not go away, and that can never be answered in fully satisfactory ways. Current approaches in cultural ecology, and its vigorous descendant, political ecology, reflect transformations in the social sciences themselves. At the same time there appears to be a diminution of the importance attached to the biophysical world and a western science understanding of it. In these postmodern times, when 'everything is socially constructed,' cultural ecology can be expected to continue to reflect changing modes of thought in the wider society.

P. W. Porter

Ecology, Deep

The term deep ecology was introduced by Norwegian philosopher and mountaineer Arne Naess (1912–) in 1972 at the Third World Future Research Conference in Bucharest. After a distinguished academic career, Naess chose early retirement to focus his expertise on addressing the global ecological crisis. Naess coined the terms deep ecology and shallow ecology to juxtapose what he regarded as two radically different approaches for problematizing (*Problematisieren*) and responding to the ecological crisis (Naess 1973). Deep ecology posits that along with humans' special capacities for reason and moral consciousness come equally special responsibilities, particularly in relation to the flourishing of nonhuman life and the ecological sustainability of the planet. In the years since introducing the term, Naess and other supporters of the deep ecology movement have written extensively, elaborating and popularizing the term in various directions. Considerable controversy and confusion has ensued, in part because deep ecology calls for a radical rethinking of our relationship to each other and nature, because provocative terminology and philosophical vagueness have been employed, and because deep ecology has unfolded over time, with substantial emendation. As a result, deep ecology has come to mean many things to many people. Regrettably, the term is now often used without discrimination to refer to three distinct entities: (a) the particular ecophilosophical approach advanced by Naess and other theoreticians of the deep ecology movement; (b) the international, grassroots, often activist oriented deep ecology movement; and (c) Naess' personal systematization of a philosophy of ecological harmony, Ecosophy T. After introducing deep ecology as a unique approach to ecophilosophy, the evolution of deep ecology will be reviewed and the remaining two entities will be briefly considered.

1. Deep Ecology as Ecophilosophy

The purpose of deep ecology as an ecophilosophical approach is to assist individuals in the process of weaving descriptive and prescriptive premises about the world, ecological science, and their ultimate beliefs into a cohesive framework for guiding decisions involving society and nature—ecologically inspired total views or ecosophies. This focus on praxis (responsibility and action) separates the deep ecology approach from more descriptive inquiries into environmental philosophy that focus on axiological questions, such as extending 'rights' to certain nonhumans or grading intrinsic value. The ontologically inspired deep ecology approach emphasizes eliminating the perception of fundamental people/environment and spiritual/physical cleavages. Its primary strategy for overcoming the ecological crisis is to help individuals avoid pseudorational thinking.

Naess argues that many regrettable environmental decisions are made in a state of 'philosophical stupor,' where narrow concerns are confused with, and then substituted for, more fundamental ones. In proposing the deep/shallow contrast, Naess applies his research on empirical semantics, philosophy of science, Spinoza, the inquiring skepticism of Sextus Empiricus, and Gandhi on nonviolent communication. His technical semantic distinction is directed at the individual's level of problematizing—the extent to which they can and do coherently and consistently trace their views, practices, and actions back to their ultimate beliefs or bedrock assumptions.

In relating this notion of persistently asking deeper questions to the ecological crisis, Naess broadens his concept of 'depth.' In the context of deep ecology as an ecophilosophical approach, depth refers to both the

general level of problematizing one employs in seeking out the underlying, coevolving causes of the ecological crisis and the extent of one's willingness to consider a broad array of social and policy responses, even if they necessitate changes that represent a radical departure from the status quo.

The 'shallow,' currently more influential, approach is identified with treating the symptoms of environmental degradation, such as pollution and resource depletion. Its central concern is the health and prosperity of people in the economically privileged countries. This reform-oriented approach is grounded not in ultimate premises that plumb the relationship between humans and nature, but in technological optimism, economic progress, and scientific management. A core premise is that all environmental problems are manageable—nature is a puzzle to be deciphered by human ingenuity and manipulated, albeit more efficiently, for human benefit. From this perspective, remedy for environmental problems is limited to economic, technological, and managerial reforms. This effort to palliate human impacts, rather than probe and address their underlying causes, favors a search for 'technical' solutions to what are more likely ethical, social, and political problems. By truncating the realm of problematizing, the shallow approach, perhaps inadvertently, prunes the set of conceivable social changes to a narrow incrementalism.

The 'deep' approach, as the other hand, while in no way discounting the exigency of addressing pollution and resource depletion, adopts a broader, long-term, more skeptical stance. Doubtful about technological optimism, critical of limitless economic growth, and decidedly against valuing nature in purely instrumental terms, it asks if the shallow approach's proposed solutions take into consideration the pervasiveness and severity of the problems they hope to rectify. Drawing on a wide diversity of philosophical or religious ultimate premises, which acknowledge that every living being has value in itself, the deep approach sees the flourishing of nature and culture as fundamentally intertwined. Nature is viewed as mentor, standard, and partner rather than vassal. A key premise is that environmental management is much more about managing the habits and desires of humans than managing nature. Remedy for environmental problems is sought by identifying and responding to the complex 'root' causes of the ecological crisis, dedicating special attention to protecting the wild and free from thoughtless human interference. Taking less for granted, the deep approach calls for the public questioning of every practice, assumption, and value that propels the ecological crisis.

By juxtaposing these two, almost caricatured, perspectives, Naess employs a technique of Gandhian nonviolent communication designed to confront core disagreements. The premise is that society's potential to overcome the ecological crisis rests on maneuvering discussion to its root causes. One of the primary root causes, Naess asserts, is the widespread disjunction between people's core beliefs and actions. People, in general, neither comprehend how their practices and everyday lifestyle choices harm the environment, nor recognize how these consequences may be in direct conflict with their core beliefs—this is the primary weakness of the shallow approach. A crucial, underlying hypothesis of the deep approach is that teasing out the presumed inconsistencies between an individual's actions and their fundamental beliefs will effect constructive change instead of generating more serious ancillary conflict.

Rather than simply calling for a new environmental ethic or a change in fundamental values, Naess' approach to ecophilosophy centers on transforming practice and policy by challenging individuals to develop more thoroughly reasoned, consistent, and ecologically inspired total views. Some will take issue with the core premise underlying this goal, namely that thoroughly reasoned and consistent positions do generally lead to improved policies and actions. There are, however, important indirect procedural benefits that can result from attempting to couple reason and values in decision making.

In any case, Naess intended his distinction between the shallow and deep approaches to environmentalism to be restricted to argumentation patterns and the diversity of policy and lifestyle changes that are given consideration. The distinction was never intended to shed light on the 'depth' of particular individuals or their values. Nevertheless, as an expert in semantics and communication theory, Naess cannot be exonerated for failing to anticipate the unfortunate derogatory connotations of his terminology.

2. *The Unfolding of Deep Ecology*

Naess' (1973) inaugural article, *The Shallow and the Deep, Long-Range Ecology Movement: A Summary*, gave both an appellation and a rudimentary philosophical framework to a movement that had been nascent for well over a century. Deep ecology as both a liberatory social movement and an ecophilosophical approach draws on at least five roots: (a) the nonanthropocentrism and reverence for wildness given voice by Henry David Thoreau, John Muir, and John Stuart Mill; (b) the ecological perspective gleaned from a scientific understanding of humans' role in creating environmental degradation, articulated by George Perkins Marsh, Aldo Leopold, Rachael Carson, and Paul Ehrlich; (c) the ecocentric vision and social criticism brought to life by the writing and activism of Paul Shepard, Gary Snyder, Edward Abbey, and Dave Brower; (d) the belief in the ultimate unity of all life, communicated through the nonviolent conflict resolution work of Gandhi; and (e) the call for individuals to be conscious of their value priorities and to counteract passivity and despair by actively making

them manifest in their daily life, explicated in the philosophical systematization of Spinoza.

Naess' brief initial article, along with establishing the deep/shallow contrast, outlined a seven-point survey, which was intended to summarize the shared norms and perspectives of the deep ecology movement. This survey introduced terms and slogans, such as 'rejection of the human-in-environment image in favor of the relational, total field image,' 'biospherical egalitarianism—in principle,' and 'complexity, not complication.' While Naess employed vagueness here intentionally to encourage widespread acceptance, these often enigmatic generalizations acted as a lightening rod for controversy.

Apart from the continuous emphasis on maintaining the 'diversity' of both human cultures and nature and the reincarnation of the 'relational, total field image' notion as Naess' subtle and rich concept of 'gestalt ontology,' these terms neither figure in Naess' more seasoned renditions of the significant tenets of the deep ecology movement nor his more mature descriptions of deep ecology as an ecophilosophical approach. Nevertheless, they do continue to resurface in many popular discussions and critiques of deep ecology. Most of the terms Naess introduces in the 1973 article, such as diversity, complexity, autonomy, decentralization, symbiosis, egalitarianism, and classlessness, do, however, figure prominently as key norms in his subsequent derivations of Ecosophy T (1977, 1989).

Naess' only book length discussion of deep ecology began with a short mimeograph, *Økologi og Filosfi* (*Ecology and Philosophy*), published in 1971. The fifth revision and expansion of this initial work resulted in the 1976 classic, *Økologi*, *Samfunn*, *og Livsstil* (Ecology, Community, and Lifestyle), which has been translated into Swedish, English (1989), Italian, Japanese, and Czech. Perhaps the earliest intimation that deep ecology should be separated into a social movement, an ecophilosophical approach, and Ecosophy T occurs in 1986, with Naess' article, 'The deep ecology movement: Some philosophical aspects.' This article offered an early presentation of the 'deep ecology platform,' which was prepared in collaboration with philosopher George Sessions in 1984.

In the late 1970s Naess' project was taken up and popularized by the California-based team of Sessions and sociologist Bill Devall. Sessions had earlier initiated the process of popularizing deep ecology with his *Ecophilosophy Newsletter*, published in six volumes, intermittently from 1976 to 1984. Devall and Sessions' collaboration culminated in the first English language, book length discussion of deep ecology (1985). Subsequently, the two deep ecology theorists worked independently. Devall published extensively on deep ecology practice (1988). Sessions continued to write on the historical foundations and theory of deep ecology, producing the most comprehensive deep ecology anthology to date (1995).

Two additional anthologies are dedicated to the exploration of deep ecology, Reed and Rothenberg (1993) focus on the Norwegian roots of deep ecology and Drengson and Inoue (1995) present an introduction to deep ecology theory and practice. Deep ecology essays and responses to critiques also figure prominently, along with ecofeminism and political ecology, in Zimmerman et al.'s leading environmental philosophy anthology (2001). In addition, Witoszek and Brennan (1999) produced one volume on deep ecology criticism, which includes dialogic responses by both Naess and his interlocutors. All of these collections, however, are necessarily highly selective. As the primary architect of deep ecology, Naess has more than 75 published articles and book chapters and more than 60 unpublished pieces to his credit. The most comprehensive selection of these articles appears in volume 10 of the 11 volume *Selected Works of Arne Naess* (2002) .

The most significant intellectual history of deep ecology and exhaustive effort to characterize what is 'distinct' about it was offered by Fox (1990). Subsequently, Glasser (1997) argued that Fox's distilling of deep ecology into 'Self-realization!' results in a vitiated version of deep ecology. McLaughlin (1993) takes up a discussion of deep ecology as a response to industrialism's role in creating and perpetuating the ecological crisis. The relationship between Naess' earlier philosophical work and deep ecology is explored by Glasser (1996), who also mines the policy implications of deep ecology. Cramer (1998) measures the degree of influence that deep ecology principles have had on American environmental politics.

While discussions of deep ecology appear in many popular and academic journals, only the *Trumpeter Journal of Ecosophy* has been devoted to advancing deep ecology theory and practice. *The Trumpeter* was under the editorship of Alan Drengson from 1983 to 1997. Subsequently, it has continued as an on-line journal, under the editorship of Bruce Morito.

3. *The Deep Ecology Movement*

The deep ecology movement is an informal, global affiliation of individuals who believe that overcoming the ecological crisis will require radical changes in the way humans relate to each other and nature. Its supporters are united not by their commitment to deep ecology as an academic ecophilosophy (which they may not recognize or embrace), but by their common commitment to ultimate premises that value nature for its own sake and their general rejection of anthropocentrism. What distinguishes the deep ecology movement from deep ecology as ecophilosophy is that it embodies praxis rather than merely philosophizes about it. The intuitions of deep ecology are not articulated as professional philosophy, but as art, poetry, ritual, conservation biology, grassroots acti-

vism, simple lifestyles, bioregionalism, and ecologically sustainable design, farming, fishing, and forestry.

The movement is perhaps best characterized as the group of individuals that do (or would) endorse the eight point Deep Ecology Platform. The 'Eight Points,' which summarize 10 years of thinking about deep ecology, were prepared to supersede the problematic seven point (1973) characterization. The first three points outline a high-level norm for protecting the planet's full diversity and richness of life forms—species, cultures, watersheds, landscapes, and ecosystems. Because the scale and character of human interference with the biosphere are currently excessive and thus incompatible with this norm and the thriving of human life and cultures (points 4 and 5), the next two principles outline a series of changes in practice and policy that can help bring them in line. The final point, without calling for specific actions or imposing particular priorities, urges those who embrace the prior seven points to help effect change.

The Eight Points are intended to express at a generic and abstract level the central views that supporters of the deep ecology movement hold in common. The Platform principles are not intended to characterize common views in particular situations. Since 1984, the Eight Points have been republished extensively along with detailed commentary and gained wide currency. Although they are frequently taken as the 'heart' of deep ecology, the eight points alone cannot effect the breadth and complexity of deep ecology as an ecophilosophical approach.

While the Platform can clearly serve as an 'ecological pillar' for Green politics, it has been criticized for not integrating the other three pillars. These concerns have been fueled by the sometimes inflammatory and ostensibly misanthropic statements that have been made by 'Earth Firsters' and others who have taken inspiration from deep ecology. While the Platform principles do not directly address social justice, grassroots democracy, and nonviolence, they are in no way inimical to them. Quite the contrary, the practical policy changes required by point six leave open immeasurable opportunities for collaboration with the peace and social justice movements. For instance, how can society characterize what constitutes a bundle of 'vital needs' for particular communities in particular situations (Point 3); how can society create new accounting systems that operationalize the distinction between 'quality of life' and 'standard of living' (Point 7); and how can society develop policies to support long-term population reduction through noncoercive and democratic means (Point 4).

4. *Ecosophy T*

Naess' personal application of the deep ecology approach results in a normative-derivational systematization akin to that of Spinoza or Aristotle. He refers to his own deep ecological total view as Ecosophy T. Naess' systematization is normative because it calls for a particular set of prescriptive premises. It is derivational by virtue of being a logical systematization, where premise-conclusion chains generate successively more specific norms (general ecological and ecopolitical principles and concrete decisions), which 'follow' from previously accepted premises and hypotheses.

Naess' survey of Ecosophy T is built on a single, highly aggregated and complex ultimate norm, 'Self-realization!' He likens it to 'the universal self,' 'the absolute,' and the Sanskrit ātman. Naess uses a capital 'S' to distinguish the norm from ego-realization and an exclamation mark to identify it as an imperative. 'Self-realization!' is an ecocentric-ontological analogue of the pareto rule in economics. The premise is that increased realization of any individual or species rests on advancing (or at least not hindering) the realization potential of all other species and individuals. While working from a single ultimate norm enables Naess to eliminate the potential for norm conflicts, it also embodies a certain artificiality that necessitates considerable word magic.

Naess draws his support for the Deep Ecology Platform from his Ecosophy T. Other supporters of the deep ecology movement, however, need not and should not draw directly on Naess' systematization. The Platform can be 'derived' from a broad variety of sometimes dissonant, ultimate norms, including those inspired by all of the world's major religions, ecofeminism, creation myths, Leopold's 'Land Ethic,' and E. O. Wilson's 'Biophilia Hypothesis' to name a few. Ultimate premises are essential building blocks for developing an ecosophy, but their breadth and abstractness insure that they only serve as general guides.

5. *Methodological Issues and Future Directions*

Deep ecology has been criticized for being too critical of pragmatic efforts to address acute environmental problems. It has also been accused of being inherently fascist, antihumanist, anti-feminist, and against having indigenous peoples share wilderness areas with nonhumans. None of these criticisms are borne out by a sophisticated reading of the literature on deep ecology as an ecophilosophical approach. This is not to suggest that deep ecology as an ecophilosophical approach has all the answers. In inspiring many people to reconsider their value priorities and more consistently relate them to their lifestyles and everyday actions, deep ecology opens more questions than it answers. Three key issues for future research loom on the horizon. First, how can society motivate value priorities for ecological sustainability when individuals do not accept the premise that nonhumans have intrinsic value? Second, does taking a deep ecological perspective over a shallow ecological perspective actually result in better policy—policies that result in long-

term protection of cultural and biological diversity, using democratic, noncoercive, and ethically unobjectionable, means. Third, how can deep ecology help to resolve conflicts in environmental decision making when they result not from pseudorational thinking, but real value conflicts.

Ecology of Aging

The ecology of aging basically draws upon the idea that old age is a period of adult development profoundly influenced by the environment. Because age-related losses in vision, hearing, mobility, and cognitive capacity have a direct impact on the relationship between the organism and the environment, the older person should be particularly vulnerable to environmental demands. In other words, this research paradigm views contextual factors as being crucial determinants of everyday behavior and life satisfaction. According to Lawton and Nahemow (1973, p. 621), the ecology of aging is defined as 'a system of continual adaptation in which both the organism and the environment change over time in a non random manner.' Within this adaptational system, the ecology-of-aging paradigm emphasizes the role of the *physical and spatial environment* on behavior. Thus, housing research ('Aging in Place') may be regarded as most typical for the ecological approach to aging.

1. Development of the Field

Since aging has long been regarded as a process mostly determined by a biological program inherent in the organism, the explicit consideration of environmental variables which affect the course and outcome of human aging was an important step in the historical development of gerontology. This paradigm shift was greatly influenced by:

(a) The growing role of the social science perspective within gerontology which began in the late forties and set the stage for the emerging field of social gerontology.

(b) The prominent role of learning theories in psychology in the fifties and sixties which underscored the importance of the environment in all stages of human development.

(c) The Chicago school of urban sociology and its human ecology perspective (Burgess, McKenzie, and Park) in the 1920s and 1930s, the writings of Lewin in the thirties and forties, as well as the emergence of ecological psychology and of the social ecology view of human development (Barker, Bronfenbrenner, and Moos) in the sixties and seventies which, among other things, placed particular emphasis on the resource character of the physical and spatial environment and hence provided another set of roots for this discipline (Lawton 1982, Wahl 1992).

The conceptual and empirical productivity within the field grew steadily during the sixties and seventies. Gerontological research has been devoted to housing alternatives for the aged, relocation processes and outcomes, and aging in institutions ever since. By the eighties and nineties, the issue of dementia led to new

research challenges based on the assumption that environmental design becomes particularly crucial when the capacity for person-based adaptations in later life is exhausted.

2. Conceptual and Methodological Basics and Role Within Gerontology

2.1 Conceptual and Methodological Basics

The ecology of aging is particularly concerned with the description, explanation, and modification/optimization of the relationship between the aging person and his/her environment. Furthermore, by drawing from Lewin's basic insight that behavior must be seen as a function of the person and his/her environment, Lawton (1982) has suggested that research on the ecology of aging cannot proceed without acknowledging the 'ecological equation,' that is, the *interaction* between the aging individual and the environment as it relates to a variety of outcomes such as well-being, social behavior, or leisure activities. The term *transaction* has been suggested to underscore the notion that person and environment are hard to separate from each other and that the view of an ongoing process of mutual interchange may best reflect the everyday world (Altman and Rogoff 1987).

With these concepts in mind, research on the ecology of aging (as well as ecological research in general) was from the beginning concerned with examining the everyday life of individuals in their own day-to-day world. Hence, empirical methods, such as real-life observations in natural settings, the retrospective assessment of day-to-day behaviors through the use of diaries, or the reconstruction of internal representations of the environment have been preferred. Methods used to describe the environment, such as checklists for housing interiors or multidimensional evaluations of institutional settings, have also played an important role (Gitlin 1998).

Although ecological research has placed emphasis upon the physical environment, it is widely acknowledged that in reality, the physical and social environment are deeply interwoven. Some work on the ecology of aging has even put the major emphasis on the question of how social environments shape the elderly's behavior in specific socio-physical settings such as nursing homes (Baltes 1996).

2.2 Role of the Ecology of Aging Within Gerontology

Research on the ecology of aging strives to understand the environment-related tasks that typically confront the aging individual. These tasks include preserving autonomy in everyday life despite physical and mental impairments through the utilization of environmental resources within (including home modifications, see Gitlin 1998) and outside the home, initiating the relocation process if desired or necessary, and adapting to new living environments (such as a nursing home or other planned housing) after relocation. These classic research themes illustrate the fact that an interdisciplinary approach—covering disciplines such as psychology, sociology, architecture, geography, urban planning, and design—is essential for the understanding of the ecology of aging. Because the major research themes are so closely tied to the everyday world of the aging individual, empirical research on the ecology of aging also has strong practical implications and thus contributes significantly to the improvement of life quality in the later years.

3. Theoretical Approaches and Empirical Key Results

3.1 Overview of Theoretical Approaches

The ecology-of-aging paradigm encompasses a whole set of theoretical perspectives, all of which seek to understand how the socio-physical environment influences adaptational processes and outcomes in the everyday life of the elderly.

In the *Press–Competence Model*, the lowered competence of the older person, in conjunction with high 'environmental press,' is assumed to negatively impact on behavior in everyday life as is also expressed in the so-called *Environmental Docility Hypothesis* (Lawton 1982, Lawton and Nahemow 1973). For example, empirical research has revealed that the social interaction patterns of elders, particularly in planned housing, greatly depend on physical distances; long distances were found to effectively undermine social relations. The *Person–Environment Fit Model* has underscored the role of motivation within transactional processes (Carp 1987, Kahana 1982); basic as well as higher-order needs have been considered in their relation to the potential and limits of the environment. Empirical evidence supports the notion that a misfit between the resident's needs and the ability of the environment to fulfil these needs contributes to the explanation of lower life satisfaction. The *Person–Environment Stress Model* (Schooler 1982) argues that certain environmental conditions—such as lack of privacy or control in institutional environments—should be regarded as a potential threat for the aging process. Subsequently, intervention studies aimed to enhance the control of elders produced positive behavioral, emotional, and health outcomes (see Schulz and Heckhausen 1999, for a summary and theoretical integration of this research). Finally, the

Social Learning Model underscores the role of operant learning processes in circumscribed socio-physical settings, most notably care interactions in institutional settings (Baltes 1996). The empirical application of this model has produced profound insights into the effect of the social environment on dependent behavior in old age by identifying a robust interaction pattern characterized as the *Dependence–Support Script*. According to this script, the social environment of elders tends to strongly reinforce their dependent behaviors, while independent acts are mostly ignored.

3.2 Critique

Theoretical approaches within the ecology of aging have been critiqued for a number of reasons. For example, it has been argued that some of these models relegate a far too passive role to the elderly individual, who seems to be nothing more than a pawn of environmental forces. Lawton (1989) has addressed this critique by introducing the *Environmental Proactivity Hypothesis* which states that elders are also active and goal-directed shapers of their environments. It has also been argued that research on the ecology of aging has—in both theory and practice—been overly concerned with safety, orientation, and support (Parmelee and Lawton 1990). Meanwhile, the environment's potential for stimulating behavior and emotion, for creating strong cognitive–emotional bonds (*place attachment*; Rubinstein and Parmelee 1992) and thereby preserving one's personal continuity, has been neglected.

4. Future Considerations

Future research on the ecology of aging is faced with at least three challenges:

(a) *Theoretical challenges*. Most of the theoretical approaches in this field were developed in the sixties and seventies. One particularly fruitful theoretical avenue may be to strengthen the links between ecological theories and promising conceptual approaches within psychological gerontology. One prototypical example is provided by psychological control theories (see Schulz and Heckhausen 1999) which focus on person–environment relations and their alterations across the human life span.

(b) *Methodological challenges*. Although the use of naturalistic methods such as observations and *in vivo* data-collection strategies have proven themselves to be indispensable tools in research on the ecology of aging—as well as for gerontology in general—the methods used are rarely comparable. One of the most important methodological challenges is creating a single set of instruments to describe the physical and spatial environment of older people (Gitlin 1998).

(c) *Application and societal challenges*. Due to the rapidly growing number of older adults and particularly 'old-old' adults beyond the age of 85, one of the main challenges of today's and tomorrow's societies is providing care for the demented elderly. Research on the ecology of aging must be strongly committed to planning and evaluating supportive environments for these people. In addition, the growing impact of information and communication technology such as the Internet, the use of high-tech solutions in housing and in public community life, as well as the rapidly growing role of technology in geriatric care have given rise to a whole range of new environmental characteristics. Research on the ecology of aging will thus continue to encounter new challenges in the future.

Ecology: Organizations

Inspired by the question, Why are there so many kinds of organizations? (Hannan and Freeman 1977), organizational ecology aims to explain how socio-political and economic conditions affect the relative abundance and diversity of organizations and to account for their changing composition over time. Ecological research typically begins with three observations: (a) diversity is a property of aggregates of organizations, (b) organizations' members often have difficulty devising and executing organizational changes fast enough to meet the demands of uncertain and changing environments, and (c) the community of organizations is unstable—organizations arise and disappear continually.

Consequently, contrasting adaptation approaches (see *Structural Contingency Theory*), which emphasize individual organizations' leaders cumulative strategic choices, ecological analyses formulate organizational change and variability at the population level, highlighting the creation of new and the demise of old organizations and populations.

Organizations, populations, and communities constitute the basic elements of ecological analysis. A set of organizations engaged in similar activities and with similar patterns of resource use constitutes a population. Organizational populations form as isolating processes, including technological incompatibilities, institutional actions such as government regulations, and environmental imprinting segregating one set of organizations from another. Populations develop relationships with other populations engaged in different activities that bind them into communities. Organizational communities are functionally integrated systems of interacting populations in which the outcomes for organizations in any one population are intertwined fundamentally with those in other interrelated populations. In broad terms, ecological theory and research focus on three themes: demographic processes, ecological processes, and environmental processes.

1. Demographic Processes

1.1 Age and Size Dependence

The relationship between organizational aging and failure is a central line of demographic inquiry. Until recently, the predominant view was the liability of newness (Stinchcombe 1965), which assumes that because they have to learn new social roles, create new organizational routines, and lack endorsements and exchange relationships, young organizations will have higher failure rates. A complementary viewpoint is that selection processes favor structurally inert organizations capable of demonstrating reliability and accountability, which requires high reproducibility. Since reproducibility, achieved through institutionalization and routinization, increases with age, older organizations should be less likely to fail (Hannan and Freeman 1984).

A related line of research examines how organizational size influences failure. Small organizations' propensity to fail results from several liabilities of smallness, including problems with recruiting and training employees, raising capital, and handling costs of regulatory compliance. Moreover, as organizations grow, increasingly they emphasize predictability, formalization, and control, increasing their reliability and accountability, and lowering their vulnerability to failure. The significance of 'smallness' stems in part from its relation to 'newness': since new organizations tend to be small, if small organizations have higher failure rates, empirical evidence of a liability of newness may actually reflect specification error. Although early studies consistently found a liability of newness, later studies controlling for time-varying size often do not, which has prompted formulation of alternative views on age dependence.

The liability of adolescence (Fichman and Levinthal 1991) predicts a $\cap$-shaped relationship between age and failure. New organizations begin with a stock of assets (e.g., goodwill, psychological commitment, financial resources) that buffers them during an initial 'honeymoon' period—even if early outcomes are unfavorable. The larger the initial stock, the longer the buffer. As initial endowments are depleted, however, organizations unable to meet ongoing resource needs because, for example, they are unable to establish effective routines or exchange relations, may fail.

Liabilities of newness and adolescence yield divergent accounts of age dependence for young organizations, but because processes underlying these models occur early in organizational lifetimes, they do not apply to older organizations. The liability of aging (Barron et al. 1994) identifies processes affecting older organizations and predicts that failure increases with aging. The liability of aging begins with another insight from Stinchcombe's (1965) essay: organizations are imprinted by their founding environment. As environments change, however, bounded rationality and

structural inertia make it difficult for individuals to keep their organizations aligned with environmental demands. Encountering a series of environmental changes may thus expose aging organizations to a risk of obsolescence. Aging may also bring about senescence: an accumulation of internal politics and precedent that impede action. Obsolescence and senescence pose separate risks. Senescence is a direct effect of aging; obsolescence a result of environmental change.

Among studies controlling for time-varying size, empirical estimates are mixed (Baum 1996). The divergent age dependence results might reflect nonproportionality (e.g., effect of age varies with size) masking 'true' age effects or alternatively variation in age dependence across populations. To resolve such questions, research must test alternative models' mediating variables directly rather than using age as a surrogate for all underlying constructs. Such an approach treats the alternatives as complementary rather than (falsely) as competing models.

1.2 Organizational Change

Most research on organizational change concentrates on content: a change to a more (less) advantageous configuration is considered adaptive (detrimental) (see *Organizational Change*). Complementing this focus, structural inertia theory (Hannan and Freeman 1984) emphasizes the change process and raises two questions.

1.2.1 How changeable are organizations? The structure in structural inertia theory refers only to core organizational features (goals, authority structures, core technology, and market strategy) related to mobilizing scarce resources for beginning an organization and the strategies used to maintain resource flows (Hannan and Freeman 1984). Peripheral features buffer an organization's core from uncertainty. Core features exhibit greater inertia than peripheral features, but the claim is not that they never change, only that 'the speed of reorganization is much lower than the rate at which environmental conditions change.' Nor does structural inertia theory remove individuals from responsibility or control over their organization's survival. Indeed, the challenge of overcoming structural inertia implies that the capacity of individuals to change organizations successfully is of great importance. Inertia also varies with age and size. Because older organizations have more formalized structures, standardized routines, institutionalized power structures, and dependencies, inertia should increase with age. Moreover, as organizations grow, they increasingly emphasize predictability, formalization, and control, becoming more inflexible. Large size, by buffering organizations from environmental demands, may also reduce the impetus for change.

Although not included in structural inertia theory, a complete understanding of change processes requires consideration of organizations' change histories (Amburgey et al. 1993). The more experienced an organization becomes with a particular change, the more likely it is to repeat it. If the change becomes causally linked with success in decision-makers' minds—rightly or wrongly—repetition is even more likely. The change process may thus itself become routinized, creating organizational momentum—the tendency to maintain direction and emphasis of prior actions in current behavior. To reconcile momentum with commonly observed periods of organizational inactivity, Amburgey et al. propose that local search processes (Cyert and March 1963) reinforce momentum immediately after a change occurs, but it subsequently declines.

Empirical studies yield mixed support for structural inertia theory; support for momentum appears stronger (Baum 1996). Overall, research indicates that, while inertia and momentum constrain them, organizations often initiate change in response to environmental shifts. Of course, inertia and momentum are not necessarily harmful: in addition to promoting performance reliability and accountability, in an uncertain environment they can keep organizations from responding too quickly and frequently to environmental change. Ultimately, whether inertia and momentum are adaptive depends on the hazardousness of change.

1.2.2 Is change beneficial? According to structural inertia theory, core change destroys or renders obsolete established routines, disrupts exchange relations, and undermines organizational legitimacy by impairing performance reliability and accountability. Thus, organizations may often fail precisely as a result of their attempts to survive—even attempts that might, ultimately, have proved beneficial. Because their structures, routines, and relationships are more institutionalized, older organizations are especially likely to experience disruption following core change. In contrast, large organizations can buffer themselves from disruption by, for example, maintaining both old and new routines during transition or overcoming deprivations and competitive challenges accompanying the change. If an organization survives the short-run hazard, its failure rate is predicted to decline as performance reliability, exchange relations, and legitimacy are re-established over time. Only if the rate of decline is faster than before the change, however, will the organization ultimately benefit from taking the short-term risk.

Empirical studies indicate that while core change is not necessarily disruptive in the short run, organizations do not necessarily improve their survival

chances in the long run either (Baum 1996). Two research design problems, however, appear likely to produce systematic underestimates of the hazardousness of change. First, the annual data typically used may not detect the deadliest core changes—those proving fatal within a year. Second, because organizations founded before a study period are not observed when they are youngest, smallest, and most likely to be subject to vulnerable change, their inclusion likely biases downward the risk of change.

2. Ecological Processes

2.1 Niche-width Dynamics

Niche-width theory (Hannan and Freeman 1977) focuses on two aspects of environmental variability to explain the differential survival of specialists, which possess few slack resources and concentrate on a narrow range of customers, and generalists, which attempt to appeal to the mass market and exhibit tolerance for more varied environments. Variability refers to the variance in environmental fluctuations about their mean over time. Grain refers to the patchiness of these variations with fine-grained variations frequent and coarse-grained infrequent. The key prediction is that in fine-grained environments, with large magnitude variations, specialists out-compete generalists regardless of environmental uncertainty. Specialists ride out the fluctuations; generalists are unable to respond quickly enough to operate efficiently. Thus, niche-width theory challenges the classic prediction that uncertain environments always favor generalists that spread their risk (see *Structural Contingency Theory*).

Table 1
Elaborations of the density dependence model

Model	Critiques[a]	Elaboration	Key references
Density delay	3	Incorporates imprinting effect of density at founding	Hannan and Carroll (1992)
Mass dependence	2,3	Weights each organization's competitive effect by its size	Barnett and Amburgey (1990)
Multiform models	2	Estimates intrapopulation microstructures and interpopulation (community) macrostructures	Barnett (1990)
Level of analysis	2,3	Estimates variation in density dependence across levels of geographic aggregation (city, state, region, nation)	Hannan et al. (1995)
Institutional embeddedness	1,4	Estimates population legitimation with relational density (endorsements by powerful actors and organizations)	Baum and Oliver (1992)
Nondensity measures	1	Estimates population legitimation with nondensity measures (certification contests, media content measures)	Rao (1994)
Localized competition	2,3,4	Weights competititive effects of organizations on each other by their proximity (size, price, location)	Baum and Mezias (1992), Baum and Haveman (1997)
Organizational niche overlap	1,2,4	Disaggregates population density for each organization based on resource (non)overlaps with other organizations	Baum and Singh (1994a, 1994b)
Location dependence	2,4	Incorporates information on spatial structure of organizational populations	Lomi (1995)
Time variation	1,2,3	Estimates variation in density dependence as a population ages	Baum (1995)
Dynamic selection	2,3,4	Incorporates variation in the strength competitive processes as a population ages	Baum (1995)
Competitive intensity	2,3,4	Weights each organization's competitive strength by its age	Barnett (1997)

a Critiques.
1 Proposed integration of ecological and institutional perspectives.
2 Assumption that each organization influences and is influenced by competition equally.
3 Inability to explain the concentration common to older populations.
4 Inattention to problems of unobserved heterogeneity.

In contrast to niche-width theory, which implies an optimal strategy for each population, Carroll (1985) proposes that, in environments characterized by economies of scale, competition among generalists to occupy the center of the market frees peripheral resources that are most likely to be used by specialists. He refers to the process generating this outcome as resource partitioning. His model predicts that in concentrated markets specialists can exploit more resources without engaging in direct competition with generalists, and so that while increasing market concentration increases the failure of generalists, it lowers the failure of specialists.

Although the specialist–generalist distinction is now common in ecological research, tests of niche-width and resource-partitioning theories' predictions are limited, and no studies explicitly contrast niche-width and resource-partitioning predictions. Recent studies frequently examine spatial and temporal environmental variation without reference to niche width, pointing to the need to elaborate niche-width models to encompass spatial as well as temporal environmental variation.

2.2 Population Dynamics and Density Dependence

Research on founding and failure in organizational ecology has paid considerable attention to endogenous population dynamics and density dependence. Prior population dynamics—patterns of founding and failure—shape current founding rates (Delacroix and Carroll 1983). Initially, prior foundings signal opportunity to entrepreneurs, encouraging founding. But as foundings increase, resource competition increases, discouraging founding. Prior failures have analogous effects. At first, failures release resources available to entrepreneurs. But further failures signal a hostile environment, discouraging founding. Resources freed by prior failures may also enhance the viability of established organizations, lowering failures (Carroll and Delacroix 1982). Density-dependent explanations for founding and failure are similar though not identical. Initial increases in the number of organizations can increase the legitimacy of a population, enhancing the capacity of its members to acquire resources. However, as a population continues to grow, competition with others for scarce common resources intensifies. Combined, the mutualistic and competitive effects imply a $\cap$-shaped relationship between density and founding and a $\cup$-shaped relationship between density and failure (Hannan and Carroll1992).

Studies of a wide variety of organizational populations provide empirical support for density-dependent founding and failure. By comparison, population dynamics findings are mixed and, when modeled together with population density, population dynamics effects are weaker and less robust. One explanation for the dominance of density dependence over population dynamics is the systematic character of density relative to the changes in density produced by founding and failure. A related explanation is the sensitivity of rate dependence estimates to outliers. These issues need to be examined more thoroughly before population dynamics is abandoned, which has been the trend in recent research.

Although support for density dependence is strong, it has received critical attention for its (a) proposed integration of ecological and institutional perspectives, (b) assumption that each organization influences and is influenced by competition equally, (c) inability to explain the concentration common to older populations, and (d) inattention to problems of unobserved heterogeneity. Several innovative elaborations, respecifications, and measures have been advanced recently to address questions raised by the initial formulation (summarized in Table 1). Although Hannan and Carroll (e.g., 1992, 1995) frequently rebuke such efforts, they nevertheless promise to improve substantive interpretation and realism of the original model.

3. Environmental Processes

Environmental processes are central to organizational ecology, shaping appropriate organizational forms and conditioning historical–structural relationships (e.g., the basis of competition).

3.1 Institutional Processes

Organizational environments are more than simply sources for inputs, information, and knowhow for outputs. Institutionalized rules and beliefs about organizations also figure prominently (DiMaggio and Powell 1983, Meyer and Rowan 1977). Institutional theory emphasizes that organizations must conform to these rules and requirements if they are to receive support and be perceived as legitimate. Density dependence theory views the relationship between ecological and institutional theory as complementary and synthesizes them within a single explanatory framework. However, institutional theory is increasingly conceived as contextual to ecological theory—the relationship between them is not only complementary, it is also hierarchical (Baum 1996).

From this point of view, the institutional environment constitutes the broader social context for ecological processes—the institutional environment may prescribe the criteria for judging whether an organization or entire population is worthy of continued survival. Ecological research on institutional processes

typically compares rates of founding, failure, change, or growth across organizational populations or time as the institutional arena of a particular population changes in terms of its political turbulence, government regulation, or institutional embeddedness (Baum 1996). Most past research has treated institutional change as exogenous. Studying how ecological dynamics of organizations shape institutional change can, however, enrich our understanding of institutional change and persistence.

3.2 Technological Processes

Technological innovation influences organizational populations profoundly by disrupting markets, changing the relative importance of resources, challenging organizational learning capabilities, and altering the basis of competition (see *Technology and Organization*). Supporting Schumpeter's characterization of technological innovation as a process of creative destruction, research supports the idea that technologies evolve over time through cycles of long periods of incremental change, which enhance and institutionalize an existing technology, punctuated by technological discontinuities in which new, radically superior technologies displace old, inferior ones, making possible order-of-magnitude or more improvements in organizational performance (Tushman and Anderson 1986).

The new technology can either be competence-enhancing, building on existing knowhow and reinforcing incumbents' positions, or competence-destroying, rendering existing knowhow obsolete and making it possible for newcomers to become technologically superior competitors. The technological ferment spawned by the discontinuity ends with the emergence of a dominant design, a single architecture that establishes dominance in a product class (Anderson and Tushman 1990), and technological advance returns to incremental improvements on the dominant technology. Although the universality of this technology cycle is debated, it has proved illuminating in a wide variety of industries.

Technological innovation creates opportunities for entrepreneurs to found new organizations and establish competitive positions as incumbents' sources of advantage decay. Technological innovation also creates uncertainty and risk for incumbents because its outcomes can be only imperfectly anticipated. An innovation's impact may not be known until it is too late for incumbents using older knowhow to compete successfully with new competitors; gambling too early on a given innovation may jeopardize an incumbent's survival if that technology turns out not to become dominant. Thus, underlying technologies and technological innovation may influence organizational populations' competitive dynamics and evolution profoundly. Ecological research relating technology cycles to population dynamics, although limited in scope, yields compelling support for this assertion (Baum 1996). Although past research typically treats technological change as exogenous, studying how ecological processes shape technological change can deepen our understanding of technology cycles by examining the dynamics of organizational support for new technologies.

J. A. C. Baum

Ecology, Political

Political ecology had its origins in multidisciplinary efforts to integrate human and cultural ecology with political economy. The incorporation of ecology into political economy influenced political economists to take ecology more seriously, while political economy gave human and cultural ecologists a means to contextualize local level studies into broader political economic relations and into history. In the 1990s, some political ecologists have drawn on cultural studies and discursive approaches for insights into the ways that identity politics and the meanings ascribed to specific landscapes shape environmental politics at various scales—from the local through the global. This expansion has led to enhanced research by political ecologists on social movements, nongovernmental organizations (NGOs), gender relations, global through local environmental governance, and other areas. To date, however, political ecology is not a coherent theory oriented around a set of common assumptions, concepts, or research methodology. Rather, it is a dynamic and growing field that has become a forum for research, discussion, and debate among a diverse group of scholars concerned with the many ways in which power and politics affect and are affected by ecology and the biophysical environment.

1. *The Rise of 'Political Ecology'?*

Since the 1970s, political ecology has emerged as a multidisciplinary approach with which to analyze complex human–environmental interactions, especially those related to economic development and environmental destruction in the Third World (Peet and Watts 1996, Bryant and Bailey 1997). Although the field of political ecology has been greatly influenced by the 'regional political ecology' model set forth by geographers Piers Blaikie and Harold Brookfield (1987), political ecology is not as yet a comprehensive theory but a common ground where various disciplines intersect. Political ecology has been described in various ways: as 'a *framework* for analyzing human–environmental relations' (Grossman 1998); as a '*research orientation* that seeks to link macrolevel political economic processes with microlevel aspects of human ecology' (Dodds 1998); as a '*historical outgrowth* of the central questions asked by the social sciences about the relations between human society, viewed in its bio–cultural–political complexity, and significantly humanized nature' (Greenberg and Park 1994); and as a '*program or movement*... begun as a reaction to certain features of human ecology or ecological anthropology [as well as cultural ecology] as it was practiced in the 1960s and early 1970s' (Vayda and Walters 1999).

In part, political ecology emerged as part of a broader critique of cultural ecology, risk–hazard studies, and ecological anthropology that began in the 1970s and stemmed from the apolitical and microlevel analytical traditions of these fields. This critique was centered on the perceived neglect of the political dimensions of human–environmental interactions, the preoccupation with homeostatic processes, and the conceptualization of human communities as fairly autonomous and homogeneous (Painter and Durham 1995). The renowned anthropologist, Eric Wolf, was among the first to use the term 'political ecology' in his criticism of cultural ecological and ecological

anthropological approaches to the study of Alpine ecology (Wolf 1972). In his role as a discussant for an anthropological symposium on the 'Dynamics of Ownership in the Circum-Alpine Area,' Wolf emphasized the theoretical need to situate local ecological realities within the broader political economy.

In order to document trends in the historic rise of political ecology, the term 'political ecology' was used to search systematically a number of relevant digital databases of published articles and books, as well as theses and dissertations. These databases included the Social Science Index (scholarly articles published between 1974 and 1999), World Cat (books, articles, dissertations, reports published between 1000 and 1999), the University of California Digital Library (Melvyl–CAT, all books included in University of California holdings), and University of Michigan Dissertation Abstracts (theses and dissertations filed between 1861 and March 1999). Comparative analysis of the results of these searches revealed similar trends across databases. Between the early 1970s and the mid-1980s, a maximum of one article, book, dissertation, or report having the term 'political ecology' in the title of the work or as a specified key word and/or subject heading was found annually. From the mid-1980s through the early 1990s, the number of such works per database was in the range 5–10 annually (depending on the database). Between the mid- and late-1990s, this range increased to 15–25 per database.

In addition to showing a significant increase in the number of scholarly works defined as 'political ecology,' analysis of the search results also demonstrated a similar distribution of disciplinary interest among the authors of these works. Across the databases, geographers accounted for $\sim 33\%$ of the works, anthropologists 20%, political scientists 15%, sociologists 10%, and philosophers 4%. Other disciplines represented included history, education, agriculture, forestry, wildlife, economics, health sciences, public health, and urban/regional planning. Depending on the year, $\sim$ 65–85% of these studies were focused on the Third World. In addition to demonstrating the growing popularity of 'political ecology,' the search results also showed an expansion over time in the number of disciplines represented by the authors, suggesting that political ecology is being embraced by an increasing number of disciplines. Analysis of the search results also pointed out two major and separate threads within the works classified as political ecological. The first of these, and the one that is the focus of this review, emanated from, and was in part a reaction to, the earlier scholarly fields of cultural ecology and human ecology. The second major strand consisted of a loosely defined set of scholarship concerned more specifically with politics *per se*, including green movements and green politics, especially in Europe and at the international and global levels.

Although the increasing popularity of political ecology is indicated by the recent plethora of studies explicitly using the term, a growing number of essentially political ecological studies were conducted beginning in the 1970s. Although not specifically employing the term, these included work on various ecological crises, the role of the state in deforestation, the human and environmental repercussions of booms and busts in the production of export commodities, and the impact of colonial policies on human–environmental interactions (Little and Horowitz 1987, Grossman 1998). Especially prescient were the 'progressive contextualization methods' urged by Vayda (1983) and the 'cultural ecology of development' approach suggested by Grossman (1984).

Embraced by geographers, anthropologists, political scientists, sociologists, historians, and many others, political ecology is closely associated with the frequently cited work of geographers Piers Blaikie and Harold Brookfield (Blaikie 1985, Blaikie and Brookfield 1987) in which they developed their conceptual framework for 'regional political ecology.' Blaikie and Brookfield (1987, p. 17) provide this definition: 'Political ecology combines the concerns of ecology and a broadly defined political economy. Together this encompasses the constantly shifting dialectic between society and land-based resources, and also within classes and groups within society itself.'

Blaikie and Brookfield (1987, pp. 23–4) specify that 'regional political ecology' also is compatible with new directions in disaster and hazards research (e.g., Hewitt 1983) that linked hazardous events to processes of proletarianization and marginalization.

Although Blaikie and Brookfield are concerned primarily with land-based resources, other political ecologists have broadened the domain of political ecology to include other aspects of the environment such as marine resources, human biology, health and nutrition, and environmental governance and policy. In general, these varied political ecological analyses explain human–environmental interactions through their relations to political economic forces (Blaikie and Brookfield 1987). A vital concern is to understand local complexity in resource use within a larger, even global context. Central to Blaikie and Brookfield's framework is the resource user ('land manager') whose decisions must be evaluated in their 'historical, political, and economic context' (Blaikie and Brookfield 1987, p. 239). Also crucial to political ecological analysis is the relative power of, and collaboration among, relevant social actors that affect access to, and management of, natural resources. These stakeholders are then linked within and among levels of analysis through relations of power (Stonich 1993, Peet and Watts 1996). Many political ecologists follow the 'chain of explanation' suggested by Blaikie and Brookfield (1987, p. 27) and focus their research efforts, at least initially, at the local level, examining resource–use patterns in relation to households (as producers and/or consumers) and conflicts within and among households. It starts with the land managers

and their direct relations with the land (crop rotations, fuel-wood use, stocking densities, capital investments, and so on). Then the next link concerns their relations with each other, other land users, and groups in the wider society who affect them in any way, which in turn determines land management. The state and the world economy constitute the last links in the chain (Blaikie and Brookfield 1987, p. 27).

Political ecological studies, focused initially at the local level, often require the intricate analysis of human–environmental relationships that also was characteristic of earlier works in cultural ecology and ecological anthropology.

Political ecological analysis frequently integrates a number of essential components as outlined by Schmink and Wood (1987) in an early theoretical discussion. First, an assessment of the various contested ideologies that direct the use of resources and influence which stakeholders benefit from and which are disadvantaged by those ideologies. Also vital is a determination of the various international interests involved, including donor agencies, organizations, and private investors that promote particular patterns of natural resource use. Increasingly of concern is the function of the global economy in advancing specific patterns in access to and use of natural resources.

Crucial as well is the role of the state, particularly in terms of determining and implementing policies that favor the interests of certain social actors over those of others. Also central to the analysis is the relationship of class, ethnic, and gender structures to conflicts over access to productive resources, the interrelations among local resource users and groups of society who affect resource use, and diversity in the decisions of local resource managers (e.g., Stonich 1993, Rocheleau et al. 1996). Finally, political ecologists also tend to agree on the significant role of historical analysis in understanding the development of social and ecological relations and their subsequent links to environmental degradation (Blaikie 1985, Blaikie and Brookfield 1987, Guha 1990, Peluso 1993, Stonich 1993).

Efforts to characterize the evolving field of political ecology are difficult given the diversity, dynamism, and rapid growth of the field. One major focus of research using a political ecology approach has emphasized human impoverishment and environmental destruction (e.g., Johnston 1994) especially stemming from dominant development models (e.g., Stonich 1993, Painter and Durham 1995). These studies emphasized the relations among capitalist accumulation, state policy, surplus extraction, environmental destruction, and human impoverishment. Scholars often couched their arguments in opposition to prevailing popular explanations of environment degradation: Malthusian pressures, the irrationality of peasants, and/or technological ignorance (Painter and Durham 1995). A number of findings from these studies potentially can help understand deteriorating human and environmental conditions in other development contexts.

First, environmental destruction identified with the economic production systems of the poor usually is an outcome of their impoverishment, either absolutely or relative to other social classes. Impoverishment often is related to diminished access to land and other natural resources and to increased repression and violence at the hands of state authorities and more powerful individual and corporate interests engaged in land speculation. Moreover, environmental destruction associated with the decisions of the poor usually is intricately linked to existing environmental parameters, especially environmental marginality.

Second, as a consequence of their vulnerability and lack of power, smallholder producers often have received a disproportionate share of the blame for environmental decline. In contrast, political ecological research has demonstrated that a great deal of land and other natural resources has been degraded by the activities of more powerful private, public, and corporate interests. Large-scale enterprises that have acted destructively frequently have been granted land on concessionary terms by the state. This allows these more powerful stakeholders to treat land as a low-cost input, and makes it more economical to move elsewhere after the environment is degraded rather than try to conserve natural resources. Third, the same policies and practices that result in wealthy interests receiving land on favorable terms are responsible for the impoverishment of smallholders, because such policies institutionalize and exacerbate unequal access to resources. In sum, the political ecology approach applied to Third World development has shown that the crucial issue underlying environmental destruction and human poverty is blatant inequality in access to resources within a socially institutionalized context (Painter and Durham 1995). While other approaches, not labeled as political ecology, have found similar results, political ecological studies tend to emphasize these conclusions.

2. *Current Trends and Debates in Political Ecology*

Recently, the research agenda of political ecology has expanded to encompass a much wider and loosely delimited range of scholarship. Of special significance are efforts to understand the social construction of the environment and the increased integration of various cultural and discursive approaches into political ecological analysis (e.g., Escobar 1999). Reflecting the growing poststructural concern with discourse in the social sciences more generally, scholars such as Escobar emphasize that perceptions and discourses about environmental problems are social constructions that reflect specific backgrounds, values, and

positions of power rather than absolute truths. Diverse constructions and associated discourses frame contested points of view about what constitutes 'environmental problems' as well as possible/suggested solutions to these 'problems.' Coupled with a concern for political economy, these scholars are examining the plurality of perceptions and definitions of environmental and natural resource problems.

A second important trend is the 'serious treatment of *politics* in political ecology,' especially attempts to integrate political action (from passive resistance, to civil society, to political parties) into questions of resource access and control (Peet and Watts 1996, p. 10). Examples of this view of political ecology have emphasized various scales or levels of analysis from the domestic (household) to the global. For example, scholars such as Rocheleau, Thomas-Slayter, and Carney have focused their efforts at examining household level gender politics involving property rights, labor, access, and control of natural resources (Carney 1996, Rocheleau et al. 1996). In comparison, other scholars have focused on the more macrolevel and specific cases such as the World Bank and post-UNCED legal frameworks. These scholars have attempted to demonstrate the linkages between power relations, institutions, and environmental governance. Among the most important issues identified by studies that 'seriously' consider the politics of political ecology are the frequent occurrences of coercive patterns of environmental conservation. This was clearly demonstrated by Peluso (1993), who showed how state power and forestry institutions in Indonesia are contested by Indonesian peasants in the context of coercive conservation measures.

A related and expanding research interest for political ecologists is civil society—especially the proliferation of social and environmental movements (including the environmentalisms of the poor) and NGOs concerned with environmental governance at various levels—from the local, to the national, to the international and global. This trend, in addition to the previously discussed expansion of political ecology into the arena of politics, may represent a movement within political ecology to integrate the two separate strands of scholarship discussed earlier.

Political ecology has been criticized for overemphasizing the explanatory power of structural forces (i.e., the political economy) while downplaying the crucial role of local resistance, household survival strategies, inter- and intrahousehold conflicts over natural resources, as well as cultural beliefs (Stonich 1993). While several political ecologists have considered how local level forces interact with broader structural forces (e.g., Stonich 1993), increased attention to civil society may help restore the balance to what is essentially part of the broader structure–agency debate within the social sciences.

Finally, a nascent but exciting new direction aims to integrate political ecology into new ecological paradigms concerned with chaotic fluctuations, instability, and disequilibria. The shift from earlier systems models of ecology that stressed stability and resilience to the new ecology of chaos presents significant challenges and opportunities to the theory and practice of a political ecology concerned with the complex dynamics of local human–environmental relations (Peet and Watts 1996).

The prospect of integrating political ecology and the 'new' ecology also highlights a key issue in current debates over political ecology that centers on the place and priority of the environment itself in political ecological research and explanation (Grossman 1998). Critics have faulted political ecology for failing to give due consideration to the environment itself (e.g., Zimmerer 1996, Grossman 1998, Scoones 1999). These critics maintain that some studies labeled as political ecology focus almost *exclusively* on the effects of politics and political economic forces *on* the environment—treating the biophysical environment solely as modified by human actions. While most critics acknowledge the importance of considering political economic factors, they point out that it is also crucial to analyze the significance of the environmental variables themselves and how they interact with political economic and other forces to affect human–environmental relations. In their provocative critique of political ecology from this perspective, *Against Political Ecology*, Vayda and Walters (1999) maintain that 'It may not be an exaggeration to say that overreaction to the "ecology without politics" of three decades ago is resulting now in a "politics without ecology".'

To some extent, the perceived imbalance between the priorities given to political economic and ecological factors in political ecological analysis and explanation pointed out by recent critics is tied to the growing importance of poststructuralism/postmodernism and discourse theory that is apparent in many of the new directions in political ecology. With its emphasis on social construction and discursive formations, discussed previously in this review, the constructionist approach has added a significant critical dimension to the earlier work by political ecologists. Especially important have been constructivist examinations of the role of science in environmental debates and the role of discourse in framing environmental problems and conflicts (especially but not exclusively in the Third World). Despite these contributions, various critics have pointed out several limitations associated with the strong idealist position inherent in constructionist arguments (see, e.g., the commentaries following Escobar's article in *Current Anthropology* (Escobar 1999)). First, the concept 'cultural and/or social construction' of the environment can overestimate the power of human behavior and actions to create, transform, or otherwise control environmental forces while simultaneously underestimating the transformative power of the

environment. The profound repercussions of the 1997–98 El Niño Southern Oscillations (ENSO) and La Niña events and of Hurricane Mitch in 1998 are persuasive examples of the power of the environment as an active agent capable of provoking widespread and significant human response. Critics maintain that political ecology must balance the cultural/social construction of the environment with a meaningful and comprehensive analysis of the environmental construction of the social and the cultural. Furthermore, they suggest that an overemphasis on constructivist discourse analysis may diminish the concern for the material issues and practice that first provoked the emergence of political ecology. From the perspective of more materially oriented political ecologists, the importance of understanding discursive formations lies precisely in what that understanding reveals about the behaviors of the diverse actors involved in social and environmental problems and conflicts.

3. *Future Directions*

The field of political ecology developed initially to provide a political economic perspective on the causes of environmental problems and degradation. During the 1990s, research interests broadened considerably but the concern with the fundamental importance of political economy remained central to the field. While political ecology may represent an emerging research agenda, neither past developments nor recent trends are theoretically integrated and it remains to be seen where existing convergences and tensions may lead. Current trends and new directions in political ecological research reveal significant stress between material and idealist perspectives that are linked to perhaps irreconcilable differences between scientific and poststructural/postmodern positions. There have been some efforts, however, to bridge the gap between these two disparate and often divisive positions (e.g., Peet and Watts 1996, Rocheleau et al. 1996). The fact that political ecology has engendered much recent debate and discussion among proponents and opponents with vastly different points of view suggests a vibrant and maturing field. It is not clear, however, if political ecology will mature into a unified field with its own comprehensive theory or rather remain an intellectual meeting ground for scholars from diverse disciplines. There is considerable debate among practitioners about the appropriate future for political ecology. There is still much to be done. As yet, a core literature has not been established and the growing number of studies conducted within the rubric of political ecology does not share any unifying principle, concepts, or methodology. Political ecologists have yet to address adequately crucial issues of scale—particularly the discontinuity between local-level complexity and specificity and larger-scale generalization and representation. In addition, most research to date has been multidisciplinary rather than interdisciplinary, despite the fact that much political ecological research has demonstrated the need for interdisciplinary approaches to understand the complex dynamics of human–environmental relations and ameliorate problems (e.g., Stonich 1993). A key implication of this review is that further research is warranted to expand the theoretical framework of political ecology, to enhance its interdisciplinarity, and to test its applicability in particular contexts as well as at the global level.

Econometric Software

This article will describe some of the characteristics of the most widely used econometric software, trace the evolution of this particular type of computer program, and explore the role of computer software in the development of applied econometrics. In order to discuss econometric software it is necessary, first, to define econometrics. We begin the discussion in Sect. 1 with a brief introduction to econometrics. Sect. 2 describes the distinctive features of the current vintage of econometric software and the progression of developments that has produced it. Sect. 3 discusses some of the common characteristics of software in econometrics. Finally, Sect. 4 will suggest some of the inter-relationships between econometric software and popular methods in econometrics.

1. *Econometrics*

Econometrics is a collection of methods and tools used to fit equations (economic models) to data. It involves both theory and measurement, and an overarching view of the process by which data come to be observed. The analysis begins with a theoretical explanation of some phenomenon, or a hypothesis about how some variables to be observed are related to each other. Measurement begins with the recording of some aspect of economic activity. Model building is the process by which these economic measurements are organized within the framework of one or more mathematical equations suggested by the economic theory. The principle behind this analytical framework is that of a 'data generating process' (DGP). There is an underlying statistical regularity at work that leads to the analyst's observation of their measurements. It is the characteristics of this underlying regularity, usually formalized as a probability distribution over random events, which are the objects of the econometric study.

In a familiar application of theory to data, observers collect pairs of observations on prices (P) and quantities (Q) exchanged in a market, such as the market for tobacco or fine wine, under the umbrella of a theory of 'demand.' The theory is embodied in a 'demand equation,' $Q = f(P \mid \alpha,\beta)$, which states that quantities traded are influenced by prices, and the nature of that response can be described by the relationship $f(\ldots)$ and the 'parameters,' α and β. The equation is made operational by computing statistics that provide information about the co-variation of prices and quantities transacted in the market. Thus, β might be an overall measure of how responsive quantities are to changes in prices, and the data are used to deduce information about the specific value of β.

In an econometric analysis, the information in a data set which may include thousands or millions of values is distilled to a few equations which are claimed to describe the DGP. The intricacy of modern econometric techniques makes essential elaborate software with capabilities that extend well beyond the ubiquitous spreadsheet programs such as Excel (4) and Lotus (10) (which would be the nearest cousins to the software considered here). (Numbers in brackets refer to the list of computer programs in the Appendix.) Econometric software is used most frequently for the manipulation of large amounts of measured data for the purpose of constructing the equations that are the model of the process which produced the data.

2. *The Evolution of Econometric Software*

The earliest software in econometrics was single purpose sets of Fortran language ('Formula Translation') code. The researcher who needed a program for a particular purpose would typically write it, or borrow it from someone else. One can find some of these programs in the appendices in some of the classic pieces in the literature, such as Nerlove and Press's (1973) development of the multinomial logit model, the first edition of Draper and Smith's (1981) exposition of regression analysis, Zellner's (1971) early

work on Bayesian estimation, and, more recently in Kalbfleisch and Prentice's (1980) work on survival modeling. A typical journal treatment is Krailo and Pike's (1984) exposition of a logit model for panel data, which contains a Fortran program listing for a standalone estimation program. Until the late 1960s, the journal *Econometrica* occasionally would publish short articles documenting computer programs developed by the authors.

2.1 Program Libraries

The process of building applications from scratch was made easier by 'libraries' of interchangeable parts for software development. The precursor to a very large group of programs currently distributed as the 'BMDP Library' (2) was a group of individual routines developed at UCLA in the 1960s under the heading of the 'BMD' (BioMedical) programs. These special purpose routines included subroutines for linear regression, Spearman rank correlation coefficients, cross tabulations, and so on. The BMDs initially existed as boxes of 80 column punched cards of Fortran code in the drawers of statistics labs. They maintained a common structure that allowed authors to write their own data setup programs to 'plug into' the package. Another programmer's toolkit that was circulated widely in the 1970s was the 'IBM SSP' (Scientific Subroutine Package) which was part of the documentation for IBM mainframe computers. This book contained Fortran and C listings of programs for such functions as inverting or decomposing a matrix, and computing a variance. ('C' does not stand for anything. It was simply an extension of 'B,' itself a derivative of 'BCPL' (the BC programming language) and a contemporary of APL (a programming language). All were languages originally written to work with the Unix operating system on DEC's original PDP-11 computers.

Most of the difficult computations being done by econometricians at this time involved complex matrix algebra, data manipulation, and random number generation. A library of well-written subroutines combined with the efforts of the analyst was quite sufficient for application development. This approach to programming has not vanished from the landscape. The *Numerical Recipes* books (C, Pascal, and Fortran) by Press et al. (1986), contain the modern counterpart to the expertly written library of subroutines contained in the SSP. The BMD libraries still exist as the commercial BMDP (2) routines, and the IMSL programs (6) and NAG (Numerical Analysis Group) (14) routines are still used by scientific programmers and in the development of major software packages. (IMSL, itself, grew largely out of a public domain library of matrix programs, EISPACK/-LINPACK. These provided the backbone for many early matrix implementations. They have since evolved to the (still) public domain package LAPACK (www.scd.ucar.edu/softlib/LAPACK.HTML and, see also NetLib at ORNL).

2.2 Integrated Packages

Early econometrics programs were single purpose Fortran programs that users passed amongst themselves and which grew over time as they were extended. The concept of a multipurpose, integrated econometrics package emerged in mid-1960s in the form of three particular programs, TSP (Time Series Processor), the Troll system, and B34S (which began as BiMed34; see Stokes 1997). TSP (23) and B34S (1) have remained active and are still under development. The early incarnations of these packages were primarily devoted to different forms of linear regression and correlation, but they have grown into vast assemblages of hundreds of thousands of lines of code (still mostly Fortran). Development of today's two largest commercial statistics and econometrics packages, SAS (17) and SPSS (20) also began at this time, though generally in social sciences other than economics and focused on techniques largely different from those of interest to econometricians. The demise of the distribution of custom written, single purpose software began in the 1970s with the emergence of TSP, SAS, SPSS, and so on.

2.3 Development Settings

With the exception of E-Views (3), which is a fairly recent arrival, and of the language platforms, MatLab (13), S-Plus (16), Gauss (5), Maple (11), and Mathematica (12), which are arguably successors to Fortran, most of the major packages in current use began development as part of a cottage industry in the 1960s and 1970s, usually by an individual or small team of innovators. This is a distinct difference from the contemporary, corporate route to major software development. The modern development centers, such as SAS, Inc. and SPSS, Inc. are creations of the 1980s and 1990s. Nonetheless, many of the programs listed in the Appendix to this survey continue to be developed by small numbers of statisticians and econometricians whose names would be recognized by practitioners (most likely in association with literature encountered as part of their graduate studies).

2.4 Programming Languages

Wither the primitive programming languages, Fortran and C? Fortran dominated the scientific computing landscape for nearly four decades until the early 1990s,

and remains the language of choice for many scientific applications, e.g., in physics and astronomy. The practitioner interested in writing a Fortran or C program may use one of the development kits for the PC (Windows) setting, such as Lahey (7) and Watcom (24). Time-shared systems, such as Sun Microsystems, also provide Fortran and C compilers and program libraries as part of the operating platforms. These vendors have extended the lives of Fortran and C as numerical language platforms, but this style of programming is a dying art. For software developers, Fortran is giving way to C, for example, in the full conversions of RATS (15) and SAS (17) and in the mixed language construction of LIMDEP (8). Individuals doing custom numerical programming increasingly rely on Gauss and its counterparts, MatLab, etc.

Recent developer's programming language implementations have gravitated toward the studio format. The studio platform consists of integrated tools for merging code in one or more languages along with numerous libraries and ancillary tools. The Microsoft Software Developers Kit (SDK) is a popular example. This approach to programming has become essential for the development of major programs. One of the very useful innovations is the seamless creation of mixed language (e.g., Fortran and C++) platforms that allow developers to exploit the best features of both these languages. The end result is that C, its successor, C++, and Fortran, continue to play a major role in the development of modern econometric software, but only in the laboratories of developers, rather than in the toolkits of practitioners.

2.5 The Internet

Finally, in what may be a surprise given the breathless surrounding hype, it appears that the Internet has had little or no impact on econometric software beyond facilitating the transfer of files, programs, and information. It is otherwise difficult to discern any ways in which the actual mechanics of econometric computing have been affected by the creation or expansion of the Internet.

3. The Characteristics of Modern Software

The software used by modern econometricians is essentially of two types. Most empirical research is done using one of the large, integrated packages that contain collections of programs for a variety of models. (See the 'Econometrics' list in the Appendix.) In these programs, complicated models are built with single, compact instructions. If a technique has gained acceptance in the applied literature, then it will appear as an 'option' in at least some of these packages. In contrast, when a technique or model proposed by an econometrician involves new methods or novel kinds of computations, then it is not likely to exist yet as a feature in an existing estimation platform. The computational tools that this analyst needs will typically be developed using one of the more primitive programming languages, such as Gauss (5), MatLab (13), S-Plus (16) or, at an even lower level, one of the native programming languages, Fortran or C++.

3.1 Packaged Expertise

The term canned routine has long been used for programs that embody the econometric expertise needed by users. Some have argued that the use of such software locks practitioners into a limiting set of models. While the argument may once have had some merit, the huge variety of techniques and the customizability provided by most large packages makes the criticism moot for current purposes. In addition, contemporary software is mature enough that developers have incorporated optimal algorithms that purists who mimic the textbook mathematical formulations might not use, or even be aware of. Least squares provides an excellent example. The analyst who writes his own program for linear least squares regression is likely to rely upon the textbook matrix formula, $b = (X'X)^{-1}X'y$. But, this is not the most accurate method of computing a least squares coefficient vector. Many large packages use much more accurate techniques, such as QR and singular value decompositions that avoid inversion and moments accumulation altogether. For the individual researcher to develop complicated low level tools such as this may well be excessively difficult.

3.2 User Written Programs

The distinction between these two types of software is somewhat blurry since the programming languages are often distributed with packages of routines that have been written by expert users. In addition, developers of code for Gauss (5) and MatLab (13) often distribute their programs on the Internet simply by posting them on their own websites, perhaps along with the research report of which the software development was a part. For example, all the major integrated econometrics packages contain an estimator for the logit model for binary choice, whereas the Gauss user must program their own. However, so many widely distributed Gauss libraries of routines contain users' versions of the logit program that for practical purposes, Gauss does contain a logit estimator. In the other direction, large integrated packages usually contain their own 'programming languages,' which allow the user to construct capabilities that are not already contained in the program. Thus, while a program such as SAS (17) may not contain a specific command for estimation of a certain kind of survival model, it does contain a programming language for matrix manipulation as well as a means for a user to access certain utilities such as a nonlinear optimization program. Thus, the SAS user can develop

a new estimator within his familiar SAS platform. TSP (123), SAS (17), SPSS (20), Stata (21), Shazam (18), EViews (3), and LIMDEP (8) to name a few, are all large integrated packages that also contain extensive matrix and data manipulation languages and access to nonlinear optimization programs which allow users to extend the modeling capabilities of the package. Thus, software developers and their users have blurred the distinction between preprogrammed procedures and programming languages.

3.3 Application Studios

The modern applied econometrician will usually maintain a toolkit of software consisting of one or more large packages, and, for less frequent usage, a low level development kit such as Gauss or MatLab, or a Fortran compiler, such as Lahey (7). Developers, conscious of this and sensing an opportunity, have begun to gravitate to a developer's studio format for econometric software. As noted, all of the large packages provide low to medium level programming capability. Current trends, such as EViews, LIMDEP, RATS, SAS, Stata, and TSP have brought the programming features closer to the front end of these large, high level packages and Gauss with its large, expanding, and widely distributed library is approaching the same format from the opposite direction.

3.4 Common Features

Most general, integrated econometrics programs are quite similar. The model building process dictates the design, and as in many settings, a standard has evolved naturally. The following functions will be found in all the integrated packages, and, over time, will be mimicked by the users of the language packages as they collect their own routines:

(a) Data input and transformation;

(b) Model estimation—the estimation of model parameters, usually of several types;

(c) Statistical inference—testing hypotheses and forming probabilistic statements about quantities of interest;

(d) Specification, testing, and iterative refinement of model specification;

(e) Manipulation of model results for forecasting and simulation;

(f) Graphics and display of results.

Programs differ in some features and there is some amount of specialization, but most or all of the preceding will be found common to all. (Reviews are regularly published, e.g., in the *Journal of Applied Econometrics*.) The second function listed is one of the major dimensions on which programs differ. For example, EViews and RATS are particularly oriented toward analysis of time series data, SAS and Stata are especially complete in their presentation of techniques used in biomedical research, and LIMDEP is best known for its selection of models for discrete dependent variables. (Markets being what they are, there is substantial and growing overlap of these features.)

3.5 Interfaces

The means of communication between the user and the software is the interface. In order to describe this, it is necessary to make a distinction between mainframe and 'PC' (desktop style) operation. A second distinction between 'batch' and 'interactive' mode use is also necessary. The two distinctions are useful for describing the way certain computer programs work, although both modes do appear in both settings. Econometric software design began on large time shared mainframe systems. The design of such systems necessitated a batch mode form of interface. In this case, the user submits a set of instructions to a computer (operator, real or virtual) and returns later to retrieve their desired results. Modern computing carried out on the desktop, in contrast, usually involves an individual operating their own system interactively in the fashion of a large calculator, submitting single instructions (perhaps in the form of mouse clicked selections from menus) and instantly receiving the results of their directive. Econometric analysis often requires a hybrid of these two modes. Many estimation problems require huge amounts of computation that may take hours or days to complete, or lengthy scripts of operations. As such, a batch mode of operation is often necessary, even on a desktop computing platform. Therefore, there is normally some means of giving the program a directive equivalent to 'carry out the following sequence of commands,' or 'fetch the set of commands contained in a certain file on disk and carry them out.'

There is a qualitative difference in the typical look and feel of a desktop computer compared to a time-shared mainframe. Modern desktop software is based on graphical user interfaces (GUIs). The amount of menuing varies from one program to another, but all modern econometrics programs are based on the GUI format. In contrast, there is relatively little GUI in the time-shared environment. The distinction is only superficial, however. The numerical functionality of most econometric software is easily replicated in both mainframe and microcomputer environments (e.g., all of the econometrics programs listed below except EViews). This is one of the strong distinctions between econometric software and, say, the programs used for graphics design or word processing. In the final analysis, the purpose of most econometric software is numerical analysis that can be done equally well in batch or interactive mode.

3.6 Estimation Procedures

To describe some of the remaining features, it is convenient to define some terms. Estimation is a

process of culling from a data set a set of statistics that summarize the process by which the data were created. Estimation results range from single numbers, such as the parameter β in our earlier demand equation example, to one to one transformations of the original data, such as a periodogram, nonparametric hazard function, or kernel density estimator. Econometric software will contain 'estimation routines.' The term derives from the earliest days in which Fortran 'subroutines' were written for these purposes. The estimation routine consists of a body of code written to be invoked with a simple 'command' and provided with the specifics of a user's problem. The command itself or the broader context of use of the software must define the kind of model to be estimated. Commands might be of the form 'Using the data on Price and Quantity, fit a linear regression model.'

For example, one popular program, LIMDEP, uses the following, fairly typical style:

Regression; Lhs = Quantity; Rhs = One,Price $

that states in words that the user wishes the program to compute the constant term (ONE) and slope in a linear regression of quantity on price, $Q = \alpha + \beta P + \varepsilon$. All integrated packages have counterparts to this kind of command, which is provided to the program by means of some kind of text processor. Some packages provide the same functionality by asking the user to select the estimation framework, then the variables in the equation from menus, instead. Many programs also allow users to choose either mode of entry. Each has its virtues—the former allows recording of steps and reuse of commands whereas the latter is generally more convenient.

A programming language such as Gauss would not contain such a broadly defined procedure. Rather, the Gauss processor would allow the user to define, using matrix expressions, the algebraic steps involved in doing the computation, including how to compute the coefficients for the model and how to compute certain statistics that the integrated processor would produce automatically. The user would then use the language's built-in functions for displaying the results of their computations. Thus it would seem that a great deal more work is required of the Gauss user than the LIMDEP user. There is, but two issues motivate the former. First, as noted, many such sets of computations already exist, in elaborate routines that programmers have written and disseminated, so that these procedures can be used, often with a single command. Second, many estimation techniques do not exist (yet) in large integrated packages, so this is the only way to proceed. (Since this market is fast moving, it would be inappropriate to mention specific techniques. By the time this article appears in print, the information will be out of date.)

The remaining functions involve manipulation of model results. Some of these are handled automatically by the software while others must be assembled by the user. At this juncture, the user of the integrated procedure is likely to use some of the programming features of the package, such as a matrix computation. For example, the literature often produces new statistics or ways to manipulate the results produced by familiar models such as the linear regression model. The SAS, Stata, or TSP user is likely to handle this situation by constructing a 'procedure' with 'adjustable parameters' that might appear as follows:

'Procedure: Regression;

Dependent variable is (Y), Independent variables are (x1, x2)

Compute residuals as variable (e).

Compute and report statistics using procedure …

End of Procedure'

Now, to invoke their procedure, the user might use a single directive such as:

'Use Regression Procedure (Quantity, One, Price).'

The generality of the procedure allows it to be used for different problems just by changing the 'call' statement. At this point, the only difference between Gauss and SAS is the detail that will have to be programmed in the first line of the procedure.

3.7 *Accuracy*

One might think that given the textbook formulas for the necessary computations, all programs would get the same right answer for any particular problem. But, in fact, this is far from correct. Even in the absence of programming errors, there are large differences in the algorithms and methods used in computer packages. For practical purposes, two approaches are used for validating econometric software: replication and benchmarking. The first of these is strictly pragmatic. For most techniques, there are no applications with known *correct* answers against which to benchmark a program. As such, it is assumed that if two or more of the major programs give the same answer for a problem, then they both have it right. If they differ, then the tricky issue arises as to which, if either is correct and, again, the issue would have to be resolved in ad hoc fashion. A contemporary study that pursues this line of inquiry is Silk (1996), whose review of estimators for simultaneous equations models presents some surprising differences (see, also, McCullough and Vinod 1999.) The same approach has been taken in a review of programs for the computation of GARCH models by McCullough and Renfro (2000).

True benchmarking is now available for many common calculations. The tradition in econometrics begins with Longley's (1967) true results to 10 significant digits for a specific problem in linear regression. The Longley standard was used for many years as the yardstick for linear regression programs; if a program could match the Longley benchmark to at least eight digits, then it could probably rise above suspicion for practical usage. Later analysis has showed that the Longley hurdle is not particularly high, and clearing it is not all that difficult, even for fairly mediocre software. The Statistical and Engineering Division of the National Institute of Standards and Technology (NIST) has published (www.nist.gov/itl/div898/strd) a suite of 57 benchmark problems in four classes: univariate statistics, analysis of variance, linear regression, and nonlinear regression. The NIST problems have been solved using very high precision methods, and correct answers have been published. In detailed reviews, McCullough (1998, 1999) found fairly wide differences in the performance of several econometrics packages. Since econometrics programs tend to be revised, refined, and updated very frequently, these differences are likely no longer to be evident by the time this article is in print.

4. *The Role of Software in the Development of Econometrics*

A convincing case can be made that several parts of modern econometrics awaited the development of software to gain currency.

In primitive incarnations, econometric software operated on a table of data with variables in columns numbered from left to right. To communicate a desired computation to a program, the user would specify columns of the table, as in 'Regress the variable in column 5 on a constant, and the variables in columns 6, 8, and 10.' TSP was among the first to allow names for variables to appear in a symbolic instruction to the program. The software went an important step further in that it allowed the components of equations to appear symbolically in words and familiar algebraic symbols. Software had begun to evolve in this direction, but TSP brought the language of equation specification up to the level of compilers such as Fortran. This major innovation changed the standard for econometric estimation programs.

The most important single development in practical econometrics in the period prior to 1970 was arguably the LSQ (Least Squares) procedure in TSP. The combination of symbolic equation specification with TSPs LSQ procedure allowed the birth of a very large literature on linear and nonlinear equation systems. The seemingly unrelated regressions model had been proposed a decade prior by Zellner (1962) and Theil (with Zellner, 1962), but the model did not appear in wide use until the appearance of LSQ. The procedure went an important step further in that it allowed the Zellner estimator to be extended to nonlinear systems of equations.

At roughly same time, Joreskog proposed a maximum likelihood approach to factor analysis and the estimation of general linear equation systems. The analytic results had been known for some time, but solvers for the likelihood equations for a general hierarchical linear equation system had not been widely distributed. Joreskog's (1970) early work included 'A Computer Program for Minimizing a Function of Several Variables,' (Educational Testing Services: Research Bulletin 70-14). In this was published the numerical engine of a package published two years later as 'LISREL' (Linear Structural Relationships—originally, ACOVS for Analysis of Covariance Structures). ETS 70-14 contained a listing of Fortran computer code for optimization, including a very clever and effective technique for the line search step in optimization. LISREL spawned a very large and still growing industry in structural equations analysis in the social sciences. The technique is a major part of the methodology; the program, itself, has become Scientific Software, Inc. (9).

Of somewhat more recent vintage, is Heckman's (1979) sample selection model. Building on his work on labor supply models, Heckman proposed a method for a regression model with a particular type of nonrandom sampling in a seminal paper in 1979. The computations involved are now fairly routine and incorporated in most econometrics packages, but in the mid-1980s, the technique became a standard tool in the microeconometricians kit as the LIMDEP program (8) became the *de facto* standard approach for implementing it.

The work of Sims (1977), Granger (1969), and Litterman (1986) in the mid-1970s on vector autoregressions (VARs) in econometric time series analysis produced a new body of theory to challenge the structural simultaneous equations models. The RATS (Regression Analysis of Time Series) (15) computer program, developed by these authors carried the methodology into the mainstream of applied econometrics. The development has also been ongoing, both of the program (Estima, Evanston, IL) and of the methodology as can be seen in any reference on time series, such as Hamilton (1994). (RATS has recently spawned CATS—Cointegration Analysis of Time Series.) Once again, the computations and the methods are not overly difficult, but the fact that they have been conveniently integrated into a general-purpose package has been an important impetus to the dissemination of the methodology in the applied literature. RATS was also an early contributor among several that significantly advanced practice by providing the user with access to an optimization program that required only a basic, again symbolic, specification of the problem. This freed the researcher from having to

learn a large amount of programming. Contemporary programs, e.g., TSP, LIMDEP, and SAS, still RATS, Gauss, and so on, all offer this capability.

The earliest work in applied econometrics required the analyst either to use someone else's program or to know how to write their own Fortran code. The latter type were in a distinct minority, so most researchers used software written by others. Current practice and contemporary software make it possible for researchers to choose among a vast array of prepackaged techniques and, with the aforementioned MAXIMIZE capabilities and the matrix programming languages of Gauss, B34S, LIMDEP, RATS, and so on, to create another vast array of extensions with easily acquired programming skills. The result has been an explosion in the variety of techniques and model formulations found in the published research.

5. *Conclusion*

The development of software has been a facilitator, and a platform for the dissemination of results and continued research in econometric techniques and methodology. But there are cross-currents in contemporary software design. As of 1999, econometric software design and publication has left the cottage industry of the 1960s and 1970s far behind; it is usually (though not always) a corporate endeavor. At the same time, technique, development, and extension of econometric methodology remain the bailiwick of a scientific community which has, to some extent, preserved the distinction between the purely commercial nature of, for example, the word processor market and the romantic, if antiquated, free exchange of scientific software among individuals and small teams of researchers. However, market competition appears to be working smoothly in the right direction, and no case could reasonably be made that market forces have inhibited the development of econometric techniques or software in the way they have, e.g., in the markets for operating systems and Internet browsers. Technological advance in software and econometric technique appears to be rapid and uninhibited.

6. *Appendix: Some of the Most Commonly Used Econometric Software*

The above is a representative list of the most widely used econometric software. For additional information about the individual programs, the reader may refer to the websites listed. Some of these programs are listed as econometrics although econometrics is not the major functionality of the program neither is its

largest user base econometricians. These would include, for example, SPSS and Stata.

Econometrics, History of

Econometrics, the statistical metric for economics, can be regarded as one of the main innovations which turned twentieth century economics into an engineering, or tool-based science, in which each application of economic theory requires special shaping to circumstances, whether for scientific purposes or in the policy domain (see Morgan 2001). The development and use of statistical tools for economics emerged in the early part of the twentieth century and, by mid-century, problems had been defined, solutions approached and usable concepts developed, so that one could legitimately refer to a distinct body of knowledge embracing both theory and practice. After 1950 econometrics became a mature field and the dominant method of applied economics.

The particularities of the history of econometrics have often been linked to the nature of its tasks and aims (see De Marchi and Gilbert 1989, Heckman 2000, Morgan 1990, Qin 1993). Economists have understood their fundamental methodological problem to be: how to establish knowledge about economic phenomena and economic laws given that most economic activity cannot be subjected to controlled experiments. Econometricians have assumed that this means that descriptions, regularities, and relations of the economy must be extracted from 'passive' observations: statistical data that result from the natural course of economic activities, with the use of statistical theories and tools. Econometrics therefore suffers from all the usual problems of an inductive science. When measurement or testing of theories is at stake, severe correspondence problems arise because of the huge gaps between the assumptions of those economic theories and the conditions of data collection.

The history of the field also has its external dynamics (Desrosières 1998, Epstein 1987). To begin with, technological changes play an important role, evidenced in the development of the field of mathematical statistics and machines of computation. The provision of data, the availability of trained econometricians, and fashions in economic theory are all relevant to the narrative, as are the stimuli from twentieth-century economic events and associated demands for econometric expertise. Econometrics in the later twentieth century became a mainstay of economic policy analysis and tool for economic intervention, yet at the same time it grew into one of the most technically demanding and methodologically sophisticated areas of economics.

1. The Development Era

In the latter nineteenth century, a few economists began to use graphs and tables of statistical data to provide empirical support for their arguments, or

to describe behavioral characteristics of economic phenomena (Klein 1997). They were quick to take up certain statistical techniques developed for biometrics, namely correlation and regression. But these 'measures of association' were not entirely adequate for economists' questions (Aldrich 1995, Morgan 1997). Where biometricians had, for example, a sample of heights of fathers and their sons, whose relation could be assessed with correlation or regression coefficients under reasonable assumptions about the individuals in the sample, economists typically used time-series observations that provided only one datum for each time date. Not only were such 'samples' considered peculiar from the viewpoint of the correlation theory of that time—which assumed that the observations within the sample had been independently drawn—but economists believed that such time-series observations reflected a number of concurrent behavioral characteristics or causal relationships varying with the time element and unit chosen.

This problem of extracting causal relationships between variables from data which contained different time patterns dominated early econometric work but the questions attacked were driven by economic and policy concerns. Measurements, for example, of market demand and supply relations for agricultural goods were undertaken at the American Bureau of Agricultural Economics during the 1920s when farmers faced falling prices in international markets and followed earlier European breakthroughs on these questions. Similarly, the problems posed by 'business cycles' were widely recognized by commerce, politicians, and economists, for the crash of 1920–1921 was only outdone by the even more spectacular and longer-lived depression of 1929–1933. Business cycle research institutes, which had begun to emerge even before the end of World War I, sprang up everywhere in the 1920s from Massachusetts to Moscow, but their truly international quest for description and explanation of the business cycle showed that the task of establishing measures of—let alone explanations for—that phenomenon, its characteristics, and its time patterns was incredibly difficult.

A concerted movement to create a more 'scientific' economics, based on both statistical and mathematical tools in economics, resulted in the foundation of The Econometric Society (in 1932), and its house journal *Econometrica* (in 1933). The most critical innovation of that decade, often overlooked, was that of the 'econometric model' formulated as an intermediary device to bridge the gap between economic theory and economic data. Such models represented elements of the economic theory in mathematical form, but were also attuned to the peculiarities of the time patterns of data evidence. With the use of such models, various kinds of knotty correspondence problems at the intersection between economic theory and data began to be understood and solutions proposed. For example, the problem of unraveling several statistical relations holding within a variable set (the multicollinearity of statistically correlated variables) was understood as different from the problem of separating out different economic relations which involved some of the same overlapping variable set (the identifiability of several behavioral economic relations). At the same time, problems of measurement errors ('errors in variables'), or of omitted variables from the model ('errors in equations') were attacked with the development of statistical tools and methods. But these 1930s answers were proposed as one-off solutions to specific applied problems, not general solutions for generally recognized problems.

However, econometrics was not without its detractors and the move to codify and formalize these somewhat disparate concepts, problems, and emergent solutions seems to have been triggered by the Keynes-Tinbergen debate in the late 1930s. Jan Tinbergen, a young Dutch economist, was the most creative of econometricians of the 1930s in the development of modeling, in understanding conceptual problems, and in suggesting solutions. He was also responsible for building and using the first macroeconometric model to analyze policy options. In this work, he developed ideas by Ragnar Frisch, a Norwegian econometrician (which later made them joint winners of the first Nobel Prize in economics in 1969) who in turn had drawn on statistical work by English statistician Yule and Russian econometrician Slutsky.

Tinbergen's macroeconometric modeling work was heavily attacked by Keynes and this attack prompted the development in the 1940s of rigorous foundations for econometrics. Despite their difference of opinion, both Tinbergen and Keynes can be seen, in retrospect, as reshaping economic theory and policy in the aftermath of the Great Depression so that, in the 1950s, Lawrence Klein (Nobel prize 1980), could develop the post-war generation of macroeconometric models on Keynesian theories with more secure statistical foundations.

The key development in this foundation work was the 'probability approach', fashioned in the early 1940s by Trygve Haavelmo (Nobel Laureate in 1989 for this work), a Norwegian econometrician, who proposed to use probability theory to establish a bridge between economic theory and passive economic observations. His bridge was designed to carry the burden in both directions: to provide guidance on how to specify econometric models as statistical hypotheses so that not only could economic theory be logically related to economic data but that there would also be a path for inference back from the data to the theory.

2. *Establishing the Mature Discipline*

Haavelmo's probability blueprint for econometrics had indicated directions for both theoretical and applied work and has been interpreted as creating a

'revolution' in econometrics. Parts of Haavelmo's program were immediately elaborated at the Cowles Commission (later Foundation), an American hothouse of econometric research in the mid 1940s (see Hildreth 1986). They assumed that the driving relations of the economy were best represented as a system of simultaneous equations that operated at a level hidden beneath the time-series observations. Their research was primarily concerned with developing appropriate identification conditions and estimation (measurement) techniques for such econometric models. In the years after 1950 an established orthodoxy developed based on Cowles' work and enshrined in textbooks in the 1960s. But, despite an active program of research at the theory level, providing technical extensions to Cowles' groundwork, cracks in that orthodoxy began to appear. There were alternatives to the Cowles program.

Applied econometric research revealed serious practical and methodological limitations in the Cowles approach, particularly in regard to model specification, model choice, and associated testing procedures. Their assumption that econometric work is anchored on *a priori* theories meant that it was rarely possible to specify, and identify uniquely, structural models for those theories. This made theories virtually unfalsifiable and the fitting of models to data an arbitrary affair, as Henri Theil and T. C. Liu pointed out in different contexts in the 1950s. This was made transparent in the specification and sensitivity analysis using Bayesian methods developed by Ed Leamer in the 1970s (Qin 1996). The Cowles assumption of simultaneity and associated lack of attention to the characteristics of time-series data, were both open to challenges. The Swedish econometrician Herman Wold, who had trained in the Russian probability school and time-series analysis in the 1930s, attacked the assumption of simultaneity and developed alternative dynamic interdependent equation models in the 1950s (Morgan 1991). These developments found a generalized form in the 1970s in the American econometrician Christopher Sims' time-series versions of Wold's models called Vector Auto-Regressions (VARs) (Qin and Gilbert 2001). Whereas Wold had shown how the Cowles structural models were special cases of his causal chain models, VARs turn out to be the least arbitrary representation of the information in time-series data.

The time-series problems of economic data, and possible solutions for Cowles measurement techniques, were analyzed at the Department of Applied Economics at Cambridge in the 1940s under Richard Stone (Nobel Laureate in 1984). However, it was the 1970s experience of stagflation in many economies (high unemployment and inflation) that spurred a more radical refashioning of economic theory and econometric approaches. The dynamic elements of economic modeling, taken seriously in the 1930s, once again became the focal issue of econometric measurement. Descriptive statistical time-series models (i.e., models not relying on economic theory) underwent a certain renaissance in the wake of disappointing prediction records from many large-scale macroeconometric models during the 1970s upheavals. Meanwhile, economic theories were being re-formulated to provide a more elaborate account of uncertainty at the microeconomic level in the form of assumptions about 'rational expectations' and their relation to the macro-level. This formed an important stimulus for Sims' work, but while VARs can be understood as the most general form of dynamic models, they were not necessarily the most interpretable in terms of economic phenomena. An alternative dynamics, analogous in form to servo-mechanistic control engineering, and associated with David Hendry and the London School of Economics was the 'error correction model' which could be more readily understood in terms of individuals' reactions to changing economic events. These developments effectively reversed the Cowles approach for they start from a summary of the data and move towards the simplest possible interpretable model that is coherent with the data.

The emergence of an especial microeconometrics occurred concurrently with these changes in macroeconometrics. In the early 1950s, Stone had struggled with the immense task of providing measurement structures appropriate for the separate components of demand in a total consumer expenditure system: a system simultaneous at the micro-level. By the 1970s, various statistical models appropriate for explaining behavior at the individual level had been adapted from 1930s biometrics into econometrics by Dan McFadden and James Heckman (joint Nobel Prize in 2000). Their treatment of survey data enabled measurement models to be developed for the discrete choices made by individuals. Such discrete choices dominate economic decision making in consumption decisions, work decisions, family formation decisions, etc. These measurement models were quickly taken up for they matched the individual utility-maximizing framework of neoclassical economic theorizing, the main orthodoxy of post 1950s western economics. The gradual appearance of large-scale 'panel data sets' (a set of individuals measured repeatedly over time) encouraged both theoretical and applied work at this microeconomics level and created a wider territory for the expansion of econometrics. Time-series work in microeconometrics was not completely abandoned however, for in the 1990s a more data-instigated style of analysis, reminiscent of the 1930s business cycle work, was developed for the analysis of financial data.

Post 1950s data-based research has not been bound by any straightjacket methodology but spawned several hybrid approaches. Guy Orcutt, believing that macro-time series data were inadequate for inference about the economy, developed the method of microsimulation, an intermediary style of econometric

research involving modeling, analysis, and simulation. This approach, difficult to achieve when he began his work in the later 1950s, has become practicable with modern computing power, and is now almost a necessity in certain areas of policy analysis. In the 1980s, attempts to model business cycles combined simulation, computable general equilibrium analysis, and the VAR model another hybrid to produce replacing 'estimation' (using statistical data to measure relations) with 'calibration': the matching of certain statistical properties predicted by the models with those found in time-series data.

3. *The Place of Econometrics in Economics*

During the early years of The Econometric Society, 'econometrics' had been defined as the union of economics, mathematics and statistics. And, in developing model intermediaries based on mathematical economic theory in that period, econometricians had developed a distinctive path compared to those found in psychometrics and sociometrics in the same period. After 1950, as economic theorizing became generally expressed in mathematical terms, the term econometrics stabilized on its current meaning: the use of statistical reasoning and methods as means to establish data-based descriptions of economic phenomena and empirically based counterparts for, and tests of, economic theories.

The spread of econometrics as an established part of economics in the post 1950s period may be understood as due not only to the strengthening of its foundations in statistical theory but also to the continuing expansion of data ('official' statistics), its establishment in the core undergraduate teaching program, and the development of cheap desk-top computing. Together these meant that econometric work became a standard tool of policy work in governments and international agencies as well as becoming endemic, in various different forms, in the sub-fields of scientific economic research. Econometric theory has developed into a formidable body of specialist statistical theory and the increasing gap between the difficult technical and theoretical questions and the apparent ease of applications might indicate a field where applications came loose from theoretical work. This has been militated by another tool, the development of specific software packages for econometrics, in which theoretical and technical developments can be quickly translated into modeling, measurement, and testing regimes at the level of applications.

This widening use of econometrics did not denote a settled field. The community in the latter part of the twentieth century found itself immersed in a number of vibrant and important arguments about how to do econometrics, based upon applied econometric experience as much as on considerations of statistical theory and philosophy of science. Should models be theoretically based or descriptively accurate? What are the relevant criteria, economic and statistical, which can be used to test the adequacy of these different models? Should the modeling process start with simple models that grow more complex, or start general and aim to become simple? Should the probability framework be classical or Bayesian? What implications does this difference have for the types of measurements made and the possibilities of inference? How far can applied econometrics be formalized and codified apart from tacit knowledge? The terms of the continued debates around such themes point to a mature field, one intimately connected to both statistical and economic theory, but in which the foundational arguments raised in early work continue to reverberate to the most recent time.

Economic Anthropology

Economic anthropology studies how human societies provide the material goods and services that make life possible. In the course of material provisioning and during the realization of final consumption, people relate to each other in ways that convey power and meaning.

1. A Definition

The degree to which something is 'necessary' for life has long been debated and differences between one society and another have environmental, historical, and cultural reasons; but some wants must be inescapably satisfied, otherwise death ensues. Therefore, there is a physical limit to relativism regarding material means of livelihood. On the other hand, nonmaterial goods such as the goodwill of deceased ancestors might be conceived as essential for the reproduction of a society. Most nonmaterial needs, however, have some material expression, such as food sacrifices during ancestor worship or wealth exchange during mortuary ceremonies. The domain of economic anthropology covers the recurring interaction of individuals, within and between social groups and with the wider environment, with the object of providing material goods and services necessary for social reproduction.

Traditionally, economic processes have been divided into production, distribution and circulation, and consumption. These analytical categories respond to observable social interaction in all societies, although the categories themselves are a product of scholarly Western tradition. People, however, engage in social relations that can be described as 'economic' and which can be analyzed as participating simultaneously in the production, distribution, and consumption categories.

Economic anthropology originally focused on the *Economic Life of Primitive Peoples* (Herskovits 1960) where many of the elements present in the Western economy (such as money, a market system) were absent. Direct observation of noncapitalist societies through ethnographic fieldwork produced impressive and contextually rich information on economic activities worldwide. The way in which anthropologists reacted to the confrontation of this diversity and how they coped with it in theoretical terms, generated most debates within economic anthropology.

2. The Intellectual Debates

The major debates in economic anthropology have centered around (a) the universal applicability of Western generated categories of analysis, (b) the question of value, (c) the question of history and connectedness between polities, and (d) the weight of culture (meaning) in economic processes.

2.1 Western Categories of Analysis

The main debate took place between those anthropologists who considered that the postulates of marginalist economics, that is, the rational (optimizing) allocation of (scarce) resources between alternative uses, were of universal application (Firth 1970); and those anthropologists who, following Polanyi (1957), thought that the theory of rational action in regard to economic decision making was only valid in the context of Western market economy, and that a real definition of the economy should be meaningful in any society whatever its process of allocation. The first group was eventually defined as 'formalist' while the second was called 'substantivist,' following Polanyi's distinction. The most useful concept that emerged during the debate, although it was not itself subject to dispute in regard to 'primitive' economies, was that of the 'embeddedness' of economic activities in other social processes. A second wave of the debate in the 1970s included anthropologists working with formal decision-making models and Marxian anthropologists working with the concept of 'mode of production' and with issues of 'transition' to capitalist economies and 'articulation' of different modes of production (Godelier 1977).

2.2 The Question of Value

The question of value is a function of exchange, of the need to reach some equivalency through comparison. Some aspects of value have constituted constant sources of debate within anthropology. First, Marx's distinction between use value and exchange value, and how it could be applied to noncapitalist societies or to peasant societies where factors of production were not fully commodified. Second, the classical labor theory of value, and how to use it in societies where the labor market, when it existed, was only marginally active. Third, the marginal utility theory of value and how to make sense of it when every good could have multiple uses and be valued according to different measures.

Finally, the cultural theory of value where local meaning attached to objects, people and situations was the measure of value, posed the problem of cross-cultural comparability in a connected world.

2.3 History and Connectedness

Another issue that became increasingly central was the need to think historically about the transformation of social relations and the need to study the interconnection between different societies through time. These problems were especially salient to those anthropologists influenced by dependency and world system theories, by European Marxist anthropology, and by what came to be known as the political economy perspective in anthropology (Roseberry 1988). The aim was to understand local processes as both being formed by and acting upon the larger processes of historical transformation (Wolf 1982).

2.4 The Weight of Culture

Cultural aspects had been taken into account in economic anthropology mainly as a context where material activities occurred. More recently, anthropologists have been arguing about the centrality of meaning for the understanding of economic processes. Bourdieu (1980) has developed the concept of 'habitus' where past material social relations are transformed into a set of dispositions, a scheme of perceptions that generate practice. Gudeman's (1986) proposition, on the other hand, stems from his preoccupation with the methodological problems that Western models of knowledge pose to the understanding of other cultures. He proposes to study how each society culturally models the processes by which it secures a livelihood, and shows that some societies have multiple articulated models of economic activity. Finally other anthropologists are using the term 'moral economies' to refer to individual and collective moralities and cultural values that pervade economic social relations.

3. Concepts and Theory

The classical categories of production, distribution and consumption, will be followed in order to present briefly the main concepts and theoretical developments that have unfolded within economic anthropology.

3.1 Production

Production generally is understood to be the human transformation of matter, through work, into some useful, consumable good. Sometimes, as in foraging and hunting, human work uses very simple technology to select and get whatever food is available in the environment. Human–nature interaction has been studied from an ecological perspective stressing energy exchanges between different species, but emphasizing 'culture' as a basic factor of human adaptation to environmental constraints. The environment, however, is not an ahistorical given where human populations dwell. Rather, past relations between individuals, groups, communities and larger polities are inscribed in the environment. Political ecology tries to include this history in its perspective.

In most societies, the process of production requires the use of complex technology and the design of cooperative labor processes. Knowledge both of the skills necessary to use a particular technology and of the coordination of the entire process is a crucial asset of control that generally is distributed unevenly among those participating in production. The way in which a society organizes access to land, labor, energy, technology, and information expresses economic and political social relations. Moreover, in all societies these relations are embedded in other institutional domains such as kinship, religion, politics, and 'pure,' disembedded, economic relations have seldom been observed. Peasant studies show, for example, how kinship and marriage, experienced through discourses of respect and love, pattern inheritance systems but also social relations of production within the household farming unit.

Cultural meanings attached to concrete tasks and/or collective or personal identities such as gender, age, caste, or ethnic group also contribute to shape work processes. The concept of 'division of labor' was designed originally to explain the 'integration of the social body' through the necessary dependence between specialized domains of work (Durkheim 1933). An example of this meaning can be found when speaking of the 'sexual division of labor' in a society where male members are ascribed certain work responsibilities while female members are ascribed others. In this sense the concept is broad and general. More frequently, 'division of labor' is used to address particular production processes and the assigning of individuals or groups to positions within the process. This has given anthropologists the opportunity to analyze minute interactions taking place between those participating in a concrete labor process.

3.2 Distribution and Circulation

The concept of distribution refers to the allocation of goods between different individuals or groups, while the concept of circulation refers to the movement of goods. These processes mediate between the 'production' and 'consumption' moments of an economy. They also reproduce differentiated categories of people in regard to the access of resources in general which makes them central aspects of social reproduction.

Economic anthropology has developed a typology of forms of distribution that was proposed originally by Polanyi (1957). Distribution was for Polanyi the element that provided continuity and structure to economic processes. Through a comparative method, he concluded that three main forms of distribution were used to integrate the economy: reciprocity, redistribution, and exchange. This typology expressed institutional arrangements not so much the form of particular transactions.

The concept of reciprocity had an early start in Mauss' 1923–4 (1968) essay on the 'gift.' The essay was based mainly on available ethnographic descriptions of the Potlatch and in Malinowski's 1922 (1961) description of the Kula ceremonial exchange. For Mauss, the 'gift' was an entirely different form of transaction from market exchange. The sustained relationship between persons and things was essential to the 'gift' value. Conversely, market exchange was based on the total disjunction between autonomous objects and individual agents. Mauss describes the 'gift' as a movement related to three obligations of a social and moral character: to give, to receive, and to return. Further developed by Sahlins (1965) who related reciprocal transactions to the social distance between the persons involved, reciprocity has become a useful concept in economic anthropology. Weiner (1992) has described how, by entering or remaining out of circulation, objects could create and regenerate social relations. Her work opens the concept beyond the give-return movement originally associated with reciprocity.

The concept of redistribution as an institutionalized process refers to centralized polities that concentrate goods through tribute or taxation systems and reassign them later between groups, individuals, and specific domains. Ethnographic examples range from 'Big-man' systems to strongly centralized state polities.

In Polanyi's typology, exchange, as an institutionalized process, relates to societies that integrate the economy through the market system. However, multiple forms of transaction can be called 'exchange,' be it the routes of trade partners crossing Australia, African market places, or the elaborate systems of ceremonial exchange in Melanesia. Exchange raises two fundamental problems of transactions: first, comparison between the items exchanged and, second, nonsimultaneity of the agents' needs. Comparison is the central question of value. Things exchanged always are valued, but how this valuation proceeds is very different from one society to the next. Generally, for a transaction to take place there must be some measure of value that enables the agents to reach an equivalence acceptable to all. When some sort of standard item is used as a measure of value we may speak of money, although some other functions that generally are associated with money, such as serving as a medium of exchange, may be lacking. Often, the process of reaching equivalences of value takes place during exchange such as in bargaining practices, while in other cases a central authority sets up a fixed rate of exchange. Yet in other cases, as the model of the market system pretends, value is reached automatically through the free circulation of all commodities subject to the constraints of supply and demand. Classical economists tried to find a universal measure of value in work: the energy spent in producing the commodities exchanged was seen as their only common element.

Most societies have various spheres of circulation where different measures of value apply. In Bohannan's (1959) example of the Tiv's (Nigeria) multicentered economy, he describes how different goods circulate in distinct spheres, each of which is marked with different moral values relating to subsistence, prestige, and alliances, and conversion from one sphere to another, while possible, always is sanctioned morally. The idea that various measures of value might simultaneously be at work in a society has proved very fruitful. Increasingly, anthropologists are paying attention to the circulation of goods among different individuals, social groups, or polities along chains of transactions. This perspective integrates the variation of meaning attached to goods or processes together with its material causes and consequences (Appadurai 1986).

3.3 Consumption

Consumption can be defined simply as the use of a good or service. Use sometimes implies the destruction of the good and precludes further use; otherwise, a good can be used in multiple ways, successively or simultaneously by different persons. The allocation of food to different ends among household members traditionally has been the focus of attention. Gender and age biases that seriously affect the intake of nutrients of certain members of a society have been studied. Issues of power, of cultural and long-term institutional constraints have come to the forefront as ethnographic research has explored the actual processes of consumption (Mintz 1986).

Economic anthropology focuses on the social relations that emerge through consumption processes in the intimate space of the household or in other, more open, public spaces. Some anthropologists underline the meaningful aspect of consumption acts conceived as signs in an information system expressing social relations (Douglas and Isherwood 1980). Others emphasize the role of consumption in the present-day, globalized world where goods, people, and information circulate widely across boundaries, and where cultural identity seems to be increasingly the center of personal meaningfulness, collective solidarity and empowerment (Miller 1995).

Bourdieu (1979) has shown how relations of differentiation and domination are constructed through

complex processes of consumption where the provisioning and access to material goods is entangled with the production and reproduction of personal and collective identities. His emphasis is on the reproduction of an entire social system. Another perspective stresses the systems of provision and underlines the connectedness between production, distribution, and consumption. From the point of production to final consumption, specific social relations contribute both to the material constitution and availability of particular goods (e.g., regarding quality or distribution networks) and to the social construction of particular meanings attached to those goods (Fine and Leopold 1993).

Most societies have different possible modes of provisioning equivalent goods and each mode conveys a particular field of meanings, power relations, and material well-being. Frequent modes of provision are those making goods available through the market (commodities), through the State (social welfare), through the household (self-provisioning), or through the community (solidary networks). People may change their modes of provision following economic, political, or other social pressures, but goods also, during circulation, may participate in different modes of provision. Here, as with multiple spheres of circulation, transfers between modes of provision have both material consequences and meaning.

The focus on consumption in anthropology has renewed the interest in objects (material culture) and on how they incorporate, circulate, create, and transform social relations.

4. *New Trends*

Suggestive contributions have been made by anthropologists studying nature. They point to the methodological need to go beyond the duality nature/society in the study of human/environment interaction. Ethnographic research also underscores the blurring of the natural/artificial boundaries, as biotechnologies become capable of producing life while commoditization reaches nature in unprecedented ways (marketing organs, cells, genetic material). Groundbreaking concepts are bound to emerge from these new realities.

Focus on the informal sector of the economy has also contributed a major breakthrough by expanding the concept of 'work.' Research on informal relations (economic or otherwise) is bound to prove fruitful as the realities of flexible production, the weakening of the nation-state model, the informational revolution, and massive population movements point to the increasing value of personal networks in the structuring of contemporary societies.

Presently, economic anthropology is moving beyond the boundaries of a conceptual economic domain. While it remains useful to retain the material emphasis of economic processes, in practice, material relations should be studied together with their cultural expressions. On the other hand, ideas of worldwide connectedness—in systems of provisioning, relations of production, cultures of consumption, labor migration, etc.—need to be taken into account. The practice of economic anthropology seems bound toward the study of social reproduction as a whole (Narotzky 1997).

Economic Development and Women

The consequences of economic development on women during the last half of the twentieth century have been tumultuous as traditional cultural protections and limitations prescribed for women are constantly being challenged and reconfigured. Around the world women have organized to influence development policies and to moderate the adverse impacts of rapid socio-economic change, an activity collectively referred to as women in international development (WID). This combination of activists, practitioners, and scholars has lobbied international agencies, national governments, and nongovernmental organizations so successfully that the consideration of women has become an integral part of development planning. The cumulative result of this political activity, given focus and visibility through the United Nations (UN) World Conferences for Women, has been the creation of a global women's movement, perhaps the most significant social movement of our times.

The first section documents the incorporation of women's issues into international development policy at the UN and at the national levels as a result of pressure by women's organizations, and reviews the four world conferences for women. The second section follows the evolution of programming for poor women in developing countries and underscores the significance of organizing women at the village or community levels. Significant debates about the goals and process of such programs are summarized. The final section shows how topical conferences organized by the UN provided a venue for inserting critical women's issues into official UN documents concerning human rights, population, and habitat.

1. *Affecting International Development Policy*

The UN was established in 1945 with its 50 members drawn largely from industrialized countries. By the mid-1960s, a majority of the UN members represented developing countries of Asia and Africa. Their concern with economic development propelled this new dimension into global politics. The first UN Development Decade 1960–70 emphasized infrastructure and industrial projects and was modeled on the successes of the Marshall Plan for redevelopment of a devastated Europe. Former colonial countries, which had often resisted granting independence, sought to maintain their trading advantage with former colonies by supplying funds and personnel to assist in modernization of these countries. Other industrialized countries as well as the former USSR and the Eastern Bloc offered bilateral assistance to selected countries. Respective UN agencies established programs in health, agriculture, employment, and education; the World Bank provided loans at low interest rates. Since some were much better positioned than others to benefit from these programs, the immediate result of these vast infusions of funds was increased inequality of income within the countries.

Concerned with this trend, the Economic and Social Council (ECOSOC) reacted to the UN Report on the World Situation by passing a resolution in 1963 tying social and economic issues together. Social issues clearly applied to women, since women delegates at the UN were often leaders of women's organizations in their own newly independent countries that were demanding a voice in planning at home, they supported a 1963 UN General Assembly resolution calling for women to be appointed to those bodies preparing national development plans (Jayawardene 1986, Snyder and Tadesse 1995) (see *Colonization and Colonialism, History of*; *National Liberation Movements*).

The debates about development priorities were reflected in the Second Development Decade 1970–80, with its emphasis on basic human needs. The refocus of development programming from macrodevelopment toward outreach to people was critical as it allowed advocates for women in development to document the distinct ways that economic development affected women as opposed to men. Poor women everywhere perform economic activities, from farming to microenterprise to household production; because income data excluded subsistence and exchange activities,

women's roles were invisible to planners who subsequently ignored or undercut women's livelihoods. Impetus for including women in development planning emerged, as do so many ideas whose time has come, from three distinct directions: from women in the UN, from women in Washington, DC, and from national women's organizations in developing countries.

1.1 Women Influencing the UN

The nineteenth-century women's movement focused on women's legal rights, particularly the right to vote (see *Women's Suffrage*). These issues, including education, continued to dominate the UN Commission on the Status of Women after it was set up in 1947 as the result of lobbying, especially by women from Latin America who had been active in a similar body of the Organization of American States. Despite a limited budget and staff, the Commission, working with international women's organizations participating at the UN, was successful in steering a series of conventions through the UN General Assembly on women's rights relating to citizenship, marriage, and inheritance. Planning for the Convention on the Elimination of All Forms of Discrimination Against Women (CEDAW) began in 1965; before it was recognized as a treaty in 1980, additional articles were added to reflect documents from the women's conferences (see below). UN conventions must be ratified by member states before they take on the force of law in a particular country, but ratification does not always mean implementation. Nonetheless, the existence of CEDAW and other UN documents exerts strong pressure on governments to expand women's rights. Women's groups often present 'shadow' reports to the UN Committee that monitors implementation when they believe their governments are not complying with the Convention (Fraser 1999, Winslow 1995).

At the same time, pressure by developing country delegates was building to consider women's economic roles, in addition to legal and social rights that were still the primary focus of the Commission. A 1969 report of a meeting of experts reiterated the evidence of increased inequality between rich and poor under the capitalist approach to development, and since development ignored women's economic roles, the report stressed the importance of 'integrating women in development', a phrase widely adopted in subsequent documents. A second experts' meeting in 1972 was convened to explore the relationships between women and development and was co-sponsored by the Commission. Rapporteur of the meeting, and member of the UN Development Planning Committee, was Ester Boserup, whose landmark book *Woman's Role in Economic Development* had been published in 1970 (Boserup 1970). Of her role in that meeting, Boserup writes that the Secretariat of the Commission 'saw it as a means to get members of the Commission to change their focus from the generally unpopular subject of abstract women's rights to the popular one of economic development' (Boserup 1999, p. 49).

Boserup had found that even in countries with a large participation of women in agriculture, women were nonetheless classified as housewives or 'non-active' persons. To challenge these data categories, Boserup assembled case studies from Asian and African countries that provided hours worked by women and men in both paid and unpaid work, including agricultural work, household enterprises, and the fetching of fuel and water (Boserup 1970). Women's work varies by agricultural system: in Africa south of the Sahara women are the primary farmers while men assist in clearing the fields and protecting their homes. The plow changed agricultural techniques and required men as well as women to work in the fields but gave men control over new technologies, to women's disadvantage. Boserup believed that population increase drove the technological change which in turn altered women's roles. Male migration to cities is easier where women are farmers as in Africa; female migration predominated in Latin America where women had little agricultural role (Boserup 1999). Her work sparked a tremendous interest in producing further case studies to corroborate or challenge this evolutionary presentation.

1.2 Adding a Concern for Women to National Policy

The UN influences the world view on issues through debate, resolutions, and world conference, but it does not set national policy. The shift of goals in the Second Development Decade documents caused the US Congress to amend its Foreign Assistance Act of 1960 to include an emphasis on basic human needs. As a result of lobbying by the women's caucus (Women in Development or WID) of the Society for International Development (SID), the amended law of 1973 incorporated language of the UN 1969 resolution to integrate Women in Development programming (Tinker 1990). An office of Women in Development was established within the US Agency for International Development to carry out the Congressional mandate.

The United States was the major donor country at the time; its policies were widely observed in the West. Because the WID amendment required existing programs to consider women's roles when implementing them, it had an immediate impact on the development community and precipitated resolutions in UN implementing agencies and changes in assistance policies in many countries. These rapid changes occurred as a result of the efforts of women within the institutions concerned as well as activists in national and international women's organizations. (Women's activities in UN agencies and in NGOs are reported in Meyer and Prugl 1999.)

1.3 UN World Conferences for Women

The growing strength and visibility of the reinvigorated women's movement supported the CSW's request for a conference to mark International Women's Year in 1975. The UN concurred, proclaiming the themes for the year and conference as 'equality, development, and peace' reflecting the primary preoccupations of the three UN Blocs of East, West, and Third World. The official World Conference for Women was held in Mexico City in June 1975. The upsurge of support for further exploration of women's changing status led the UN to declare a Decade for Women 1976–85, and to hold both a Mid-decade Conference in Copenhagen in 1980 and one discussing 'Forward Looking Strategies' in Nairobi in 1985. In 1995 a Fourth UN World Conference for Women was convened in Beijing.

At each major UN world conference since 1972, nongovernmental organizations have organized a parallel event, an NGO Forum, that is open to the public. These meetings combine professional panels with the gaiety of a fair; they provide a way to disseminate new ideas and research to UN delegates as well as among the growing NGO community. Participants at the parallel NGO conferences far exceeded official delegates and provided most of the media coverage. The number of women and a few men attending NGO activities has risen steadily: 6,000 at Mexico City, 8,000 at Copenhagen, 14,000 at Nairobi, and 20,000–25,000 at Beijing; official delegates of states and UN agencies have increased to about 3,500 while the number of NGO representatives allowed to observe the official proceedings has grown to nearly 1,000. Nearly 30,000 participants and numerous media gave exceptional visibility to women's issues during the Beijing meeting.

Official UN conference documents are the subject of many rounds of debates in regional meetings and in preparatory committees, and the language is freighted with global debates of the day (Tinker and Jaquette 1987). Limited amendments are possible during the two-week conferences, but overtime activists learned how to insert phrases and paragraphs throughout the process so that the resultant documents reflected issues of concern raised by women's organizations and research centers. Although official UN documents lack the force of law, the moral power of conventions is considerable and provides activists in individual countries with a powerful tool to demand reform at home.

The psychological dimensions of this mobilization process should not be underestimated. The four world conferences and the many events that surrounded them provided the opportunity for women to recognize that women's agendas are legitimate, and united women across ideological and national boundaries. The networking that grew out of these lobbying efforts fed the global women's movement.

1.4 Development as a Woman's Issue

Of the three themes of the Second Decade, development was the newest and most salient to the Global South. Information on women's roles in development was scarce. A major seminar, convened by the American Association for the Advancement of Science, preceded the Mexico City conference and brought together over 100 women and men who had studied these issues. The official conference created the UN International Research and Training Institute for the Advancement of Women (INSTRAW) to facilitate further documentation, and the UN Statistical Office began to request sex-disaggregated data from all member countries. The International Labor Organization produced studies on women workers around the world (Beneria 1982). Scholars from the developing countries wrote reports for the Copenhagen conference. This outpouring of literature on women and development documented women's economic contributions to family and country, the existence of women-headed households, the impoverishment of women that followed monetization of the economy, the activities of women's organizations and NGOs in poverty alleviation programs, and the limitations placed on women by religion, culture, class, and law. Development policies have been reconceptualized as a result of these studies that make women's work—and the discrimination against them—visible.

2. WID Programming

The United States, as the major donor country, exerted strong political influence within the UN agencies as well as with the Office of Economic Cooperation and Development, a consortium of European and North American countries involved in development assistance. WID programming became an integral part of these agencies and of the many nongovernmental organizations which received funding from them. These implementing groups accepted the underlying liberal economic approach to development while criticizing policies that impacted negatively on the poor, especially women. In contrast, many academic women writing on WID issues identified themselves as marxist and emphasized the subordination and oppression of women resulting from patriarchy and capitalism (see *Feminist Theory*).

To convince skeptical development bureaucrats, practitioners advanced the 'efficiency' argument: including women as economic actors would enhance the possibility of meeting project goals. Since previous programs that dealt with women focused on women as mothers and wives, the WID office consciously avoided projects on maternal and child health or on population, to avoid the stereotype of dependent mother. Subsequently, women's health, family planning, and education programs were often combined

with income-generating projects (see *Reproductive Rights in Developing Nations* and *Reproductive Rights in Affluent Nations*).

At first the tendency was to add programs for women to existing projects with little understanding of the political or economic practices in the recipient countries. For example, providing information on subsistence crops to men in Africa was not effective since women are the primary farmers in areas south of the Sahara. Similarly, including women in village meetings to decide where a well might be placed ignored cultural prescriptions against women speaking in public.

To reach poor rural women and understand their needs, women's organizations, international NGOs, and development agencies began to focus their projects on women. The UN funneled grants to women's community groups through the Fund for Women, now UNIFEM, that was set up at the Mexico City Conference (Snyder 1995). Rural women farm, collect fuel and water, and process, prepare, and cook food. More efficient cookstoves, easier methods of grinding rice or grain, and closer wells or piped water reduced women's work hours. Groups of women were assembled to learn the new technologies; literacy was often part of the training so women could read simple instructions. Activists took the issues of women in agriculture, technology, and energy to UN World Conferences on these topics. Lobbying at these conferences broadened the base of support for WID beyond women's organizations.

Whatever the goal of the particular development project, other women's issues quickly surfaced; a characteristic of women's groups globally is that they address a wide range of concerns. For example, after the end of the Korean war, village women were brought together every month to receive birth-control pills. These women had seldom been out of the family compound once they were married. To open up their world by meeting other women and talking to the educated women from Seoul who convened the meetings expanded their horizons. These women extended their activities to reforestation, another government priority and therefore acceptable to husbands. Some groups used their income to visit shrines: for many women, riding a train was a novel experience.

As men migrated to cities in search of jobs, many rural women became temporary or permanent household heads. In contrast, in Latin America, women migrated while men stayed on the farms. Globally, about one-third of all households are supported by women; women with children are generally among the poorest households. Women-headed households became a new focus for programs directed toward reducing poverty.

The rapid monetization of the economy required married and unmarried women, urban and rural, to earn cash beyond their noncash economic activities. Income projects became the focus of many organizations. Early programs that emphasized crafts and sewing often produced poor-quality goods and seldom understood marketing. Even projects built on traditional skills seldom earned women significant profits.

Microcredit schemes have proved to be more widely successful. An early model is the Grameen Bank in Bangladesh. Landless women are organized into groups that use social pressure as collateral to ensure repayment. Members of the Bank must agree to Sixteen Decisions which encourage fiscal discipline, healthy lifestyles, and smaller families. The Grameen Bank trains the poor to reduce spending as well as to save and utilize credit. After learning to save even a few cents at each weekly meeting, women are allowed to borrow small amounts of money for entrepreneurial activities: raising a cow, selling street foods, buying a pedicab for a male relative, or even acquiring land to farm. Originally men were also borrowers, but their repayment rates were much lower; today the Grameen Bank members are about 98 percent women.

The Grameen Bank approach has been widely replicated, often without the specific social commitments required of Bank members. In Latin America, village banking is the predominant model. Women actually organize and run small banks. This model is more adapted to higher income countries. Microcredit programs have been widely introduced in the South (see Mehta et al. (1995) for a comprehensive list) and also in the United States.

Studies indicate that when women earn and control income it increases the health of their children, reduces domestic violence, and generally raises their bargaining power in the family (Tinker 1990, pp. 123–49, 150–61; see *Family Bargaining*). Increased self-confidence of the women contributes to their greater role in community and women's organizations. Other writers caution against the increased indebtedness that results from microcredit schemes. Still, credit at 16 percent per year is clearly an improvement over loans from moneylenders whose charges may be as high as 40 percent per month. Thus most families with loans increase their standard of living even if their new enterprises are not successful. Further, the poor understand the dangers of becoming beholden to moneylenders. A seven-country study of street food vendors found that the source of their capital was family and savings, not loans (Tinker 1997).

2.1 Debates About Program Efficacy

Development programs for women are multifaceted. Assisting women in traditional subsistence activities reduced the pressures on their spare time and allowed them to pursue income activities. When men migrated, women learned to make decisions and to write to their absent husbands. In cities, women often managed community organizations, earned money selling street

foods, rented out rooms even in their squatter houses, and participated in building their own homes, all with the help of development or advocacy organizations. The unintended impact of these projects was often more significant than the original goal; social engineering is not an exact science.

Debates continue about which programs actually alter existing gender relationships or challenge the systematic subordination of women (Sen and Grown 1987, Moser 1993, Mosse 1993, Kabeer 1994). Many who work within the system to increase access to resources for women and the poor are vocal critics of the dominant economic model. Others argue for programs that strategically undermine gender hierarchy and often oppose capitalist reformism. These perspectives may seem difficult to reconcile, but both groups challenge programs that adversely affect poor women, and both support the empowerment of women. In fact, most programs organize women as part of the process; once organized, women's world views expand and their sense of power increases.

A second debate concerns the positioning of women's programs within the bureaucracy. Many involved in development organizations are concerned that women's issues are still treated apart from the larger projects. Such separation results in low budgets and marginalization. These women advocate 'mainstreaming' women's programs and encourage women's organizations and NGOs to monitor project implementation to ensure women's participation (Jahan 1995). Others fear the submersion of women in mainstream programs and urge a balance with programs focused on women.

A third debate concerns the term gender, a useful analytical tool for scholars but confusing in the real world. Not only is this abstract term difficult to translate, it is almost always used as a euphemism for women. In some countries, relabeling women's programs as gender programs has diverted funding for training from women to men. Many activists believe that the use of the term gender undercuts the political importance of organizing women and creating the global women's movement, perhaps the most significant social movement of the twentieth century (Basu 1995).

3. *Contemporary Agenda for Women in International Development*

As globalization is having a greater impact on the livelihood of women and men in the South than development assistance, efforts to change policy have shifted toward international trade and monetary institutions. Structural adjustment measures imposed by the International Monetary Fund generally resulted in reduced social spending, affecting women as caretakers as well as workers. National indebtedness in the South has sparked a campaign for debt forgiveness, arguing that the gap between rich and poor cannot be closed while countries must spend a high percentage of their foreign earnings repaying debt. The World Trade Organization is challenged by a host of activists across the political spectrum. NGOs organized Women's Eyes on the World Bank.

Women's organizations are also challenging patriarchy by declaring that women's rights are human rights. Enunciated at the UN World Conference on Human Rights in Vienna in 1993, this concept challenges customary law that enshrines women's subordination and places domestic relations under civil law, and strengthens CEDAW.

Resolutions passed at the UN Conferences on Population, 1994, and Habitat, 1996, further strengthen women's rights. Enhancing women's education, eliminating violence against women, and allowing women to control their own fertility are now proclaimed as preferable ways to limit population growth (see *Gender and Reproductive Health*). Access to land and housing is recognized as a critical tool to alleviate poverty among poor women (see *Land Rights and Gender*).

Women are affecting trade policies and changing laws about women's rights by strengthening international networks and by increasing their participation in democratic institutions, particularly in those countries formerly communist countries in Europe (Funk and Meuller 1993) or in Asia (Tinker and Summerfield 1999) and in the postauthoritarian states of Latin America (Jaquette and Wolchik 1998). These dual roles in the civil society are supported by many development agencies who previously limited themselves to economic activities.

Economic Education

Economic education (or economics education) focuses on the scholarship of teaching economics. It encompasses the organizations advocating the need for economic literacy as well as those delivering the subject of economics. Scholars in the area address the content to be taught, methods of teaching, evaluation of those methods, and information of general interest to teachers of economics. Although economic education topics can address issues at any education, training, or schooling level, they are typically concerned with the secondary and tertiary levels. A comprehensive review of work in economic education can be found in Becker (1997) and Siegfried and Walstad (1998). The primary academic journal devoted to the topic is the *Journal of Economic Education*.

1. Organizations

In the United States, the end of World War II sparked the creation of the Joint (now National) Council on Economic Education. In the 1950s, the Committee on Economic Education was created by the American Economic Association; both work to advance the teaching of economics within the United States and throughout the rest of the world. Numerous other organizations (e.g., Junior Achievement) raise and spend money worldwide in the name of economic education, although many have a public relations mission that goes beyond the teaching of economics as a social science and a means of analysis. Most of the developed countries including the former Soviet Union now have programs aimed at increasing the economic literacy (or specific economic issue awareness) of their citizens.

Within the United States, the organizations that advocate teaching economics at precollege levels were successful in getting economics included in the Goals 2000 Educate America Act as one of 10 subjects in which every student should demonstrate competence. This 1994 United States Government Act also specifies the goal that every US adult citizen will be sufficiently literate in economics to understand and compete in a global economy. Although endorsed by the United States Department of Education, these national disciplinary content standards are not mandates from the federal government. Unlike Australia, for example, where level 12 curriculum exams (which include economics) are mandated for all students, the United States standards are intended to be a resource that local school districts adopt voluntarily.

Beyond policy statements and getting economics into precollege curricula, documentation of the actual learning outcomes of these organized efforts has been and will likely continue to be mixed. For instance, opinion surveys from North America, Europe, and Australia suggest that respondents can identify economic principles in some contexts (e.g., international trade) but not in others (e.g., minimum wage legislation) (Anderson 1999). Rapid depreciation of knowledge and skills gained in economics courses also suggests that more than a few courses in economics are required if individuals are to 'think like economists,' which at least at the upper-secondary and tertiary levels is the primary goal of courses in economics (Siegfried et al. 1991, p. 199).

2. Content

Samuel Brittan's seminal survey in Great Britain, 'Is There an Economic Consensus?' (Brittan 1973), provided evidence of the degree to which noneconomists

are thinking like economists by measuring the degree of agreement among the views of economists on economic issues and the views of a group of non-economists. His comparison groups were academic, government and business economists, members of parliament, and journalists. His questions were drawn from secondary and tertiary multiple-choice tests: the *Scottish Test of Economics Comprehensive*, prepared at the Esmee Fairbairn Economics Research Centre at Edinburgh's Heriot-Watt University, and the National Council on Economic Education's *Test of Understanding in College Economics* (TUCE).

In the 1970s, economic education researchers operated as if multiple-dimension learning outcomes could be measured validly and reliably by multiple-choice, fixed-response test questions. These standardized, advanced, secondary, and tertiary tests of economics typically include the textbook microeconomic concepts related to (a) scarcity and opportunity costs, (b) equity and efficiency, (c) cost, revenue, and profit maximization, (d) demand and supply analysis, (e) market structures, and (f) market failures and externalities. The macroeconomic concepts include (a) national income accounting, (b) real versus nominal values, (c) investment and saving, (d) money demand (liquidity) and money supply, (e) aggregate expenditure (demand) and supply, (f) stagnation and growth, and (g) monetary and fiscal policy. (The investment and saving, liquidity and money supply, and aggregate expenditure and supply framework found in tertiary economics textbooks is typically called the IS-LM-AS model.) Concepts from international trade and finance are treated on both micro and macroeconomic portions of these examinations (Saunders 1991).

Economic educators do not dispute the importance of the above macroeconomic concepts for those thinking of majoring in economics. Because so few students go on to become economists (Economists, doctored, 1998), however, the debate concerns whether the content in introductory or principles courses should be driven by the desires of those who teach more advanced courses. Unlike the mathmatically oriented economics required for more advanced study, the vocabulary of macroeconomics required for everyday life can be found in articles from the *Economist*, *Business Week*, the *Wall Street Journal*, and like publications. Kennedy (1992) provides the macroeconomic concepts that appear regularly in the news media but receive scant attention in textbooks and standardized tests. Kennedy's five key relationships that have met the test of time are (a) the discouraged–encouraged worker phenomenon and changes in reported unemployment, (b) inventories and production forecasting, (c) nominal versus real interest rates in a variety of guises, (d) inflation rate differences and exchange rate changes (purchasing power parity), and (e) the loose tendency for real, but not nominal, interest rates to be equal across countries (interest rate parity).

Once past these basic macroeconomic relationships, the debate among macroeconomists comes to the forefront. For example, Mankiw (1990, pp. 1645–6) believes that 'The IS-LM model, augmented by the Phillips curve, continues to provide the best way to interpret discussions of economic policy in the press and among policy makers.' David Romer states that even though countless teachers, students, and policymakers have found the IS-LM-AS model a powerful tool for understanding the economy, it must be updated to reflect the reality of monetary policy in different countries (Romer, 2000). Romer's reality, and also recent media headlines in the United States, place less emphasis on the money supply and more emphasis on interest rate rules.

Until macroeconomists settle the debate about the appropriateness of alternative models for macroeconomic analysis, students and their teachers of macroeconomics will be left to their own devices regarding the preferred method of analysis. Other than for definition and recall-type questions, economic educators can be expected to continue to have difficulty devising fixed-response, multiple-choice questions in this environment.

In microeconomics, Shapiro and Varian (1999) question the usefulness of concepts and nonrealistic textbook applications found on standardized multiple-choice tests. They argue that a brand new economics is not needed; instructors need only get past the concepts and ideas that no longer have much relevance in the information age. Becker (in press) summarizes those concepts and principles not covered or emphasized in principles and intermediate textbooks but which are emphasized by Shapiro and Varian (1999) in their analysis of the information industries: (a) bundling and complementarity, (b) experience goods and property rights, (c) signaling, screening, and selection, (d) expectations and risk, (e) switching costs and lock-ins, (f) cost- versus value-based pricing, (g) innovation- versus price-based competition, (h) competition within and between standards, (i) demand and supply dependence, and (j) network economies and externalities.

Competitive markets as described in textbooks adequately represent many markets (e.g., agricultural commodities, base metals, and similar primary goods), but they are not adequate for all items of interest to students. When quality depends on price (as in used-car markets, insurance, and labor markets), equilibrium may be characterized by inequality between quantities demanded and supplied; identification and a neat separation of demand and supply curves may not be appropriate. Textbook discussions of rising supply curves are problematic when marginal costs are approximately zero, as is the case for many goods at the beginning of the twenty-first century.

To get clear of the concept-laden approach to teaching economics, the national disciplinary content standards developed as part of the United States Department of Education Goals 2000 project attempt

to avoid the rhetoric employed in microeconomics (e.g., economies of scale, elasticity, diminishing marginal returns) and the controversies of macroeconomics. An attempt is made to make the language of economics accessible by 95 percent of high-school graduates (Siegfried and Meszaros 1998, pp. 143–4). In the process, however, the committee writing the standards may have made the standards so simple that they are of no practical use (Pennar 1997). Economic educators are struggling with the problems of changing the focus of examples to capture current situations better, and adapting analytical techniques to fit those examples in a meaningful way. In early 2000, however, there is no universal agreement on what knowledge, skills, and abilities are required to be economically literate.

3. *Methods of Teaching*

The Report of the Commission on Graduate Education in Economics calls for bringing 'real-world issues into the classroom' (Krueger et al. 1991). However, the Commission's assumed instructional mode is lecture. It concludes that the lack of emphasis on exposition skills is at least in part 'a judgment that the appropriate style of professional communication is something (graduate) students can figure out for themselves by watching their teachers' (p. 1049). The report of a committee of economics faculty members from prestigious liberal arts colleges in the United States (Kasper et al. 1991) emphasizes the need for graduate students to have breadth in content coverage to become good teachers of undergraduates, but it gave no attention to the need for breadth and training in teaching methods.

Until the late 1990s, economists paid little attention to teaching methods even though the American Economic Association's Committee on Economic Education had been active since the 1950s. Academic economists spoke of 'exposing' students to concepts and 'imparting' knowledge. For the transmittal of factual information and demonstrations of mathematical and graphical constructions, the lecture and blackboard were the simplest delivery modes and teachers of economics used little else (Becker and Watts 1996).

Some circumstantial evidence suggests that declining numbers of economic majors at the tertiary levels in the 1990s led academic economists to devote more time and energy to teaching. For example, Becker (2000) reports that at the 1999 Allied Social Science Association meetings in New York, 12 sessions focused on the teaching of economics, ranging from Nobel Laureate Paul Samuelson's principles textbook to faculty advisors dealing with student apprehensiveness about economics. At the 1998 ASSA meetings in Chicago, 14 sessions were devoted to teaching economics, including one headed by Nobel Laureate Ronald Coase on teaching business economics. As recently as 1996, the San Francisco meetings listed six sessions, and the January 1994 Boston meetings had four sessions on economic education, with similar small numbers in the 1980s.

Along with other educators, economic educators are now seeing the importance of small classes that require in-class interaction (Benzing and Christ 1997). The student: teacher ratio is the most important constraint in the teaching and learning process because two-way communication becomes increasingly difficult as class size increases (Rosen 1987). In small classes, each student has an opportunity to get to know and communicate with the teacher and fellow students. Emphasis can easily move from the teacher exposing and imparting knowledge to students doing economics.

Numerous activities have been developed by economic educators to get students actively involved in the classroom. Becker and Watts (1996) and Keenan and Maier (1995) describe many of these activities that can be used in the teaching of economics. For example, a 'think, pair, share' classroom activity is a cooperative learning method that might be initiated by having students think about the best way to describe the incidence and length of economic expansions in the United States since World War II. Next, they are required to 'pair up' with neighboring students and compare, discuss, and refine their answers. Finally, one member shares the team's responses with the class if asked to by the instructor. The think, pair, share activity requires only a few minutes, but provides a break in standard lectures by involving students and it allows instructors to assess quickly, and on a regular basis, what students are learning.

Students are not alike in their willingness to get involved in classroom group activities. Cooperative classroom learning experiences can require large amounts of time. As long as decisions outside the classroom are made on an individually competitive basis, students may choose to perform individually in the learning environment as well. Instructors in economics are now expected to employ alternative teaching strategies—strategies that can keep students actively involved, with both practice and feedback. Researchers in economic education have found that technology can complement traditional classroom activities (Agarwal and Day 1998). As demonstrated by the exponential growth in the number accessing the *Journal of Economic Education* World WideWeb site, and the creation of the 'Online' section of that journal, economists are increasing their use of the Internet in their teaching. At the tertiary level departments of economics are exploring ways to offer courses via the Internet. However, unless computers and other high-tech systems can replace the instructor and support personnel, their introduction always adds to the cost of instruction.

Replacing the instructor with technology that adapts to the needs of individual learners is a dream that no instructional developer has come close to achieving. Physical capital may be a poor substitute for human capital in economic education. Rosen (1987) observed that no major innovation in education has occurred since the printing press made inexpensive book publication possible. Higher education is a major contributor to technological advances elsewhere in the economy, yet practitioners in higher education appear to be unable to capitalize on this technology in teaching. The World Wide Web may lead to changes in educational practices, but it is too early to say much about the effectiveness and efficiency of Internet tools in teaching economics.

The speed with which economists embrace new technologies in teaching and participate in the scholarship of teaching depends on individual interests, monitoring methods, reward structures, and market forces. In a search for the best of these technologies, economic educators have learned that the conclusion of Siegfried and Fels (1979, p. 953) still holds: 'Different students learn economics in different ways. The best teaching strategy provides alternative learning methods.'

4. *Assessment of Teaching and Learning*

Assessment of teaching and learning in economic education is of two forms: formal quasi-experimental work aimed at publication and informal classroom review of students and teachers.

4.1 *Quasi-experiments*

Rendigs Fels provided the impetus for quantitative analysis of teaching techniques in economic education with his 1969 Presidential Address to the Southern Economic Association, 'Hard Research on a Soft Subject: Hypothesis Testing in Economic Education.' Until the 1990s, researchers typically specified a multiple-choice score, or the change in scores from the beginning to the end of the course, as the dependent variable produced by human capital inputs (preknowledge of economics or some other subject, grade points, previous courses of study), utilization measures (time spent by student or teacher in given activities), and technology, environment or mode of delivery (lectures, group work, computer use).

Of all the variations in outcome measures and models considered, Becker (1997) concluded that the only variables that consistently appear as significant and meaningful explanatory variables of the postcourse scores are the preaptitude measures, such as the precourse test scores. There also is some work that suggests the qualifications of the teacher, math skills, prior exposure to economics, gender, and type of teacher and student interaction are important in explaining success in tertiary economics courses. However, there are major problems with the input–output approach on which economic education research is based.

First, production functions are only one part of a student's decision-making framework. Observed outcomes are the result of the entire decision-making process, and each student's learning goals and process may be different. Second, data loss and the resulting prospects for sample selection bias in the standard learning model design are tremendous, with 20–40 percent of those taking the precourse tests not taking the postcourse tests. Third, from statistics we know that failure to reject the null hypothesis does not imply its acceptance. That an experimental program shows no statistical significance over the control does not imply that the experimental and control programs have equal effects. Finally, and possibly most important, education is a multiproduct output that may not be reflected in a single multiple-choice test score. In the 1990s, economic education researchers began to build models and employ estimation techniques aimed at overcoming these problems in testing for learning effects. These developments are discussed in Becker (1997), with new findings typically published in the *Journal of Economic Education*.

4.2 *Classroom Assessment of Students*

Within the United States, fixed-response, multiple-choice tests are a staple of assessment in economics, especially at the principles level. In most of the rest of the world, even at the principles level, free-response questions are the norm. An often-asked but unanswered question is whether the added cost of grading essays, reports, term papers, and the like is worth the information gained by students, instructors, and their institutions. In large enrollment principles classes, cost considerations require the use of multiple-choice tests, but this does not imply that they cannot be used creatively to get students involved and interacting with each other. For example, after a quiz has been machine scored, and returned to students, the instructor can have students interact with those sitting around them to determine the correct answers—a frenzy of activity ensues. After several minutes, the room is quieted and each student is allowed to resubmit a new answer sheet for partial credit.

Individual multiple-choice questions have also been used outside an examination setting to stimulate student interaction in class. For example, a single multiple-choice question can be projected in a traditional large lecture hall. Each student answers the question on a sheet distributed in the classroom. For a second question, each student marks 'A. Certain' to 'E. Doubtful' to indicate confidence. Students then discuss their answers with neighbors—the lecture hall is abuzz. After a few minutes, students continue the

process with question three (a repeat of question one) and final confidence given in question four (a repeat of question two). Student attendance and participation increase with the use of this activity, if students get some credit for attempting answers, as well as for the correct answer to number three, when responses are scanned and machine scored. The instructor also gets feedback on student confidence in what they are doing.

From Harvard seminars on college teaching, Light (1990, 1992) reported on the subjects students respect and from which they learn most. The crucial features are immediate and detailed feedback, with frequent points of assessment, and high demands and standards but with ample opportunity to revise and improve work as part of the grading process (i.e., learning from mistakes). Students also claim to learn from the reinforcement of their peers. Multiple-choice tests are crude instruments for assessing student learning but, as already illustrated, they can be used in educationally sound ways. Allen Kelley's TIPS program (Kelley 1973) was innovative in the early 1970s and its principal components (frequent multiple-choice testing in large classrooms with immediate detailed feedback) are easily implemented by anyone with access to machine scoring. It is especially attractive to anyone teaching in a small computer laboratory where assessment material can be delivered directly and uniquely to each student in the class, as I am doing in my teaching of business and economics statistics. In a large high-tech auditorium, where each student's response on a keypad can be monitored by the instructor, software programs permit rapid display of responses and their distribution, offering instructor and students immediate checks on learning.

Especially outside the United States, as already noted, there is a belief that no matter how they are delivered, multiple-choice questions are inferior to questions in which students construct their own responses. But within the United States, the perception is that they measure the same thing (Hansen 1998, p. 83). Walstad and Becker (1994, p. 196), for example, reported in their study of the Advanced Placement examination in economics (administered to selected twelfth graders in the USA) that 'the coefficients of correlation for the multiple-choice score and the essay score were relatively high (0.69 micro and 0.65 macro), … consistent with previous studies that found no difference or only slight differences, in what the two types of tests and questions measure.' Becker and Johnston (1999), however, point out that a correlation coefficient of 0.69 implies that only 48 percent of the variability in scores on one set of fixed-response (multiple-choice) or construct-response (essay) questions is explained by the other.

More importantly, once account is taken of the measurement error and simultaneous relationship that exists between scores on essay and multiple-choice components of an exam, the Becker and Johnston two-stage least-squares estimates demonstrate that they measure different dimensions of student knowledge. Hence it is important to use both forms of testing and not to abandon essay questions in favor of the multiple-choice form or vice versa. Second, females do not seem to be disadvantaged by multiple-choice questions, although they may have an advantage at essay writing, again suggesting that no one form of test should be employed. Economic educators such as Hansen (1998, p. 83) now suspect that tests with all essay response questions, or the exclusive use of multiple-choice response questions, must be avoided in the assessment of economics.

4.3 Assessment of Teachers

In economics departments at colleges and universities in the United States, there is an almost exclusive reliance on end-of-semester student evaluations of teaching (SET) as the measure of the instructional product (Becker and Watts 1999). That 'the primary purpose of the common end-of-course evaluation form is to provide comparative data for administrators … ' (Walstad and Saunders 1998, p. 339) is troubling. Typically SET scores explain less than 50 percent of the variability in other teaching outcomes (e.g., test scores, scores from trained classroom observers, postcourse reviews, etc.). Thus, when administrators use SET scores to compare individual instructors against an average, they are condemning half of their teachers based on a suspect instrument. Teachers (agents) can be expected to respond to SET and, even if inappropriate, adjust their behavior in accordance. For that reason, there are principal-agent problems associated with end-of-semester SET.

Unfortunately, the SET forms used in economics usually ask few questions that deal with what education specialists say is important: active student learning and group (or collaborative) learning. Furthermore, although academic economists call for the use of better applications and examples in teaching, these items are among the least-often-asked questions on SET. Although there is lip service about implementing new technology in teaching economics, questions about the use of technology are rare on SET forms. The teacher's overall effectiveness, communication skills, organization and planning, and knowledge of material are among the top four items on which student opinion is sought (Becker and Watts 1999). These items, however, fail to address what instructors can do to improve teaching. An instructor interested in improving the learning of his or her current students needs feedback before a semester is nearly over. Questions asked of students must elicit responses that suggest a desirable change in instructor behavior. They need not be of the standard SET type.

In addition to my participation quizzes, similar classroom checks on student understanding such as the 'minute paper' provide a proven framework to

assess what students are and are not learning during the course (Chizmar and Ostrosky 1998). The minute paper is typically assigned in the last minutes of each class when maintaining student attention is difficult. Each student is required to respond to two questions: (a) what was the most important thing you learned in class today? and (b) what question is unanswered? Although answers may or may not be graded, these written responses can be used to monitor both comprehension and attendance. It is only one of many vehicles for monitoring the process of education from the start of a course to its termination, which fits well with the industrial model of total quality management. On resident campuses with ample computer facilities and programming staff, electronic technology makes periodic assessment easy. Students need not complete assessment instruments in a classroom; they can complete questionnaires at their leisure sitting at terminals. Students can be required to complete the periodic questionnaires as part of a course requirement. If the unit processing the forms is independent of the instructor, individual student responses can be associated with the student or reported anonymously to the instructor.

Classroom observation, peer review of teaching materials, and subsequent student enrollments and student behavior in subsequent economics courses are some alternatives to SET, but these are not being used in the evaluation of teaching in economics (Becker and Watts 1999). For example, peer review of teaching is used by only 37 percent of the United States economics departments at research universities and by 52 percent of the baccalaureate institutions, as defined by the Carnegie Foundation for the Advancement of Teaching. Wherever peer reviews are employed, the Department Chair typically appoints the evaluators. Classroom observation is the most common form of peer review of teaching. Evaluators also examine course syllabi, instructional materials, and examinations. Few departments in the United States ask evaluators to consider student drop rates, although some give attention to grade distributions.

5. *Conclusion*

The scholarship of teaching economics is diverse. It encompasses the organizations advocating and delivering economic education. More importantly, it provides a body of knowledge and views regarding what is and should be taught, how it is and should be taught, its assessment and evaluation with regard to student learning and attitudes, and teacher performance in generating those changes in students.

Economic Geography

Economic geography is the study of the geography of economic activities. The field includes the study of where economic activities are located (their pattern or distribution), why they are found where they are (the processes by which they are located), and what their impact is on that place and other places. In addition, normative studies of optimal location (where activities should be located) also fall within economic geography.

1. *The Scope of Economic Geography*

Economic geography includes a wide range of topics that span production, consumption, and distribution activities. The subject matter of economic geography encompasses the traditional sectors of economic activity: the primary sector (agriculture, fishing, forestry, and mining), the secondary sector (manufacturing, including processing and assembly), and the tertiary sector, or services. Services, the most rapidly-growing part of most of the world's economies, are often disaggregated into quaternary (information-related) and quinary (decision-making) services. The interrelationship of these sectors and changes in them affect employment and how one makes a living. In addition to the sectors of activity, economic geography has seen as a central objective to understand the uneven development of regions, one of the foremost impacts of the location of economic activities.

Most human impacts on the earth's environment have been the result of economic activity of one type or another. These processes take place at various scales (local, regional, national, global) simultaneously (see *Scale in Geography*). The interconnected nature of human economic activity is seen in the interaction between subsistence farming and the market, which provides nonfarm work and income as well as goods that may compete with traditional commodities.

The primary sector remains integral to the field. The range of forces that affect agriculture include the physical environment, economic behavior and demand, institutional, social and cultural influences; in turn, agriculture affects the natural environment (Grigg 1995). Among the more prominent forces that affect agriculture are technological change, which has permitted massive increases in productivity, and the increasingly global links from growers to consumers. Globalized agribusiness illustrates the central role of large, transnational firms in the organization of this (and other) economic activities (Goodman and Watts 1997, Le Heron 1993).

Dependence on the primary sector has numerous disadvantages. Oversupply has weakened countries that are producers of many mineral commodities. Deforestation is a common result of high levels of demand for scarce types of wood. Energy and other natural resources are typically addressed separately (see *Energy, Geography of*; *Resource Geography*).

The secondary sector, manufacturing and processing industries, is the core of industrial geography, although the latter increasingly incorporates any or all of the sectors as firms have begun to operate across traditional sectoral boundaries (see *Industrial Geography*). Although economic geography formerly was largely focused on production, it has grown to include the services, finance, information, technology, consumption, and state regulation (Martin 1994).

Services, the tertiary sector, comprise intangible activities ranging from personal services such as cutting hair to research and legal advice. Services have expanded enormously in recent years as higher incomes permit more people to travel and eat in restaurants and to use computer software.

A conventional textbook organization of economic geography begins with population and resources—population because people are both workers and consumers in the economy, and resources because what is available locally will determine to some degree what must come from elsewhere via trade. Distribution activities (especially transportation), agriculture, cities, the international economy and variations in economic development are standard topics.

2. *A Brief Historical Look*

Economic geography has perhaps the widest scope of all of the systematic areas of geography. It originated to a large degree from the identification of resources that had commercial or economic value. Extraction and manufacturing, comprising commercial geography, formed the principal focus of research by economic geographers in the first quarter of the twentieth century. The intervening decades saw a great deal of

research related to transportation (see *Transportation Geography*) and cities, where most economic activity takes place (see *Urban Geography*), industry location and, increasingly after the Second World War, to retailing and (what would now be called) the geography of the service economy (see *Service Economy, Geography of*; *Retail Trade*; *Market Areas*). Most research remained quite local, however, concentrating on specific areas and individual industries. As economic activity became less dependent on direct inputs from agriculture, mining and other primary activities, economic geographers found less relevance from their colleagues in physical geography.

Theoretical concerns in economic geography for many years centered on examining patterns linked to theories and models, such as central place theory and empirical verification (Berry et al. 1988). During this period, economic geographers were among those involved in the founding of regional science as an interdisciplinary field (see *Regional Science*). Regional science also brought to economic geography an array of models for optimal location of industrial and service activities and of transportation and trade flows (see *Location Theory*; *Spatial Optimization Models*; *Spatial Interaction*; *Spatial Equity*). Many of the foci of optimization modeling concern flows related to economic phenomena, such as journeys to work and shopping trips. It has been difficult to utilize equilibrium approaches to explain some flows, such as of traded goods. Theories of trade, for example, do not encompass adequately the growth in intrafirm and intraindustry trade or the effect of government decisions and policies (see *International Trade: Geographic Aspects*).

3. *The Concerns of Economic Geography*

It has been necessary to cross several disciplinary boundaries, not only that with economics. It is common for geographers to rely on research in planning, sociology, engineering, and other fields in order to understand better the processes that form the patterns found on the landscape. Within the core of economic geography, several topics helped to set the direction of the future: the world economy and the capitalist system, firms and linkages among them, regional development and planning, and work and employment.

3.1 *Understanding the World Economy*

Paradoxically, understanding the economic geography of places and regions within the world economy has become more significant with the process of globalization. Globalization has taken place simultaneously with the rise of the service industries and their concentration in world cities (see *Globalization: Geographical Aspects*; *Cities: Capital, Global, and World*).

Regional development, the impact of change in the type and nature of economic activity, has been a significant focus of both theoretical and policy-related research since the 1970s, as massive spatial changes accompanied the end of the golden era of economic growth. Regional development attempts to capture the range of economic, political, and social influences on regional patterns of employment opportunity. The patterns and processes of change typically exhibit uneven development, which is central to the study of economic geography (Massey 1995). This includes economic restructuring, the term used for developed economies, development theory, referring to less developed countries, and economic transformation or transition, referring to the evolution from central planning to a market economy (see *Economic Restructuring: Geographic Aspects*; *Uneven Development, Geography of*; *Economic Transformation: From Central Planning to Market Economy*). As active policy initiatives fell in importance during the 1980s, research became more local in focus, highlighting the unique cultural and social circumstances of particular localities (see *Local Economic Development*; *Community Economic Development*).

Research into the nature of capitalism attempts to understand how the capitalist system works through analytical approaches. A major conclusion of analytical research on capitalism is that the 'golden path of accumulation' in a capitalist system is unstable, and that a focus is needed on disequilibrium paths, centrally those surrounding technical change (Webber and Rigby 1996). The slowdown of accumulation, or fall in profitability, that began in 1973 and resulted in falling productivity can be attributed to technical change, which enhances the ability of firms, industries and regions to avoid the persistently falling rate of profit. While the disequilibrium view finds many adherents, most research in this area on technical change is limited to process innovations, and not to new products, which many would credit with the bulk of capitalism's ability for Schumpeterian 'creative destruction.' The view of the economy as evolutionary and of firms as heterogeneous finds stimulus in several branches of economics outside the neoclassical mainstream, and especially on the topics of economic growth and technological change (Nelson 1998).

The political economy approach explicitly recognizes that 'capitalism is not just a phenomenon of economic geography. It is also at one and the same time a social, cultural, and political geography' (Peet and Thrift 1989). From this perspective and others, economic geography now incorporates social, cultural and political processes on a regular basis (Lee and Wills 1997).

The incorporation of cultural, social, political, and institutional influences within economic geography is fundamental to the topic of industrial districts and

networks, which has highlighted the social embeddedness of these influences. On this phenomenon, identified throughout the world, processes beyond the purely economic are seen as critical (Lee and Wills 1997, Martin and Sunley 1998). These include institutions, culture, and social ties and conventions, all of which affect dramatically economic geography, whether production or consumption.

To understand the capitalist world economy requires understanding the role of money and finance. Financial flows have become not only international but continual as markets in London, New York, and Tokyo serve as continental financial markets. The nature of global money is just beginning to be understood (see *Finance, Geography of*).

Money, knowledge, and other phenomena move throughout the world economy via networks, whether physical or virtual. Attempting to understand telecommunications has been especially important as those technologies have become pervasive within and among firms as well as elsewhere in everyday life. The transforming systems of computers and telecommunications are outcomes of technological change taking place at a large (global or regional) scale as new infrastructures enable new forms of production, including many producer services (see *Information Society, Geography of*).

Technological change is a source of resilience in the capitalist system, and repeatedly alters the nature of economic activity and its geography. This is the case particularly through the creation of new products, which broaden the range of possibilities for consumers and present substitutes for inputs. The topic of technological change also examines patterns of technological change, including the origins of new innovations, or places where technological goods and services are produced, whether called high-technology regions or technology districts (see *Technology Districts*).

3.2 Understanding Firms

Early studies focused on actual spatial patterns of industrial location, as well as optimal patterns, a theme that continues (see *Location Theory*). The object in geographers' study of firms is less the organizational or industrial form of these entities than their actual behavior. Understanding the mechanisms by which firms and industries operate and their impact on industrial location and regional development also is a central issue in *Industrial Geography*. Along these lines, of particular interest have been studies of vertical integration and disintegration, or what is inside a firm and what is obtained from other firms.

As companies became vertically integrated, absorbing necessary processes in-house, studies of large firms evolved into what was known as the 'geography of enterprise.' Globalization is an effect of the actions of large (multinational, transnational, global) companies, whether through trade, foreign direct investment (see *Foreign Investment: Direct*), or other arrangements (Cox 1997, Dicken 1998). This work has been complemented if not largely superseded by the view that large firms are less influential in their own right than merely taking advantage of divisions of labor, an interpretation that goes a long way toward explaining the geography of production (Massey 1995, Sayer and Walker 1992).

In addition to large firms, entrepreneurship and small firms are a central feature of both flexible accumulation and creative destruction, and therefore have received increasing attention as their significance in most economies has grown. This is most evident in the case of regions where new firms and new industries are common (see *Technology Districts*).

3.3 Connections Among Firms

A surge of flexibility appeared to signal the vertical disintegration or 'outsourcing' of production as firms increasingly 'bought' rather than 'made' needed physical and service inputs. Flexible production became the dominant paradigm in economic geography, yet it is but one of several manifestations of a dramatic change or restructuring of economic activity (Barnes 1996, Martin 1994). The shift toward services and the interdependence of goods and services stand out in this regard.

Vertical integration had not vanished, however, but was transformed through complex relationships with suppliers and subcontractors. The global economy operates through complex webs of linkages, both vertical and horizontal, that form production chains that take different form in each industry (Dicken 1998) (see *Globalization: Geographical Aspects*). Large firms remain central to many industrial districts and other centers of flexibility because of their ability to control global networks. Despite their power, large firms have had to make painful adjustments and adaptations of flexible forms and processes. Adjustments to structural conditions are not simple, as sunk costs and uncertainty make even the largest firms unable to make optimal choices (see *Industrial Geography*).

The study of the interdependence of firms takes two forms: aggregate input–output relations and more detailed firm-specific linkages. Input–output structures, while often based on surveys of firms, provide economy-wide, usually national, structures of interindustrial links, but also regional and interregional. Disaggregated studies of linkages, by contrast, focus on a single firm or a small number of firms, illuminating the geographical area within which a firm's economic activities have influence. This may range from very local to global, depending on the firm and its sector, and only detailed study identifies which.

3.4 Economic Development and Restructuring

Economic development, long considered a national-level process, has been viewed widely to have broken-down to more regional and local processes. It is less frequently national states and more frequently regions where the dynamics of economic change take place (Scott 1998, Storper 1997).

Some of this work has looked at the restructuring as a transition from the capitalist 'golden age' to something different (Webber and Rigby 1996). Economic restructuring within capitalism is a result of the several distinct processes: sectoral change, especially from manufacturing to services (deindustrialization and tertiarization), flexibilization, the increasing feminization of the labor force, the new technologies of the information economy, hyper-consumerism, globali-zation, and deregulation and privatization (Martin 1994, Townsend 1997).

Fundamental to analysis of restructuring is the idea that interfirm competition is more intense and less stable than previously, with new rivals emerging from both other industries and from newly founded firms. New firm formation, or entrepreneurship, is particularly prominent in new industries, aided by the instability fostered by technological change. New firm formation is perhaps most a product of social class and of industrial history that create the culture and social norms in places (Massey 1995).

Spatial manifestations of restructuring—changes in firms' locational decisions—are seen both inter-regionally as some regions rise and others decline, and intraregionally as some suburban nodes become cores of economic activity, especially of producer services. Innovative milieus represent an intriguing interplay between firms and territories, where those territories include not only other firms but also infrastructures, knowledge, and institutions and organizations (see *Economic Restructuring: Geographic Aspects*).

The optimal location of activities falls under the umbrella of location theory, and is closely related to the 'new' economic geography that has developed within the discipline of economics in recent years (see below). That research has developed models to determine optimal and/or equilibrium patterns of location (see *Location Theory*). It should be noted that location theory is suited poorly to incorporate the realities of industrial location, especially the maximization of the quality of inputs rather than the minimization of transport and input costs.

3.5 Work and Workers

Uneven development and the spatial division of labor created are among the most fundamental constructs in economic geography. The spatial division of labor puts at the forefront the fact that not only different numbers of jobs (or varying amounts of economic opportunity) are found in different places, but also that different kinds of jobs are found in different locations. This view of spatialized social relations results in a geography not of the distribution of jobs but of power relations, of dominance and subordination, of enablement and influence (Massey 1995). Class, gender, and the division of labor are 'intertwined structures' that affect virtually all aspects of work and the geographies of the labor market (Hanson and Pratt 1995, Peck 1996, Sayer and Walker 1992) (see *Spatial Labor Markets*).

The types of work made available in a place affect its potential for entrepreneurship and economic development. Some occupations are more amenable to new conditions and innovative activity, and a great deal appears to be cumulative. Existing theories, however, generally are unable to account for empirical patterns found.

3.6 The 'New' Economic Geography

A much more narrow definition of economic geography is that employed by economists practicing what is termed the 'new' economic geography (Krugman 1991, 1995, 1996, Ottaviano and Puga 1998). In this view, economic geography is 'the location of production in space,' the most striking feature of which is its agglomeration or concentration—'clear evidence of some kind of increasing returns' (Krugman 1991).

Models in this genre tend to focus on two regions (urban and rural or rich and poor) and two sectors, and aim toward or assume equilibrium or multiple equilibria, rather than the reality of disequilibrium. The highly restrictive models fail to approximate 'real places' or to incorporate spatial scale (Martin 1999). Echoes of this critique of mainstream economic growth theory lament the failure to include technological advance as an essentially disequilibrium process, a theory of the firm in which capabilities and differences across firms are central elements, and incorporation of a richer body of institutions (Nelson 1998). The difference between 'formal theory' and 'appreciative theory' is useful in the context of the debate on the new economic geography.

The 'new economic geography' models the centripetal forces that foster geographic concentration and agglomeration against the centrifugal forces such as immobile factors (including land, natural resources, and people) (Krugman 1998). Several 'modeling tricks' are used to arrive at an equilibrium solution, or multiple equilibria, to topics and situations studied by geographers several decades ago, such as central places and rank-size distributions (Berry et al. 1988). It is not surprising that 'geography turns out to be perhaps the most naturally 'nonlinear' area of economics' (Krugman 1998), but to geographers the critical point is the diversity of reasons why this so, not merely the mathematical approximation of it (Martin 1999).

Geographers are more inclined to focus on the empirical reality present in the world and the many geographies they represent (Lee and Wills 1997). Rather than linear, mechanistic metaphors, biological and evolutionary metaphors may capture more accurately the emergence of economic change. The broader conception draws not only from interdisciplinary links with other social sciences, but also from economics, where development in both institutional and evolutionary economics have meshed well with geographers' broader view of the world. In general, economists prefer to assume equilibrium, whereas geographers', restricted cognitive understanding of the world, and unequal locational advantage as the rule rather than the exception (Sheppard et al. 1998). The world is much more diverse than a single set of models can hope to capture (Martin 1999).

Spillovers and externalities (and interfirm linkages) are at the center of the debate. The presence of economies of scope and diverse locales turns the standard increasing returns model on its head, because it is based on an industrial organization that benefits more from intraindustry linkages than from scale of production. Likewise, knowledge spillovers across industries are ignored in the 'new' economic geography because they are not well understood or systematically measured and tracked (Krugman 1991), and they are seen as a consequence of market interactions involving economies of scale at the level of the individual firm (Krugman 1995). By contrast, untraded interdependencies, which are not able to be modeled, are central to much of the current thrust of research by geographers on learning in regions and localities (Pinch and Henry 1999, Storper 1997).

3.7 *Clusters, Agglomeration, and Territorialized Learning*

Among the most powerful processes for regional transformation and renewal is the process of regional learning. If organizations and regions can learn, it is because they are able to build and use relationships with other organizations in their environment. Low-tech as well as high-tech firms are able to draw upon spillovers of knowledge in this way (Maskell et al. 1998).

The presence of horizontal (interindustry) linkages and spillovers is expected especially within industrial districts and technology districts, now seen as special cases of clusters. Paradoxically, as globalization continues, regions—whether city-states such as Singapore, metropolitan areas, or cross-border territories—have become more significant as the loci of economic activity (Scott 1998, Storper 1997). Each region evolves a unique mix of products and technologies, skills and resources, conventions and customs, leading to a set of capabilities not found elsewhere. These geographically-specific capabilities—'people' in Krugman's list of centrifugal forces—can serve as enduring competitive advantages of agglomeration (Maskell et al. 1998). They also create the variety that is evident in the economic geography of our world.

4. *Conclusion*

The breadth of economic geography makes it virtually certain that research focuses on one or more of the field's topics. Economic geography has blossomed well beyond its original focus on the location of production to embrace the many other human forces—social, cultural, political, and institutional—that affect and are affected by economic activity.

Economic Globalization and Gender

Economic globalization and gender is a topic that has grown in importance since the1970s. Although 'globalization' has occurred in specific periods for centuries, it was not until the early 1970s that attention was drawn to the importance of understanding the gendered effects of economic globalization and, in turn, their implications for sustainable human development.

1. *Definition and Context*

Economic globalization involves a wide variety of processes, opportunities, and problems related to the spread of economic activities among countries around the world. There have been many periods in which it occurred, most recently including the latter nineteenth century to WWI, the quarter century after WWII, and the late 1960s/early 1970s to the present.

The latest period has involved several major trends, as capitalism has spread throughout more of the world. First, there has been an increased reliance on markets (versus government involvement in the economy) by most nations (including industrialized countries, developing countries, and formerly socialist countries like China with over one-fifth of the world's population). Second, many developing countries have shifted to the more open export-oriented approach based on production for external trade from an import substitution development strategy (production of essential goods for the internal market). Third, multinational corporations (MNCs) in manufacturing, service, and finance sectors have moved into new tiers of countries and have established burgeoning networks of subcontractors in many areas. Fourth, since the late 1970s, economic globalization has also involved structural adjustment policies (SAPs), mandated by the International Monetary Fund (IMF) as a condition for granting countries loans. SAPs require governments to take many steps that further promote globalization. They also require austerity measures that fall heavily on the poor, particularly women. Fifth, there have been shifts in the power of key institutions internationally. On the one hand, the influence of many national governments has been eroded by the rising importance of institutions like the MNCs, the IMF, and World Bank (WB), and trade organizations such as the World Trade Organization (WTO). On the other hand, there has been an increase in nongovernmental organizations (NGOs) advocating for the rights of groups of citizens (see Pyle 1999 for more information regarding each of these five trends).

Economic globalization has involved an increase in the international movements of goods and services, capital (portfolio investments or foreign direct investment by MNCs), and labor as people migrate for employment. This phase of globalization has been particularly facilitated by changes in technology (telecommunications and information technology) and transportation (UNDP 1999). It is often characterized as 'neoliberalism' because it is putatively based on increased reliance on markets (and correspondingly less on governments), liberalization of trade and investment policies, and a growing openness among economies. However, economic globalization has occurred in a very uneven manner. Countries are integrated into the global economy to very different degrees (UNDP 1999). This has resulted in rising inequality and tension, which are increasingly considered the flip side of the increased reliance on market forces and the changes in the international power structure. In the 1970s, scholars began to explore the gendered impacts of changes in the global economy. Gender has both a biological dimension (categorization as male or female) and socially constructed components. The latter reflect a society's views regarding appropriate roles for men and women and are reinforced by economic, political, social, cultural, and religious institutions. Global organizations such as MNCs and the IMF often use these social constructions to their advantage; however, globalization can undermine them or cause them to be more firmly defended. This article outlines the importance of the evolving study of the gendered impacts of economic globalization, the current issues regarding research, theory, and methodology, and likely future directions.

2. History and Changing Emphases

Before the 1970s, women or gender issues were rarely mentioned in the development literature. That changed with the publication of Boserup's (1970) book *Woman's Role in Economic Development*. Most regard this as a turning point that spurred thinking about women in the development process and initiated what has become a very large literature. The conceptual approaches taken and the strategies for change they imply have, however, changed over the years. Scholars and activists associated with the Women in Development (WID) approach of the 1970s sought to make women's roles visible. Women's issues typically were tacked on to existing approaches or institutions, however, rather than fundamentally integrated. WID focused on individuals and on fostering change within existing structures. Seeing these limitations, others developed a focus on gender. This approach emphasized unequal power relations between men and women and the ways they are institutionalized in households, culture, schools and religious organizations, the state, and international organizations. (See Kabeer 1994 and Visvanathan et al. 1997 for more information on this history; see Visvanathan et al. 1997 for selected readings.)

In the 1990s, the international political economy changed considerably with the ending of the Cold War and the impetus this provided to all the dimensions of globalization listed above. The discourse shifted to examination of the gendered impacts of economic globalization, broadening the focus to include gendered effects in all countries—industrialized and formerly socialist as well as those the development literature has concentrated on—and adding important dimensions to the analysis. For example, since globalization has involved increasing movements of people as well as goods, services, and capital, many industrialized countries have immigrants from developing countries who have been profoundly affected by these forces. This conceptualization includes them.

In spite of these substantive changes, and although gender increasingly is recognized as a relevant perspective, there continued to be a lack of attention to gender in the 1990s by most economists and many sociologists specializing in the study of development or globalization. Feminists continued to break new ground, however, in exploring these issues. Feminist sociologists have long critiqued approaches to development such as modernization, dependency, and world systems theories. (See Ward 1993 for an example regarding the world system approach.) Feminist economists have asked new types of questions, transformed some traditional economic approaches to include gender, and posed alternative approaches to development (Beneria 1995, 1999, Sen and Grown 1987, World Development 1995). Many now recognize the critical importance of understanding the gendered impact of these dimensions of economic globalization—and their impact, in turn, on growth and sustainable human development. For example, it has been found that low investment in women's education, often a result of SAPs, can hinder a country's economic growth (World Bank 2001).

These conceptual changes and the activism they spawned since the 1970s have fostered the rise of NGOs, many of which were founded to alleviate the effects of globalization and to address women's needs. International institutions have been forced to incorporate gender issues into their thinking, planning, and programs. The United Nations designated 1975 the International Year for Women. It held World Conferences on Women in 1975, 1980, 1985, and 1995, bringing people together from around the world to assess the status of women and draft policy recommendations to address gender inequalities. Special divisions have been established within the UN and the WB; considerable information and data have been collected (United Nations 2000). The United Nations Development Programme (UNDP) has emphasized human development throughout the 1990s; its annual *Human Development Report* focused on gender and human security in 1995 and globalization with a human face in 1999 (UNDP 1995, 1999).

There have been critiques of the efforts of these institutions to mainstream gender issues. In response, these organizations have developed more inclusive approaches, engaged experts in the field of gender and development as employees or consultants, and established substantive websites to disseminate information and invite discussion. The UN sponsored Beijing Plus 5 in 2000 to assess progress for women since the 1995 Conference on Women in China. The WB published a new report that focuses on the importance of gender for development and examines the factors that affect gender equality (WB 2001). Particularly active in advocating for women is the United Nations Development Fund for Women (UNIFEM), which grew out of the First World Conference on Women. UNIFEM Director Heyzer drafted an Agenda for Women in the twenty-first century (Heyzer 1995). UNIFEM's new volume (UNIFEM 2000) is designed to help women hold powerful institutions accountable for gendered outcomes of globalization—including the UN, IMF and WB, MNCs and other businesses, and civil society organizations such as unions, community-based groups, and business or professional associations.

3. Current Issues

Because economic globalization and gender is a broad topic with multiple dimensions, this section can only highlight some of the key issues scholars and activists are addressing regarding research, theory, and methodology. Newer work is beginning to cross disciplinary boundaries, offering opportunities to examine the

gendered effects of globalization from perspectives that may include economics, sociology, political science, gender studies, or anthropology. Increasingly, women from the Third World are shaping the questions asked, the type of research conducted, the methodologies used, the policy recommendations suggested, and the activist endeavors undertaken (Heyzer 1995, Kabeer 1994, Sen and Grown 1987).

As economic activities become more global, some benefit, but the hardships of many others are increased. There are many aspects that can be considered in assessing the differing effects of globalization on men's and women's income earning opportunities and household economic responsibilities—including access to employment in formal or informal sector jobs, wages and earnings (relative to the amount required for a reasonable standard of living), the types of occupations, job conditions (health and safety, rights to organize, work-life balance), opportunities for skill acquisition and promotion, and the effects of all these on one's position in the household and community. The analysis is complicated, however, because research reveals that the impact also varies by class, race/ethnicity, age, and other attributes. Ironically, although technological advances are a foundation of this phase of globalization, and even though technology offers a possible means for women to access information, develop broader networks of support, and increase their standards of living, women do not have the necessary access and are not receiving equal benefits of technological advances.

The internationalization of basic economic activities—production, trade, and finance—produces effects that differ by gender. The globalization of trade can have divergent effects on women. For example, if women work in sectors producing goods for international trade, they may benefit from economic globalization—as long as they make a living wage and their employer (often a MNC or its subcontractor) remains in their area. Many female small business owners are forced out of business by the cheaper imports that trade liberalization brings. Gender differences in the impact of trade typically have not been considered as trade organizations such as the WTO formulate policies.

Much production (clothing, electronics, toys, shoes, and sporting goods) and provision of services (data entry, reservations, business services) have moved internationally, becoming part of the 'global assembly line.' Many MNCs prefer lower cost women workers who they believe are unlikely to resist adverse conditions. Women working in MNCs or their subcontracting networks often consider this employment a better option than otherwise available. However, working conditions can be oppressive, characterized by long hours, fast pace, few breaks, no opportunities for advancement, harassment, and unsafe and unhealthy workplaces. In addition, such employment is precarious. When labor costs rise as workers seek to improve their conditions, MNCs use some combination of automating and new technologies, suppressing worker demands, moving to other developing countries with lower labor costs, or establishing subcontracting networks where workers are lower cost and can be terminated immediately. These strategies typically have adverse effects on women.

Financial globalization involves not only foreign direct investment by MNCs but also portfolio investment (buying/selling of stocks) and international loans and aid. As conditions for receiving loans, the IMF and WB typically require countries to adopt SAPs. These involve opening their borders to foreign trade and cutting government employment and expenditures on health, education, housing, and food subsidies. The IMF argues these policies will increase revenues needed for loan repayment. The effects of SAPs fall heavily on women, however, who try to maintain their families' standards of living. They take on added household responsibilities (to compensate for decreased government services) and obtain extra income earning activities, often in the informal sector.

As a result of these economic aspects of globalization, many women are increasingly pushed into the informal economy (Moghadam 1998, Pyle 1999). Poverty levels rise. Large numbers of women, particularly from lower-income Asian countries, are forced to migrate internationally to find employment, often leaving families behind. Women in many countries must resort to earning a living as domestics or sex workers. Conditions in these occupations can be highly exploitative.

As a result of background studies in these areas, scholars are developing a broader theoretical understanding of the systemic linkages among the global expansion of capitalist production, trade, and finance and the increases of women in the informal sector, rising inequality and female poverty, and higher levels of female migration (Pyle 1999). Feminist perspectives are being used to question and transform orthodox models of human behavior and, in turn, their implications for understanding the gendered impacts of globalization (Beneria 1999).

Research on economic globalization and gender involves problems, however, that include: gaining acceptance for new concepts that challenge and replace traditional views, operationalizing concepts empirically, obtaining appropriate data, developing alternative policies, and fundamentally reconsidering the usefulness of current approaches and institutions (whether they can be transformed or new ones are needed). For example, the reconceptualization of women's 'work' to include unpaid work in the household is controversial; there are conflicts about how to measure and value it. In addition, to adequately examine the gendered effects of globalization, data that measure the desired concepts and is comparable cross-country must be available. However, many countries have little data available; in others, in-

formation may be incomplete or of questionable quality.

There are the dilemmas involved in developing alternatives to policies like SAPs. Such innovative policies would enable countries to obtain loans but the focus would be on how to foster sustainable human development and gender equality rather than on how to ensure loan repayment. There is also the key question of what the focus of strategies for change should be—whether on changing the individual's position or the group's (and, if the group, at what level—family, community, nation, region, international) and whether to increase women's capabilities or confront the social, economic, and political structures that disadvantage or discriminate against females. This is particularly important to think carefully about, given the context of the larger shift in the distribution of power (from national governments to MNCs and international organizations like the IMF).

4. *Future Directions*

In the future, there will be continued progress in the creation of concepts and theories that enhance our understanding of the gendered impacts of globalization and the importance of these effects for sustainable human development. This work will be based on new ways of looking at issues, a wider array of studies of the gendered effects of globalization, and analyses that examine the more nuanced and complex patterns that emerge from such studies. This research may also involve the generation of new methodologies. As in the past, these concepts and theories will be important for developing strategies for change.

To illustrate each of these points briefly, scholars and activists will continue to develop and extend new concepts and perspectives. For example, concepts such as 'caring labor' will be acknowledged, respected, and utilized more widely (UNDP 1999). There will be increased attention to the gender dimensions of the insecurity created by globalization. Beneria is examining women's security globally, focusing on women's different employment problems, paid/unpaid labor share, female-headed households, and economic restructuring. By fully understanding the many aspects of insecurity, better policies can be developed to address them.

Newer methodologies may be developed based on these innovative conceptualizations and perspectives; existing methods will be extended and made more gender sensitive. For example, work will continue on the construction of broader indicators that measure women's well-being, economic security, and progress in participating more fully in economic, political, and social life.

Each of the issues outlined in the last section will be more fully studied at many levels of analysis—from the household level to the international. Multilevel analyses reveal more of the two-way linkages between the micro- and macrolevels. Not only do macroeconomic changes have gendered impacts on people and households at the microlevel, but microlevel processes contribute to macroeconomic well-being. For example, studies have shown that when women have access to income (a microlevel event often shaped by macrolevel forces), their children are healthier and better educated and, in turn, contribute more to sustainable development (WB 2001).

Case studies that explore the gendered effects of globalization on people who differ by culture, race/ethnicity, class, age, sector, and region as well as sex will shed considerable light on the role of these factors in shaping the gendered effects of economic globalization. This will provide insight into what broader socioeconomic changes may be needed for more gender equality as globalization continues.

Along with these advances, there will be continued fundamental challenges to disciplines that study development and globalization and their theoretical underpinnings (Beneria 1999). Disciplinary approaches will be recast to integrate gender perspectives; new interdisciplinary paradigms or areas of study may be created.

Women will continue to resist adverse effects of globalization and seek to improve their positions. Creative strategies will be crafted to enhance women's capabilities, empower them, and increase their socioeconomic security. These approaches will include access to and creative use of new technologies. NGOs will extend their work in these areas—not only locally or within a country, but increasingly at national, regional, or international levels. For example, as the gendered effects of globalization are more widely recognized, people in similar jobs or situations worldwide (e.g., sweatshops) may form alliances in order to address the problems they face.

There will be efforts to increase women's voices at all levels of government and develop ways to strengthen the state, an institution that can still be important for garnering the benefits and combating the problems of worldwide economic changes although its power has been eroded by forces such as MNCs and the IMF's structural adjustment policies. There may be continued changes in the level of awareness of gendered effects of globalization by international institutions (WB and IMF, UN and its many divisions, and the ILO) and in their interest and ability to design programs and policies to alleviate the adverse impacts. It is also possible that entirely new forms of global governance will be created that are more gender aware and focus on human development (health, education, safety, and opportunities for employment and income earning) rather than on finance and trade (UNDP 1999).

Economic Growth: Measurement

Economic growth is the sustained increase in welfare of an economy—nation, region, city—together with the ongoing changes in that economy's industrial structure; public health, literacy, and demography; and distribution of income. In the long run, as this economic transformation evolves, so do social, political, and cultural norms. Societies change profoundly and multidimensionally, as economic performance improves.

To measure economic growth is to quantify this increase in welfare and to endow with numerical precision these large-scale economic and social changes. Given the breadth of possibilities, it is impossible to undertake this measurement exercise without guidance—what can be pared away, what is essential—from *some* view on the causes of growth (see, e.g., *Economic Growth: Theory*).

This article sets down some key (measurement) facts concerning economic growth, and documents how they have evolved, if at all, over time. In doing this, the article attempts also to illustrate the historical interplay between two lines of research, measurement of and theories about economic growth, each influencing the other.

1. National Income

The panorama above of profound social and economic changes can be simplified dramatically by concentrating on just a single key economic variable, income per capita. (We will return in Sect. 8 below to issues of broader structural transformations).

Income per capita is the per head measure of the total value of all goods and services produced in an economy. Taking national income—measured by either gross national product (GNP) or gross domestic product (GDP), or its regional counterpart—and dividing it by population in the appropriate nation or region gives a convenient first measure on the state of economic well-being. Since total income is the same as total output, this measure might sometimes be usefully replaced by output per worker, or *labor productivity*, where the denominator is then the size of the labor force; or, even output per worker-hour, where the measure then takes into account the time spent working by the labor force.

In some detailed analyses, these alternatives can provide different useful insights into economic performance—different countries, at different times, have had their labor force markedly different from their population, or have had workers and firms make different choices on the length of their workday. However, for the kind of long-horizon, large-scale developments that are typically of interest in economic growth, these differences are inessential. Potentially more important is whether this one measure can suitably proxy for the wide spectrum of different variables of concern in economic growth.

Across countries, per capita income is positively correlated with a broad range of alternative indicators for economic performance—including life expectancy, (the negative of) infant mortality, and adult literacy

(Ray 1998). Thus, economists and many other social scientists have focused, primarily although not exclusively, on growth in per capita income as the preferred first measure of economic growth more generally.

One obvious and crucial shortcoming in this, however, is that income per capita, by definition, says nothing about income inequality. Thus, a potential tension between economic growth and income inequality arises, on top of an analytically-driven hypothesis that rising average incomes might be associated with a widening of the income distribution. We will return to this below in Sect. 7.

2. Early Work

Economic growth—significant, sustained increases in welfare—is a relatively recent occurrence (Maddison 1982, Romer 1986). While steady improvements in the lot of humanity over the last 50,000 years had been noted, most of those came tortuously slowly.

The Netherlands began the eighteenth century as the leading economy in the world. But economic growth here was neither sustained nor pronounced. Almost a century afterwards, labor productivity in the Netherlands was 6 percent *lower* than in 1700.

In 1785 the UK had risen to become the new world leading economy. However, despite immense strides in technological progress due to the Industrial Revolution, the UK's labor productivity grew by only 0.5 percent per year from 1785 through 1820. From then through the beginning of the twentieth century, the UK remained the world's economic powerhouse. But in this time UK labor productivity grew by only 1.4 percent per year. Only after the US overtook the UK following the end of the nineteenth century, did the world begin to see the kind of long-run, sustained growth rates that are now typical: US labor productivity grew at 2.3 percent from 1890 through 1979.

3. Kaldor's Stylized Facts

The concept of GNP was only developed in the early twentieth century, not for measuring economic growth, but for assessing the state of a national economy. Not long after, Kaldor (1961) observed that the ongoing growth in per capita national income came with several empirical regularities:

(a) Income per capita grows steadily over long stretches of time;

(b) Factor income shares—the fractions of total income accruing to the labor force and to physical capital—show no secular trend;

(c) The ratio of total national income to the aggregate stock of physical capital—the total value of machines, highways, bridges, buildings, physical infrastructure—remains roughly constant.

These observations, typically labeled *Kaldor's stylized facts*, constitute a first important growth measurement that economists sought to understand and to explain.

According to Kaldor's measurements, while economic growth occurs, its benefits divide up in a stable way between rewards to capital and labor—no one factor input, taken as an aggregate, benefited more than another from economic growth. Moreover, since capital's income share can be viewed as the stock of capital multiplied by capital's rate of profit, Kaldor's stylized facts also implied that the profit rate is, in the long run, constant.

4. Physical Capital Accumulation

The most successful of the different explanations for Kaldor's growth observations was given in Solow (1956). This immensely influential work produced a widespread conventional wisdom that was simultaneously a profoundly important policy implication. The line of work, however, then led to yet further measurements (Solow 1957) whose later reinterpretation would eventually overturn the original consensus.

Conventional wisdom following Solow (1956) had investment—the accumulation of physical capital—constituting the critical engine of growth. Solow (1956) assumed that total output obeyed a *production function* taking values that increased with the quantities of physical capital and labor employed in the economy. Because no well-behaved function can give at all times a perfect fit relating output, capital, and labor, Solow (1956) hypothesized further an unobservable residual to the production function relation, a residual that he interpreted as exogenously evolving *technical progress* or, more simply, technology. Together with some other reasonable assumptions on the behavior of savings (and therefore investment), labor force growth, and technology's impact on the effectiveness of labor and capital, the model generated outcomes successfully reproducing Kaldor's stylized facts.

The result envisioned had economic growth in two conceptually distinct phases. First, there is the long-run steady state, where the capital-output ratio is constant, and growth in per capita income occurs entirely from technical progress. Second, there is transition to the steady state: along this transition path, physical capital accumulates rapidly due to relatively high investment, driving up the economy's growth rate as the economy itself converges towards its long-run, steady-state growth path. If the second phase were that more relevant to the real world, as many supposed, then accumulating physical capital—building machines, factories, roads, and bridges—constituted the engine of economic growth. Policy-

makers from Joseph Stalin in the Soviet Union through Lee Kuan Yew in Singapore through leaders in developing country after developing country took this implicit advice to form a cornerstone of their development plans. Encouraging savings—voluntary or forced—became key to economic progress.

In Solow's work, technology bore two different meanings. One, because by assumption it influenced the effectiveness of factor inputs, technology was also labeled *total factor productivity* (TFP)—it improved the productivity of all the factor inputs in an economy. Two, because it emerged as a residual in the production function accounting exercise, it was also viewed, derisively, as a 'measure of our ignorance' (on the part of the modeller). Early research on growth measurement, therefore, took one of its goals to be the minimization of this residual, the idea being that the smaller TFP became, the more successfully one had explained economic growth.

Measurements undertaken by Solow (1957) showed that for the US over the first half of the twentieth century, almost 90 percent of economic growth was due to TFP, with only the remaining one-tenth accounted for by capital accumulation. Taken at face value, this surprising empirical finding sharply contradicted the conventional wisdom and policy advice many had taken to follow from Solow (1956). The hoped-for reconciliation was that by measuring accurately enough the factor inputs—accounting for improvement in quality of capital and labor—this Solow residual would be diminished.

By contrast, more modern work (Sect. 6 below) favors the first interpretation of TFP, that is, that it is correctly viewed as enhancing the productive potential of an economy. Thus, economies with large TFP are considered high-growth, high-performance economies. The research focus has shifted from trying to minimize measured TFP to trying to understand its evolution, typically in terms of its being driven by science and research and development (R&D).

Another important idea arose from this early work on measuring economic growth: convergence, or the tendency for economies not already on the steady state path to approach it. Stated more fully, the Solow (1956) model implies that capitalist economies where capital and labor are rewarded their *marginal products*—the contributions each make, on the margin, to final output—are economies that are stable around their steady states. If an economy is not already at steady state, it has a tendency to go there. Economies relatively poor have a tendency to converge to, or catch up with, those relatively rich.

5. *Rich and Poor*

Difficult as it initially was to compile systematic national income accounts for even the advanced countries, obtaining comprehensive and comparable data across countries was an order of magnitude more complex. This task has only recently been accomplished (Summers and Heston 1991) to a degree where researchers can now meaningfully compare incomes and therefore economic growth across countries.

Because different countries collect and report income data in their individual, respective currencies, cross-country comparisons can be made only after converting national incomes to a common basis. To achieve this, one possibility is to use official current exchange rates to convert national–currency figures into numbers denominated in some single currency. However, such exchange rates are highly volatile, and need not always accurately reflect the purchasing power, or the command over real resources, of the respective national currencies. Importantly, currency exchange rates cannot reflect the prices of nontradeable goods and services. To the extent that nontradeables are relatively lower-priced in poorer countries, conversion using official exchange rates *underestimates* the incomes of relatively poor countries, and thus exacerbates the true gap between rich and poor.

As just one example, consider the following. Even though between 1985 and 1990, Asia was the world's fastest growing region, its share of world GDP—calculated using official exchange rates—fell from 8 percent to 7 percent. The reason for this is that Asian currencies depreciated sharply against the US dollar in this 5-year period. In this instance using exchange-rate adjusted national incomes disguised (and indeed misled on) actual changes in economic performance.

Summers and Heston (1991), in collaboration with the United Nations, constructed rescaled national incomes for a broad cross-section of countries. They used a *purchasing power parity* (PPP) correction to overcome the measurement difficulty just described. Taking into account prices on close to 700 individual items—traded and nontraded—across different countries, and then adjusting for differential spending patterns, the Summers–Heston data provide the most reliable indicators to date, allowing comparison of economic growth across countries. These data now constitute the professional standard, and have been used in over 1,000 empirical studies on economic growth.

Allowing cross-country comparisons has opened up striking new questions in both the measurement and theory of economic growth. Using 1993 official exchange rates, Switzerland was the world's richest economy; Tanzania, the world's poorest. The ratio of per capita incomes between them approached an incredible 400. By contrast, when PPP-corrected and averaged across the last five years of the 1980s to smooth out short-run fluctuations, the ratio between richest and poorest economies (now the US and Chad, respectively) falls to a little over 40. This latter number accords better with less formal evidence and with casual observation on differing costs of living. However, even though PPP correction has reduced the

dramatic disparity between rich and poor across the world, the divide obviously remains considerable.

The Summers–Heston data reveal the following: between 1960 and 1989 world per capital income grew by 2.25 percent per year. Averaged over the five years 1960–64, per capita income at the bottom 10th-percentile point (in the cross-section of countries) was 0.22 times the world average, with the 90th-percentile point 2.70 times the world average (Quah 2001). The 90:10 ratio was, therefore, 12. Almost three decades later, averaged over 1985–89, per capita income at the bottom 10th-percentile point had fallen to 0.15 times the world average while the 90th-percentile point had risen to 3.08 times the world average. The 90:10 ratio thus nearly doubled over this period of high average growth worldwide. More detailed study of the growth dynamics in this post-Second World War cross-section of countries has revealed, not just a widening of income disparities across rich and poor, but also an emerging polarization, with the middle-income group of countries dwindling in number (Quah 1997a).

This finding, that in the post-War era, poor economies do not obviously catch up to the rich, has its interpretation disputed by research arguing that, provided one conditions on the appropriate indicator variables—investment and schooling, in particular—then convergence does occur. That kind of convergence, however, is no longer between rich and poor, but is convergence of each economy towards its own specific steady state growth path (Barro and Sala-i-Martin 1992, Levine and Renelt 1992). Hundreds of auxiliary variables have been suggested in these cross-country growth and convergence studies as appropriate alternative or additional conditioning variables (see, e.g., the compilation of studies in Durlauf and Quah 1999).

The evidence in Durlauf and Johnson (1995) shows that poor economies do indeed tend to converge to relatively low income levels, and rich ones to high, even after conditioning on savings and literacy rates. This study suggests, therefore, that as economic growth proceeds, then even with conditioning, the polarization into rich and poor described in Quah (1997a) remains empirically relevant.

6. *Ideas—Science and Technology*

Observing that country disparities are large and growing, that is, that convergence is not happening; and that so much of economic growth is due to TFP has motivated some researchers to investigate models of *endogenous technological change*. (One notable exception is Mankiw et al. (1992) who argued that taking into account *embodied human capital*—the quantity of schooling embodied in the labor force—suffices to explain both observations.)

In work on endogenous technology, TFP is no longer taken to be exogenously given. Instead, economic theory is used to shed light on the incentives and forces shaping TFP's evolution (Aghion and Howitt 1998, Grossman and Helpman 1991, Romer 1990). The problem of explaining cross-country disparities then becomes one of understanding the dynamics of cross-country technology dissemination (Coe and Helpman 1995, Helpman 1993). This work predicts that knowledge inputs—scientists and engineers, R&D, patents, knowledge spillovers, ideas—drive economic growth. The key empirical findings are twofold: First, significant spillovers occur across countries, so that worldwide knowledge accumulation drives worldwide economic growth. Second, country-specific knowledge stocks, resulting from that country's own R&D, do matter importantly, and help explain each country's pattern of economic growth.

The hypothesis of knowledge-driven economic growth, while suggested by the logical sequence of earlier measurements and theoretical developments, remains controversial. For one, many observers consider it implausible that the poorest economies—those in sub-Saharan Africa, say, in the latter part of the twentieth century—are poor because they do not do enough scientific research. This, however, is an overly-literal interpretation of knowledge inputs. The ability of people in different economies to absorb and economically exploit scientific developments or even just best-practice production techniques obviously differ. The question then becomes one of incentives to use ideas—why do the very poorest economies not use frontier technologies to raise the productivity of factor inputs? The economics of creating and disseminating ideas, or *intellectual property* more broadly, are subtle; so too, but much less-studied, the economics of using ideas.

However, even in the richest economies, empirical evidence is ambiguous on knowledge-driven economic growth. US scientists and engineers employed in R&D grew five-fold from 200,000 in 1950 to over 1 million in 1990; the growth rate of US GDP failed to increase by anything remotely comparable over this period (Jones 1995).

7. *Inequality*

As measuring economic growth has continued to focus on progressively fewer observable variables, an implicit tension has correspondingly sharpened: if welfare is proxied only by average income, then income inequality—or more generally, the distribution of income across people—might be unobserved worsening to where an average seriously misleads as an indicator for the economic welfare of the population overall.

The Kuznets (1955) curve describes a key empirical regularity between growth and inequality: Cross-sectionally across economies, inequality is low when per capita incomes are low, increases at moderately higher per capita income levels, and finally falls again at the very highest levels of per capita income. Put

differently, the relation between inequality and levels of development is an inverted U. This early finding suggested to many researchers the possibility that, indeed, economic growth might disadvantage the very poor, due to increases in inequality.

More recent empirical analyses (Li et al. 1998) have shown, however, that as economies grow, the change in inequality is small: most of the measured variation in inequality is that *across* countries. Over time, inequality can change but much, much more slowly than economic growth varies.

8. Structural Drift

The more recent focus on measuring economic growth using just changes in per capita income has de-emphasized the evolution in industrial structure of economies as growth proceeds. By contrast, research such as that in Kuznets (1966) consistently documented such basic changes. Quah (1997b) has noted that such structural drift continues, away from manufacturing, towards high value-added intangible services.

Over the nineteenth century, as economies grew, their industrial composition shifted away from an emphasis on rural agriculture, and towards manufacturing and urbanization. Economic activity became progressively more markets-based, so that traditional informal, nonmarket work at home was replaced by formal employee arrangements. Education became more institutionalized; foreign commerce increased; and natural resources were relied on progressively less.

9. Where Next?

Measuring economic growth is an intricate and subtle exercise. It has a scope that can be large and unmanageable. In practice, the history of measuring economic growth has been one of intimate interplay with economic theorizing, leading from improvements in the accuracy and relevance of growth data, to hypotheses on the critical sources of economic growth, to explaining deep changes in the structure of national economies.

Total factor productivity, previously a measurement residual to be minimized, has since been reinterpreted, and has emerged as the key driver for economic growth. Ideas—scientific and engineering knowledge, R&D, expertise—constitute the prime candidates for explaining TFP, but the supporting empirical evidence remains weak.

Economic Growth: Theory

Growth theory was developed in the 1950s and 1960s, and some early growth models are collected in Stiglitz and Uzawa (1969). After a lull in the 1970s, the arrival of better data in the 1980s prompted a burst of activity during which economists refined their models so that they could better answer question like: Why did growth take off two hundred years ago and why in England and then the West, and why do Africa, Latin America, and most of Asia lag so far behind? And, what measures will improve things, especially in the poor countries? It is mostly the new crop of models that will be surveyed here.

1. *Growth*

What determines the rate at which our standard of living grows? Economic theory has settled on three broad categories:

(a) the progress of science and productive knowledge;
(b) the growth of individual skills; and
(c) incentives.

Incentives impinge on every economic decision, of course, including the decision to accumulate knowledge and skill. Still, (a) and (b) are listed separately because science and skills have evolved, in part, spontaneously or accidentally as people went about their business or pursued their curiosity.

1.1 *Science*

The world's wealth grows thanks mainly to the growth of knowledge. As with anything else, when adding to knowledge, there is strength in numbers. Even before the fifth century BC and the beginnings of science, early stone tools, farming, the domestication of animals, the wheel, and other inventions spread not by parallel and independent invention, but by imitation. If I was alone in the world, I would have to do my own inventing. But if there are two of us and you have invented the wheel already, I don't need to reinvent it, I can just copy your design. In copying you, moreover, I do not deprive you of your wheel—we both can make a wheel even though you alone came up with the idea. Thus, knowledge is a form of social capital that grows when anyone adds to it, and a bigger world will grow faster simply because more people will think up more new ideas. From the first stone tools to the steam-engine, electricity, and the computer, the mass of the people who derived some use from new ideas have had no part in coming up with them. So, if the overriding constraint on growth is scientific progress, a more populous world is one in which living standards will rise at a faster rate.

Arrow (1962) argued that we get new ideas when we use our old ideas, and that invention is incidental to normal production activity. He called this process 'learning by doing' and he assumed that the process operates in the machine-producing industry: The more machines we make, the better at it we get. The learning process operates at the level of the industry as a whole in that each producer learns from the experience of all other producers.

Because it relies exclusively on learning by doing, however, Arrow's growth mechanism contains only a small part of the engine that drives modern growth. After all, how many of our big inventions were made fortuitously at the workplace? Even when it is an accident—penicillin and the Post-it note, for example—a discovery usually occurs, instead, in the research lab. Moore's law, the observation that the speed of computers doubles every two years, is driven by research on the computer chip, and not by the mere fact that the world produces a lot of chips. Of course, if we made a greater number of chips, we would probably also be choosing to do more research to make them faster; the rate of production and the rate of growth of chip-quality would, in this sense, be positively related, but it would still be the research scientist and not the production worker whom we would have to thank for that quality growth.

Romer (1990) recognizes the importance of research. In his model, the more researchers we have, the faster we can invent, and the faster we grow. As in Arrow's model, then, here too a bigger economy grows faster. This positive effect that the scale of the world has on growth holds up well historically. Kremer (1993) finds that the rise in the world's population has, at least until around 1900, gone hand in hand with a rise in the rate of growth of income per head. The industrial revolution thus took place only when people came up with enough ideas—e.g., the steam engine—that then kicked off the industrial era.

1.2 *Skills*

Science cannot be all there is to growth and development. For one thing, large parts of the world

seem almost untouched by the many scientific inventions of the past century—many people are still illiterate and still live without electricity and running water. Moreover, the world is becoming more populous, and its cadre of scientists is growing by leaps and bounds, yet since the Second World War, income per head has grown more or less steadily at about 1.5 percent per year. This, too, Jones (1995) tells us, is not consistent with science-driven models which predict that a bigger world should grow faster as long as the well of ideas has not run dry. But there is not much evidence that the supply of new ideas is dwindling—on the contrary, computer-aided simulation has made research easier.

The constraining force on growth seems, instead, to now be the cost of adopting new ideas—the fact that to put new ideas into practice requires resources and skill. True, some technologies are so user friendly that their use demands no skill at all; to use a light bulb, for instance, all you have to do is screw it in. But you cannot do much with a computer if you have no education and no experience with computers. And, since the costs of technological adoption are likely to be proportional to the number of users, adoption is as costly in a big world as in a small one. Society inevitably spends much less on research and invention than its does on implementing what it has invented.

Even in the USA, research effort absorbs a mere twentieth of what is spent on educating and training the workforce. And in a developing country that imports all of its technology, the constraint on growth is purely the speed with which its citizens can enhance their skills and get the requisite machines. Lucas (1988) models such a world, a world in which countries share the same technology but not the skills of their workers. In his model, people augment their skills everywhere at the same rate, and if labor cannot move from one country to another, differences in skill-levels and, hence, in development persist indefinitely. Because education and work-experience differ so much among countries, his model explains differences of development among regions and countries. On the other hand, an Arrow–Romer type of model can explain the growth history of the world as a whole.

1.3 Incentives

We now come to incentives. Incentives to invent things, and to implement inventions, perhaps by acquiring the needed skills, or by investing in something else. It is impossible, for example, to explain European stagnation during the Dark Ages without mentioning the barriers that authority placed on intellectual progress. Baumol (1990) and Mokyr (1992) argue that, historically, material progress has depended less on the state of science and the supply of potential innovations that on whether people have had the incentive to implement them:

> The museum at Alexandria was the center of technological innovation in the Roman Empire. By the first century BC, that city knew of virtually every form of machine gearing that is used today, including a working steam engine. But these seemed to be used only to make what amounted to elaborate toys. The steam engine was used to open and close the doors of a temple (Baumol 1990 p. 910).

In other words, good ideas were plentiful two thousand years ago, but the environment for using them productively was unfriendly. The Roman Empire, Europe in the Dark Ages, China in the Middle Ages, and various nations today, have all been hostile to new ideas.

Hostility to technological change can show up in a variety of ways. Parente and Prescott (2000) show, for example, that established monopoly rights over an old technology can allow it to survive the threat of entry by firms wanting to use a better new one, and that this can have a big drag on development. The real challenge, however, is to understand how the policies are chosen. Krusell and Rios-Rull (1996) show that even a democracy may well choose to erect a barrier to technological change, because the majority of the voters may stand to lose from the adoption of a new technology as it would devalue their skills.

The incentive to save has also varied a lot historically and it varies now from one place to another because of policy differences. However, growth theory predicts only modest effects of frugality—a permanent rise in national saving has only a temporary effect on income growth. How long the stimulus lasts depends on how much physical capital matters in production. The evidence on whether frugality leads to even a temporary rise in growth is mixed (Barro and Sala-i-Martin 1995).

2. Inequality

Growth theory also aims to explain inequality. The world has gotten richer, but inequality in living standards is greater than ever. The poverty that most Africans, Asians, and Latin Americans now find themselves in isn't just relative—it isn't just that living standards in the poor world seem low because they are dwarfed by the great wealth in the USA, Western Europe, and Japan. On the contrary, living standards in the poor world are low by any historical standard. People there often face starvation and epidemic disease, and they do not live much better than their distant ancestors did. At the end of the twentieth century, US income per head is only six times what it was at the start of the century, yet it is 30 times as high incomes in Chad or Ethiopia. This means that people in Chad and Ethiopia are much worse off than Americans were a century ago. Why is the gap so wide today and why aren't the poor countries catching up?

2.1 The Causes of Inequality

Although one can always ask for a still prior cause, the following five are causes of inequality that seem, to the author, fundamental:

2.1.1 Geography. Some points on the globe are natural sites for economic activity—e.g., the estuary of a large river. Such advantages of location are compounded by economies of agglomeration such as the cost savings afforded by the sharing of cable lines, roads, railways, parks, parking lots, airports, etc. In cities, one can more easily share knowledge as well, and, as Lucas (2001) shows, this can explain why rents are so high in city centers. These economies of agglomeration draw economic activity to some points in geographical space and not others, and output per square foot of land varies a lot from one place to another.

2.1.2 Specialization. Economic efficiency dictates that people who start out as equals should sometimes end up different. One reason is specialization—we cannot all be doctors and university professors, someone must clean the streets, wait tables, etc. Lucas (1988, Sect. 5) explains how a natural advantage in specializing can backfire in the long run. He describes a world in which an initial comparative advantage in farming can cause a region to become a food producer; growth potential may, however, lie not in farming but in industrial goods, goods that people living in regions that do not have good farmland will turn to. Such people will eventually become expert manufacturers, whereas farmers will in the long run lag far behind because they specialized in a good with no growth potential.

2.1.3 External effects and market failure. Backwardness offers a society the option to 'free ride' on the efforts of the leaders. Eeckhout and Jovanovic (1998) argue that the option to imitate the ideas of others can lead to a stable situation in which some will prefer the role of a perpetual follower because this allows him to copy their inventions at a fraction of their original cost. Similarly, not everyone can always use cutting edge equipment. Jovanovic (1998) argues that firms in poor regions will use a technology and equipment that embodies it after the world's leaders are done with it and after it has become cheaper—an external benefit that the leader bestows on the follower indirectly, through prices. A country can be poor because its internal markets provide incorrect signals and intervention can then improve things. Murphy and co-workers (1989) model a situation where technological development is unprofitable for any single firm unless enough firms decide to go ahead and invest simultaneously—the 'big push' idea. Similar market failures occur in the models of Azariadis and Drazen (1990), and Galor and Zeira (1993).

2.1.4 Policies. The overriding cause of poverty in the world—and surely the one that dwarfs every other—is bad or corrupt government. The world's governments vary from democracies at the one end of the spectrum to totalitarian governments—right-wing, left-wing, and theocratic—at the other. As a result, people in different countries face vastly different policies, institutions, and laws and, hence, incentives. A policy that is bad for the average citizen may persist if it benefits or protects a minority that has somehow managed to gain power and influence. Corruption and bad policies repel foreign capital and cause domestic capital to flee. The burden falls on the average citizen who has to pay high taxes, tariffs, license fees, bribes, etc. It is hard to imagine, for example, how Burma can develop while its citizens are shut off from contact with the outside world.

3. How to Reduce World Inequality

The conflict between equality and efficiency, familiar in discussions of personal income differentials, is present at the world level as well. Some of the world's inequality is unavoidable and, indeed, simply signals that markets work. Nothing much can or should be done about inequality over geographical regions *per se*, or inequality that represents a reward for past sacrifices such as a high rate of national saving, investments in education, and so on.

An enlightened government can set taxes and subsidies so as to correct for market failures. Capitalism may seem to be at a loss in such circumstances, but perhaps not: in the late nineteenth century, a handful of bankers coordinated the actions of a big chunk of American business and the railroads in particular—with anticompetitive side effects to be sure—and seem to have engineered the big push that propelled the USA into industrial leadership. Later on, the US government started to regulate the banks and American business in general.

Whatever good governments may have done domestically, it is quite evident that on the international front government policies have done great harm. Governments have set policies that limit the flow of people, capital, and ideas. If so, the ultimate culprit for a country's poverty is the national boundary that keeps the citizens hostage to the policies of their rulers. Once this much is clear, several solutions to the problem of world inequality spring to mind at once.

3.1 Aid

One can help the poor world by taxing the rich countries, and, since the poor hold a majority at the

moment, a world democracy would, presumably, do just this. But under today's political system, we rely, instead, on voluntary contributions—aid—which, even when they occur, do not lead to improved government policies, and provide only a temporary fix.

Another solution is to bribe the offending politicians into give up power, or at least changing their policies. Such bribery has, in fact, been going on for decades, under the name of 'conditional lending'—a country gets a loan if its government agrees to adopt a pro-trade policy, etc. This is better than unconditional aid, but it, too, has not worked because the 'conditions' of loans cannot be enforced as funds are diverted from their intended uses and into private bank accounts.

3.2 Freer Migration of Labor

A better solution is to let people vote with their feet more freely than they can at present. As in Tiebout (1956) a country that adopts bad policies would find its constituents leaving for greener pastures. The lesson of the European Union is that when the boundaries come down, policies must harmonize and economic welfare converges. In spite of its size, the unified US labor market has far less income inequality than the world does, and immigrants manage to catch up to the US average after just a couple of generations. Right now, the rich countries limit immigration to a trickle so as to avoid a stampede that could prove disruptive, but immigration rates can probably be higher than they are today and still not endanger the fabric of life in the rich world. The rich countries are now unifying their markets (e.g., NAFTA and the EU), but markets in the poor world—the former Eastern Bloc, Africa, and Asia—are, for the time being, left out.

4. Where We Are Headed

If we can manage to avoid another global conflict, the political organization of our world will probably ease into a federal structure in which each nation will retain much of its sovereignty, but in which its government will set its policies in the face of free labor mobility. This Tiebout type of a world organization will produce far less inequality than we see today, as each government will have to adopt policies that make its jurisdiction an attractive place to work and live.

Without centralized intervention, however, the world's rate of growth would be less than optimal. Each local government would not, on its own accord, take enough trouble to save the ozone layer, the rainforests, and the endangered species, and, in particular, it would not do enough to promote activities that push the frontiers of knowledge out—research and development, education, etc.—or enough to protect intellectual property. A global market failure involving these activities will need correcting by policies set at the world-government level. A research subsidy will raise the world's growth rate, but it will also raise inequality because research will be done in the skill-abundant parts of the world, which also is where the highest-paid workers will live. The world federation that we are headed for will thus still face the perennial tension between efficiency and equity—it will still not be possible to have the largest pie and to distribute it equally. But the sort of inequality that we are now so used to will be a thing of the past.

Economic History

1. The Pioneer Period (1776–1914)

It is never easy to track the birthday of an intellectual discipline. Like many children of Clio, economic history was taking shape even before it was born. Politicians, literary men, philosophers, theologians, artists, and scientists have always used economic phenomena of the past to illustrate or elucidate their theories on private property, unequal distribution of wealth, interest and usury, the labor theory of value, and the just price. Merchants, lawyers, businessmen, and other 'practitioners' (as Paul Samuelson labeled these authors) in their writings frequently turned to the past, searching for similar experiences or comparative data that could be applied in their daily work. Later, the rapid growth of international commerce and the rise of powerful merchant states after the Middle Ages inspired the leading writers of the Mercantilist Era to develop some ideas on the history of trade, the balance of trade, monetary flows, exchange rates, and state intervention. Carlo M. Cipolla has quite rightly observed that if economics was preceded by 'protoeconomics' (the so-called political arithmetics of the seventeenth century), then the works of many mercantilist authors constitute a kind of 'protoeconomic history.'

Adam Smith (1723–1790) was the first modern scholar to use economic history as a tool of economic analysis. In his famous book *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776) he described and analyzed the working of Mercantilism in its historical perspective in order to criticize it and to propose a better, more efficient system, the free market system. Smith preferred inductive reasoning and therefore saw economic history as a kind of laboratory in which he could test his theoretical assertions. His work laid the foundations for classical economics. The most eminent representatives of this tradition, however, did not follow the path of the founding father and deprived the newborn theoretical economics of its historical dimension. David Ricardo (1772–1823), James Mill (1773–1836) and William Stanley Jevons (1835–1882) developed economics into an analytical instrument, based on mathematical abstraction and logical theory. Ricardo, whose works ironically would inspire so many economic historians, liked to present his ideas as abstract mechanisms without referring to historical events or even existing institutions. Most classical economists remained interested in institutional economics but concentrated their scholarly efforts more exclusively on constructing economic laws and concepts to explain the working of the market, leaving economic history aside. Notable exceptions, such as Alfred Marshall (1842–1924), used economic history rather in an eclectic way, presenting institutional structures and developments as clarifying illustrations of their theoretical analyses. As a result, by 1900 economists elaborated elegant and symmetric models of general equilibrium in which the historical presence of time was completely lacking.

From the 1840s onwards, a German Historical School emerged, reacting systematically against the deductive theoretical approach of the English classical economists by emphasizing that the inductive method, based upon economic history, should be the starting point of all theoretical reasoning. As the German economists were also interested, as were the English, in institutional economics, but, in contrast to the latter, wanted to add a specific historical dimension to it, they focused their research on describing and explaining the changes over time of institutions and systems. Inspired by their historical research they constructed theories of economic development in stages (the so-called 'Stufen' theories). Friedrich List (1789–1846) was a pioneer in this respect, subdividing the historical development of production into four subsequent stages of dominant economic activity: the stage of hunting and collecting, the agricultural stage, the agricultural–manufacturing stage, and, finally, the agricultural–manufacturing–trading stage. During the second half of the nineteenth century, his colleagues and followers, such as Bruno Hildebrand (1812–1878), Wilhelm Roscher (1817–1894), Karl Knies (1821–1898), Karl Bücher (1847–1930) and Gustav von Schmoller (1838–1917), elaborated the 'Stufen' idea still further. They introduced other 'economic criteria' as determining variables in the process of development, for example the way of exchanging goods (barter, money, and credit) or the distance between producer and consumer (closed domestic economy, city economy, national economy, and world economy).

The younger members of the German Historical School, active at the end of the century and at the beginning of the twentieth, remained faithful to the 'Stufen' hypothesis but widened the scope of their research. Werner Sombart (1863–1941), for example, added social and cultural variables to the economic ones, characterizing the stages more broadly as 'pre-capitalism,' 'early-capitalism,' 'high-capitalism,' 'late-capitalism,' and 'socialism.' Max Weber (1864–1920), being a sociologist as well as an economist, deepened his analysis by focusing on the links between Protestantism and the rise of capitalism in early modern Europe. Karl Marx (1818–1883), finally, combined the German Historical School's approach with the analytical methods of the classical economists when analyzing the transitions from a primitive society to economies based on slavery, later, on feudalism, which then evolved into capitalism, and from there would lead to socialism–communism.

Many young historians from neighboring countries, completing their studies in Germany, were fascinated by the themes of the German Historical School and integrated them into their own research. The Belgian historian Henri Pirenne (1862–1935), for example,

would analyze in depth the institutional development of industrial and commercial capitalism in Flanders and Brabant during the late medieval period. In Germany these scholars, who in their countries would soon hold university chairs themselves and have students of their own, became attracted by the study of economic phenomena in the past. They were also profoundly influenced by the new methodology that in the second half of the nineteenth century had found acceptance in the history departments of many German universities. This new methodology was the famous 'seminar' system that Leopold von Ranke had successfully introduced at the University of Berlin in 1833. Within these seminars, students had a direct contact with primary sources. Students were trained to solve problems of identification and interpretation by combining the techniques of a rapidly increasing variety of auxiliary sciences (paleography, chronology, numismatics, metrology, etc.) with the fine skills of internal and external source criticism. With the integration of this rigorous methodology, the economic historian started to distinguish himself from mainstream economists who showed less concern with the collection, use, and general validity of the data.

By studying economic–historical development in such a systematic way, the members and imitators of the German Historical School became, *de facto*, the founding fathers of economic history. Although the scholars contributed little to the further development of economic theory, their historical approach would remain influential during the whole twentieth century. Several economists of the twentieth century, in particu′ lar those studying modern economic development, such as Joseph Schumpeter (1883–1950), Arthur Lewis (1915–1990), and Walt W. Rostow (1916), were inspired by the ideas and methods of the School when elaborating their own theories.

During the second half of the nineteenth century, an English Historical School had also emerged, reacting in its turn against the too abstract approach of the classical economists. A first group of English scholars, under the influence of Positivism, became interested in historical statistics, proclaiming that serial history was a necessary tool for verifying or falsifying abstract economic theories and laws. At the middle of the century, Thomas Tooke (1774–1858) with his *History of Prices* had already paved the way, but it was James E. Thorold Rogers (1823–1890), publishing a large-scale history of agricultural prices in England between 1866 and 1902, who became the real pioneer of the group. A second group studied economic development in a historical perspective, similar to what the Germans had already done and were still doing. However, the English, as could be expected, were focusing in the first place on their own national experience. Arnold Toynbee (1852–1883), for example, studied the English Industrial Revolution and William J. Ashley (1860–1927), in the same vein, decided to undertake a survey of the whole English economic past. John H. Clapham (1873–1946), on the contrary, compared the development of France and Germany during the nineteenth century and also wrote a masterly survey of the economic history of Britain. Some American scholars can be considered belonging to the same group, because of their interest in economic institutions and their evolution over time: Thorstein Veblen (1857–1929), for example, focused on American capitalism during the second half of the nineteenth century.

The success of the German and the English Historical Schools was undoubtedly the most important but by no means the only factor that explained the promotion of economic history as an independent discipline within the historical sciences. Two other causes should be mentioned as well. First, the spread of Marxism, which became more and more influential among intellectuals and in academic circles, also favored the interest in economic history. The conviction that the production of goods and services determined political, social, cultural, and spiritual processes stimulated scholars to study themes such as the means of production, the relationships between social groups, landed property, the distribution of income and wealth, the evolution of wages, labor conditions, and other related topics. A second factor that certainly contributed to the development of the new discipline was the industrial revolution and the subsequent industrialization of great parts of the European continent in the second half of the nineteenth century. The new production methods, new techniques and, above all, the impressive economic growth in many countries created a favorable intellectual climate to study in a systematic manner the context and the conditions in which the new economic phenomena took shape.

Before World War I, economic history had developed into a healthy and respected discipline that confirmed its new status with an increasing number of students and with specific journals, university chairs and congresses. Of course, there were marked national differences. In Germany, hardly a surprise considering the importance of the Historical School in this country, a course on 'Wirtschaftsgeschichte' (economic history) was already announced at Heidelberg University in 1853, but never took place. The famous London School of Economics organized lectures on economic history right from the outset (1895), but the first university chair in the world would be installed in the United States. This happened at Harvard University where W. J. Ashley (1860–1927), a fellow of Oxford, accepted this position in 1892. The first chair for economic history in Britain was established at Manchester in 1910 and held by George Unwin (1870–1925). In the Netherlands, N. W. Posthumus (1880–1963) occupied the first chair of economic history, at Rotterdam, in 1913. The chair of economic history at the Sorbonne was created in 1927 and given to Henri Hauser (1866–1946). Meanwhile, economic history

already had its first journals. Again, Germany was the first country with a specific journal entirely devoted to economic and social history: this was the *Vierteljahrschrift für Sozial- und Wirtschaftsgeschichte* with its first issue in 1903. France followed with the *Revue d'histoire économique et sociale* in 1908. The famous *Annales d'histoire économique et sociale* that would strongly promote research in economic history only dates from 1929 and was therefore preceded by a.o. the *Economic History Review* (UK, 1927) and the *Journal of Economic and Business History* (USA, 1928). Except for the Italian *Rivista di Storia Economica* (1936) and the American *Journal of Economic History* (1941), all major journals date from the postwar period.

2. Between the Wars

In the inter-bellum period, economic history would expand further. However, it shifted its focus, towards economic problems arising from the war, such as war and postwar inflation, or towards problems becoming critical during the thirties, such as the chaos resulting from the world crisis. In the view of economic historians, the use of historical statistics could help substantially in deepening the analysis in both cases. An International Scientific Committee for Price History was created in 1931, on the initiative of Edwin F. Gay (Ashley's successor in 1902) and William H. Beveridge (1879–1963), to set in hand price studies in England, France, Germany, Austria, the Netherlands, the United States, Spain, and Poland. From 1934 onwards, several price studies concerning these countries were published. After World War II the Committee would not be active any more, but publications of historical price series still multiplied, not only in the countries mentioned above, but also in Belgium, Denmark, Russia, Italy, and many other countries.

In France, the construction of long-term price series aimed originally at verifying or falsifying quantitative monetary theory. François Simiand (1873–1935) was a pioneer in this respect, but he on extended his research to explore also the role of wages in the economy, basing it, once again, on historical statistics. Ernest Labrousse (1895–1989) took over Simiand's legacy, orienting it, however, towards the analysis of cyclical fluctuations in Europe during the *Ancien Régime*. His student, Jean Meuvret (1901–1971), integrated demography into the cyclical analysis, as did the German economic historian Wilhelm Abel (1904–85), in his famous study on agricultural fluctuations in central Europe since the late Middle Ages (*Agrarkrisen und Agrarkonjunktur*). Economists and economic historians, in particular in the Anglo-Saxon countries, were more interested in the study of the 'modern' business cycle. Scholars, such as Arthur F. Burns, W. C. Mitchell, Arthur D. Gayer, Joseph Schumpeter, Ernst Wagemann (with his Institut für Konjunkturforschung at Kiel), Walt W. Rostow and many others, published quantitative historical surveys of the British, American, German, and other business cycles during the nineteenth and twentieth centuries. The tradition would be continued after the World War II by R. C. O. Matthews, Philip A. Klein, Robert A. Gordon, and Erik Lundberg, among others.

Apart from the creation of the International Committee on Price History, two other important innovative initiatives were taken during the inter-bellum period, which, as was also the case with the history of prices, would continue to influence postwar economic historiography substantially. First to be mentioned is the ambitious project of publishing a multi-volume *Cambridge Economic History of Europe*, written by a large, international team of qualified scholars. The first volume appeared in 1941 and was followed by many others. The creation in 1929 of the French journal *Annales d'histoire économique et sociale* by Marc Bloch (1886–1944) and Lucien Febvre (1878–1956) was a second important event. The two founders had the ambition to encourage a new kind of social and economic history, focusing on daily material life, and to make this kind of history truly interdisciplinary by integrating the social sciences. In its first years, the *Annales* remained faithful to the quantitative-historical Simiand–Labrousse tradition, its themes of research being very diversified. Outside of France, the impact was still minimal. Gradually the journal moved more systematically in the direction of historical anthropology and global history in which the qualitative approach was gaining ground. When Fernand Braudel (1902–1985) took over control of the journal in the early 1950s, the Braudelian vision of a qualitative 'new global history' became the predominant idea of the *Annales* School. Its impact on European economic history now grew quickly, and with some time lag, the influence could also be felt in England, and in the United States as well.

3. The Heyday (1950–1980)

No doubt, the pre-war initiatives, mentioned above, were crucial for the postwar expansion of economic history to become one of the main disciplines of the economic and historical sciences, but several new initiatives taken after World War II by economists and economic historians alike were as decisive. During the immediate postwar decades, the Anglo-Saxons clearly dominated the scene of innovation. Keynesianism became the great fashion in economics, but it was soon complemented by theories of economic growth. The more dynamic approach of the growth theories stimulated the interest of the American economists, such as Moses Abramovitz and Colin Clark, in long-term economic-historical development. In 1950, during the Paris world conference of historical sciences, Clark incited the economic historians to join the economists in taking up research on long-term economic growth.

The appeal was heard. At the end of the 1950s, the American Economic History Association and the National Bureau of Economic Research were joining efforts in studying the evolution of income and wealth in the United States during the nineteenth century. During the first international economic history conference in Stockholm in 1960, themes on industrialization, human capital, and technology as factors of economic growth became predominant in the modern history sessions. Based on historical experience, concepts and theories on the 'take-off' (Walt W. Rostow), on the 'great spurt' (Alexander Gerschenkron), and on capital formation and capital utilization (Evsey Domar) were formulated.

Soon the scope of the discussions widened, leading, *inter alia*, the following new questions.

(a) Had planned economies a comparative advantage or disadvantage vis-à-vis the free-market economies in promoting economic growth?

(b) How to explain regional growth disparities in the West from a historical point of view?

(c) How to explain uneven economic development in the world?

(d) Finally, how to specify the links between growth and income?

The last question would be analyzed in depth by Nobel Prize winner, Simon Kuznets (1901–1985), who started to use reconstructed historical series of national accounts for that purpose, emphasizing that economic growth could only be studied scientifically if it was based on trustworthy macroeconomic statistics. Kuznets' appeal would generate a large-scale research movement of reconstructing national accounts. Phyllis Deane and W. A. Cole's successful book *British Economic Growth, 1688–1959*, first published in 1962, used such statistics, and encouraged the movement still further. Scholars in the United States, France, Germany, Belgium, the Netherlands, Spain, Switzerland, Sweden, Finland, and Portugal were launching projects to reconstruct historical national accounts of their own countries. In the United Kingdom, Charles Feinstein, Nicholas F. R. Crafts and others soon would start working on correcting and improving the estimates of Deane and Cole. Research on the links between growth and income, on the other hand, increased interest in the social aspects of growth and development. Marxist and non-Marxist economic historians in the following years would expand this field of research very much, emphasizing the importance of socio-institutional factors in the process of growth and development.

As far as the economic history of the *Ancien Régime* was concerned, the influence of Michael M. Postan (1899–1981) was prominent during the immediate postwar years. His long-term Malthusian demographical approach would become a model of interpretation for European economic development during the Middle Ages as well as during the early modern period. The Postan model would lead to the creation of the Cambridge Group for the History of Population and Social Structure under the directorship of Edward A. Wrigley, Roger S. Schofield and Peter Laslett. The French would join the English Malthusian demographical approach, although Michel Fleury, Louis Henry, Jean Meuvret and Pierre Goubert analyzed short- and medium-term demographical fluctuations in particular. For that purpose, Fleury and Henry would introduce the prosopographical method into historical demography and develop a method for family reconstitution based on the information in the parish registers. Emmanuel Le Roy Ladurie, on his part, would integrate, somewhat later, Postan's long-term model into his own research on French and European agricultural history in the early modern period.

During the same period the *Annales* School, now firmly dominated by Fernand Braudel, was extending its influence via the Ecole Pratique des Hautes Etudes de la Sorbonne, not only among the French economic historians, but also in the whole of Europe and soon beyond. From the late 1950s onwards until the early 1980s, the School would inspire a large part of economic historical research on:

(a) The late Middle Ages (for example Georges Duby and Jacques Le Goff).

(b) The early modern times (for example Pierre Jeannin, Jean-François Bergier, Pierre Deyon, Bernard H. Slicher van Bath, Jerzy Topolski, Pierre Chaunu, Felipe Ruiz Martin and Herman Van der Wee).

(c) The French Revolution period (for example François Furet and Denis Richet).

Originally, research was often focused on geographical studies of economic development, following the example of Braudel's pioneering study on the Mediterranean, but, in contrast to Braudel, most of these studies combined qualitative approach with quantitative analysis. Gradually, the qualitative 'global history' approach became predominant. Within this framework, under the influence of Marxist economic historians such as Immanuel Wallerstein, the socio-institutional aspects were getting increasingly more attention in the analysis of the agricultural, commercial, industrial, and financial development of Europe during the *Ancien Régime*.

While the methodological trend in the *Annales* School from the 1950s onwards was moving in the direction of a more qualitative approach to economic history, in the United States the trend during that period moved clearly in the opposite direction. In 1954, at Purdue University in Lafayette (Indiana), economists and economic historians already used primitive computers for the processing of statistical data. Three years later, during a conference of the American Economic History Association in 1957, Alfred H. Conrad and John R. Meyer launched the idea of a 'New Economic History,' aiming at integrating economic theory, quantitative methods, and his-

tory into one discipline. They illustrated the relevance of their idea by applying a microeconomic input–output method when analyzing the profitability of slavery in the American South during the nineteenth century. Nobel Prize winner Robert Fogel and Stanley L. Engerman later took up the theme. This led to a large-scale research project, its conclusions being published in *Time on the Cross*, 1974.

Some young economic historians received Conrad and Meijer's idea with enthusiasm. It gave birth to 'Cliometrics,' soon a well-established subdiscipline of American economic history. In the early 1960s, Robert P. Thomas had already applied the cost–benefit analysis method to explore the effects of the British Navigation Laws on the economy of the American colonies. More spectacular was the research undertaken by Robert Fogel and Albert Fishlow on the contribution of the railroads to American economic growth. To measure their impact, Fogel constructed a hypothetical world and used a counterfactual proposition: what would have happened to an economy if, contrary to the facts, one or more important features of that economy had never existed? Or applied to his research: if a railway system had not been introduced in the United States during the second half of the nineteenth century, could an alternative transport system, such as a system of existing and new canals, have generated as many social gains and dynamic effects as the railways did? The results of Fogel's cliometric test were fascinating: the difference would have been minimal since the 'social savings' would have represented less than 5 percent of national income in 1890. The cliometricians, now organized in an autonomous association, the Cliometric Society, and holding their own yearly meetings, began revisiting all major themes of American economic history, hoping that their methodology would lead to a complete reinterpretation of that history. Major themes studied by the cliometricians were:

(a) the economic reconstruction of the South after the Secession War;

(b) the impact of labor and migration on American growth at the end of the nineteenth century (cf. the model of Jeffrey Williamson, applying macroeconomic equilibrium theories);

(c) money markets and banking systems as factors of growth in the United States in the nineteenth century;

(d) the American Industrial Revolution;

(e) the Great Depression of the 1880s;

(f) the World Crisis of the 1930s; and

(g) the role of the residual factor in American productivity growth.

The methodological innovation, introduced by the American New Economic History, would spill over to the rest of the world, in particular to Canada, Australia, and some European countries, particularly the United Kingdom, Germany, France, and Sweden. Moreover, from 1970 onwards each world congress of the International Economic History Association would have a session on methodology, dominated from the beginning by the American cliometricians. However, the impact of the New Economic History outside the United States remained limited and certainly did not gain widespread recognition. F. Redlich, for example, described the counterfactual deduction in 1968 as 'fictitious history' and 'not history at all.' Was it because neoclassical theory was found to be less applicable to the European pre-industrial period than to the nineteenth-century American economy? Alternatively, were institutional factors, such as the separation between economists and economic historians who are normally active in the arts faculties, responsible for the emotional aversion towards the blend of history, economic theory, and econometrics? Even in the United States itself, dissidents soon emerged. Nobel Prize winner Douglass North, who had been applying the New Economic History methods in his studies on American growth, withdrew from cliometrics and reoriented his research to the institutional aspects of growth, using the historical experience to construct and verify his hypotheses. In his view, the protection of 'property rights' and the lowering of 'transactions costs' were the decisive factors in the history of economic growth. In the same vein as North's New Institutional History, but more innovating and with a much larger impact in and outside the United States, was Alfred D. Chandler Jr's founding of the 'New Business History.'

When creating the Center of Entrepreneurial Studies at Harvard in the late 1930s, Joseph Schumpeter and Arthur Cole had hoped to replace the hagiographical tradition of prewar and interwar business history by a more scientific approach. However, it was Chandler who, from the 1960s onwards, realized that ambition fully with his books *Strategy and Structure* (1962), *The Visible Hand* (1977), *Scale and Scope* (1990) and *Inventing the Electronic Century* (2001). Careful historical investigation, combined with in-depth institutional economic analysis, revealed the crucial role of business management and business organization in the successful rise of American capitalism. This was soon completed by studies on the rise and development of European and Japanese capitalism. Chandler's hypotheses and methodology became standard all over the world and are still so. Up to the present day, they are the main source of inspiration to the 'New Business History.' A last new economic history group, emerging after World War II, should be mentioned: the 'New Urban History,' integrating sociological, geographical, and economic theories and quantitative methods into the historical analysis of towns and urbanization. In 1962, an interdisciplinary Urban History Group was established, followed three years later by the 'Commission Internationale pour l'histoire des villes' directed by scholars such as Henri Aubin, Hektor Ammann, and Philippe Wolff. However, the Anglo-Saxon historians, once again,

were pioneers in the field, H. J. Dyos, Jan de Vries, Paul M. Hohenberg, Lynn Hollen Lees, Peter Clark and many others.

Postwar economic history was also influenced by the social effects and economic problems generated by the spectacular expansion of the Western economy during the postwar period. Indeed, research was much inspired by the increasing number of publications, such as the report of the Club of Rome (1972), revealing the problems caused by economic growth, or by movements protesting against the negative effects of growth in the West, such as the activist policies, formulated by the UNCTAD in the course of the 1960s and 1970s. Responding to these reactions, new themes emerged in the programs of the world conferences of the International Association of Economic History. These included, from the 1970s onwards, in particular: 'Natural Resources and Economic Development in History,' 'Oil in the World Economy,' 'Environment and Urbanization in History,' 'Ecological History,' 'The Economic History of Leisure and Recreation,' 'Typology of Colonial Economic Development,' 'The Economic History of the Third World,' 'Loans, Debts and Economic Development in the Nineteenth and Twentieth Centuries,' *inter alia*. The Cold War and its ideological conflicts would lead to a number of studies comparing the efficiency of the two economic systems in an historical perspective.

4. *Shifts and Changes (1980–2000)*

From the 1980s onwards, new shifts occurred in the postwar development of economic history. The first important shift originated from two new circumstances: economic history, as an autonomous discipline, crossed its traditional European and North American borders and acquired strong positions also in many Latin American and Asian countries, Australia and New Zealand and, to a lesser extent, the African continent. Moreover, globalization of the world economy, from the 1980s onwards, clearly accelerated its pace. The effect of both factors on economic history was twofold. Firstly, seen in relative terms, research was re-orienting itself increasingly in the direction of contemporary history, at the expense of medieval and early modern history. Secondly, a geographical re-orientation took place: research on non-European topics, particularly concerning Asian and Latin American countries and again in relative terms, expanded remarkably.

Another important shift was thematic. Economic development was increasingly considered a part of a much more complex reality, in which mental, cultural, and socio-institutional variables were as crucial as the economic ones for understanding and explaining it. This changing view on the place of economic history in the scientific approach to reality generated many new fields of research. Themes such as 'Ethnic Minority Groups and their Impact on Economic Development,' 'Guilds, Economy, and Society,' 'Women and the Practice of Credit,' 'Film: an Industry on the Crossroads of Economics, Politics, and Arts,' 'Consumption, Lifestyle, and the Standard of Living,' 'Gender and Labor Migration,' 'Courts as Economic Institutions,' etc., were very successful during the conferences.

A third important shift was the increasing interest of economic historians iicro-historical research: an interest in the experience of the individual ('*l'expérience vécue*'), an interest in the uniqueness of historical events ('*das Einmalige*'), an interest in the narrative and the descriptive at the expense of a more analytical history, and looking for recurrent patterns in historical development. Many economic historians preferred the meticulous approach of specific, atypical, idiosyncratic cases to broad but abstract theories or structural change analysis. Themes such as 'Cities at War,' 'The Economy of Private Households,' 'Education and Career of Business Managers,' 'Potatoes and Famines in mid-nineteenth Century Europe,' were significant for the rise of this kind of micro-history.

At the end of the twentieth century, economic history had expanded and diversified its research so much that it would be difficult to summarize its development in a nutshell. In a simplifying view, one could distinguish two main tendencies. A first one could be considered a modern version of the traditional socioeconomic historiography, presenting in a descriptive way the results of new research in the archives, particularly concerning aspects of daily life not yet studied much; for example, sexuality, criminality, discrimination against women, food, clothing, games, leisure, fashion, the environment, and domestic services. The second tendency, and by far the more important, aims at integrating elements of economic theory and methodology into historical analysis. This second tendency is split into two subgroups. A first group of scholars, now a minority within the discipline and mostly members of departments of economics in Europe and Northern America remains faithful to the American 'New Economic History.' However, by organizing themselves in a Cliometric Society (and partly also in the European Economic Association), they isolate themselves somewhat from the rest of the discipline. The second subgroup, the more numerous one, also uses economic theory and statistics. These scholars, however, do not formulate their hypotheses in the formal way as the cliometricians do. They prefer not to verify or falsify their hypotheses with econometric techniques as used by the cliometricians, and they include demographical, cultural, anthropological, mental, and institutional variables in their economic analysis.

Economic History, Quantitative: United States

Economic history is a hybrid discipline, concerned with recording and interpreting the economic events of the past. It should not be confused with the 'history of economic thought', the study of the intellectual history of economics as a discipline. Although the practice of compiling historical statistics goes back to the nineteenth century, if not earlier, the term 'quantitative economic history' refers to a self-conscious movement dating from the 1950s and 1960s, also known as the 'new economic history' or 'cliometrics', which set out to revolutionize the field by incorporating explicit economic analysis and quantitative methods into the study of past economic performance. In subsequent decades, practitioners have extended and redirected this agenda, by drawing upon diverse branches of economic theory to analyze the historical evolution of market and nonmarket institutions, technology, preferences, and other elements commonly taken as exogenous by mainstream economics. The resulting literature stresses the influence of historical experience on ensuing economic patterns, an intertemporal linkage known as 'path dependence.' This article traces the main tendencies within quantitative economic history since the mid-nineteenth century, though it is by no means a comprehensive survey.

1. The Origins of Economic History

Recognition of economic history as a distinct subject is traceable to the consolidation of British neoclassical economics at the turn of the twentieth century, under the towering influence of Alfred Marshall and his Cambridge successor, A. C. Pigou. The analytical core of the dominant school held that economies tended towards 'long-run equilibria' that were independent of initial conditions (although Marshall himself was by no means dogmatic about this doctrine in practice). Having lost out in the struggle for the disciplinary identity of economics itself, the 'historical school of economics' emerged at that time as a reaction against the neoclassical paradigm and the laissez-faire program with which it was associated. Drawing ideas and inspiration from the 'German historical school' of Gustav Schmoller and Friedrich List, early historical economists emphasized the virtues of inductive studies

as contrasted with the deductive or axiomatic approach. Methodological preferences were reinforced by their affinity with 'neomercantilist' policies, including promotion of national industries, social reforms, and the regulation of enterprise. The organization of economic history as an academic field in Britain was prompted as much by a search for refuge as by the emergence of a distinctive research agenda. William James Ashley, first president of the Economic History Society at its founding in 1926, lamented: 'the theoretical economists are ready to keep us quiet by giving us a little undisputed garden plot of our own; and we humble historians are so thankful for a little undisputed territory that we are inclined to leave the economists to their own devices' (quoted in Koot (1987, p. 7).

Similar tensions persisted in the United States, but the separation between economics and economic history was slower to develop. The inductive approach of the 'institutional' school associated with such figures as John R. Commons and Thorstein Veblen was dominant within labor economics and in other parts of the parent discipline, displaced only by the rise of Keynesian economics in the 1930s and 1940s. In the same era, 'progressive' historians such as Frederick Jackson Turner and Charles Beard put economic conflict and change at the center of their 'economic interpretation of history.' Although neither of these groups would be recognized today as economic historians, they did provide outlets for those dissatisfied with the deductive methodological approach. Thus, the (American) Economic History Association was founded only in 1940, and lacked the ideological identity and fervor of its British counterpart.

Between the 1930s and the 1950s, a few exceptional figures such as Carter Goodrich could have a significant impact on both economics and economic history. But the majority of EHA members were historians, whose works made little use of economics and had little influence on the thinking of economists. The same could be said for entrepreneurial history, which flourished for a time at the Harvard Center for Entrepreneurial History, under the leadership of Arthur H. Cole. In retrospect, many of the detailed descriptive studies from this era have lasting value, perhaps best reflected in monographic series entitled *The Economic History of the United States*, published between 1945 and 1962. But as economics became increasingly analytical and quantitative, economic history at the time appeared to be something of a stodgy backwater.

2. *The Rise of Quantitative Economic History*

The two decades after World War II saw a significant expansion of economic history within economics, much of it quantitative in character. This was mainly an American development, and largely (although by no means exclusively) focused on the economic history of the United States. The immediate stimulus was the new postwar interest in economic growth. Following the lead of Simon Kuznets, father of the national income accounts, a new generation of economic historians sought to extend the statistical record of the American economy back to its origins early in the nineteenth century, drawing upon the rich potential of the decennial census and making ingenious use of other diverse archival sources. The major results of these efforts were presented in landmark volumes published by the National Bureau of Economic Research (Parker 1960, Brady 1966). Estimates developed by Robert Gallman suggested that growth in the United States had reached modern rates by the middle of the nineteenth century, and should not therefore be seen as the consequence of political upheavals at the time of the Civil War (as hypothesized by Charles Beard). Adapting Gallman's estimates into a regional framework, Richard Easterlin showed that the slave economy of the South also shared in the growth acceleration, though per capita income in that region was some 25–35 percent below the national average.

A second and more controversial thrust was the deployment of tightly constructed deductive models to address specific hypotheses about this statistical record. The advent of this 'cliometric' approach is often dated from the publication in 1958 of 'The Economics of Slavery in the Ante-Bellum South' by Alfred H. Conrad and John R. Meyer (reprinted in Fogel and Engerman 1972). In this article, Conrad and Meyer set out to settle a perennial debate over the 'profitability of slavery,' by treating slaves as a form of capital and posing the question as an explicit rate-of-return-on-investment calculation. Their conclusion was that investments in slaves were just as profitable as alternatives such as railroad bonds. Other studies tackled broader questions about the origins of growth and the impact of government policies. Douglass North (1961) interpreted the acceleration after 1815 as a dynamic response to the potential of expanding markets, primarily through interregional specialization and trade. Fogel (1964) and Fishlow (1965) generated comprehensive estimates of the contribution of railroad construction to national economic growth, by posing explicit historical counterfactual circumstances within an analytical framework. Both the methods and the conclusions of these provocative works were the subjects of intense academic debate for many years after publication.

One strand of this discussion represented a reaction by 'old economic historians' against attempts to subsume historical complexity into what they regarded as hypothetical and unrealistic abstractions. A second strand, however, came from within the economics discipline, reflecting dissatisfaction with the limitations of deductive models as the working tools for structuring research in economic history. In 1972, two collaborative efforts summarized the major results of

the New Economic History (Davis et al. 1972, Fogel and Engerman 1972). The overall yield was impressive, an upgrading of the quantitative base of historical knowledge, and a richer appreciation of the presence of market forces in history. Signs of growing unrest were also evident, however, and in retrospect these volumes have the character of closing chapters in a methodological cycle that had largely run its course by that year. This interpretation may be elaborated by a review of two major research areas.

2.1 The Economic Analysis of Technological Change

Economic historians of all stripes had no difficulty agreeing that a central component of economic growth was technological change, broadly defined to include organizational change and the diffusion of existing techniques, in addition to the more famous 'inventions' that have long been standard fare in textbooks. But the dominant tradition in economic analysis has long been accustomed to regarding technological change as exogenous, not part of the domain of a discipline specialized in analysis of the *implications* of such change for the economy. One might reasonably hope therefore that quantitative economic history would be able to say more about the timing, pace, and direction of particular historical technologies, if not to uncover historical laws of motion for technological change in general.

In the context of American economic history, these questions were brought to the fore by a landmark book published in 1962 by the British economic historian H. J. Habakkuk, *American and British Technology in the Nineteenth Century*. Habakkuk hypothesized that American industry pioneered the development of capital-intensive methods as compared with Great Britain, in response to the scarcity of labor relative to land in the United States. This apparently straightforward thesis subsequently proved exceptionally difficult to capture analytically or to confirm empirically. An extended stream of contributions by Peter Temin, Robert Fogel, Nathan Rosenberg, Paul David, Alexander Field, John James, David Hounshell, and Kenneth Sokoloff, among others, succeeded in elaborating many characteristic features of the technologies emerging as an American national specialty in the nineteenth century. In comparison with the British, American techniques were not only capital intensive, they were also resource using, faster paced, skill saving (at least for traditional craft skills), and adapted for long production runs of standardized final products. As useful as this accumulated descriptive knowledge may be, the question remains: What sort of economic analysis would allow the quantitative economic historian to come to terms with the origins and nature of this list of characteristics?

The long-running debate over the 'labor scarcity paradox' brought out most clearly that so long as the analytical framework was defined by standard neoclassical analysis, the subject matter would be transmuted into the language of 'relative factor abundance' and substitution, terms derived from the assumption that a 'production function' is given by technical factors. Within this constraint, the economic historian was powerfully driven towards the exercise of rationalizing observed historical choices. The impulse was observed most clearly when the choice-of-technique question was transported to the other side of the Atlantic, and cliometricians assessed the popular indictment of British entrepreneurs for their reluctance to adopt American methods. Virtually without exception, the conclusion was that British choices were entirely appropriate responses to prevailing factor prices and market conditions. Although this verdict may be valid, the uniformity of results understandably gave rise to doubts about whether it constituted an authentic inference from historical evidence, or merely an assumption imposed on the evidence by the methodology.

This approach to technology proved unduly constraining for a number of reasons. As subsequent research has demonstrated, the 'factor endowments' taken to be fundamental determinants were themselves not really exogenous, being subject to influence not just by policy but by technology as it unfolded through time. For example, the large inflows of unskilled immigrants to the United States are most readily explained by the growth of industrial jobs adapted to that type of labor, a result in other words of an attribute of the new technology. Even the apparent American abundance of mineral resources, coal, iron ore, copper, petroleum, and many more, turned out on closer inspection to have been more the *result* of technological development and capital investment than its cause (David and Wright 1997). To a significant extent, minerals constituted a 'knowledge industry' even in nineteenth-century America. As such, its development was part of the broader evolution of national technology, or learning. Evidently, the development of an analytical *interpretation* of such phenomena required a new set of tools.

2.2 The Slavery Debate

No topic tested the limits of deductive economic history more fully than slavery. Conrad and Meyer (1958) set out to measure the 'profitability of slavery,' and thereby to test the thesis that slavery would have died out for economic reasons, in the absence of the Civil War. Among others, Yasuba pointed out that because slave imports were ended by legislation in 1807, a more appropriate measure of the private economic viability of slavery was the level of 'capitalized rent' embedded in the price of slaves 'high and rising on the eve of secession, according to Yasuba's estimates (1961, reprinted in Fogel and Engerman 1972). The 'profitability' finding is best understood as

an indication that slave prices were approximately correct as capitalizations of the expected stream of future returns, which may be taken as evidence that 'commercial' motivations were dominant in the operation of the slave system. The achievement of consensus around this broad proposition, however, redirected attention towards more difficult and challenging historical issues, including the political and ideological dimensions of slavery, and the longer-term consequences of slavery as a mode of social organization.

This was the setting for the appearance in 1974 of *Time on the Cross*: *The Economics of American Negro Slavery*, by Robert W. Fogel and Stanley L. Engerman. Fogel and Engerman (1974) went well beyond the previous consensus, presenting total-factor-productivity calculations implying that slave plantations were as much as 35 percent more efficient than free family farms. Not only was the slave system highly productive, but the book went on to assert that material and social conditions among slaves were far better than historians had recognized. Using such indicators as diet, clothing, housing, life expectancy, and family stability, the authors compared the lives of slaves favorably with those of immigrant workers in the northern states. It is hardly surprising that these incendiary claims generated an explosive reaction.

The full range of the ensuing debate cannot be recounted here. As with the response to Conrad and Meyer, one part of the reaction represented traditional historians objecting to the coldhearted nature of the calculations, and the apparently cavalier treatment of the feelings and behavior of the slaves themselves. Another component, however, came from within the profession. Detailed scrutiny of the statistical evidence ultimately led to significant modifications of the relatively benign picture of slavery, most notably in health conditions and family life. It would be a mistake to characterize the alternative views on these issues along simplified dimensions, such as the economist's inclination to presume that historical operators are rational and market oriented. For example, subsequent research suggests that slaves were bought and sold much more frequently than Fogel and Engerman believed, often separating not only husbands from wives, but even mothers from their children (Tadman 1989). On this count, *Time on the Cross* if anything actually understated the ruthlessly profit-driven character of American slavery.

Debates over empirical evidence are a normal feature of any social science. The dimension of the slavery debate with more enduring import for quantitative economic history concerned the *conceptual* underpinnings of the analysis of slavery, specifically the emphasis on calculations of efficiency in production. Because plantations produced multiple outputs with heterogeneous inputs, it emerged that the efficiency results were highly sensitive to relative values assigned to cash crops (such as cotton) vs. food crops (such as corn), and to factors of production (such as farm land of varying quality, or male vs. female slave labor). The debate may be followed in David et al. (1976), and a subsequent exchange in the *American Economic Review*. The deeper issue was whether it was possible, or perhaps whether it was meaningful and historically informative, to separate the calculation of productive efficiency as a technical matter, from the task of locating slavery as a system of property rights in historical time and space. From this perspective, property rights in slaves may be seen to have had a decisive influence on the course of economic development in the southern states, not only on human capital investment, but on geographic patterns of settlement, transportation infrastructure, and urbanization.

In several respects, the course of the slavery debate highlights the new directions in which quantitative economic history has moved since the 1970s: study of the evolution of institutions, incorporation of political, social and ideological dimensions into economic history, and identification of lasting effects of earlier historical phases on later events. These evolutionary tendencies are well illustrated by the careers of two of the founding figures of the New Economic History.

2.3 The Nobel Prizes

In October 1993, the Royal Swedish Academy of Sciences awarded the Nobel Prize in Economics to Robert William Fogel and Douglass North, noting that 'they were pioneers in the branch of economic history that has been called the "new economic history" or "cliometrics".' In essence, the two economic historians were cited for helping to launch the quantitative economic history movement. In what must be a rarity among Nobel laureates, at the time of the award both men had moved some distance from the approach for which they were honored.

North's early work in American economic history was both quantitative and analytical. He developed new statistical time series on the US balance of payments, and on the long-term decline in transportation costs. North (1961) drew upon concepts from theories of location and comparative advantage to interpret the quantitative record of regional performance. His first venture outside American economic history (North and Thomas 1973) was consistent with this focus on market incentives, emphasizing the role of limited government and secure property rights in explaining the comparative historical performance of nations. By 1981, North's range of explanatory material had broadened considerably, to include *ideology* (including norms and belief systems) as a primary element in comprehending the persistence of order in the world, essential for the effective functioning of markets. North (1990) cast the net even more widely, pointing to the critical economic role of

institutions, defined broadly to include all 'the humanly devised constraints that shape human interaction.' One part of North's personal evolution derived from an expansion of his research horizons, generating an awareness that the effectively functioning market society found in the United States is exceptional in a global context. In many ways, however, North's later work marked a return to themes and interests that had occupied economic historians for generations prior to the cliometric revolution.

Fogel's intellectual trajectory was rather different. Fogel (1964) and Fogel and Engerman (1974) built sweeping historical interpretations on the results of complex and ambitious quantitative procedures. After 15 years of further research on slavery, Fogel (1989) devoted more than half of his next book to an account of the rise of antislavery opinion in Europe and the United States, emphasizing the force of religious, political and ideological factors. Fogel wrote: 'I began [this research], like many other cliometricians, not because I was especially interested in the history of American slavery, but because an accident of scholarship made the economics of slavery a major testing ground for the application of cliometric methods. Once drawn into the subject, however, it was the substance of the issues that maintained my interest. Although my principal professional expertise was, and is, in the areas of economics and demography, I found myself led down a road that forced me to grapple with the work of colleagues in cultural, political, and religious history' (p. 13). To be sure, Fogel's later work on historical nutrition and physiology remains solidly quantitative in its essential scope and methods, but his interest in subjective and ideological aspects of history has persisted. It seems safe to say that by 1990, cliometrics had outgrown the historical naivete of its youth.

3. *New Directions in Quantitative Economic History*

In recent decades, quantitative economic history has become steadily more diverse and expansive in both its methods and its subject matter. Some of these tendencies reflect growing diversity in the composition of the cliometric intellectual community, which at the start of the twenty-first century includes many more women and scholars of differing nationality than was true in the 1960s and 1970s. Once almost exclusively an American phenomenon, cliometrics is now also pursued by small but thriving groups in Europe, Latin America, Canada, and elsewhere. Another force for diversification is the expanding range of topics now covered within economics itself, including ecology, law, family, gender, and race, all of which have strong historical dimensions. Since the full range of scholarship cannot be surveyed here, a brief account will be given of two general areas in which historical aspects of economic life seem especially compelling.

3.1 *Increasing Returns, Path Dependence, and Technology*

In 1984, William N. Parker organized a session at the annual meetings of the American Economic Association, on the role of economic history in graduate economics education, the proceedings of which were published in Parker (1986). Among the many spirited defenses of history by such economists as Kenneth Arrow, Robert Solow, Peter Temin, D. N. McCloskey, and others, one contribution proved to be particularly lasting as an illustration of path dependence: Paul A. David's account of the rise and persistence of the QWERTY typewriter keyboard. Although many evidently superior layouts were designed and marketed during the typewriter's post-Civil War diffusion, the standard became 'locked in' to QWERTY by the 1890s, illustrating the power of historical accident and 'network externalities' to shape the course of technological history. Drawing in part upon theoretical work by W. B. Arthur, David argued that because choices were interdependent 'since manufacturers, employers and typists all wanted to use the same keyboard that others were using' the system never shook off the circumstances of its origin, despite the suboptimality of the equilibrium choice.

The QWERTY story has emerged as a popular metaphor for the proposition that 'history matters' in economic life. The typewriter example and its meaning have been hotly controversial, and its appropriate scope and significance have by no means been settled. But its relevance for quantitative economic history has been to confirm the historical character of the economics of technology. As noted above, the study of technological change had never fit comfortably within the New Economic History. Nathan Rosenberg, a member of the first cliometric generation whose research on technological change diverged from the reigning paradigm, had long been engaged in *Exploring the Black Box* (1994), i.e., trying to understand technological change as it would be seen by technical people. In *The Lever of Riches*, Joel Mokyr (1990) elaborates the many context-specific factors that have served to encourage, retard, or channel technological progress. The broad conclusion of this research is not to deny the proposition that technology is responsive to incentives, quite the contrary, but to argue that these responses are sharply conditioned by the historical and institutional setting, including the cognitive structures through which knowledge is codified and transmitted.

3.2 *Institutions and Economic History*

In the heyday of the New Economic History, 'institutional' was used as a term of dismissal if not

contempt, to refer to old-fashioned descriptive work that lacked theoretical foundations. As the field has evolved, 'institutional' economic history has again become respectable, although in new and more analytical clothing. Indeed, many argue that the study of institutions is at the heart of the case for historical economics. Whereas the parent discipline specializes in the functioning of markets, the domain of the economic historian is the institutional foundations that allow markets to function as they do. These subject areas have become more pressing in the light of the varied experiences of formerly planned economies in their transition to market systems.

In its first phase, the so-called New Institutional Economics identified 'institutions' with the property rights, rules and regulations defined and enforced by the state, interpreting institutional change as responses to exogenous shifts in population, technology, or the scope of markets. Beginning with North and Thomas (1973), numerous historical studies examined the implications of these institutions for economic performance, broadly confirming the general proposition that securely enforced property rights are favorable for economic efficiency and growth. Deviations from this pattern are attributed commonly to the influence of special interest groups, with transactions costs standing as barriers to more efficient systems.

Dissatisfaction with this framework gradually began to build, with the realization that the simple cause-and-effect scenarios took as exogenous much of what was most historically interesting. An essential next step was to broaden the concept of institutions, to include not only explicit and state-enforced rules, but also informal and uncodified constraints on behavior. To say that institutions are 'constraints', on individual behavior, however, does not mean that they must be seen as having been 'imposed' on the society in question. By analogy with market prices, institutions may be viewed as exogenous to the individuals, yet endogenous to the society as a whole. When the underlying conception has been broadened in this way, a natural theoretical framework is provided by game theory, depicting institutions as self-enforcing equilibria arrived at through the interaction of historical players. Avner Greif (1994, 1997) has been a pioneer in the application of game theory to historical institutions, using these tools to analyze the bases for the rise of long-distance trade in late medieval Europe.

Greif argues that appropriate historical uses of game theory must be context specific. In many strategic situations there are multiple equilibria, implying that outcomes are not uniquely predetermined. Constructing a context-specific model that captures the essence of a situation requires microlevel historical study, to provide the specific details of the model, and to facilitate the task of confronting predictions with historical evidence. Thus, the process has a large inductive component, drawing on cultural, political, and social factors and also upon economic motivations. Although this specificity may seem to limit the potential scope for application, Greif (1994) was able to use these tools to extract sweeping implications from the contrasting cultural beliefs of the Maghribi traders (who used collective social instruments to discipline the behavior of their members) and the Genoese (from whose rule-based system the Western legal traditions descend). Because institutional evolution typically entails individual behaviors that are interdependent, such models often exhibit increasing returns and path dependence, similar to patterns observed in technological systems subject to network externalities.

In many ways, modern quantitative economic history has returned to the roots of economic history, in its renewed appreciation of institutions and culture. But there is a major difference. Whereas earlier versions of 'institutional economics' tended to be 'anti-theory', stressing the sheer weight of historical reality as contrasted with abstract rationalizations, the newer forms of institutional economic history are firmly lodged within the parent discipline, drawing on frontier developments in economic theory as well as quantitative methods. The ability to deploy more eclectic theoretical tools allows cliometricians to extend their reach into new subject areas, that previously were preserves of purely descriptive work. Examples include historical studies of financial markets and financial institutions, which now use theories of information and principle-agent relationships; and the history of labor markets and institutions, where the roles of norms, prejudices and family institutions are too prominent to be ignored.

An illustration of this progression is Claudia Goldin's book on the economic history of American women (Goldin 1990). The early chapters developed new quantitative evidence on relative wages and labor force participation rates of American women, interpreting two major upward surges (1820–1850 and 1890–1930) in terms of supply and demand forces, driven largely by technology. By the latter half of the book, however, Goldin found that 'institutional' aspects of the record were inescapable, from the 'marriage bars' of the 1920s and 1930s 'which forced women to resign from jobs upon marriage' to patterns of socialization and peer influence, detectable in behavioral shifts from cohort to cohort across the twentieth century. Significantly, these insights were not advanced as a rejection of quantitative economics, but as an enrichment of the analytical and quantitative tools within the core disciplines of economics and history.

Reflecting on her own evolution, Goldin wrote: 'I began this study more as an economist but have ended with a fuller appreciation of how the distant past affects the present, how norms and expectations impede change, how discrimination can survive even in highly competitive markets, and how slow genuine change can be.' Much of Goldin's personal account

could be applied to economic history as a whole, in its increasingly self-conscious identity, not as a branch of applied economics, but as a distinctive approach to the study of economic life in general.

Economic Panel Data

1. Introduction

A panel (or longitudinal or temporal cross-sectional) data set is one which follows a number of individuals over time, and thus provides multiple observations on each individual in the sample. Prominent examples are the University of Michigan's Panel Study of Income Dynamics, the National Longitudinal Surveys of Labor Market Experience, and National Longitudinal Survey of Youth in the US and the Social Economic Panel, the Expenditure Index Panel of Intromart, and the Labor Mobility Survey from the Organization of Strategic Labor Market Research in the Netherlands. These labor market data samples contain thousands of individuals and variables followed over a number of years. In addition, panel data are also common in marketing studies, biomedical sciences, and financial market analysis, etc.

The increasing popularity of panel studies is partly a consequence of more cost effective ways of developing and maintaining panels (e.g., Mátyás and Sevestre 1996). More importantly, panel data offers many more possibilities for exploring analytical and substantive issues than purely cross-sectional or time series data. However, new data sources also raise new issues. This entry reviews the major advantages and limitations of panel data in the context of specific econometric methodologies. Section 2 gives an overview of the major advantages of the informational content of panel data. Section 3 reviews typical specifications for the linear models. Section 4 discusses issues of nonlinear models. Section 5 considers the implication of sample attrition and sample selection. Conclusions are in Sect. 6.

2. Advantages of Panel Data

Panel data offer several advantages over a single cross-sectional or time series data. For instance, the use of panel data may:

2.1 Improve the Accuracy of Parameter Estimates

Most statistical estimators converge to the true parameters at the speed of the square root of the degrees of freedom. Models for panel data are based on many more equivalent observations than a cross-sectional or time series data, and hence can yield more accurate parameter estimates.

2.2 Lessen the Problem of Multicollinearity

Many economic variables tend to move collinearly over time. The shortage of degrees of freedom and severe multicollinearity problems found in time series data often frustrate investigators who wish to determine the individual influences of each explanatory variable. Panel data may lessen the degree of multicollinearity in the time dimension by appealing to inter-individual differences.

2.3 Allow the Specification of More Complicated Behavioral Hypotheses

A single time series is not useful for discriminating hypotheses which depend on different social–demographic factors. Cross-sectional data cannot be used to model dynamics. Cross-sectional data can show what proportion of the labor force is unemployed or describe the distribution of wage rates at a point in time. Aggregate time series data can provide indications of general trends and cyclical patterns in unemployment, wages, income, and so forth. But neither cross-sectional nor time series data can provide information regarding how many of those unemployed in one month can find employment in the next month. Neither can the data provide information on whether the tendency of welfare families to stay on welfare occurs simply because the same factors that cause them to be on welfare keep them there or whether, in addition, the experience of receiving welfare has some addictive effect that induces continuing welfare dependence. For instance, suppose that a cross-sectional sample of married women is found to have an average yearly labor force participation rate of 50 percent. At one extreme this might be interpreted as implying that each woman in a homogenous population has a 50 percent chance of being in the labor force in any given year while at the other extreme it might imply that 50 percent of the women in a heterogenous population always work and 50 percent never work. In the first case, each woman would be expected to spend half of her married life in the labor force, and half out of the labor force, and job turnover would be expected to be frequent, with an average job duration of two years. In the second case, there is no turnover, and current information about work status is a perfect predictor of future work status. Panel data, by providing sequential observations for a number of individuals, offer the possibility to distinguish inter-individual differences from intra-individual dynamics and to construct a proper recursive structure to study the effects of changes by comparing the differences before and after the changes (e.g., Heckman 1981).

2.4 Provide Possibilities for Reducing Estimation Bias

A standard assumption in statistical specification is that the random error term representing the effect of omitted variables is orthogonal to the included explanatory variables. Otherwise, the estimates are subject to omitted variable bias when these correlations are not explicitly allowed for. Panel data provide means to eliminate or reduce the omitted variable bias through various data transformations when the correlations between included explanatory variables and omitted variables follow certain specific patterns (e.g., Baltagi 1995), Chamberlain 1984, Hsiao (1986). For instance, suppose that

$$y_{it} = \underset{\sim}{\beta}' \underset{\sim}{x}_{it} + \underset{\sim}{\gamma}' \underset{\sim}{z}_i + u_{it}, \quad i = 1, \ldots, N, \; t = 1, \ldots, T \quad (1)$$

where the explanatory variables $\underset{\sim}{x}_{it}$, vary across individuals i, and over time t, and the explanatory variables $\underset{\sim}{z}_i$, vary across i, but stay constant over t, such as sex status, social-demographic background variables, etc. the error term u is assumed to be uncorrelated with $\underset{\sim}{x}$ or $\underset{\sim}{z}$. The least squares regression of y on x and z will yield consistent estimates of $\underset{\sim}{\beta}$ and $\underset{\sim}{\gamma}$. But if $\underset{\sim}{z}$ are correlated with $\underset{\sim}{x}$, yet are unobservable, the least squares regression of y on $\underset{\sim}{x}$ will yield bias estimates of $\underset{\sim}{\beta}$. However, in the pairwise difference,

$$y_{it} - y_{i,\,t-1} = \underset{\sim}{\beta}' (\underset{\sim}{x}_{it} - x_{i,\,t-1}) + (u_{it} - u_{i,\,t-1}) \quad (2)$$

the explanatory variables $\underset{\sim}{z}_i$ longer enter. Regressing $(y_{it} - y_{i,\,t-1})$ on $(\underset{\sim}{x}_{it} - x_{i,\,t-1})$ can yield consistent estimates of $\underset{\sim}{\beta}$.

MaCurdy's (1981) life-cycle labor supply of prime-age males under certainty is an example of this approach. Under certain simplifying assumptions, MaCurdy shows that a worker's labor supply function can be written as in Eqn. (1), where y is the logarithm of hours worked, $\underset{\sim}{x}$ is the logarithm of the real wage rate, and z is the logarithm of the worker's (unobserved) marginal utility of initial wealth, which, as a summary measure of worker's lifetime wages and property income, is assumed to stay constant through time but to vary across individuals. Given the economic problem, not only is $\underset{\sim}{x}_{it}$ correlated with z_i, but

every economic variable that could act as an instrument for $\underset{\sim}{x}_{it}$ (such as education) is also correlated with $\underset{\sim}{z}_i$. Another example is the 'conditional convergence' of the growth rate. The growth rate regression model typically includes investment ratio, initial income, and measures of policy outcomes like school enrolment and the black market exchange rate premium as regressors; however, an important component, the initial level of a country's technical efficiency z_{i0}, is not observed. Since a country that is less efficient is also more likely to have lower investment rate or school enrolment, one can easily imagine that z_{i0} is correlated with the included regressors. Neither model can be estimated with cross-sectional data, but both can be estimated using Eqn. (2) if panel data are available.

2.5 Reduce Computational Complexities

The use of panel data is often perceived as increasing computational complexities because the data contain both cross-sectional and time series dimensions. In many cases, however, panel data become a distinct advantage computationally. For instance, if one were to estimate a dynamic model using time series data with censored or missing observations in between, the computation can be horrendous because of the need to compute multiple integrals when the conditional variables are censored. To see this, consider the model

$$y^*_{it} = \gamma y^*_{i,\,t-1} + u_{it} \tag{3}$$

where u_{it} is independent normal with mean 0 and variance σ^2_u. Conditional on $y^*_{i,\,t-1}$, y^*_{it} is normally distributed with mean $\gamma y^*_{i,\,t-1}$ and variance σ_u. If instead of observing y^*_{it}, however, one observes the censored counterpart y_{it}, where $y_{it} = y^*_{it}$ if $y^*_{it} > 0$ and $y_{it} = 0$ if $y^*_{it} \leqslant 0$, then the conditional distribution of y_{it} given $y_{i,\,t-1} = 0$ becomes

$$\int_{-\infty}^{0} (2\pi\sigma_n^2)^{-1/2} \exp\left\{-\frac{1}{2\sigma_u^2}(y_{it} - \gamma y^*_{i,\,t-1})^2\right\} f(y^*_{i,\,t-1})\,\mathrm{d}y^*_{i,\,t-1} \tag{4}$$

where $f(y^*_{i,\,t-1})$ denotes the marginal density of $(y^*_{i,\,t-1})$. When there are a number of censored observations over time, Eqn. (4) becomes relatively complicated to solve. With panel data, one can often adopt models that ignore observations that are censored and focus on those individuals for which successive observations are greater than zero to simplify the computation (e.g., Arellano et al. 1999).

2.6 Simplify Statistical Inference

In estimating a dynamic model using time series, the limiting distribution depends on whether the system is stable, integrated, or explosive. With panel data, as long as the cross-sectional dimension approaches infinity, the limiting distribution of the coefficients of lagged dependent variables is typically normal no matter what the time series properties of a process are. The limiting distribution remains the same whether the time series dimension is fixed (Anderson and Hsiao 1982) or approaches infinity (Levin and Lin 1993, Phillips and Moon 1999).

2.7 Obtain More Accurate Prediction of Individual Outcomes

When people's behavior is similar in nature, namely, they satisfy De Finnetti's (1964) exchangeability assumption, each individual's behavior can be better understood by observing the behavior of other similar individuals, hence can yield more accurate predictions of individual outcomes by pooling the data (e.g., Hsiao et al. 1989).

3. Linear Models

Panel data, by its nature, put emphasis on individual outcomes (see *Longitudinal Data*). Different individuals may be subject to different influences. In explaining individual behavior, one may extend the list of factors *ad infinitum*. It is neither feasible nor desirable to include all the factors affecting the outcome of all different individuals in a model specification. It is typical to leave out those factors that are believed to have insignificant impact or are peculiar to a given individual. However, when important factors peculiar to a given individual are left out, the individual outcomes conditional on the included explanatory variables may not be viewed as random draws from a common population, so standard statistical procedures may mislead. Therefore, one focus of panel data modeling is to determine whether heterogeneities exist among cross-sectional units over time that are not captured by the included explanatory variables, say $\underset{\sim}{x}$. If they are, one needs to control the impact of such unobserved heterogeneity in order to draw inference about the population characteristics.

If the unobserved heterogeneity among N cross-sectional units over T time periods can not be completely captured by $\underset{\sim}{x}$, there are two primary ways to model it. One is to incorporate it into the error term. The other is to let the coefficients vary across individuals and over time. For instance, if the heterogeneity among individual units is due to some individual specific and time invariant variables, $\underset{\sim}{z}_i$, that affect y_{it} linearly, then the scatter diagram between y and x conditional on $\underset{\sim}{z}$ may look like Fig. 1 in which the broken-line circles represent the point scatter for an individual over time, and the broken straightline represents the mean relationship for the ith individual

Figure 1
Scatter diagram of y and x conditional on z

conditional on $\underset{\sim}{z}_i$. The dark line indicates a simple pooled estimates of a model

$$y_{it} = \alpha + \underset{\sim}{\beta}' \underset{\sim}{x}_{it} + v_{it} \tag{5}$$

where v represents the effects of omitted factors and the subscript, it, indicates observations of the ith cross-sectional unit at tth time period. It is obvious that the simple pooled estimates give a very misleading relationship between y and $\underset{\sim}{x}$. For data of the form of Fig. 1 it is necessary to specify a variable intercept model of the form

$$y_{it} = \alpha_i + \underset{\sim}{\beta}' \underset{\sim}{x}_{it} + u_{it} \tag{6}$$

where α_i represents the effect of unobserved $\underset{\sim}{z}_i$.

A more complicated structure to capture the unobserved heterogeneity lets

$$y_{it} = \alpha_{it} + \underset{\sim}{\beta}'_{it} \underset{\sim}{x}_{it} + u_{it} \tag{7}$$

but this specification is not very useful for drawing inferences about the population because the coefficients are individual and time specific. Neither can it be estimated because there are more unknown parameters than degrees of freedom. In order to take advantage of panel data, a structure has to be introduced that allows the possibility to draw inference about the population characteristics while controlling for the impact of unobserved heterogeneity.

Suppose that the unobserved heterogeneity is due to some individual specific but time invariant variables, then an unrestricted linear model will have the form

$$y_{it} = \alpha_i + \underset{\sim}{\beta}'_i \underset{\sim}{x}_{it} + u_{it} \tag{8}$$

If T is large, Eqn. (8) can be estimated by Zellner's (1962) seemingly unrelated regression method; however, most panel data contains a large number of individuals observed over a short period of time. When T is fixed, increasing N increases the number of unknown parameters, α_i and $\underset{\sim}{\beta}_i$, $i = 1, \ldots, N$. This is the classical incidental parameter problem. The presence of the incidental parameters violates the usual regularity conditions for the consistency of the maximum likelihood estimator (MLE). Neither is Eqn. 3.4 very useful to draw inference about the population because each individual has a different behavioral pattern. Assuming Eqn. (8) is tantamount to assuming that the cross-sectional observations come from heterogeneous population. In this case there is no particularly appealing reason to pool the data.

To draw inference about the population, one must impose restrictions on Eqn. (7) or Eqn. (8). For instance, if the slope coefficients are the same, $\beta_i = \beta$, for all i as in Eqn. (6), the incidental parameter α_i can be eliminated by pairwise differencing of individual time series observations as in Eqn. 2 or by taking deviations from the individual time series mean:

$$(y_{it} - \bar{y}_i) = \underset{\sim}{\beta}(\underset{\sim}{x}_{it} - \bar{\underset{\sim}{x}}_i) + (u_{it} - \bar{u}_i) \tag{9}$$

where $\bar{y}_i = (1/T)\sum_{t=1}^{T} y_{it}$, $\bar{\underset{\sim}{x}}_i = (1/T)\sum_{t=1}^{T} \underset{\sim}{x}_{it}$ and $\bar{u}_i = (1/T)\sum_{t=1}^{T} u_{it}$. Applying the least squares method to Eqn. (9) yields the so-called covariance or within estimator of β. The covariance estimator of β is consistent when either N or T or both N and T tend to infinity (e.g., Hsiao 1986).

Alternatively, one can assume that $\underset{\sim}{\beta}_i$ and/or α_i in Eqn. (8) are randomly distributed with common mean $(\underset{\sim}{\beta}', \alpha)$ and covariance matrix Δ or assume that some of the coefficients are randomly distributed with common mean and constant covariance matrix, while others are fixed and different. Decomposing $\underset{\sim}{x}_{it}$ into $(\underset{\sim}{w}_{it}, \underset{\sim}{z}_{it})$, various formulations can be represented as placing different restrictions on the unconstrained model Eqn. (8):

$$\underset{\sim}{y} = W\underset{\sim}{\delta} + Z\underset{\sim}{\gamma} + \underset{\sim}{u} \tag{10}$$

where $\underset{\sim}{y} = (\underset{\sim}{y}'_1, \ldots, \underset{\sim}{y}'_N)$, $W = \mathrm{diag}(W_i)$, $Z = \mathrm{diag}(Z_i)$, $\underset{\sim}{y}_i = (\underset{\sim}{y}_{i1}, \ldots, \underset{\sim}{y}_{iT})'$, W_i and Z_i are $T \times k_1$ and $T \times k_2$ submatrices of T observed values of $(1, \underset{\sim}{x}'_{it})$, $\underset{\sim}{\delta} = (\underset{\sim}{\delta}'_1, \ldots, \underset{\sim}{\delta}'_N)'$ and $\underset{\sim}{\gamma} = (\underset{\sim}{\gamma}'_1, \ldots, \underset{\sim}{\gamma}'_N)$ are $Nk_1 \times 1$ and $Nk_2 \times 1$ vectors of $(\underset{\sim}{\alpha}'_i, \underset{\sim}{\beta}'_i)$, $i = 1, \ldots, N$. Suppose that the coefficients of $\underset{\sim}{w}_{it}$ are subject to stochastic constraints:

$$\underset{\sim}{\delta} = A_1 \bar{\underset{\sim}{\delta}} + \underset{\sim}{\varepsilon} \tag{11}$$

where A_1 is an $Nk_1 \times m$ matrix with known elements, $\bar{\underset{\sim}{\delta}}$ is an $m \times 1$ vector of constants, $\underset{\sim}{\varepsilon}$ is random with mean $\underset{\sim}{0}$, covariance matrix C and $E\underset{\sim}{\varepsilon}W' = \underset{\sim}{0}$, $E\underset{\sim}{\varepsilon}Z' = \underset{\sim}{0}$.

Suppose that the coefficients of z_{it} are subject to deterministic constraints:

$$\gamma = A_2\bar{\gamma} \tag{12}$$

where A_2 is an $Nk_2 \times q$ matrix with known elements, and $\bar{\gamma}$ is a $q \times 1$ vector of constants.

The model given by Eqns. (10)–(12) is of a mixed form: the coefficients of W_i are assumed to be random and the coefficients of Z_i are assumed fixed, (e.g., Hsiao and Tahmiscioglu 1997). When $W = 0$, $A_2 = \varrho_N \otimes I_{k_2}$, we have a common model for all NT observations, where ϱ_N denotes an $N \times 1$ vector of ones, I_p denotes a $p \times p$ identity matrix and $\otimes$ denotes Kronecker product. When $W = 0$ and $A_2 = I_{Nk_2}$, model Eqn. (8) results. when $W = 0$, $Z_i = (\varrho_T, X_i)$, $A_2 = (I_N \otimes \iota_{k_2} : \varrho_N \otimes I^*_{k_2-1})$, ι_{k_2} is a $k_2 \times 1$ vector of $(1, 0, \ldots, 0)'$, and $I^*_{k_2-1}$ is a $k_2 \times (k_2 - 1)$ matrix of $\binom{0'}{I_{k_2-1}}$, model Eqn. (6) (e.g., Mundlak 1978) is a special case. When $X_i = \varrho_T$, $A_1 = \varrho_N$, $\Delta = \sigma^2_\delta I_N$, the model is the error components model (e.g., Balestra and Nerlove 1966). Finally when $Z = 0$, $A_1 = \varrho_N \otimes I_{k_1}$, $C = I_N \otimes \Delta$, we have the random coefficients model (e.g., Swamy 1970).

Substituting Eqns. (11) and (12) into Eqn. (10) yields

$$y = WA_1\bar{\delta} + ZA_2\bar{\gamma} + v \tag{13}$$

where $v = W\varrho + u$, $Evv' = WCW' + \mathrm{Cov}(u)$. Model Eqn. (13) can be estimated by the generalized least squares (GLS) method. The individual coefficients δ can be estimated by a Bayes estimator which is a weighted average of the GLS estimator of $\bar{\delta}$ and the individual least squares estimator of δ (e.g., Hsiao et al. 1993).

The issue of whether to treat β_i and/or α_i or a subvector of them as fixed or random is an issue of whether conditional on x, one can treat the outcome variable as a random draw from a common population. If it is, then the individual and time subscript, it, can be viewed as purely a labeling device and *a priori*, $E(y_{it} \mid x) = E(y_{js} \mid x)$. This is what de Finnetti (1964) called the exchangeability criterion and it is more appropriate to treat β_i and α_i as random. If the distribution of β_i is not independent of x_{it} or conditional on x, individual outcomes are more appropriately viewed as generated from a heterogenous population, then the subscript, *it*, contains specific information about which heterogenous population the particular observation is generated from. It is therefore more appropriate to treat β_i and/or α_i as fixed parameters. Unfortunately, *a priori*, very little knowledge is available about which coefficients should be treated as random and different, and which coefficients should be treated as fixed and different. Hsiao and Sun (2000) have argued that the random versus fixed effects specification should be viewed as a model selection issue and suggest a Bayesian approach for model selection. Their limited Monte Carlo studies appear to favor the Schwarz (1978) information criterion to select the appropriate specifications. The Schwarz criterion works here because although from a Bayesian perspective there is no real difference between random effects and fixed effects since every parameter has a distribution, there is a difference between how the prior is formulated under the random and fixed effects formulation. Under the di Finnetti exchangeability criterion, β_i is distributed independently of x_i with a common mean $\bar{\beta}$ and constant variance C (e.g., Eqn. (11)). On the other hand, under the fixed effects formulation, each β_i is supposed to be independently distributed with a different mean and different variance because of the correlation between β_i and x_i or because each β_i is a random draw from heterogenous population.

4. Nonlinear Models

The estimation of a nonlinear panel data model involving individual specific effects is particularly difficult to handle. If the individual specific effects are treated as random, just as in the linear model, we no longer have the incidental parameters problem; however, the estimation of the structural parameters requires integrating out the individual specific effects which can be nontrivial. For instance, consider a binary choice model in which y_{it} takes the value of either 1 or 0. Suppose that the probability of observing $y_{it} = 1$, $P(y_{it} = 1 \mid x_{it})$, is given by $F(\beta' x_{it} + \alpha_i)$, where the individual specific effects α_i is randomly distributed with density function $f(\alpha_i)$. Even though conditional on α_i, y_{it} may be independently distributed over i and t, unconditionally, y_{it} is correlated over T. The log-likelihood function is of the form

$$\log L = \sum_{i=1}^{N} \log \int \prod_{t=1}^{T} F(\beta' x_{it} + \alpha)^{y_{it}} [1 - F(\beta' x_{it} + \alpha)]^{1-y_{it}} f(\alpha)\, \mathrm{d}\alpha \tag{14}$$

Equation (14) is a function of finite number of parameters and maximizing it under weak regularity conditions will yield consistent estimator of β (and the parameters characterizing the density function of α_i). However, maximizing (Eqn. (14)) is often computationally infeasible. For instance, if $F(\cdot)$ takes the form of an integrated standard normal distribution function, then a probit model results. Conditional on α_i it involves a univariate integration. Maximizing (Eqn. (14)) but without the conditioning involves the evaluation of T-dimensional integrals (e.g., Hsiao 1986).

On the other hand, suppose that the individual specific effects are fixed. First, in general there is no simple transformation of the data as in Eqns. (2) or (9) to eliminate the individual specific effects (incidental parameters). Second, the estimation of the individual specific parameters and the structural (or common) parameters are not independent of each other. When a panel contains a large number of individuals but only over a short time period, the error in the estimation of the individual specific coefficients propagates into the estimating of the structural parameters, and hence leads to inconsistency of the structural parameter estimation (e.g., Anderson and Hsiao 1982).

Many approaches have been suggested for estimating fixed effects nonlinear panel data models. One approach is by conditioning the likelihood function on the minimum sufficient statistics for the incidental parameters to eliminate the individual specific parameters (Andersen 1973, Chamberlain 1980). For instance, consider a binary logit model (e.g., see *China: Sociocultural Aspects*) in which the probability of $y_{it} = 1$ is given by

$$P(y_{it} = 1) = \frac{e^{\alpha_i + \beta' x_{it}}}{1 + e^{\alpha_i + \beta' x_{it}}} \tag{15}$$

For ease of exposition, assume that $T = 2$. It can be shown that when $x_{i1} = 0$ and $x_{i2} = 1$ the MLE of β converges to 2β as $N \to \infty$, which is not consistent (e.g., Hsiao 1986). However, one may condition the likelihood function on the minimal sufficient statistic for α_i . We note that those individuals i satisfying $y_{i1} + y_{i2} = 2$ or $y_{i1} + y_{i2} = 0$ provide no information about β since the former leads to $\hat{\alpha}_i = \infty$ and the latter leads to $\hat{\alpha}_i = -\infty$. Hence one can concentrate on those individuals with $y_{i1} + y_{i2} = 1$. For those individuals satisfying $y_{i1} + y_{i2} = 1$, let $d_i = 1$ if $y_{i1} = 0$ and $y_{i2} = 1$ and $d_i = 0$ if $y_{i1} = 1$ and $y_{i2} = 0$. Then

$$\text{Prob}(d_i = 1 \mid y_{i1} + y_{i2} = 1) = \frac{e^{\beta'(x_{i2} - x_{i1})}}{1 + e^{\beta'(x_{i2} - x_{i1})}} \tag{16}$$

Eqn. (16) no longer contains the individual effects α_i and is of the form of a standard logit model. Therefore, maximizing the conditional log-likelihood function on the subset of individuals with $y_{i1} + y_{i2} = 1$ is consistent and asymptotically normally distributed.

Alternatively, one can transform the data to eliminate the individual effects if the nonlinear model has a latent linear structure, and then apply semiparametric methods. For instance, consider a binary choice model with $y_{it} = 1$ if $y_{it}^* > 0$ and $y_{it} = 0$ if $y_{it}^* \leqslant 0$, where

$$y_{it}^* = \alpha_i + \beta' x_{it} + u_{it} \tag{17}$$

If u_{it} follows a logistic distribution, a logit model results; if u_{it} is normally distributed, a probit model results. Then

$$\begin{aligned} \beta' x_{it} > \beta' x_{i,t-1} &\Leftrightarrow E(y_{it} \mid x_{it}) > E(y_{i,t-1} \mid x_{i,t-1}) \\ \beta' x_{it} = \beta' x_{i,t-1} &\Leftrightarrow E(y_{it} \mid x_{it}) = E(y_{i,t-1} \mid x_{i,t-1}) \\ \beta' x_{it} < \beta' x_{i,t-1} &\Leftrightarrow E(y_{it} \mid x_{it}) < E(y_{i,t-1} \mid x_{i,t-1}) \end{aligned} \tag{18}$$

Rewriting (Eqn. (18)) into the equivalent first difference form, Manski (1975) proposes a maximum score estimator (MS) that maximizes the sample average function

$$\frac{1}{N} \sum_{i=1}^{N} \sum_{t=2}^{T} sgn[(x_{it} - x_{i,t-1})'\beta](y_{it} - y_{i,t-1}) \tag{19}$$

where $sgn[(x_{it} - x_{i,t-1})'\beta] = 1$ if $(x_{it} - x_{i,t-1})'\beta \geqslant 0$ and $sgn[(x_{it} - x_{i,t-1})'\beta] = -1$ if $(x_{it} - x_{i,t-1})\beta < 0$. The MS estimator is consistent but is not root-n consistent, where $n = N(T-1)$. Its rate of convergence is $n^{1/3}$ and $n^{1/3}(\hat{\beta} - \beta)$ converges to a random variable that maximizes a certain Gaussian process.

A third approach is to find an orthogonal reparameterization of the fixed effects for each individual, say α_i, to a new fixed effects, say g_i, which are independent of the structural parameters in the information matrix sense. The g_i are then integrated out of the likelihood with respect to an uninformative, uniform prior distribution which is independent of the prior distribution of the structural parameters. Lancaster (2001) uses a two period duration model to show that the marginal posterior density of the structural parameter possesses a mode which consistently estimates the true parameter.

While all these methods are quite ingenious, unfortunately, none can claim general applicability. For instance, the conditional maximum likelihood cannot work for the probit model because there are no minimal sufficient statistics for the incidental parameters that are independent of the structural parameters. The data transformation approach cannot work if the model does not have a latent linear structure. The orthogonal reparameterization approach works only for particular models. In short, the methodology for and consistency of nonlinear panel data estimators must be established case by case.

5. *Sample Attrition and Sample Selection*

Missing observations occur frequently in panel data. If individuals are missing randomly, most estimation methods for the balanced panel can be extended in a straightforward manner to the unbalanced panel (e.g., Hsiao 1986). For instance, suppose that

$$d_{it} y_{it} = d_{it}[\alpha_i + \beta' x_{it} + u_{it}] \tag{20}$$

where d_{it} is an observable scalar indicator variable which denotes whether information about (y_{it}, x_{it}') for

the ith individual at tth time period is available or not. The indicator variable d_{it} is assumed to depend on a q-dimensional variables, w_{it}, individual specific effects λ_i and an unobservable error term η_{it},

$$d_{it} = I(\lambda_i + \underset{\sim}{\delta}' \underset{\sim}{w}_{it} + \eta_{it} > 0) \tag{21}$$

where $I(\cdot)$ is the indicator function that takes the value of 1 if $\lambda_i + \underset{\sim}{\delta}' \underset{\sim}{w}_{it} + \eta_{it} > 0$ and 0 otherwise. In other words, the indicator variable d_{it} determines whether $(y_{it}, \underset{\sim}{x}_{it})$) in Eqn. (20) is observed or not.

Without sample selectivity, that is $d_{it} = 1$ for all i and t, Eqn. (20) is the standard variable intercept (or fixed effects) model for panel data discussed in Sect. 2. With sample selection and if η_{it} and u_{it} are correlated, $E(u_{it} \mid \underset{\sim}{x}_{it}, d_{it} = 1) \neq 0$. Let $\theta(\cdot)$ denote the conditional expectation of u_{it} conditional on $d_{it} = 1$ and $\underset{\sim}{x}_{it}$, then Eqn. (20) can be written as

$$y_{it} = \alpha_i + \underset{\sim}{\beta}' \underset{\sim}{x}_{it} + \theta(\lambda_i + \underset{\sim}{\delta}' \underset{\sim}{w}_{it}) + \varepsilon_{it} \tag{22}$$

where $E(\varepsilon_{it} \mid \underset{\sim}{x}_{it}, d_{it} = 1) = 0$. The form of the selection function is derived from the joint distribution of u and η. For instance, if u and η are bivariate normal, then we have the Heckman (1979) sample selection model with

$$\theta_{it} = \theta(\lambda_i + \underset{\sim}{\delta}' \underset{\sim}{w}_{it}) = \sigma_{w\eta} \frac{\phi(\lambda_i + \underset{\sim}{\delta}' \underset{\sim}{w}_{it})}{\Phi(\lambda_i + \underset{\sim}{\delta}' \underset{\sim}{w}_{it})} \tag{23}$$

where $\sigma_{w\eta}$ denotes the covariance between w and η, $\phi(\cdot)$ and $\Phi(\cdot)$ are integrated standard normal density and distribution, respectively and the variance of η is normalized to be 1. Therefore, in the presence of sample attrition or selection, regressing y_{it} on $\underset{\sim}{x}_{it}$ using only the observed information is invalidated by two problems—first, the presence of the unobserved effects α_i, and second, the 'selection bias' arising from the fact that $E(u_{it} \mid \underset{\sim}{x}_{it}, d_{it} = 1) = \theta(\lambda_i + \underset{\sim}{\delta} \underset{\sim}{w}_{it})$.

When individual effects are random and the joint distribution function of $(u, \eta, \gamma_i, \lambda_i)$ is known, both maximum likelihood and two or multi-step estimators can be derived (e.g., Heckman 1979). The resulting estimators are consistent and asymptotically normally distributed. The speed of convergence is proportional to the square root of the sample size. However, if the joint distribution of u and η is mis-specified, then even without the presence of α_i, both the maximum likelihood and Heckman (1979) two step estimators are inconsistent. This sensitivity of parameter estimate to the exact specification of the error distribution has motivated interest in semiparametric methods.

The individual specific effects in Eqn. (20) are easily eliminated by time differencing for those individuals that are observed for two time periods t and s, i.e., those individuals i satisfying $d_{it} = d_{is} = 1$. However, the sample selectivity factors are not eliminated by time differencing. Ahn and Powell (1993) note that if θ is a sufficiently 'smooth' function, and $\hat{\underset{\sim}{\delta}}$ is a consistent estimator of $\underset{\sim}{\delta}$, observations for which the difference $(\underset{\sim}{w}_{it} - \underset{\sim}{w}_{is})' \hat{\underset{\sim}{\delta}}$ is close to zero should have $\theta_{it} - \theta_{is} \simeq 0$. They propose a two-step procedure. In the first step, consistent semiparametric estimates of the coefficients of the 'selection' equation are obtained. The result is used to obtain estimates of the 'single index, $\underset{\sim}{w}_{it}\hat{\underset{\sim}{\delta}}$,' variables characterizing the selectivity bias in the index equation. The second step of the approach estimates the parameters of the equation of interest by a weighted instrumental variables regression of pairwise differences in dependent variables in the sample on the corresponding differences in explanatory variables: the weights put more emphasis on pairs with $\underset{\sim}{w}_{it}'\hat{\underset{\sim}{\delta}} \simeq \underset{\sim}{w}_{i,t-1}'\hat{\underset{\sim}{\delta}}$.

Kyriazidou (1997) generalizes this concept and proposes to estimate the fixed effects sample selection models in two steps: in the first step, estimate $\underset{\sim}{\delta}$ by either Chamberlain (1980) conditional maximum likelihood approach or the Manski (1975) maximum score method. In the second step, the estimated $\hat{\underset{\sim}{\delta}}$ is used to estimate γ, based on pairs of observations for which $d_{it} = d_{is} = 1$ and for which $(\underset{\sim}{w}_{it} - \underset{\sim}{w}_{is})' \hat{\underset{\sim}{\delta}}$ is 'close' to zero. This last requirement is operationalized by weighting each pair of observations with a weight that depends inversely on the magnitude of $(\underset{\sim}{w}_{it} - \underset{\sim}{w}_{is})' \hat{\underset{\sim}{\delta}}$, so that pairs with larger differences in the selection effects receive less weight in the estimation. The Kyriazidou (1997) estimator takes the form

$$\hat{\underset{\sim}{\beta}} = \left\{ \sum_{i=1}^{N} \sum_{1 \leqslant s < t \leqslant T_i} (\underset{\sim}{x}_{it} - \underset{\sim}{x}_{is})(\underset{\sim}{x}_{it} - \underset{\sim}{x}_{is})' K \left[\frac{(\underset{\sim}{w}_{it} - \underset{\sim}{w}_{is})' \hat{\underset{\sim}{\delta}}}{h_N} \right] d_{it} d_{is} \right\}^{-1} \left\{ \sum_{i=1}^{N} \sum_{1 \leqslant s < t < T_i} (\underset{\sim}{x}_{it} - \underset{\sim}{x}_{is})(y_{it} - y_{is}) K \left[\frac{(\underset{\sim}{w}_{it} - \underset{\sim}{w}_{is})' \hat{\underset{\sim}{\delta}}}{h_N} \right] d_{it} d_{is} \right\} \tag{24}$$

where K is a kernel density function which tends to zero as the magnitude of its argument increases and h_N is a positive constant that decreases to zero as $N \to \infty$. Under appropriate regularity conditions, Eqn. (24) is consistent but the rate of convergence is much slower than the standard square root of the sample size.

6. *Conclusions*

Panel data have opened up avenues of research that simply could not have been pursued otherwise, but their power depends on the extent and reliability of the

data as well as on the validity of the restrictions upon which the statistical methods have been built. Otherwise, panel data may provide a solution for one problem, but aggravate another. For instance, consider the income-schooling example given by Griliches (1979):

$$y = \alpha + \beta_1 S + \beta_2 A + u \tag{25}$$

where y is a measure of income, S is a measure of schooling, A is an unmeasured ability variable which is assumed to be positively related to S. If S and A are uncorrelated, the least squares regression of y on S will yield consistent estimates of β_1. If S and A are correlated, then the least squares estimator of β_1 will suffer from omitted variable bias. If A is a purely 'family' variable in the sense that siblings have exactly the same level of A, then estimation of β_1 from differences between the brothers' earnings and differences between the brothers' education is consistent. But, if ability, apart from having a family component also has an individual component related to the schooling variables, then the within family estimate of β_1 is again biased and the bias is not necessarily less than that of the least squares estimate.

This example demonstrates that the usefulness of panel data in providing particular answers to certain issues depends on the validity of the assumptions implicit in the model. Since there is no universally acceptable way of modeling unobserved heterogeneity in panel data, it would be more fruitful to explicitly recognize the limitations of the data and focus attention on developing models and estimation methods based on what is observable, avoiding imposing arbitrary assumptions on the model and data. For additional discussions on panel data methodology, see Baltagi (1995), Hsiao (1986), and Mátáyes and Sevestre (1996).

Economic Restructuring: Geographic Aspects

The term 'economic restructuring' typically is used in a very general sense to indicate changes in the constituent parts of an economy. In many respects it is a 'catch-all' phrase, incorporating factors such as the changing nature of industrial sectors, corporate organization, management strategies, occupational structures, and working practices. However, the term restructuring has also become associated with a series of geographical studies with distinctive perspectives on changing economies.

1. *Economic Restructuring: Common Underlying Themes of Geographic Studies*

Geographical studies of economic restructuring seek to explain geographical variations in economic development. The approach taken in most such studies differs from the neoclassical approach within economics, which attempts to discover universal principles or 'laws' of economic behavior that are relevant in all places at all times. In addition, the neoclassical approach places faith in the ability of market mechanisms within a capitalist economy to produce the most efficient allocation of resources in a way that is beneficial for all concerned. In marked contrast, the restructuring approach within geography sees economic behavior as highly dependent upon the social customs, cultural norms, institutional practices, and wider forces of capitalist development in operation at the time, and in the place, in which that behavior takes place. Furthermore, rather than a consensual outcome which is to the benefit of all concerned, the process of restructuring under capitalism typically is seen as a struggle between competing interest groups, leading to winners and losers. Geographical studies have therefore focused upon both the creative and destructive outcomes prompted by the continuous need for capitalist firms to generate profits (Storper and Walker 1989).

The restructuring approach has generated a vast body of literature undertaken by geographers and other social scientists interested in geographical issues, including regional economists and urban sociologists. These studies have been prompted by recognition of the fact that geography is a central element in the restructuring process. Not only does restructuring vary from one place to another but, in addition, the differences between areas are used by various agents—governments, corporations, entrepreneurs, trade unions, and workers—to affect the outcome of the restructuring process itself. Geography—sometimes referred to as place or space—is, therefore, not just a reflection of these processes, it is a constituent part of the restructuring process itself (see *Place in Geography*). A good example of the role of space is when a corporation moves employment from an area in which labor costs are high to a low labor cost region, or from an area in which workers are resistant to new working practices to one in which they are more compliant.

Restructuring studies focus upon the processes leading to restructuring; the mechanisms through which this restructuring is achieved; and the social consequences of these processes in terms of factors such as: income distribution, occupational structures, the prevalence of unemployment, and the incidence of two-career households. Nevertheless, it is possible to group restructuring studies by a number of empirical foci and theoretical approaches spatial divisions of labor; new industrial spaces; globalization; services; feminization; the public sector; and knowledge economies.

2. *Spatial Divisions of Labor*

The first geographical approach to focus explicitly upon economic restructuring was spatial divisions of labor (Massey and Meegan 1982, Massey 1995). This concept highlights the fact that throughout the first part of the twentieth century there was a shift in regional economic structures away from sectors towards functions. Within regional sectoral specialization, regions tended to specialize in all aspects of the production process of particular products, such as ships, cars, or textiles. Classic examples of regional sectoral specialization are the car manufacturing complex of Detroit or the once world-leading shipbuilding region of the Clyde in Scotland. However, following a shift towards regional functional specialization, in the second half of the twentieth century regions tended to specialize in particular stages in the production process of a wide range of products. The spatial divisions of labor approach therefore implies that there is a tendency for different types of work to be undertaken in different places. Thus, corporate headquarters tend to be concentrated in large cities, design centers may be concentrated in high-technology clusters, whilst the routine assembly of products may be based in regions with low labor costs.

Spatial divisions of labor are manifest at other scales in addition to the region. At the city-wide scale areas of manufacturing specialization are often termed 'industrial districts.' However, decentralization in the latter half of the twentieth century promoted functional specialization as new forms of work—and especially services—were introduced into suburban areas following the outmigration of people from inner cities. Spatial divisions of labor can also be seen at the international level, leading to the new international division of labor thesis. Hence, the advanced capitalist

regions of North America, Europe, and Japan may be seen as global centers of corporate control, finance, product design, and innovation, whilst routine assembly jobs are undertaken in developing countries. However, research soon made it clear that there were few, if any, clear-cut geographical patterns, and the shift from sectors to functions was a tendency or trend rather than a specific outcome. Hence, different industrial sectors produced complex spatial divisions of labor, some of which overlapped and some of which did not.

The spatial division of labor approach attributed this geographical restructuring to the continual need of capitalist firms to enhance their profitability. There is much debate about the processes that led to low productivity and declining profitability in many industries in the second half of the twentieth century. One important influence was growing international competition from low-cost locations outside the Western world. Other factors were a lack of investment in new machinery and boring repetitive work (often associated with labor unrest). Another factor prompting the desire for economic restructuring in the early part of the 1980s was the influence of corporate raiders who issued junk bonds to gain control of major corporations. They then enhanced share values by asset-stripping: putting new management into particular corporate divisions to enhance productivity through reductions in manpower and the introduction of new working practices, and then selling-off the revitalized units. Prosecutions for insider dealing led to a progressive decline in the influence of the raiders but gradually pensions funds and major financial institutions began to exert similar pressures on corporations to enhance productivity and profitability.

Geographical studies drew attention to processes that were particularly important in the late 1970s and early 1980s as companies began to respond to declining profitability at that time (Massey and Meegan 1982). First, there was rationalization, a euphemism for the reduction of industrial capacity through factory closure or massive workforce cutbacks. This process was especially prominent in the UK in the 1980s under the Thatcher governments. Thus the first nation to experience the Industrial Revolution became the first nation to experience a massive process of deindustrialization. Job losses and factory closures were especially pronounced in the older industrial areas of the UK, a pattern which was replicated in the US, Europe, and Australia. Rationalization frequently was associated with spatial relocation as routine production functions were transferred to areas with low labor costs in developing countries. Not only were shopfloor workers made redundant, intermediate level white-collar workers were also laid off as corporations stripped out their elaborate managerial and administrative hierarchies (a process sometimes termed 'delayering' or 'downsizing'). Second, there was the process of investment and technical change. This involved capital investment in new machinery and equipment in an effort to increase productivity and the quality of products. This frequently was also associated with losses of employment. Third, there was the process of intensification: increases in labor productivity through managerial and organizational change.

Many of these changes were made to increase flexibility. Rather like restructuring, this is a word with a wide range of meanings but in the context of economic restructuring it has taken on two further important associations. First, there is functional flexibility, the capacity of firms to extend the range of skills of their employees. This has often involved breaking down the barriers between different types of occupation. Second, there is numerical flexibility, the capacity of employers to alter the numbers of workers employed at any given time. This has involved a wide range of strategies including the increased use of temporary workers, part-time staff, casual employees, job-sharing, shift working, flexitime, annualized hours, and a wide range of innovative forms of job contract.

Two important factors underpin the need for flexibility. First, there is the ever increasing pace of technological change, both of products and the means by which they are produced. Increased use of computerization has tended to break down some of the divisions between mechanical-based and electronic-based occupations. The other factor is increasing market volatility. Markets for certain mass-produced goods have become saturated while niche markets for specialized goods change rapidly. Producers therefore need to be able to adjust quickly and efficiently to variations in demand.

As with other aspects of industrial restructuring, the capacity to introduce flexibility shows complex geographical patterns and wide variations among regions. For example, in an attempt to escape from labor hostility to flexible working practices in older industrialized areas with a tradition of trade unionism, many companies have established new factories in areas that are free of such traditions. The location of new US car plants by Nissan in Smyrna, Tennessee, and Toyota in Georgetown, Kentucky, illustrate this trend. Restructuring has greatly affected the economic fortunes of different places, favoring some and devastating others. This led to a series of studies—especially in the UK—that became known as the localities approach, focusing upon the collective impact of restructuring upon the life-chances of people in different places (Cooke 1989).

One of the most quoted and influential aspects of the spatial divisions of labor approach was Massey's use of the geological metaphor. The economic geography of an area was likened to various phases or 'rounds' of investment in factories, plant, machinery, and labor. Each round leaves an imprint in the form of a layer or strata of development. Some of these layers become eroded over the years by subsequent rounds of

the restructuring process but collectively they serve to shape the economic landscape (see also *Local Economic Development*;*Uneven Development, Geography of*).

2.1 Japanization

Concepts of flexibility were initially imported into the US and Europe from Japan in the 1980s. During their period of reconstruction after the second world war Japanese manufacturers became eminently successful at combining high productivity with high quality products. Initially they did this to overcome the disadvantages faced by Japanese companies compared with western producers but in so doing made a virtue of necessity. Shortages of capital meant that Japanese firms had smaller amounts of machinery than their Western counterparts and had to learn ways of using existing machines more flexibility (for example, by changing the dies of dedicated machines more rapidly so they could be used for more than one purpose).

Limited capital also meant that they were forced into making contracting arrangements with numerous small producers to deliver components just at the time they were needed in the final assembly plant. Not only did this cut down on expensive stocks of components (since these larger firms were initially short of capital) but it enabled closer relationships to develop between firms. A process of collective learning thus ensured the delivery of high quality components. This process, known as contracting-out, distancing, or outsourcing, is another important form of economic restructuring. These processes have been copied widely by Western manufacturers as part of the restructuring process. This is sometimes termed Japanization (Elger and Smith 1994) or the development of lean production (Harrison 1994).

Japanese manufacturing practices drew attention to a rather different structure to regional functional specialization. Because of the need for close links with suppliers, large Japanese firms began to perpetuate and enhance regional sectoral specialization. Indeed, there has emerged a second strand to the restructuring approach that argues that clustering of firms making the same products (known as regional agglomeration) was once again an important feature of the advanced economies.

3. New Industrial Spaces

The second approach in restructuring studies, focusing on new industrial spaces, has been prompted by the fact that some regions lead the world in the design and production of particular products (Castells and Hall 1994). The classic case is Silicon Valley in California that leads the world in semiconductors (Saxanien 1994). Other examples include racing car production in southern England, textiles in northern Italy, and machine tools from the Baden-Württemberg region of Germany. Rather than regional functional specialization, these examples suggest we are witnessing the resurgence of the industrial districts of an earlier age and there are various schools of thought that have attempted to explain their existence (see also *Technology Districts*).

Scott (1988) explained these clusters as the outcome of transaction costs. Transaction costs are the costs of transforming inputs into products and services. Companies are faced with three choices in minimizing transaction costs. They can undertake activities internally (in-house) through some form of *hierarchy*; subcontract activities to external suppliers and contractors through the *market*; or adopt a halfway house and engage in collaborative activities with other companies through networks. Scott argued that changing economies of scale and scope were affecting transaction costs and leading to firms clustering together geographically in collaborative networks.

Regulation theory has also been called upon to explain industrial agglomeration. This theory, originally developed by a group of French Marxian economists in the 1970s, attempts to relate developments in particular nations to broader trends in the evolution of capitalism (Amin 1994). Regulation theory holds that over time broad sets of conditions will emerge that enable production and consumption in capitalist societies to be brought together in a stable state, known as a regime of accumulation. For example, in the early part of the twentieth century, increases in productivity were brought about by increasing the efficiency with which inputs were used (known as the intensive regime of accumulation). This gave rise to the system of large factories based on internal economies of scale (see *Regulation Theory in Geography*).

Economies of scale are factors that cause the average cost of a commodity to fall as the amount of output of the commodity increases. Internal economies of scale are those factors that apply to individual firms (irrespective of the size of the industry to which they belong). These internal economies usually ensure that the optimal scale of output is large in order to recoup the high costs of research, development, and specialized capital equipment. It is these factors that led in the past to the growth of large factories. This system has been termed Fordism after the system of mass production pioneered by Henry Ford in Detroit for the production of cars.

External economies of scale, in contrast, apply when the industry to which the firm belongs to (rather than the firm itself) is large. External economies include the development of specialized ancillary services, pools of skilled labor, and specialist component suppliers. If the output of the latter is large, this can reduce costs, thus potentially benefiting the industry as a whole.

Economies of scope are factors that make it cheaper to produce a range of commodities (rather than to produce individual types of commodity in isolation) and again these economies of scope can be internal or external.

Regulation theorists argue that since the 1980s we have witnessed the emergence of a new regime of accumulation based on flexibility. Increasing market volatility and technological change have meant that internal economies of scale have been breaking down, leading to horizontal disintegration: the tendency for producers to become smaller and more numerous. In addition, there have been declining internal economies of scope, leading to vertical disintegration: the creation of specialist subcontractors (Scott 1988). Smaller firms have been able to take advantage of external economies of scale and scope, often by clustering together to reduce the costs of interacting with the numerous specialist suppliers upon which they are dependent.

The regulation theorists argued that whereas the regime of accumulation was a very broad abstract concept, the ways in which the problems of capitalist systems were resolved depended upon a mode of regulation that differs in some respects from nation to nation. This latter concept involves the norms, regulations, and institutional practices that govern issues such as trade and competitiveness policy, finance, and labor law. These issues will depend upon the particular historical development of the nation state concerned. Critics point out, however, that the transaction-cost approach is based on an economic logic which ignores these historical factors (Sayer 1989). This critique has led to an approach in restructuring studies that recognizes the social embeddedness of economic activities.

3.1 The Social Embeddedness of Economic Activity

The concept of social embeddedness recognizes that all economic activity depends upon the social context in which it takes place (Granovetter 1985). Economic systems are seen as the product of conventions applied by highly 'reflexive' (i.e., thinking and aware) human agents. All economic systems depend upon systems of meaning that are usually specific to particular places. In the context of regional development this has led to a focus upon the institutional structures that encourage or inhibit economic activity. Work has therefore focused upon the cultural factors that generate a strong sense of common purpose, trust, and skill development amongst geographically clustered firms. This has led to the concept of the learning economy (Lundvall and Johnson 1992) and the learning region (Morgan 1997). In addition, it has also led to a focus upon the local work cultures—such as that in Silicon Valley—that facilitate factors such as high rates of technological innovation (Saxanien 1994).

4. Globalization

Those who are sceptical about the importance of these 'new industrial spaces' have pointed to the overwhelming power of the forces of globalization, and this forms another major focus within studies of economic restructuring (Dicken 1998). Globalization is—like most aspects of restructuring—a highly controversial and much disputed concept. The term is usually associated with the growing importance of multinational (or transnational) companies that operate in more than one country. However, large corporations such as Ford have long manufactured outside of their parent nation, producing goods for consumption in distant markets. Globalization therefore refers to a more recent process in which the operations of transnationals, both in the spheres of production and distribution, are increasingly integrated on a global scale. Thus, products typically incorporate components made in diverse locations throughout the world. Furthermore, whilst the appearance of products such as cars may be tailored to meet the demands of particular local market conditions, this diversity is underpinned by many common elements (such as the floorpans and engines in the example of automobiles) to reduce production costs. Globalization is also associated with the global spread of Western values of materialism and consumerism (see also *Globalization: Geographical Aspects*).

Globalization has had a crucial effect upon economic restructuring. In particular it has led to the emergence of so-called 'world cities' (or 'global cities'); command centers of the new world economy which house the headquarters of the major corporations and the financial system (Sassen 1994) (see also *Cities: Capital, Global, and World*). Examples include New York, Los Angeles, London, Paris, and Tokyo. The occupational structures of global industries are such that these cities tend to be characterized by extremes of affluence and poverty. While few cities can claim true global status, there is a sense in which all urban centres are now global, for they are all affected by events outside their boundaries and they are all engaged in a fierce competition to attract mobile capital investment into their districts. Those who are sceptical of the new industrial spaces thesis argue that it is the elaborate structures of global corporate hierarchies that shape economies rather than industrial clusters in specific regions.

One approach to reconciling the conflict between the globalization and 'new industrial spaces' schools of thought is through the concept of neo-Marshallian nodes (Amin and Thrift 1992). This concept is named after Alfred Marshall, one of the first economists to draw attention to the positive advantages that firms can derive by locating closely together in a geographical cluster, such as common pools of knowledge and skill. This concept draws attention to the importance of geographical clusters of small firms but at

the same time recognizes that they are frequently dependent upon the activities of major corporations (see also *Industrial Geography*).

5. Services

Geographic studies of economic restructuring also focus upon the growth of services (Daniels 1993) (see also *Service Economy, Geography of*). Although services are notoriously difficult to define, a common theme is economic activity that does not involve the material transformation of a physical product. However, services are defined, there is little doubt that service activity is dominant in terms of total employment and is on the increase in Western societies. Growth has been especially pronounced in financial and business services, retailing, leisure, and entertainment industries. Growth in services has tended to concentrate outside the traditional manufacturing centres of the Western economies (for example, in the 'Sunbelt' of the US and in the South East of the UK). However, new telecommunications systems are enabling back-office activity (i.e., relatively routine service activity) to be decentralized away from areas of rapid service growth into older industrial areas.

The restructuring of services has had profound effects upon the social structure of economies. In particular, it has led to social polarization with increases in both the affluent and the less well off. Whereas the declining traditional heavy manufacturing industries had substantial proportions of blue-collar, relatively well-paid, middle-income jobs, services tend to be associated with both relatively high-paying and low-paying jobs. Closely connected with the growth of services has been the increasing numbers of women in the workforce. Whereas men were employed in most of the relatively well-paid jobs in manufacturing, many of the new relatively low-paid service jobs (but also some of the well-paid service jobs) are held by women.

6. Feminization

Although the spatial divisions of labor and the new industrial spaces approaches to economic restructuring recognized that women were often employed in routine assembly work, feminist perspectives have highlighted the neglect of gender issues in many of these earlier studies. Early regulation theory, for example, focused upon work dominated by men—most notably the assembly of cars or high technology research and design work—even though women frequently were engaged in routine 'Fordist' assembly work. Regulation theory tended to adopt the reserve army of labor theory to explain the position of women in the labor market (i.e., it assumed that they were a variable pool of workers taken on in times of high demand but rapidly laid off in times of recession). A number of flaws were soon apparent in this theory. First, it simply did not fit the facts; in the last quarter of the twentieth century women were an ever increasing proportion of the workforce rather than a reserve army. Second, previous studies frequently ignored the socially embedded character of women's employment. The issue of skill illustrates this point well. For example, rather than being an innate attribute, women's so-called 'nimble-fingers,' which supposedly make them suitable for low-paid routine assembly work in light industry, are now seen as socially ascribed. Subsequent work has shown how the combination of workplace, household, and community arrangements structure the job opportunities available to women (Hanson and Pratt 1995). Gender issues are therefore a crucial element in processes of economic restructuring, as are many other socially ascribed human characteristics related to factors such as family status, ethnicity, disability, and age (see also *Gender and Feminist Studies in Geography*).

7. Economic Restructuring and the Public Sector

Although initially applied to the private sector, concepts of restructuring have also been used to analyze the extensive changes in public sector organizations in recent years. In a public sector context the flexible firm model involves a core of public sector managers who draw up contracts for work to be subcontracted to various private sector organizations, a structure which is already utilized in many US and European local governments. As with the restructuring of private sector organizations, the geography of public sector restructuring shows complex overlapping patterns, but some generalizations are possible. In the UK, for example, the contracting-out of services tends to be greater in districts in which local management is in favor of change, where there are fewer logistical problems for private sector contractors, and where there are relatively compliant trade unions (Pinch 1997) (see also *Welfare State, Geography of*).

8. Knowledge Economies

The most recent strand of economic restructuring work by geographers has focused around knowledge economies (see also *Information Society, Geography of*). Various terms have been used to draw attention to the increasing importance of knowledge in contemporary societies including: knowledge-based capitalism (Florida 1995), the network society (Castells 1996) and reflexive accumulation (Lash and Urry

1994). This role of knowledge is reflected in the ever-increasing pace of technological change and the rapidity of changes in consumer fashions and styles. This means that rather than compete by providing goods and services at the least cost, many firms increasingly compete on the basis of factors such as quality, performance, style, and design. Rapid developments in the sphere of telecommunications—teleconferencing, faxes, email, the Internet, and various types of specialist computer networks—mean that knowledge can be disseminated much more quickly throughout corporate hierarchies or networks of collaborating firms. The term telematics is used to indicate services that link computer and digital media equipment over these telecommunications links. Central to these developments are new communications channels based around satellites and fiber optics that permit the exchange of greater and more complex amounts of information much more quickly over longer distances.

So far there has been relatively little restructuring research on the impact of telematics and the information economy (Graham and Marvin 1996). Certainly telematics facilitate globalization and ever increasing distances between the various elements in the production chain. In addition, they facilitate telecommuting: linking people into global information networks and enabling them to work in their own homes. While some claim new technologies will result in the dissolution of city life, paradoxically there has been a recent resurgence of interest in cities as sites of innovation and creativity. The reason for this is that creativity in knowledge-based industries is fostered by having dense networks of people in close physical contact in places where trust and reciprocity can facilitate learning. Furthermore, much of the expensive infrastructure for telematics is heavily concentrated in urban areas.

9. *Overview*

Rather than a single integrated approach, geographical studies of 'economic restructuring' represent a series of foci: on spatial divisions of labor, new industrial spaces, globalization, services, feminization, and knowledge economies. Nevertheless, these studies share a common desire to understand the many complexities of economic restructuring without recourse to simple 'laws' of economics that are assumed to work in all places at all times. In addition, they are all committed to unraveling the crucial role of geography as a constitutive element of restructuring processes. Although many generalizations have been possible, the geographical manifestation of economic restructuring shows many complex, ever changing, and cross-cutting patterns. This has led to a dynamic field that has become known as the 'new' regional geography (for example, Bryson et al. 1999) (see also *Economic Geography*). Although somewhat distinct from the approaches typically utilised by economists, it has attracted considerable interest from a wide range of scholars in related disciplines such as urban studies, planning, sociology and cultural theory.

Economic Sociology

In his 1936 presidential address to the American Sociological Society, Henry Pratt Fairchild lamented the estrangement of economics and sociology. 'The time is now ripe,' he declared, 'to correct this lesion, and to bring about such a rapprochement of the two sciences as shall serve to round out and solidify them both' (Fairchild 1937 p. 4). Economic institutions, noted Fairchild, ought 'to be incorporated in sociological theory on a par with the family, the state, or the school' (p. 7). In Fairchild's vision, economists would continue to study economic relations while sociologists studied the social organizations within which those economic relations took place.

As a recognized specialty, economic sociology only began to fulfill Fairchild's vision some four decades after his 1936 exhortation. True, economic activity has figured importantly in sociology from the time of Karl Marx, Max Weber, and Emile Durkheim (Swedberg 1998). As economists' studies of economic growth proliferated after World War II, furthermore, sociologists often joined them in examining the interplay of economic growth with changes in population, family structure, education, and other social phenomena. But those sociologists typically defined themselves as specialists in modernization, development, social mobility, or social change rather than as economic sociologists. Talcott Parsons and Neil Smelser's (1956) attempt to synthesize economic and sociological approaches attracted considerable attention, but failed to galvanize a new specialty.

Economic sociology as such began to gain coherence and strength in the 1980s. Arthur Stinchcombe, for example, published his *Economic Sociology* in 1983 and two years later Mark Granovetter (1985) published an influential article on embeddedness. Here are some other milestones: the *Encyclopedia of Social Sciences* published in 1937 contained no articles devoted to sociologists' treatments of explicitly economic processes; the *International Encyclopedia of the Social Sciences* (1968) included a general article on Economy and Society but none called economic sociology; while this encyclopedia singles out economic sociology as a specialized field.

In its recent form, economic sociology offers a sociological account of economic phenomena, more specifically, the production, consumption, distribution, and transfer of assets, goods, and services. In the process, it goes well beyond Fairchild's vision. It subverts the division of labor prescribed by Fairchild. The new agenda treats economic processes and behavioral assumptions—such as markets, rationality, or self-interest—as products of underlying social processes. As Harrison White (1988, p. 232) puts it, market activity is 'intensely social—as social as kinship networks or feudal armies' (for other general statements, see e.g., Smelser and Swedberg 1994a, Dobbin 1994, Barber 1995, Beckert 1996, Ingham 1996, Bourdieu 1997, Swedberg 1997, Fligstein 1998, Collins 1999).

Recent changes in the world economy have made the agenda of economic sociology both more urgent and more promising. Growth of international capital markets, expansion of multinational firms, pursuit of global commodity marketing, collapse and transformation of centrally planned economies, and recognition that capitalist economies depend on complex institutional infrastructures all challenge economic sociologists to locate economic transactions in their social settings.

1. *Approaches to Economic Activity*

Within recent economic sociology, we find three somewhat distinct approaches to economic phenomena. They vary with respect to economics in two regards: their proximity to standard economic explanations, and their proximity to conventional economic subject matters. We might call them *extension*, *context*, and *alternative*.

Extension theorists apply relatively standard economic models to social phenomena economists themselves have not treated extensively or effectively, for example, household behavior, sporting competition, religious recruitment, and compliance with states.

A *context* approach identifies features of social organization that work as facilitators or constraints on economic action. This position is intent on revamping economists' portrayals of individual and collective decision-making, for example, by specifying conditions other than short-term gain that influence decisions. Advocates of context often speak of the 'embeddedness' of economic phenomena in social processes, and often refer to interpersonal networks when they do so. As Michel Callon (1998, pp. 10–11) puts it: 'What benefits accrue from social network analysis? Answer: a simple explanation of the possibility that agents have of calculating, when caught up in situations of extreme uncertainty. They do not have to open up to their environment in order to exchange or get information, or to negotiate and coordinate their decisions so as to lay the foundations of a possible order. They are open and connected: it is from these connections that they derive their ability to calculate. *Homo clausus* of economic activity is re-

placed by *homo apertus* of social network analysis.' Given their orientation to the agenda of economics, followers of this approach have continued to focus on firms and different kinds of markets.

In the *alternative* perspective, sociologists propose competing accounts of economic transactions. Rather than expanding the economic approach or complementing it, one prominent view argues that in all areas of economic life people are creating, maintaining, symbolizing, and transforming meaningful social relations. As a result, the subject matter certainly includes firms and markets but also ranges over households, immigrant networks, informal economies, welfare transfers, or organ donations. Indeed, economic sociologists who pursue extension and context strategies often fail to recognize alternative analyses as part of their specialty.

By and large the *extension* approach pays little attention to culture, interpersonal ties, or categorical differences, such as class, gender, race, or nationality. *Context* theorists typically take just one of these—culture, ties, or categorical differences—and make them an explicit part of the explanation. *Alternative* perspectives give more explicit attention to combinations of culture, networks, and categories.

To detect differences among the three approaches in concrete areas of economic life, it is therefore convenient to ask repeatedly to what extent and how they employ culture, interpersonal ties, and categories as part of their explanation. Let us employ those rules of thumb in looking at four contrasting areas of economic life: firms, labor markets, households, and consumer markets. The first two sectors figure prominently in standard economic analyses, the second two, less so.

1.1 Firms

Economic sociologists study features of firms that managers and economists have thought to be ruled by rational efficiency and show how these corporate features depend on social categories, interpersonal ties, and culture. What, for instance, motivates workers in capitalist firms? The simplest economic answer is that employer and worker strike a bargain in the exchange of human capital for wages. Economists and economic sociologists have moved out of that efficiency-driven position by examining other organizational rationales for payment systems. Trond Petersen (1992), for instance, documents how variation in types (and not just levels) of payment within department stores establishes a hierarchy of jobs and returns from work.

As Aage Sorensen's (1994) useful synthesis of standard thinking about systems of compensation shows, the literature on payment systems divides between analysis from employers' perspectives and from workers' perspectives. From the employers' perspective, the literature looks at variation in payment systems as incentive structures, techniques for manipulating motivation. From the workers' perspective, a less abundant literature portrays payment systems as opportunity structures.

While such analyses provide thin organizational context for a well-known economic process, other sociologists offer competing accounts of organizational rationales. A case in point is Calvin Morrill's (1991) ethnography of executives employed by a large American corporation. Responding to structural transformations within the firm along with a rash of hostile takeovers these executives generated a new public style of competition and conflict resolution. The new system by no means simply matched material rewards to task performance.

Instead the system demanded adherence to a symbolically charged code of honor. Honorable executives or 'white hats' who followed the rules were rewarded not only by reputation and esteem but, Morrill found, expanded power and greater access to resources than their dishonorable 'black hat' colleagues enjoyed.

This sort of analysis takes the economic sociology of firms in a far different direction than wage: performance matching. Pure efficiency explanations of payment systems, as effective performance measures or reward structures, fail to account for the creation, changing acceptability, and diversity of arrangements for compensation.

1.2 Labor Markets

When it comes to labor markets, many economic sociologists have shifted radically away from models assuming socially unfettered rational exchanges between workers and employers. Instead, sociologists identify a vast set of structural, cultural, and categorical factors shaping the operation of labor markets. Consider the problem of how people find jobs. Traditional economic accounts of labor markets look at the intersection of two search procedures: workers searching for job opportunities, employers searching for workers. The individual on each side, the theory tells us, is trying to maximize self-interest by looking for the best possible bargain. Employers want to find the worker with the best qualifications, while workers are seeking the highest price for their labor.

Mark Granovetter's 1995 [1974] study seriously complicated this neat equation by introducing third parties. A job seeker's existing social networks, he showed, shaped the job search process in fundamental ways, by providing information and access to jobs. Granovetter coined the term 'strength of weak ties' to convey a key finding: connections to distant acquaintances were significantly more effective referral sources than close friends or family. More generally,

Granovetter points out that economic transactions are embedded in complex social relations which constrain them.

In a similar vein, other economic sociologists have examined the operation of migration networks, informal economy, ethnic niches, and internal labor markets (see e.g. Portes 1995). Such studies extend into the examination of culture (e.g. within the segments of labor markets) and of categorical difference (e.g. discrimination by gender, race, and ethnicity). In his detailed analyses of labor markets within corporations, for example, Ronald Burt (1998) has shown that, on the whole, men's breadth of connections to the firm's various power centers directly affects their relative success while involvement in self-contained cliques inhibits men's advancement. For women, however, involvement in a small circle that includes a powerful boss actually enhances their chances for success.

This work frequently moves away from contexts or extensions of standard economic work into clear alternatives. Economist Chris Tilly and sociologist Charles Tilly (1998, p. 19) state the program for a full-fledged alternative in the following terms: 'What vision, then, do we hold of work and labor markets? At the center of our analysis stands an image of a worker and an employer, each involved in extensive social networks that connect them not only with each other but with many others inside or outside the place of employment. The worker and employer are bargaining out the terms of work, using the material and organizational resources (including existing and available technologies) at their disposal. They draw on previously existing social relations—both work-generated and otherwise—in seeking their advantages. In the process, they generate new agreements, understandings, and social ties, which in turn constrain subsequent interaction. They interact within strong limits set by their shared culture and by the previous history of the productive organization.'

2. *Households*

Firms and labor markets occupy center stage in mainstream economic thought. Household economies, in contrast, have typically remained at the sidelines, part of a nonrational social world seemingly run by affect, not efficiency. The predominant model of what Amartya Sen (1983) calls the 'glued-together' family further discourages questions about the allocation, distribution, and expenditure of family resources among family members. Reacting to the pioneering work of Gary Becker (1981), feminist economists and their allies in economic sociology have challenged straightforward applications to households of firm-level models. Their work has integrated bargaining models, multiple utility schedules, and gender differences into the analysis of household economies. Another group of sociologists studying families and gender dynamics addresses parallel issues, but works in almost complete isolation from economic sociology.

One difficult problem has preoccupied both groups of researchers in sociology: causes and effects of household divisions of labor. Why do wage-earning women continue to do the bulk of household work? Why does men's household work respond so little to changes in household circumstances, and indeed, even tend to decline when their wives' income surpasses theirs? Why are household tasks often as segregated by gender as are labor markets? Why are women's earnings, even when substantial, commonly treated as discretionary income?

Answers to the housework puzzle have ranged from extensions of economistic models which see women's unpaid household labor as exchange for their husband's economic support to culturalist models where ideologies of gender shape material household exchanges. Julie Brines (1994) combines both perspectives. Brines argues that what she calls a dependency model accounts for women's domestic labor, but it fails to explain their husbands.' When it comes to men, Brines claims, adhering to masculine gender expectations leads dependent husbands to do less, not more, housework. Housework, from this perspective, acts as a symbolic marker of traditional gender relationships.

To get beyond this dichotomy will require us to find a model of interaction and bargaining within households. Marjorie DeVault's (1991) observations on food preparation as a bargaining form of social interaction among wives, husbands, and children points in that direction. Thus labor markets and household economies yield similar lessons. Without models of meaningful social interaction, economic sociology cannot get much farther in explaining such complex phenomena.

3. *Consumption*

If households have remained peripheral to economics and economic sociology, consumption splits down the middle. Some aspects of consumption have long been recognized and extensively documented by both groups of specialists. Other dimensions of consumption have become the province of specialists in family, class, gender, ethnicity, and community, in studies significantly removed both from economics and economic sociology.

Within self-defined economic sociology explicit studies of consumption have taken second place to the study of production. To be sure, for half a century sociologists and economists collaborated in surveys of consumer expenditures and behavior, a line of work that significantly influenced market research. Yet that nucleus excluded many aspects of consumption, such as family dynamics of consumption and social con-

nections among consumers. On their own, economic sociologists have related consumption to inequality and class position. The best documented cases tell of the acquisition of goods as cultural markers of class position, one aspect of which Thorstein Veblen (1953 [1899]) treated as 'conspicuous consumption' and another aspect of which Pierre Bourdieu (1984) identifies as the formation of 'cultural capital.'

The representation of class through consumption is only a special case of the relationship between social position and consumption patterns: other studies establish variation by ethnicity, gender, race, and locality. All such studies pose the classic economic sociology problem of embeddedness. Given variation in consumption from one social location to another, how do social relations actually shape the acts of consumption?

Paul DiMaggio and Hugh Louch (1998) provide one answer. They survey pre-existing noncommercial ties between buyers and sellers in consumer transactions involving the purchase of cars, homes, as well as legal and home repair services. DiMaggio and Louch find a remarkably high incidence of what they call within-network exchanges. A substantial number of such transactions take place not through impersonal markets but among kin, friends, or acquaintances. Noting that this pattern applies primarily to risky one-shot transactions involving high uncertainty about quality and performance, DiMaggio and Louch conclude that consumers will be more likely to rely on such noncommercial ties when they are unsure about the outcome. As in studies of firms, labor markets, and households, analyzing relations between economic transactions and social ties promises great returns for economic sociology.

Meanwhile, outside of economic sociology, in company with numerous anthropologists, historians, and social critics, sociologists have created a wide-ranging literature on cultures of consumption. Three questions dominate these studies: how does consumption vary with social position? How do changing patterns of consumption affect the quality of social life? and how does material culture create social meaning? This work has produced an enormous range of rich descriptive material and a great variety of conflicting interpretations. For example, students of consumption outside of self-defined economic sociologists have reproduced a great controversy that has troubled social commentators for centuries: do commodification and monetization of goods and services depersonalize and corrupt the social relations involved? Or, on the contrary, does their contribution to efficiency, productivity, and connections actually augment social well being? Economic sociologists and other students of consumption would greatly benefit from closer interaction between their separate spheres of investigation.

Firms, labor markets, households, and consumption do not of course exhaust the range of economic sociology. Scholars have investigated a wide variety of economies, from financial markets, gift economies, industries, international flows of goods and capital, to ethnic economies, education, religion, health, sexual economies, leisure, and the environment. They have paid attention as well to comparative and historical developments (see e.g. Smelser and Swedberg 1994b). In these various fields we again find examples of extension, context, and alternative models. For example in the study of technological change, some sociologists elaborate on existing economic choice models, some examine the immediate social context of innovation and its applications, while others treat technological innovation as a form of power struggle.

Although it is convenient to distinguish extension, context, and alternative, we should not exaggerate the rigidity of the boundaries between them. Indeed, in recent sociology, lines of investigation that began as attempts to provide contexts for economic analysis (for example, in studies of informal economies and gender inequality) have repeatedly developed into alternatives to standard economic analyses. Nor should we imagine that economists have stood still in these regards; institutional economists have been moving into intensive conversations with economic sociologists of all three tendencies.

In the immediate future it would be unwise to try to forward one perspective to the exclusion of the others. Each yields its own insights into the joint agenda of economics and sociology. Extension views build on existing economic theory, context accounts provide the challenge to improve on existing economic theory, correcting it when necessary, while alternative models replace existing economic theory with other principles of explanation. In the long run, the alternative perspective opens up the prospect of going beyond the embedding of economic activity. It examines ostensibly economic phenomena as the construction of meaning, formation of relationships, and organization of categories.

For understanding the complex economies of the twenty-first century, the analytical contribution of sociologists will be crucial.

Economic Status, Inheritance of: Education, Class, and Genetics

1. Introduction

Economic status is transmitted from parents to offspring. The perpetuation across generations of a family's social class, or their position in the distribution of income, is generally thought to reflect the combined effects of the genetic and cultural transmission of traits, such as cognitive functioning, that contribute to economic success, as well as the inheritance of income-enhancing group memberships and property. The superior education enjoyed by the children of higher status families contributes to this process of economic inheritance. While recent research has illuminated important aspects of this account, the factors contributing to the extent of intergenerational transmission of status and the ways that genetic and cultural transmission and the inheritance of property and memberships contribute to this process remain obscure.

First, the extent of intergenerational economic status transmission is considerably greater than was thought to be the case a generation ago, with some intergenerational correlations of parent–offspring income exceeding Francis Galton's original estimate (two-thirds) for height (Galton 1889, p. 97). Second, the genetic inheritance of traits contributing to the cognitive skills measured on IQ and related tests explains very little of the intergenerational transmission of economic status, even if the heritability of IQ is quite high. Third, the combined genetic and cultural inheritance processes operating through superior wealth, cognitive levels, and educational attainments of those with well-off parents, while important,

do not fully explain the intergenerational transmission of economic status. The article will identify some as yet overlooked individual traits that enhance economic success in the members of both generations and are transmitted across generations.

2. The Intergenerational Transmission of Economic Status

Economic status may be measured in discrete categories—by membership in hierarchically ordered classes, for example—or continuously, by earnings (wages and salaries), income (earnings plus income from property and other sources), an occupational prestige index, or wealth.

Continuous measures of status—like height in Galton's example—allow a simple metric of persistence, the intergenerational correlation coefficient ρ, the square of which measures the fraction of the variance in this generation's measure of economic success that is statistically associated with the same measure in the previous generation. The persistence of economic status is measured using a first order Markov process

$$y_o = (1-\beta_y)\bar{y}+\beta_y y_p+\varepsilon_y \qquad (1)$$

We use subscripts 'o' and 'p' to refer to offspring and parental measures, respectively, so y_o is an individual's economic status, adjusted so that its mean, $\bar{y}$, is that of the parental generation, β_y is a constant, y_p is the individual's parental y, and ε_y is a disturbance uncorrelated with y_p. In this setup, inspired by Galton's treatment of height, and extended in Goldberger (1989), regression to the mean is measured by $1-\beta_y$. Little explanatory power is gained by using higher order Markov processes to take account of the effects of earlier generations (Warren and Hauser 1997, Behrman and Taubman 1989). The intergenerational correlation is

$$\rho_y = \beta_y \frac{\sigma_{y_p}}{\sigma_{y_o}}$$

where σ_y is the standard deviation of y. if y is the natural logarithm of wealth, income, or earnings, the standard deviation of y is a common measure of inequality. Thus, if inequality is unchanging across generations, so $\sigma_{y_p} = \sigma_{y_o}$, then $\rho_y = \beta_y$. In the empirical work reviewed below earnings, income, wealth, and other measures of economic success are measured by their natural logarithm unless otherwise noted. Thus, β_y is the percentage change in offspring's economic success associated with a one percent change in parents' economic success.

Early studies following the work of Blau and Duncan (1967) estimated intergenerational correlations for income or earning among men in the US to be in the neighborhood of 0.15, leading Becker and Tomes (1986) to conclude that:

> Aside from families victimized by discrimination, regression to the mean in earnings in the United States and other rich countries appears to be rapid … Almost all earnings advantages and disadvantages of ancestors are wiped out in three generations (S32).

But the appearance of such high levels of mobility was an artifact of two types of measurement error: errors in reporting income, particularly when individuals were asked to recall the income of their parents, and transitory components in current income uncorrelated with underlying permanent income (Bowles 1972, Bowles and Nelson 1974, Atkinson et al. 1983, Solon 1992, Zimmerman 1992). The high noise to signal ratio in both generations' incomes depressed the intergenerational correlation, and when corrected using a variety of methods and distinct data sources, the intergenerational correlations for economic status appeared quite substantial, as is indicated by the data in Table 1. Another useful survey of these data is Bjorklund and Jantti (1999), and the discussion in Mulligan (1997) and Solon (2000). Estimated intergenerational correlations generally rise with age, are greater for sons than daughters, and are greater when multiple years of income or earnings are averaged. Behrman and Taubman (1989) using the Michigan Panel Survey of Income Dynamics find that the estimated intergenerational correlation of parental income and offspring earnings is 0.58 when 18 years of earnings are used compared to 0.37 for a single year.

Unlike the entries in a transition matrix, μ_{ij}, which indicate the extent to which one's prospects are

Table 1
Intergenerational persistence of some economic characteristics, β_i

Economic characteristic	Number of Estimates	Range	Average
Years of schooling	8	0.14–0.45	0.29[a]
Log earnings or wages	16	0.11–0.59	0.34[a]
Log family income	10	0.14–0.65	0.43[a]
Log family wealth	9	0.27–0.76	0.50
Log family consumption	2	0.59–0.77	0.68

Source: Mulligan (1999).
a If recent studies of the US only are included these averages of 0.35, 0.33, and 0.38 respectively

Figure 1
Intergenerational status transmission when $\rho = 0.4$ and $\rho = 0.5$. The vertical axis represents the probability of attaining the decile on the horizontal axis or higher deciles, for an individual from the top decile in parental background, relative to an individual from the bottom decile in parental background

conditioned by one's origins, the intergenerational correlation, ρ_y, is relatively difficult to interpret. However, the degree of conditioning implied can be illustrated by given values of ρ_y assuming that the underlying relationship is linear in y_o and y_p and that both are distributed normally. Figure 1 represents the transition probabilities implied by these assumptions and two different correlation coefficients, $\rho = 0.4$ and $\rho = 0.5$. The horizontal axis represents cumulative position in the income distribution, and the vertical axis represents the probability that an individual in the highest (first) decile of parental income attains at least this position divided by the probability that an individual in the lowest (10th) decile of parental income attains at least this position.

It can be seen, for instance, that an individual whose parents are in top decile is roughly 44 times as likely to attain a position in the top decile as an individual whose parents are in the bottom decile when $\rho = 0.5$, and 16 times as likely when $\rho = 0.4$. Similarly an individual whose parents are in the top decile is about 20 times as likely to attain a position in the top quintile as an individual whose parents are in the bottom decile when $\rho = 0.5$, and nine times as likely when $\rho = 0$. Studies allowing for nonlinear effects in Eqn. (1) suggest that our assumption of normality may lead these figures to understate the actual degree of persistence in the tails of the income distribution (Corak and Heisz 1999, Cooper et al. 1994).

The role of various forms of inheritance in the transmission process is now considered. Equation (1) is merely a summary of the results of a number of distinct processes having little in common except that they result in parent–offspring similarities for traits statistically associated with the degree of economic success in both generations. While candidates for the list of income generating traits with strong parent–offspring similarity are many, there are few for which both economic relevance and parent–offspring similarity have been empirically demonstrated. Among these are cognitive performance, the level of schooling, and ownership of wealth, each illustrating distinct transmission processes.

A common measure of economic success, income—that is, the sum of labor earnings (wages and salaries) and returns to assets—is treated as a phenotypic trait influenced by the individual's genotype g, environment e, and ownership of income earning assets. Genotypic and environmental influences jointly determine individual skills and other traits relevant to job performance, sometimes termed 'human capital.' Among the environmental influences are cultural transmission from parents, schools and other learning environments. Income, human capital, and assets are transformed to their natural logarithms, and then all variables normalized to have zero mean and unit variance, represented by y, l, and k, respectively. Here and below, $\tilde{y}$ is total income, while y is earnings from labor, represented as a return to human capital. So

$$l = h_y g + \beta_{le} e + \varepsilon_l \quad (2)$$

$$\tilde{y} = \omega l + \pi k + \varepsilon_{\tilde{y}} \quad (3)$$

which imply the reduced form

$$\tilde{y} = \omega(h_y g + \beta_{te} e) + \pi k + \varepsilon'_{\tilde{y}} \quad (4)$$

where $\varepsilon'_{\tilde{y}}$ is a disturbance uncorrelated with the independent variables, and the constants ω, h, β_{te} and π give the effect in standard deviation units of a standard deviation change in the relevant variable. Thus h_y^2 is the heritability of earnings, namely that portion of the variance of individual earnings that would be explained by the variance of g, were e and g uncorrelated.

Using Eqn. (4), the intergenerational correlation $\rho_{\tilde{y}}$ can be decomposed, yielding additive terms expressing the contribution of each of the above variables. Let r_{uv} be the simple correlation between variables u and v. The intergenerational correlation coefficient can be expressed as

$$\rho_{\tilde{y}} = \sum r_{j\tilde{y}_p} \beta_{\tilde{y}_o j} \quad (5)$$

where $r_{j\tilde{y}_p}$ is the simple correlation of the parental economic status measure ($\tilde{y}_p$) with some another variable j, and $\beta_{y_o j}$ is the normalized regression coefficient of the variable j in an equation like (7) below, predicting the current generation's economic status (y_o). Then if parent–offspring similarity in g, e, and k are the only sources of parent–offspring similarity in $\tilde{y}$ (i.e., $\varepsilon'_{\tilde{y}_p}$ is uncorrelated with $\varepsilon'_{\tilde{y}_o}$), the intergenerational correlation of incomes can be decomposed as follows

$$\rho_{\tilde{y}} \equiv r_{\tilde{y}_o \tilde{y}_p} = \omega(h_y r_{g_o \tilde{y}_p} + \beta_{te} r_{e_o \tilde{y}_p}) + \pi r_{k_o \tilde{y}_p} \quad (6)$$

expressing three fundamental mechanisms of intergenerational transmission of economic status: genetic, cultural and asset-based. What can be said about the relative importance of each? To answer this question we consider particular components of the genetic and environmental influences on economic success.

3. *The Role of Genetic Inheritance of Cognitive Skill*

Both the similarity of parents' and offspring's scores on cognitive tests and the statistical association of test scores and earnings are well documented. This suggests an appealing explanation of the process of intergenerational status transmission via inheritance of cognitive skills.

Correlations of IQ between parents and offspring are substantial, ranging from 0.42 to 0.72, the higher figure referring to average parental vs. average offspring IQ (Bouchard and McGue 1981). The contribution of cognitive functioning to earnings has been established using survey data to estimate the natural logarithm of earnings y as a function of a measure of parental economic and/or social status y_p, years (and perhaps other measures) of schooling s, and performance on a cognitive score c—often, in US data sets, the Armed Forces Qualification Test (AFQT), a cognitive test developed to predict vocational success—as well as an error term and other variables, such as work experience, race, and sex, which will not be covered here. This equation may be written in a normalized form as

$$y_o = \beta_{y_o y_p} y_p + \beta_{y_o s_o} s_o + \beta_{y_o c_o} c_o + \varepsilon_{y_o}. \quad (7)$$

Sixty-five estimates of $\beta_{y_o c_o}$ have been located, appearing in Fig. 2. The mean of these estimates 0.15, indicating that a standard deviation change in the cognitive score, holding constant the remaining variables, changes the natural logarithm of earnings by about one seventh of a standard deviation. By way of contrast the mean value of $\beta_{y_o s_o}$ is 0.22, suggesting a somewhat larger independent effect of schooling. We checked to see if these results were dependent on the weight of overrepresented authors, the type of cognitive test used, at what age the test was taken and other differences among the studies and found no significant effects (Bowles et al. 2001).

Does the fact that measures of cognitive functioning are robust predictors of individual earnings, along with the similarity of the cognitive scores of parents and offspring imply a major role for genetic inheritance of cognitive ability in the process of intergenerational economic status transmission? To answer this question one needs to understand the determination of schooling (s_o) and offspring cognitive scores (c_o) which appear as the independent variables in Eqn. (7). Suppose h_c^2 is the heritability of cognitive skill and that the relevant processes are described by

$$c_o = h_c g_o + \beta_{c_o y_p} y_p + \beta_{c_o c_p} c_p + \varepsilon_{c_o} \quad (8)$$

$$s_o = \beta_{s_o y_o} y_p + \beta_{s_o c_o} c_o + \varepsilon_{s_o} \quad (9)$$

where all variables are expressed in normalized form, ε_{c_o} and ε_{s_o} are error terms uncorrelated with the independent variable in their respective equations.

The cognitive test ideally would be taken by an adolescent just prior to the minimal school leaving age, thereby being a good predictor of adult cognitive functioning while still having an effect on the level of schooling attained. Figure 3 illustrates the causal model implied by Eqns. (7)–(9).

Equation (5) allows a decomposition of $\rho_{\tilde{y}}$ showing that the genetic inheritance of IQ contributes to the intergenerational status transmission process because it results in a correlation of parental income with offspring cognitive level $r_{c_o y_p}$, which in turn affects offspring income both directly ($\beta_{c_o y_o}$) and indirectly via its effect on the level of schooling attained ($\beta_{y_o s_o} \beta_{s_o c_o}$). Using Eqn. (5) to decompose $r_{c_o y_p}$ one has

$$r_{c_o y_p} = \beta_{c_o y_p} + r_{c_p y_p} \left(\beta_{c_o y_p} + \frac{h_c^2}{2} \right) \quad (10)$$

The genetically transmitted portion of this correlation is the term $r_{y_p c_p} h_c^2/2$, since the direct part r^g from g_p to

Figure 2
Normalized regression coefficient ($\beta_{y_o c_o}$) of cognitive score on the logarithm of income or earnings by year: 65 estimates from 24 studies (Bowles et al. 2001)

Figure 3
A causal model of intergenerational status transmission

g_o is just the genetic relatedness of parents and natural offspring, which is 1/2. Summing the direct and indirect effects one obtains the contribution of genetic inheritance of IQ to intergenerational transmission of earnings

$$\rho_c^g = r_{y_p c_p} r^g h_c^2 (\beta_{y_o s_o} \beta_{s_o c_o} + \beta_{y_o c_o}) \qquad (11)$$

Representative values have already been introduced for $\beta_{y_o s_o}$ (0.22) and $\beta_{y_o c_o}$ (0.15). Estimates (Jencks 1979) of $r_{y_p c_p}$ suggest a value of 0.35, and as an estimate of $\beta_{s_o c_o}$ the preferred estimate of Winship and Korenman (1999) is taken, which is 0.53. Therefore, $\rho_y^g = 0.047\, h_c^2$, indicating that even for $h_c^2 = 1$, the genetic inheritance of IQ accounts for a rather modest portion of the observed levels of intergenerational economic status transmission. The calculation is

$$\rho_y^g = 0.35 \frac{h_c^2}{2} (0.22(0.53) + 0.15) = 0.047 h_c^2$$

This of course assumes there is no assortative mating of parents. If parental IQ phenotypes have correlation m, and if the heredity coefficient h_c is the same for parents as for offspring, then $r^g = (1 + h^2 m)/2$. It follows that the maximum value ρ_y^g could have, which occurs when $h_c = 1$, is $0.047(1+m)$. The considerably lower values for h_c^2 suggested by recent research of Devlin et al. (1997), Otto et al. (1995), and Plomin (1999) are consistent with the conclusion that one twentieth or less of the observed intergenerational status transmission is due to genetic inheritance of IQ. Some of the data used in this exercise are not estimated very precisely (h_c^2 in particular) but the main point is robust with respect to reasonable alternative values.

Indeed it is thought that available estimates overstate the importance of general cognitive skill as a determinant of earnings for the simple reason that taking a test is more than a little like doing a job—the results measure performance, which is the joint effect of skill along with other contributors such as the disposition to follow instructions, persistence, work

ethic, and other traits likely to contribute independently to one's earnings. Eysenck (1994, p. 9) writes:

> Low problem solving in an IQ test is a measure of performance; personality may influence performance rather than abstract intellect, with measurable effects on the IQ. An IQ test lasts for up to 1 hour or more, and considerations of fatigue, vigilance, arousal, etc. may very well play a part.

Thus, some of the explanatory power of the cognitive measure in predicting earnings does not reflect cognitive *skill* but rather other individual attributes contributing to the successful performance of tasks. The importance of the performance rather than capability aspect of the test score as a determinant of earnings is suggested Bishop (1991), who found a measure of computational speed on time tested exams to be a more robust predictor of earnings than two alternative measures—a normalized sum of academic tests as well as a measure of technical competence.

4. *The Inheritance of Wealth and Educational Attainment*

The intergenerational inheritance of income-earning assets provides an alternative explanation that competes for simplicity with the inherited cognitive skills account. Table 1 shows that the intergenerational correlation for wealth status is quite substantial—within the range of parent–offspring similarity in cognitive scores—and that it exceeds the persistence of family income (to which it contributes) which in turn exceeds the persistence of earnings (which do not include income from property). While comparisons of imprecisely estimated parameters across differing data sets are notoriously unreliable, Mulligan (1997) uses a single data set and common methods for his estimates of persistence with respect to earnings, income, wealth, and consumption. His results confirm that consumption, wealth, and income regress to the mean more slowly than do earnings or wages.

These data are consistent with the inherited wealth account of economic status persistence, but for most individuals and families, income from property constitutes a negligible fraction of their total income. Only among the very well-to-do is property a major source of income. Correspondingly, very few individuals receive inheritances of significant magnitude. Mulligan (1997) estimates that estates passing on sufficient wealth to be subject to inheritance tax in the US constituted between two and four percent of deaths over the years 1960–1995.

Because wealth inheritance contributes to intergenerational income persistence, one would expect to find that persistence varies with the level of wealth of the individual's parents. For instance, in a rare study with sufficient sample size to derive good estimates of persistence for different positions in the distribution of income (Corak and Heisz 1999) the degree of income persistence for the very rich was markedly greater than for the rest of the distribution, with $\rho_{\tilde{y}} = 0.8$ for the top percentile.

However, the apparent simplicity of the inherited wealth account is misleading. The intergenerational persistence of wealth is not explained simply by bequests but reflects as well parent–offspring similarities in traits influencing wealth accumulation, such as orientation towards the future, sense of personal efficacy, work ethic, schooling attainment, and risk-taking. Some of these traits covary with the level of wealth: less well off people are more likely to be risk averse, to discount the future, and have a low sense of efficacy, for example (Bardhan et al. 2000, Fong 2000).

Like wealth levels, schooling attainments persist across generations although, as Table 1 indicates, less so. Nonetheless, father–offspring correlations for years of schooling reported by Behrman and Taubman (1989) are substantial (0.34, and would be closer to 0.4 were they corrected appropriately for errors in measurement). As in the case of wealth, the persistence of schooling attainments results from actions taken by parents and offspring, and these are influenced by beliefs and preferences that are themselves subject to intergenerational transmission. Some of the individual dispositions favoring high levels of school attainment are correlated with parental schooling levels and incomes, thereby fostering higher levels of educational attainment by the children of the well educated. This tendency is exacerbated where the children of the less well off experience schooling as a hostile or unpleasant environment, and where their families, limited incomes and inability to borrow make the students' potential labor services valuable to the family.

Because schooling attainment is persistent and has clear links to skills and perhaps other traits that are rewarded in labor markets, this human capital based account of intergenerational status transmission has strong *prima facie* plausibility, especially when deployed with the inherited cognitive skills account. Indeed, it was once commonly assumed that when adequate measures of schooling quality were developed the only effects of parental economic status on offspring earnings would operate through effects on cognitive functioning and schooling, with the direct effect of parental on offspring earnings vanishing, that is, $\beta_{y_o y_p} = 0$ in Eqn. (7).

But as the measurement of school quality has improved over the years, estimation of $\beta_{y_o y_p}$ have proven resilient. Note that $\beta_{y_o y_p}/\rho_y$ measures the importance of the direct effect of parental economic status relative to the total amount of intergenerational transmission. Mulligan (1997), controlling for a large number of measures of school quality as well as the AFQT and standard educational and demographic variables, finds that an estimate of parental income is an important and statistically significant predictor of

the natural logarithm of the hourly wage rate in 1990 and 1991 in the National Longitudinal Study of Youth. A little more than two-fifths of the gross statistical association between parental and offspring economic success (ρ_y) apparently operates independently of the influences of these conditioning variables. Specifically, the effect of an estimate of the logarithm of parental income on offspring's logarithm of income in a regression conditioned on measures of schooling quantity and quality, employment, and cognitive performance is between two-fifths and one-half of the estimated effect of parental income unconditioned on these variables. Mulligan's work repeats the finding in Atkinson et al. (1983) for a sample with direct measures of incomes of fathers and sons in the UK in which two-thirds or more of the substantial intergenerational transmission of income status is independent, in the sense just defined, of the covariation of parental income with a range of measures of son's schooling including the number of Ordinary and Advanced level exams taken, and the selectivity of the school. Finally, Bowles and Nelson (1974) found that between 33 and 60 percent of the covariation of parental economic status and respondent's income (not its logarithm) was not accounted for by the statistical association of parental status with childhood IQ of years of schooling.

It is possible, of course, that $\beta_{y_o y_p}$ measures the effects of wealth inheritance (none of the three studies includes measures of parental wealth or bequests) directly on earnings of indirectly via effects on unmeasured determinants of earnings, such as quality of schooling. But this seems unlikely given the very small number of individuals receiving any significant bequest in the samples in question. A more cautious interpretation is that it indicates an important gap in our understanding of how economic status is passed on from generation to generation: roughly half of the intergenerational transmission coefficient is unaccounted for. It is also true that typically one can statistically account for less than half of the variance of the earnings or income using the conventional variables described above, but this fact does not explain the limited success in accounting for the intergenerational correlation, as this measures only that part of the variation of earnings that can be explained statistically by parental economic status.

5. *The Relative Importance of Genetics, Culture, and Bequests*

The face that the earnings and schooling attainments of identical twins (more technically, monozygotic twins, which is abbreviated to 'mz' in equations) appear to be substantially more similar than fraternal twins (or dizygotic, which is abbreviated to 'dz' in equations) suggests that genetically inherited traits other than cognitive skills may account for some of the intergenerational correlation of earnings. Taubman (1976) uses a sample of monozygotic and dizygotic twins to measure the relative importance of genes and environment in income determination. Figure 4 presents data from the Twinsburg, US sample, the Australian Twin Register, and the Panel Study of Income Dynamics (US). Direct inferences about the degree of heritability of income from these data are likely to be misleading for the following reasons. First, the identical twins appear to have shared more similar environments than dizygotic twins and other siblings (Loehlin and Nichols 1976), so environmental differences contribute to the greater similarity of the monozygotic twins. Second, the twin data are not corrected for errors in measurement. An adequate treatment of this problem requires information on the degree of correlation of errors, which seems likely to be higher for the identical than the other twins. If this supposition is correct, error correction would increase the monozygotic correlations by less than the dizygotic correlations. Third, the identical twins are all same-sex pairs, while the dizygotic twins include mixed-sex pairs, and sex contributes to the within pair difference in economic success. However the difference in the earnings correlation between monozygotic and same-sex pairs of dizygotic twins in the NRC (Taubman 1976) sample and the Swedish Twin Registry (Isacsson 1999) is 0.24 (in both data sets). The brothers' data set addresses this latter issue, but includes, as social siblings, unrelated members of the same household, so the genotypic correlation among them is less than 0.5. All three problems imply that the naïve calculation of heritability from these data will constitute an overestimate.

It may be of interest, nonetheless to see what this estimate yields. Assuming the degree of similarity of the environment influence on earnings and schooling attainments is identical for the two sets of twins, one can calculate the heritability of these phenotypic traits

Twin and Sibling Earnings Similarity, r_y

Study	Monozygotic Correlation	Dizygotic Correlation	Brothers' Correlation
Twinsburg[a]	0.56	0.36	
Twinsburg[b]	0.63	0.37	
Australian Twins[c]	0.68	0.32	
U S Brothers[d]			0.45

Figure 4
Earnings and genetic similarity of monozygotic twins, dizygotic twins, and non-twin brothers.
Notes: (a) Ashenfelter and Kruger (1994), with earnings measure log wage; (b) Rouse (1999) and personal communication, with earnings measure log wage; (c) Miller et al. (1995), with earnings measure log occupational income; (d) Bjorklund and Jantti (1999) with earnings measure log annual earnings

as $h_i^2 = 2(r_i^{mz} - r_i^{dz})$, where r_i^{mz} and r_i^{dz} are the correlations of the monozygotic and dizygotic twins for trait i. Estimates of h_i and β_{ie_i} are not very sensitive to assumptions concerning the degree of assortative mating, measured by the correlation of parental phenotypes, m_i but depend critically on assumptions concerning the difference in the environmental correlations experienced by the dizygotic and monozygotic twins, $r_{e_i}^{mz}$ and $r_{e_i}^{dz}$, respectively. Relaxing these assumptions requires that h_i and β_{ie_i} be estimated simultaneously, using the equations below, where the subscript i refers to the trait in question

$$r_i^{mz} = \beta_{ie_i}^2 r_{e_i}^{mz} + h_i^2$$
$$r_i^{dz} = \beta_{ie_i}^2 r_{e_i}^{dz} + h_i^2(1 + h^2 m_i)/2$$

The greater the difference in the environmental correlations, the lower is the estimate of h_i^2 and the higher is the estimate of $\beta_{ie_i}^2$. Correspondingly, larger values of m_i increase the estimate of h_i^2 and decrease the estimate of $\beta_{ie_i}^2$. If the correlation for earnings-affecting environments for monozygotic and dizygotic twins are 0.8 and 0.7 respectively (rather than both being 0.8), and if $m_i = 0.25$, the estimates reported obtain. Twin correlations from Ashenfelter and Krueger (1994) for hourly wages and from Behrman and Taubman (1989) for years of schooling attained yield estimates of $h_i^2 =$ 0.4 both traits. Assuming that the correlation of parental genotypic and phenotypic income is h_y itself, the estimated contribution genetic inheritance to the intergenerational transmission of these measures of status is just $(r^g h_y^2)$ or one-fifth. While this estimate may overstate its influence, it is not doubted that genetic inheritance plays a role, perhaps a substantial role in the intergenerational transmission of economic status, even if (as has been seen) this process operates substantially independently of the cognitive skills measured on available tests.

Similar methods yields estimates for the environmental effects. If the correlation of parental income and the environmental influences on offspring income is approximated by the correlation of parental (permanent) income or other measures of socioeconomic status with offspring schooling attainment, the estimate of $r_{e_o y_p}$ is about 0.45. An estimate of β_{le}^2 is obtained from the Ashenfelter–Krueger twin data as $(r^{mz} - h^2)/r_e^{mz}$ where r_e^{mz}, the correlation of monozygotic twins' environments, is assumed to be 0.8, giving a value of 0.2. Thus, the environmental contribution to the intergenerational correlation of earnings $(\beta_{le} r_{e_o y_p})$ is the same magnitude as the genetic contribution, namely 0.2, giving an intergenerational correlation for earnings of 0.4.

Note that $\beta_{le} = \sqrt{0.2} = 0.45$ is an estimate of the effect on earnings, in standard deviation units, of a standard deviation change in the environmental influences on human capital and hence on earnings, and may be compared with β_{ys}, the mean estimate of which (Bowles et al. 2001) is just half of β_{le}, suggesting that

Figure 5
An expanded model of intergenerational transmission of income. The dashed lines represent the causal model but are not used in calculations

while educational attainment captures important aspects of the relevant environments it is far from inclusive.

To complete the analysis we turn to the intergenerational correlation for income, including return to property, and thus take account of the intergenerational transmission of assets. Figure 5 illustrates the causal model of the determination of income underlying Eqns. (2) and (4), with the paths from y_p through g_{y_o} and e_o to y_o depicting the transmission process for earnings addressed in the paragraphs immediately above. The contribution of wealth inheritance to the transmission process is simply the correlation of parental income and offspring wealth $(r_{y_p k_o})$ multiplied by the contribution of offspring wealth to offspring income, expressed as a normalized regression coefficient, π. An estimate of π is simply γ, the percentage change in income associated with a one percent change in assets suitably normalized. If the rate of return on one's assets is constant, γ is simply the share of income from assets as a fraction of total income, (e.g., if the rate of return on capital is 7 percent, and the average capital holding is three times the average income, γ is about 0.2). Expressing π as a normalized regression coefficient we have

$$\pi = \gamma \frac{\sigma_k}{\sigma_{\tilde{y}}}$$

The inequality of property holdings is considerably greater than the inequality of earnings or of income, and as a result γ is likely to differ among families, with values approaching zero for the asset poor, and approaching unity for the very wealthy. This implies that importance of wealth inheritance in the intergenerational persistence of economic status is likely to differ by wealth level. If the variance of the logarithm of assets is four times the variance of the logarithm of incomes (the variance of a logarithm is a common unit free measure of dispersion) we have $\pi = 0.2(2) = 0.4$. Finally if $r_{y_p k_o}$ is midway between the intergenerational correlations for income (0.43) and for wealth (0.50), or 0.46, the property inheritance contribution to the intergenerational income correlation becomes $0.2(2)(0.46) = 0.18$.

	Earnings	Income
environmental	$r_{e_o\tilde{y}_p}\beta le = 0.2$	$\omega r_{e_o\tilde{y}_p}\beta le = 0.14$
genetic	$h_y^2 r^g = 0.2$	$\omega h_y^2 r^g = 0.14$
wealth		$\pi r_{k_o\tilde{y}_p} = 0.18$
intergenerational correlation	= 0.4	= 0.46

Figure 6
Contribution of environmental, genetic, and wealth inheritance to intergenerational transmission

To calculate the contribution of g_o and e_o to the intergenerational correlation of income one simply multiplies the contributions estimated above by the path from earnings (or human capital) to income. One needs to assume that $h_y \cong h_{\tilde{y}}$ and $r_{e_o y_p} \cong r_{e_o \tilde{y}_p}$. This (following the above reasoning) is estimated as

$$\omega = (1-\gamma_o)\frac{\sigma_l}{\sigma_{\tilde{y}}}$$

If the variance of human capital is four-fifths as large as the variance of income, then $\omega = 0.72$. Of course this value would be close to unity for population groups with no source of income other than earnings (if $\gamma_o = 0$, then $\sigma_{\tilde{y}} = \sigma_l$), and could be much smaller among the wealthy.

The implied contributions to the intergenerational persistence of income based on the above assumptions are genetic = 0.14, environmental = 0.14, asset based = 0.18, giving an intergenerational correlation of 0.46 which, as one would expect, somewhat exceeds the analogous correlations for earnings alone. These results are illustrated in Fig. 6.

The substantial contribution of wealth inheritance to intergenerational transmission of economic status among the wealthy is unsurprising, and the mechanisms through which it works relatively transparent. The same cannot be said for the genetic and environmental contributions, for as has been seen, neither IQ nor schooling provides an adequate account of these influences. Thus, both genetic and environmental influences remain black boxes. We know they are important but we do not know why.

6. Conclusion

This article has shown that recent evidence points to a higher level of intergenerational transmission of economics position than previously thought. Moreover, although the level of intergenerational IQ inheritance is also considerable, the latter accounts for little of the former. Indeed, some combination of environmentally and genetically transmitted noncognitive personality traits probably account for most of the correlation between the economic positions of parents and children. Personality differences, like group membership, affect earnings and display parent–offspring similarity. They thus join the genetic and cultural inheritance of cognitive skills, property bequests, and other influences of wealth, and parent–offspring similarity in schooling attainments as aspects of the process of intergenerational transmission of economic status.

We do not know, of course, if a more inclusive view of the transmission process and of the traits being transmitted taking account of group effects, personality, and other aspects would substantially improve this empirical account of the intergenerational correlation. For many of the traits identified data are available that would permit an assessment of their importance in the transmission process.

However, for many of the personality variables, there is a lack good research on the transmission process. Heritability estimates for these variables are quite reliant on comparisons of monozygotic and dizygotic twins which may substantially over-estimate heritability, and consequently underestimate the role of vertical cultural transmission and other influences of siblings' shared (family) environments. It is known that schooling contributes to cognitive functioning independently of genetic inheritance but that most of the contribution of schooling to economic success is unrelated to the learning of cognitive skills in school (Bowles et al. 2001, Gintis 1971). It seems likely that schools contribute to economic success in part by fostering personality traits rewarded in labor markets, rather than simply by enhancing cognitive functioning, but this appears not to be the case for either the Rotter Scale or the social maladjustment measures studied by Osborne.

Economic Transformation: From Central Planning to Market Economy

The analysis of transformation from central planning into a market economy is one of the youngest fields of geographical research. While in the 1980s neither the overwhelming majority of theoreticians nor practical experts could conceive a collapse of socialism, nowadays library shelves are stuffed with literature dis-

cussing the transformation of Central and Eastern European countries. As a research field, transformation analysis was not merely new but also unexpected. This is why descriptive case studies predominate its ever increasing literature, while its theoretical foundations and terminological background are rather defective.

1. Transformation into the Market Economy: Concepts, Models, Myths

More than ten years after the collapse of the central planning economy, transformation analysis is still analysis is still characterized by controversial concepts and models, misconceptions, and myths. A short review of these delusions is inevitable.

1.1 The Concept of Transformation into a Market Economy

Transformation into a market economy involves a process in which the Central and Eastern European countries, having drifted to the periphery of the world economy after 1945, transform their economic systems from central planning into market economy, in step with the transition of highly industrialized countries.

Consequently, transformation into a market economy involves a threefold process:

a fundamental change of the economic and social system, that is, the elimination of the central planning system and the building up of the market economy;

an economic catch-up of former socialist countries; and

an adjustment to the highly industrialized countries' transition from a Fordist-type mass production into a 'post-Fordist' type flexible production.

1.2 Models of Transformation into a Market Economy

Highlighting the individual subprocesses and complexity of transformation into a market economy is of significance because at the moment unidimensional models prevail in the analysis of transformation into a market economy. Two such models have become widespread: the model of delayed development and the model of stages.

The model of delayed development assumes that, with a significant delay in time, subsequent to 1990 the countries of Central and Eastern Europe started following the same course of development as trodden by highly industrialized countries ever since the mid-1970s. Among others, Dostal and Hampl (1996), Enyedi (1996) and Gorzelak (1996) are all of the opinion that in the 1950s and 1960s basically similar models of extensive economic development became prevalent in highly industrialized countries and socialist countries. In the early 1970s, they think, the courses of these developmental models began to move away from one another. On the one hand, from this time on, highly industrialized countries left this course and the Fordist mass production characterizing the extensive period, and adopted an increasingly flexible production, thus shifting to the so-called intensive (or 'post-Fordist') period. On the other hand, socialist countries went on to maintain their earlier economic development model. What is more, they even intensified it to an 'over-extensive kind of development,' as Dostal put it.

Due to the discrepancy between the models of development, by the 1980s the gap between the Western and the Central and Eastern parts of Europe had widened and the process finally led to the collapse of the socialist system in 1989–90. In the wake of this political breakpoint, each single country in Central and Eastern Europe sank into a deep 'transformational recession' and they got out of it only in the middle of the 1990s. Dostal, Hampl, Enyedi and Gorzelak think that, from this economic turning-point, i.e., from the end of the transformational recession and the beginning of a consolidation of market economy, the Central and Eastern European countries have also been following the post-Fordist flexible production model.

At this point the critical remark needs to be made of the model of delayed development: namely that it completely neglects the fact that despite certain similar features in terms of extensive economic development, there are fundamental differences between a central planning system and a free market economy. Moreover, it must be stressed that delay in development processes is not tantamount to a mere time delay, but also involves economic, social, and regional distortion of the processes, for the shapes these processes take in the former socialist countries are rather different from their Western counterparts.

In contrast to the model of delayed development, the other unidimensional model, that of stages, does not focus on historical continuity, but on the momentum of breaking away from the previous development course. Fassmann (1997) says that the model of stages may be divided into three stages. The first one is the initial state of affairs of transformation into market economy, namely the period of central planning. The next stage is an intermediary stage: a gradual breakdown of the central planning system and a parallel building up of the market economy. The third stage of the model includes stabilization of the market economy. In Fassmann's view, the intermediary stage may be further divided into two substages. One of them is the period of transformational measures, in which the élite in control of transformation into the market economy makes the most important economic decisions (e.g., decisions concerning the liberalization of the economy, the privatization of state-owned property, the discontinuance of government subsidies, etc). The next stage

is a later period of transformational phenomena, a time when the results of economic political measures become manifest in practice (e.g., in restructuring foreign trade, the changes of ownership statuses, increased unemployment, and emerging enterprises).

All the above said notwithstanding, fault is also found with the stage model. Following the scheme of causality, it is seen that the model overemphasizes the role of its actors and attributes the regional processes of transformation into a market economy to a single factor: the activity of the participants of transformation. This is to say that on the one hand, the stage model neglects the—incredibly long-lasting, in some cases several centuries old—regional disparities, which had a significant impact on the regional processes of the transformation into the market economy after 1990. Another factor the stage model overemphasizes is the significance of the goals and ideals of the élite that steers the transformation into a market economy. Though these objectives undoubtedly influenced the participants' activities, it does not follow that the actual reality of transformation into a market economy would or should have any kind of palpable objectives or a final status whatsoever.

1.3 The Myths of Transformation into a Market Economy

The individual subprocesses and complexity of transformation into a market economy are worth stressing also, because certain myths still make their influence felt in research. In the first place there are three particularly powerful myths: the overvaluation of the regional policy pursued in the socialist era, the unique historical character of the transformation into a market economy, and the significance of global processes.

In the period between 1960 and 1990 the political leaders of the countries of Central and Eastern Europe declared an egalitarian regional policy, which claimed to reduce dramatically or even eliminate regional disparities. However, there was an enormous gap between the declared objectives and reality: the socialist regional policy based on a completely centralized redistribution of development resources—presumed to be purposeful—yielded fictitious results. As Meusburger and Klinger have pointed out, the socialist regional policy somewhat mitigated regional disparities between living standards and residential infrastructure but it was simply incapable of reducing the disparities in really tough local factors, in particular in the field of human resources.

Discernment is further impeded by the fact that in the countries of Central and Eastern Europe before 1990 regional statistics were frequently and deliberately manipulated, forged, and framed in categories incomparable to those used in highly industrialized countries. Socialist regional policy rather obscured and concealed the internal regional disparities of the countries of Central and Eastern Europe, instead of reducing or eliminating such disparities. An uncritical acceptance of the self-image offered by socialist regional policy and an overestimation of its performance imply the danger that the regional consequences of transformation into the market economy are studied from a false point of view, and that the effects of regional disparities brought along from the socialist era, which have a significant impact on transformation into market economy, are neglected.

The second myth related to the transformation into a market economy (namely, the overvaluation of the unique historical character of the transformation process) is an unintentional 'children's disease' of transformation research. It does not follow, from the mere fact that transformation from a central planning system into a market economy is a unique process of economic history, that this process cannot be described and interpreted within the framework of concepts and processes characterizing the economy of highly industrialized countries. The prime reason why this myth is to be considered dangerous is that it depicts the processes that arose after 1990 as if they were something completely new in the region.

Just to give an example: for ideological reasons, in the countries of Central and Eastern Europe there had been no unemployment in the socialist era. To be more precise, excess manpower was employed—from state subsidies—at factories. Actually, there already was significant hidden unemployment in the 1980s, but the official socialist policy declared it nonexistent. After 1990, hidden unemployment suddenly became manifest, as a result of emerging market conditions and opening the economy to the world market. In consequence, unemployment figures skyrocketed in each country of Central and Eastern Europe, something that was conceived as a new and unprecedented process, and as a rule, new phenomena were frequently interpreted as symptoms of the newly emerging regional disparities. Based on analyses of East Germany and Hungary, Cséfalvay (1997) pointed out that the regional pattern of unemployment was nothing new at all—rather it rested on the different processes forcing people, regions, and countries to the periphery—and these had existed already in the socialist era.

The third myth of transformation research includes the overvaluation of the role played by global processes in the regional processes of transformation into a market economy. This myth takes the planet Earth for a mere arena of general processes, and presumes that such processes should appear in every country and region sooner or later. Historical experience shows, however, that the Earth is not an arena for global processes, rather it is a multifaceted mosaic of regions with divergent economic strength and development opportunities. Plenty of the processes that emerged in Central and Eastern Europe in the course

of its transformation into the market economy and have been taken for global processes actually differ markedly from the processes characteristic of highly industrialized countries.

An extremely fast tertiarization took place, for instance, in all the countries of Central and Eastern Europe after 1990. While the rate of people employed in the service provision sector remained below 45 percent before 1990, the corresponding figure was between 55 percent and 60 percent in the mid-1990s. In economic and regional studies it has become a matter of doctrine to consider an increase in the rate of employment in the tertiary sector as one of the major indicators of postindustrial development, and to see a close connection between economic progress and the high proportion of people employed in the service-provision sector. However, in Central and Eastern Europe the sudden increase of the rate of people employed in the service provision sector was not an indication of postindustrial development at all; it was merely the outcome of a succession of winding ups and the closing down of nonprofitable socialist factories, a single, rapid, and dramatic deindustrialization. The example of Central and Eastern European countries is indicative of the fact that there may be very different explanations behind tertiarization—a process considered to be global. On the one hand, the assumption that a high rate of people employed in the tertiary sector involves a high capability of economic performance does not hold true for Central and Eastern Europe, for here GDP per capita is less then 50 percent of the average in the European Union. On the other hand, the underlying reasons for deindustrialization, which actually induce tertiarization, are markedly different. While in Western Europe these processes are triggered by a relocation of mass production, in Central and Eastern Europe the main reason is the disintegration of socialist industry. Finally, another significant difference is that in Western Europe the process of tertiarization took several decades, but in Central and Eastern Europe it required only a few years.

2. *The Consequences of Transformation into the Market Economy in Central and Eastern Europe*

All the subprocesses of transformation into the market economy—like the change in the economic system, catch-up, and the process of adjustment—resulted in peculiar regional consequences in the different countries of Central and Eastern Europe.

2.1 *The Regional Processes of Transformation into the Market Economy*

The change that took place in economic system, the disintegration of the centrally planned economy, and the evolution of the market economy—particularly the privatization of government-owned enterprises and the liberalization of trade—triggered a dramatic revaluation of the individual regions. Thus, subsequent to 1990, three regional processes of extreme importance took place simultaneously. In the centers of former socialist large-scale industry, privileged before 1990, the elimination of inefficient plants resulted in the evolution of crisis zones. Simultaneously, since mass dismissals affected primarily those who had low qualifications, the areas poor in human resources sank down to the level of a periphery. Finally, selective dismissals suddenly raised the value of large cities, for these have favorable human resource features and they are centrally located. With respect to their process in the course of time, the majority of these events of regional concern took place in the first half of the 1990s, thus most Central and Eastern European countries have left this stage behind.

Another subprocess of transformation into the market economy includes the efforts made for catching up with the economic achievements of the West. This endeavor took shape in two fundamental regional processes: in the strengthening of the nation-state concept at a high level of organization and in a loosening of the earlier closed borders of nation states. The concept of the strengthening of the nation state at a high organizational level and the renaissance of nation states in Central and Eastern Europe—and in particular in South Eastern Europe—are generally explained by a revival of ethnic conflicts. Even though ethnic conflicts are deeply rooted in the history of these countries, catch-up efforts are highly perceptible in the present renaissance of nation states. This is something to do with the fact that the different countries of the region had set their admission to the European Union as a primary goal. However, it soon turned out that 'nonproblematic' small states had much greater chances for an early admission than states under internal ethnic tensions or those loaded with seriously underdeveloped regions (i.e., the peaceful separation of the Czech Republic and Slovakia in 1993). Nevertheless, the renaissance of nation states is still a rather controversial phenomenon. This is because Central and Eastern European countries have achieved independence and sovereignty—after many decades or for the first time in history—exactly at the time they have to give up an increasing number of elements of sovereignty as a result of Europe's increasing integration and to the benefit of a supranational level of organization.

The other regional consequence of catch-up processes involves the loosening of earlier strictly-closed borders, which ran its course in a similarly controversial manner in Central and Eastern Europe. Though political motifs had significant roles in this process as well—just think of the demolition of the Berlin Wall and the Iron Curtain in 1989—economic incentives went deeper. With borders closed no Euro-

pean integration or economic catch-up may be realized. Only free crossing—the flow of resources, capital, goods, labor force, and information—may create chances for Central and Eastern European countries for a catch-up with the West. In Central and Eastern Europe, however, the majority of borderland areas have become mere passageways of the crossroads type except for the single area of the Austrian-Hungarian border region, which has turned into a rapidly growing economic zone. Capital, labor force, and information all find their ways through such crossroads as well. However, the flow of resources is not targeted at the borderlands themselves; they merely pass such regions and go on to farther located centres.

Finally, the third subprocess of transformation into the market economy includes adjustment to the transition of highly industrialized Western countries. This also triggered differentiated regional processes in Central and Eastern Europe. In the last two decades of the twentieth century the industrialized countries of the West saw a transition characterized—at least from the point of view of the adjustment Central and Eastern European countries—by two fundamental processes: the penetration of flexible production methods and the relocation of the labor force and cost-intensive mass production. Thus Central and Eastern European countries have got three alternatives from which to choose for adjustment. Fordist reindustrialization means the acceptance of relocated high-tech industrial mass production from highly-developed countries. Another way is given in the post-Fordist neoindustrialization or the promotion of naturalizing flexible production methods. The third alternative offers the possibility of developing post-Fordist central regions primarily by strengthening the transfer of capital and knowledge in the large cities. From among these three alternatives for Fordist reindustrialization, or the settlement of labor-intensive industrial production, is unambiguously predominant, while post-Fordist neoindustrialization and the evolution of post-Fordist regional centers are isolated phenomena in Central and Eastern Europe.

2.2. *The Regional Pattern of Transformation into a Market Economy in Central and Eastern Europe*

The best known and the most popular regional pattern of Central and Eastern European transformation into the market economy was created by Gorzelak (1996). In Gorzelak's view the losing and winning regions of transformation from centrally planned economies into market economies follow the traditional west vs. east developmental division of Central and Eastern Europe suit. The losing regions along the eastern borders of Poland, Slovakia, and Hungary constitute a single continuous underdeveloped zone he calls the 'eastern wall'. In contrast to these, the winning regions are located mainly in the western part of Central and Eastern Europe. If the winning cities are connected by a fictitious line, the form of a 'boomerang' is given, commencing from the port of Gdansk, proceeding towards the west through Poznan and Wroclaw to Prague and then, following the curve of the boomerang to pass Brno, Vienna, and Bratislava down to Budapest. However, this boomerang is not a consistent formation because the Budapest–Bratislava–Vienna triangle has a special role within it. This is the region where the speediest transition to a market economy was experienced and which had become growth regions already by the middle of the 1990s. The northern arm of the boomerang, however, is more of a fictitious supplementation of this developmental zone, while Warsaw and Lodz have been left out of its merely on account of their geographical distances.

Already its shape suggests that this 'boomerang' wishes to be a counterpart of the well-known western 'blue banana' (i.e., the primary economic zone of European urbanization that stretches from southeast England through the Ruhr area to the large agglomeration in South Germany and North Italy) and therefore assumes that such a developed zone evolved in Central and Eastern Europe after 1990. As a critical remark it must be mentioned, however, that the two zones significantly differ from each other in several respects. On the one hand, the highly industrialized zone of the 'blue banana' of Western Europe is not a recent development on our map, for the region at issue has always been the innovative driving force of Europe, whether the point is the spread of literacy in the early Middle Ages, Reformation in the seventeenth century, or industrialization at a later period. As against this, the cities of the 'Central European boomerang' have not invented but received many of these innovations from the 'blue banana', moreover, with a considerable delay in time.

Another significant difference is that the cities of the 'blue banana' are interlinked with myriad economic and social ties; the economic and social relations of the cities making the 'boomerang' are rather feeble, though historical development was similar to the western region. The reason is that the cities of Central and Eastern Europe have never focused on one another; on the contrary, each of them has always had a western orientation. Prague, for instance, was linked with Berlin and Nuremberg, while Budapest focused on Vienna and Munich.

3. *What Has the Future in Store?*

At the turn of the millennium the majority of Central and Eastern countries are over the hump of the most sensitive period of transformation into the market-economy, the period which required the

greatest social sacrifices. Private property has prevailed in the economy, the most important institutions of the market economy have been established, foreign working capital has flowed into the countries and the economy has stabilized. Transformation analysis has been more or less capable of following these changes, though a few questions remain unanswered. In the operational market segments, for instance, we have uncertain knowledge first and foremost of the housing and labor markets. There is the issue of a missing coherent 'grand theory' which would be able to give a consistent framework to the explanation and interpretation of the regional processes and consequences of transformation into the market economy.

However, in the beginning of the twenty-first century the above issues are not the only questions to deal with. Radical new issues will have to be faced by Central and Eastern European countries. One of the most serious challenges of the first few decades of this century will certainly include European integration, and more specifically their admission to the Union. This is a challenge that will certainly trigger whole trains of changes both in the western and in the eastern regions of Europe.

Economics and Ethics

The economy is a central component of society. To a large extent, it determines our wellbeing, our freedoms and opportunities, our social life, our health, and many other features of our lives. It also determines how equally or unequally these things are distributed across the people. Indeed, the economy is perhaps more important than anything else in determining how our lives go. Consequently, an essential task for ethics is to assess how well the economy is doing and how it might be improved.

Since the working of the economy is complex, and the science of economics is technical, philosophers rarely have the skills needed to progress far with this ethical task. It commonly falls to economists instead. The branch of economics that is devoted to the ethical assessment of the economy is known as welfare economics. It is a sort of applied ethics. Because of its special subject matter, it has its own special methods. But because it is applied ethics, it needs some foundations in ethical theory. Inevitably, welfare economists working back towards the foundations of their subject have encountered moral philosophers working forwards towards applications of theirs. Several particular topics lie within the domains of interest of both welfare economists and moral philosophers. Section 4 gives some examples.

When they look for foundations for their work, many welfare economists have simply adopted an existing ethical theory. They have formalized it—sometimes distorting it in the process—and applied it to their subject. One example comes from the theory of 'optimal tax,' which flourished in the 1970s. Optimal tax theorists tried to devise a scheme of taxation that would best achieve a particular objective. They took the objective from ethical theory. Some (e.g., Mirrlees 1971) adopted the utilitarian objective of maximizing the total of people's wellbeing, others (e.g., Phelps 1973) the 'maximin' objective of maximizing the wellbeing of the worst-off person. The latter group was inspired by the publication in 1972 of John Rawls' *A*

Theory of Justice (Rawls 1972) However, they distorted Rawls' view, because Rawls favored maximizing the worst-off group's access to 'primary goods,' rather than the worst-off person's wellbeing.

Other welfare economists have been less passive and more critical in their attitude to ethical theory. They have themselves contributed to the theory's development. They have found that the methods of economics are useful equipment for doing so. Like most of economics, welfare economics is a rather formal discipline, and it has evolved a range of formal tools to serve its purposes. These tools contribute to the ethical assessment of economies, but they have turned out to be useful for other ethical purposes too. Moreover, theoretical tools from other branches of economics have also turned out to be useful in ethics. Section 3 gives examples of formal methods developed in economics that can be valuable in moral philosophy.

In sum, the connections between economics and ethics are multifarious, and run in both directions. It is therefore not surprising that many important moral philosophers have also been important economists. Adam Smith, Karl Marx, John Stuart Mill, and Henry Sidgwick are examples from the past. As a general rule, economist-philosophers have been utilitarians. Economists in general, too, have generally shown utilitarian inclinations. Since the rise of 'classical' economics in the eighteenth century, economists have mostly been concerned with increasing the wellbeing of the people—a concern that is utilitarian in a broad sense.

Liberalism is another philosophy that is closely associated with economics. However, most liberal economists are liberal for instrumental reasons. Their liberalism derives from their utilitarianism; they believe that economic freedom is a good way to promote people's wellbeing. For example, in *An Inquiry into the Nature and Causes of the Wealth of Nations*, Adam Smith (1776) argued that extensive free trade deepens the global division of labor, which in turn leads to economic growth, and that is good for people. More recently, a similar conclusion has been drawn from some theorems in welfare economics. The theorems show that free economic competition leads to efficiency, defined in a special way, and efficiency is held to be generally beneficial. However, there are many occasions when economic freedom is undoubtedly not generally beneficial. For instance, monopolies may use their power to delay innovations, and companies freely pursuing their own profit may damage the environment. In these cases, economists are typically in favor of restricting freedom by regulation. This shows that their support for freedom is only instrumental.

Utilitarianism, understood broadly, remains the dominant moral philosophy of economics. But within economics, utilitarianism has been radically altered and even emasculated as a result of the progress of economic theory. So close is the association between economics and utilitarianism that these changes have strongly influenced the progress of utilitarian thinking as a whole. Sections 1 and 2 outline the development of utilitarianism within economics.

1. *Utility Theory*

Utilitarianism is an ethical theory, but its development within economics has largely been driven by the development of an associated psychological theory, which has come to be called 'utility theory.' Utility theory is the economist's core account of people's behavior. This section describes it, and Sect. 2 describes its influence on economists' moral theory. Utility theory says that each person chooses her actions so as to maximize her utility. But 'utility' is a term of art, which can be defined in various ways, and different definitions lead to very different sorts of utility theory. This has allowed the theory to undergo a major metamorphosis in the course of two centuries.

Utility theory's origin may plausibly be traced to an article by the mathematician Daniel Bernoulli, published in 1738 (Bernoulli 1738). Bernoulli thought that each person acts to maximize her *emolumentum*. (He wrote in Latin.) *Emolumentum* may be translated as 'benefit' or 'advantage,' so Bernoulli held a version of utility theory in which utility is benefit or advantage. Later, Jeremy Bentham (1789) made the more specific assumption that each person acts to maximize her pleasure. (He treated pain as negative pleasure.) So he held a version of utility theory in which utility is pleasure. (Bentham himself used the term 'utility' differently.) Bentham's view was nothing other than the ancient doctrine of psychological hedonism, but he gave it such detailed analysis that it may now be seen as an early form of the mathematical utility theory we have today.

Utility theory became important in economics only in the 1870s, when the so-called 'neoclassical' school rose to dominance. This was when economists first took a serious interest in the behavior of consumers, and utility theory was the theory of behavior they adopted. At the beginning of the neoclassical school, the economist William Stanley Jevons (1871) explicitly took his utility theory from Bentham, and went far beyond Bentham in his analysis.

Like Bentham, Jevons thought that each person acts to maximize her pleasure. But in defense of this view he said: 'Call any motive which attracts us to a certain course of conduct, pleasure … and it becomes impossible to deny that all actions are governed by pleasure.' Jevons evidently hoped to make his theory of behavior as nearly as possible true by definition. Later economists followed his lead. In the 1930s, in the course of a movement in economics known as 'ordinalism,' it took them to a radically different version of the theory. The doctrine of ordinalism was proclaimed by Lionel Robbins in 1932 (Robbin 1932). Ordinalist utility theory was formally set out in a pair of articles by John Hicks and R. G. D. Allen (1934). It was refined by later

work into what is best called 'axiomatic utility theory.' This is the version that is generally presented in textbooks of economics today.

Axiomatic utility theory is a theory of preferences. Given all the possible acts a person might do, it assumes the person to have preferences amongst them. It treats a preference as a disposition to choose: to prefer one act to another is to be disposed to choose the first over the second if faced with a choice between them. A person's preferences constitute a relation amongst possible acts, and the theory assumes that this relation satisfies a number of axioms. Provided it does so, a formal proof shows that a mathematical function called a 'utility function' can be defined to represent the preferences in a particular sense. The utility function assigns a number called a 'utility' to each of the acts, and it does so in such a way that one act is assigned a greater utility than another if and only if it is preferred to the other. This is the sense in which the function represents the preferences. The dispositional definition of preference ensures that, when faced with a choice between two acts, the person always chooses the one that is preferred. This one has the greater utility. So we may conclude that the person always acts to maximize her utility. In this way, utility theory is confirmed, but only because a person's utility is defined to make it true. Utility is defined as what the person maximizes.

Whereas Bernoulli's and Bentham's utility theories made substantive commitments about what a person maximizes, the axiomatic theory does not. It is not committed to hedonism, or even to an assumption that people always act self-interestedly. Since the commitments of earlier theories were not very plausible, this was a significant advance in economics.

In a sense, ordinalism made utility theory true by definition. However, it did retain some commitments. It is not always possible to define a utility function for a person in a way that makes her a utility maximizer. We can only be sure this is possible if the person's preferences satisfy the axioms of the theory. This is the theory's commitment: that preferences satisfy the axioms. In effect, the axioms ensure that the person can be construed as maximizing something, and utility is defined as what she maximizes.

The principal axiom is transitivity: that if one alternative is preferred to a second, and the second to a third, then the first is preferred to the third. If a person's preference relation is transitive, it constitutes an ordering of the options. The utility function represents this ordering. It puts the options in the same order as the preferences do. Any utility function that puts the options in this same order will represent the preferences equally well. Consequently, many different utility functions can represent the same preferences. The only significant feature of a utility function is its ordering of the options. A utility function defined this way is said to be 'ordinal.' Hence the name 'ordinalism.'

Axiomatic utility theory was later extended by John von Neumann and Oskar Morgenstern (1944) and by Leonard Savage (1954), independently of earlier work on the same lines by Frank Ramsey (1931). The extended theory recognizes that the outcome of an act is normally uncertain. It assumes that a person's preferences among acts are determined by the possible outcomes that may result from each act, and by the likelihood that they will result. It assumes that the preferences satisfy the same axioms as before, and also some more axioms that are concerned with the pattern of outcomes that may result from each act.

As in the simpler theory, a theorem shows that the preferences can be represented by a utility function. But because the extended theory makes more assumptions, it is able to establish stronger conclusions. In the extended theory, the utility function assigns utilities both to acts and to their possible outcomes. As before, one act is assigned a higher utility than another if and only if it is preferred. The special feature of the extended theory is that the utility of an act is the expected utility of its possible outcomes. (Expected utility is defined as the sum of the utilities of the possible outcomes, each multiplied by the outcome's probability of resulting.) Let us call this the 'expectation property' of the utility function. It means that, of two acts, the person always prefers the one that has the greater expected utility. She maximizes expected utility. Once again, this is only because of the definition of utility. Provided a person's preferences satisfy the axioms, the person can be construed as maximizing the expectation of something, and utility is defined as that thing.

The extended theory is known as 'axiomatic expected utility theory.' An important feature of it is that the utility function that represents preferences is not merely ordinal. Within the theory, not only does a utility function order acts in accordance with the preferences, but it also has the expectation property. This turns out to imply that differences—increases or decreases—in utility can be significantly compared with each other. Many different utility functions can still represent the same preferences. But if, according to one of these functions, the difference between the utilities of one pair of acts is greater than the difference between the utilities of another pair, then the difference is also greater according to any other function that represents the same preferences. A utility function in which differences of utility are comparable is said to be 'cardinal.'

2. *Utilitarianism and the Pareto Principle*

Utilitarianism in a broad sense is simply a concern to promote people's wellbeing. More precisely understood, it is the view that one ought to act so as to maximize the arithmetic total of people's wellbeing. Important consequences follow from the precise version that do not follow from the broader one. For

example, suppose we assume that the richer a person is, the less extra wellbeing will be brought her by adding an extra dollar to her wealth. This plausible assumption is known as 'diminishing marginal benefit of wealth.' An argument in favor of equality can be derived from it, together with precise utilitarianism. Diminishing marginal benefit suggests that rich people derive less benefit from extra money than do poor people. So, as extra money becomes available, giving it to poor people adds more to the total of wellbeing than giving it to rich people does. Precise utilitarianism therefore favors sending money towards the poor. This argument for equality is subject to important limitations, but it was nevertheless a significant contribution that economics made to utilitarian thinking. It was popular among economists before the 1930s, including Alfred Marshall and A. C. Pigou.

However, the arrival of ordinalism brought skepticism about the measurement of wellbeing. If we are even to make sense of precise utilitarianism, we must be able to make sense of an arithmetic total of wellbeing. Two conditions are necessary for that. First, each person's wellbeing must be an arithmetic quantity. To be more precise, it must be a cardinal quantity, which is to say that differences—increases or decreases—in a person's wellbeing must be significantly comparable with each other. Second, differences in one person's wellbeing must be significantly comparable with differences in any other person's: we must be able to say whether a particular increase or decrease in one person's wellbeing is greater or less than a particular increase or decrease in another's. Ordinalism made economists skeptical about both these conditions.

The source of their skepticism was epistemic. The ordinalists regarded a person's preferences as observable in principle. Since they defined utility to represent preferences, they regarded utility too as observable in principle. Because of this, they assigned ordinal utility a high epistemic status; Robbins called it a 'scientific' concept. But they were much more doubtful about other features of a person's psychology.

What about wellbeing? The ordinalists seem to have taken it for granted that a person prefers one thing to another if and only if it gives her more wellbeing. This view may be called 'preferencism.' On the face of it, preferencism is implausible. For example, presumably a person might altruistically prefer one thing to another, even if it gives her less wellbeing, because it is better for someone else. But the ordinalist espoused the doctrine of operationalism. According to operationalism, the meaning of a concept such as wellbeing is given by the operations we use in order to apply it. The ordinalists recognized no operation that would allow us to apply the concept of wellbeing except the operation of observing people's preferences. So they thought that the only meaning wellbeing can have is given by the preferencist formula. This means that utility measures wellbeing in an ordinal way: higher utility indicates higher wellbeing. The order of wellbeing therefore counts as a scientific concept, but the ordinalists acknowledged no other aspect of wellbeing. Wellbeing could not be counted as an arithmetic quantity, and nor could differences of wellbeing be compared between people. The preconditions of precise utilitarianism could therefore not be met.

Nevertheless, the ordinalists were utilitarian at heart. Consequently, they clung to the flimsy remnant of utilitarianism that survived their epistemic censure. They accepted the 'Pareto criterion,' named in honor of Vilfredo Pareto (1927). The Pareto criterion says that one state of affairs is better than another if everyone either prefers the first to the second or is indifferent between them, and if someone definitely prefers the first. This sufficient condition for one alternative to be better than another was the sole evaluative principle that the ordinalists were prepared to recognize. Few pairs of alternative economic arrangements will satisfy it, and so will few pairs of alternatives that are interesting elsewhere in ethics. So shrinking utilitarianism to the Pareto criterion is to cripple it. Ordinalism stultified welfare economics for decades. In particular, it denied that any judgment could be made about the value of equality.

A possible escape from the ordinalist straightjacket seemed to be offered by expected utility theory. Because expected utility theory yields cardinal utility functions, some authors thought it might allow wellbeing to be measured cardinally. But this thinking was confused about the relation between utility and wellbeing. Granted preferencism, utility measures wellbeing ordinally. But even granted preferencism and granted also that cardinal utility can be defined within expected utility theory, it does not follow that this cardinal utility measures wellbeing cardinally. Differences in utility are comparable, but it does not follow that they represent comparable differences in wellbeing. Furthermore, the second condition of precise utilitarianism remains unsatisfied. Nothing in expected utility theory makes one person's wellbeing comparable with another's.

Nevertheless, John Harsanyi in the 1950s produced no less than two new and important arguments that were intended to show that, indeed, the cardinal utilities defined by expected utility theory do have a place in ethical judgments.

His first argument (Harsanyi 1953) was this. Suppose we are comparing societies, asking which is the best. Harsanyi argued that this question could be answered by imagining a person who is allowed to choose among the different societies. She enters the one she chooses, but without knowing which position she will occupy within it. She has an equal chance of finding herself in the best position, or the worst, or anywhere else. Harsanyi claimed that the society she would choose under these circumstances is the best.

This is an appeal to the idea of a 'veil of ignorance,' which was later taken up by John Rawls.

From the subject's point of view, she is choosing between acts whose results are uncertain: the result of choosing a particular society will be that she ends up in an unknown position within that society. According to expected utility theory, for this person there will be a utility assigned to each position in the society. The utility for her of entering the society will be the expectation of all these individual utilities. Since she is assumed to have an equal chance of ending up in each position, this expectation is just the average utility of all the positions. So, of the alternatives available, the person will choose the one with the greatest average utility. If we assume every society has the same population, this is also the one with the greatest total utility. According to Harsanyi, then, the best society is the one with the greatest total utility. So this argument does indeed give a place in ethical judgments to utility, as expected utility theory defines it.

Does it also support utilitarianism? Precise utilitarianism implies that the best society is the one with the greatest total of wellbeing. So if utility measures wellbeing cardinally, Harsanyi's conclusion resembles precise utilitarianism. But Harsanyi's argument falls short of a complete argument for utilitarianism, because we still have no reason to think utility does measure wellbeing cardinally. Furthermore, the problem of comparing one person's wellbeing with another's remains.

Harsanyi's second argument (1955) was a formal theorem that is too complex to describe here. It is entirely distinct from the first argument, and it does not rely on a veil of ignorance. Still, it arrives at a similar conclusion, that the best society is the one with the greatest total of people's utility. For the same reasons as before, it does not amount to a complete defense of utilitarianism. Nevertheless, Harsanyi's two arguments cast an important new light on utilitarianism, and went a long way towards providing it with completely new foundations.

These foundations are based on preferences, and they depend on preferencism. Within moral philosophy as well as economics, it has become increasingly popular in recent years to base utilitarianism on preferences rather than, say, pleasure and pain. One reason is the prestige given to preference-based utilitarianism by Harsanyi's impressive work. His work issued, in turn, from the dramatic revision of utility theory caused by ordinalism. These are examples of the strong influence that economics has had on utilitarian thought.

3. *Tools for Ethics*

Economists have developed for their own purposes various formal tools that also turn out to be useful in ethics. Utility theory is one: apart from its contribution to utilitarian thought, it has other significant applications within ethics. For one thing, it constitutes a partial account of practical rationality; it specifies conditions that a person's preferences ought rationally to satisfy. An account of practical rationality is an essential background to ethical theory. For another thing, utility theory can easily be converted from a theory of preferences to a formal theory of the structure of value; its axioms can be made to apply to betterness instead of preferences (see Broome 1991).

Game theory is a second prominent example of a tool useful in ethics. The 'prisoners' dilemma' and related 'games' have led to some radical rethinking of the nature of rationality. Some authors (e.g., Gauthier 1986) have argued that they call for an understanding of individual rationality that somehow embodies an ethic of cooperation. Bargaining theory too—a branch of game theory—has proved useful at the foundations of contractualism (see Gauthier 1986, Binmore 1994, 1998).

A third example is social choice theory. Social choice theory is a branch of welfare economics that is principally concerned with 'aggregation.' It examines how the interests of individuals are aggregated together to determine the overall goodness of a society. One example of a principle of aggregation is the utilitarian principle that overall goodness is the arithmetic total of people's wellbeing.

Social choice theory originated in Kenneth Arrow's *Social Choice and Individual Values*, published in 1951 (Arrow 1951) (see Arrow's theorem). As an ordinalist, Arrow was concerned with aggregating preferences, specifically. However, his conclusion was negative; he demonstrated that people's preferences cannot generally be aggregated together in a plausible way to determine an overall ordering of the alternatives, ranking them from best to worst.

As a result, since Arrow's time, social choice theorists have gone beyond the bounds of ordinalism. They are no longer concerned with aggregating preferences only. A leader in this movement is Amartya Sen, whose *Collective Choice and Social Welfare* both codified social choice theory and set the scene for this new departure (Sen 1970). Ordinalism combined a utilitarian concern for people's wellbeing with skepticism about a quantitative notion of good. One can give up the skepticism, and many economists nowadays unashamedly take for granted a quantitative notion of a person's good or wellbeing. Or alternatively one can give up the utilitarianism and focus concern on something that is less prone to skepticism. Sen has lately been promoting people's capabilities—what they are enabled to do by the resources at their disposal—as the proper focus of concern.

4. *Shared Topics*

Economists and moral philosophers share an interest in several specific, practical subjects. But the co-

operation between the discipline is less than it should be. This section mentions two examples.

4.1 The Value of Life

For practical purposes, welfare economists are faced with the need to set a value on people's lives. For example, railways can be made safer by spending money on them. One benefit of doing so will be that fewer people are killed in train accidents. Economists need to decide how much money it is worth spending to achieve this benefit. So they need to determine how much good is done by saving a person's life or, equivalently, how much harm is done by a person's death.

Since ancient times, philosophers, too, have been interested in the value of life. Some modern discussion (e.g. Nagel 1979 and Feldman 1991) has been stimulated by an argument of Epicurus.' Epicurus tried to show that death is harmless to the person who dies, and the modern issue is still whether death is an evil and whether life has value. Some other modern philosophical writing takes it for granted that life is valuable, and asks more quantitative questions. For example, one issue that has been discussed is whether the value of a life is more affected by events that happen late in life or by those that happen early in life (e.g., Velleman 1991).

This is just the sort of question that should concern economists in their practical work, since it affects the comparative value of saving young people compared with saving old people. So this is a place where ethical theory could contribute to practical economics. Conversely, a more formal framework, of the sort that economic methods could supply, would improve the philosophical argument. But actually there has been virtually no contact between the economists and the philosophers working in this area. Economists have generally circumvented the need for theory by basing their valuations on the preferences people have about risks to their lives, unmoderated by theory. Perhaps because of this untheoretical approach, philosophers have reciprocally ignored the work of economists.

4.2 Equality

For a long time, welfare economists have been concerned with the value of economic equality; examples of important recent contributions are by Atkinson (1970) and Sen (1973). The same subject has also recently become important in moral philosophy; leading works are by Parfit (1995) and Temkin (1993). In this area, too, the contact between philosophers and economists has been limited, and both disciplines would benefit greatly from more.

The philosophers can fairly be said to have discovered an important distinction. Two very different moral concerns can have similar effects. One—generally called 'prioritarianism'—gives priority to improving the wellbeing of badly-off people, over improving the wellbeing of well-off people. Prioritarianism will generally lead one to steer resources towards worse-off people, which will generally have the effect of moving those people closer to equality with the better-off. So it will generally lead one to promote equality, but equality is not its direct object. A different concern is simply to reduce the distance between the better-off and the worse-off; this is sometimes called simply 'egalitarianism.'

The distinction is genuine, but because their effects are similar, it is difficult to specify the precise difference between prioritarianism and egalitarianism. But the formal methods of economics have the resources to do so. Indeed, the economic literature on inequality implicitly contains detailed analyses of both concerns. Despite that, the distinction has not been clearly recognized in economics; it is something that economics needs to learn from philosophy. Conversely, all the formal analysis that is already available within economics could help philosophers clarify the distinction they are making, and better understand its consequences. On the subject of equality, more cooperation would be very fruitful.

To summarize: economics and ethics have learnt a great deal from each other, but they could learn a great deal more.

Economics, History of

Economics emerged from the more venerable discipline of political economy during the latter half of the nineteenth century. The science of economics offers explanations of phenomena such as money, prices, and the production and exchange of goods. At its broadest sweep, it seeks the means to human happiness and prosperity.

1. Historical Background

While insights on economic phenomena can be found in the works of Plato (c. 427–347 BC), Aristotle (384–322 BC), and the medieval commentaries their work spawned, it was only in the early modern period, coincident with the Scientific Revolution, that a full-fledged discourse emerged. Nicolaus Copernicus (1473–1543), Jean Bodin (1530–96), Thomas Mun (1571–1641), William Petty (1623–87), and John Locke (1632–1704) are some of the more prominent figures of the sixteenth and seventeenth century who wrote on the subjects of money and trade. Copernicus and Bodin articulated the quantity theory of money, that a growth in the money stock results in a rise in prices, a phenomenon observed in Europe since the influx of gold and silver from overseas. Mun, a leading mercantilist and advocate of net exports as the key to England's prosperity, recognized that market forces transcend legal and institutional arrangements, and that genuine wealth comes from the growth of domestic production and the enrichment of the land. Petty was one of the first to devise quantitative measurements of economic phenomena, including per capita output. Locke refined the quantity theory of money, noting the velocity of money, and devised a labor theory of value. He also wedded the historic right to private property with the virtue of industry, and thus launched the liberal doctrine of political economy which subsequently played a profound role in the American constitution.

In the eighteenth century, the most distinguished treatises and essays on political economy were issued by Richard Cantillon (c. 1680–1734), David Hume (1711–76), François Quesnay (1694–1774), Ferdinando Galiani (1728–87), James Steuart (1712–80), and Adam Smith (1723–90), but there were hundreds of lesser known contributors to the subject. Hume and Quesnay were the most influential thinkers prior to Smith. Hume's *Treatise of Human Nature* (1739–40) argued that property claims were artificial and not natural, and thus had no deeper links to justice. Promise-keeping and contracts were privileged as the original steps in the formation of human society. In a series of *Political Essays* (1750), Hume made a number of brilliant insights on money, including his celebrated specie-flow mechanism whereby the gold supply and price level equilibrate via international trade. Hume also recognized that a sudden and unanticipated growth in the money stock can have real effects on output, at least in the interim between the influx of gold and the adjustment of prices. Hume also celebrated the advent of commerce as the means to bring peace and civility. Whereas Locke had highlighted the advent of money in prehistoric times as the critical moment when the accumulation of wealth became ethical, Hume pointed to the much more recent ubiquitous use of money, 'where no hand is empty of it,' as the more critical transition in human history.

Quesnay founded the first school of economics, known as Physiocracy, or the rule of nature. The Physiocrats or *les économistes* maintained that wealth only comes from the gifts of nature, from the fact that one plants one seed in the spring and obtains two in the fall. Wealth thus only truly grows in the agrarian sector, and so all policy measures should be taken to promote the cultivation of the land. All manufacturing activities were deemed sterile, merely transmuting materials but incapable of augmenting them. Quesnay devised one of the first models in economic theory, his celebrated *tableau économique*, which depicted the economy as a circular flow of money and goods between three sectors, the farmers, the artisans, and the landowners. The tableau adumbrated a nascent version of the multiplier via the 'zig-zag' transference of wealth from one sector to another over the course of a year. Physiocracy was widely influential, particularly on the work A. R. J. Turgot (1727–81) and Smith.

Adam Smith's *Wealth of Nations* (1776) canvassed the entire field of economics, including the theories of value and distribution, trade and development, public finance, even economic history and the history of economics. Smith rightly is admired for his concept of the 'invisible hand,' that highlighted the unintended and beneficial consequences of self-interested behavior. The idea that private vices might have public benefits had already been articulated by Bernard Mandeville (1670–1733), in his parody of human society, the *Fable of the Bees* (1714). Smith explored at length the problem of virtuous action in his *Theory of Moral Sentiments* (1759), which grounded human action in a natural capacity for sympathy and the desire for the approval of others. For all his emphasis on the pursuit of wealth, Smith saw it as a hollow dream, the futile pursuit of trinkets and baubles. But because we are deceived into thinking that wealth brings happiness, we work hard and thus keep the world going. Arguably no one has surpassed Smith in weaving such a penetrating and cynical view of human nature into such an expansive theory of material well-being.

Smith's ideas were extended and refined by, most notably, Thomas Robert Malthus (1766–1834), Jean-Baptiste Say (1767–1832), David Ricardo (1772–1823), and John Stuart Mill (1806–73), a tradition now known as the Classical school of political economy (see *Political Economy, History of*). The Classical economists emphasized a cost-of-production (labor) theory of value and the competing claims of the three economic classes (laborers, landowners and capitalists) over the annual product, most aptly depicted as the fall harvest of corn (wheat). Landowners and their servants were engaged in unproductive labor insofar as they did not produce tangible goods for consumption or investment. Malthus advanced a theory of population growth that reinforced the view that capital accumulation would reach a plateau in the not too distant future. Say popularized many of Smith's principles and also argued against the possibility of gluts in production.

Ricardo devised a novel theory of rent, as a return to the original and indestructible powers of the soil. Rent was a pure residual, and did not enter into the formation of prices. Ricardo highlighted the inverse tendencies of wages and profits, and recognized the importance of transfers of capital between different sectors of the economy. He also worked out the principle of comparative advantage in trade, predicated on the international immobility of capital. Mill extended the analysis by introducing nation-specific patterns of demand and rigidities in foreign exchange rates.

For the Classical economists, pricing came about after distribution, which was in turn determined by natural laws, for example, Malthusian laws governing the growth of population and the diminishing returns of the soil. Because of this emphasis on the natural order, the Classical economists tended to view their laws as inexorable, the result of forces deeper then any human action or process of deliberation. Even money was seen as having a motion of its own that transcended human agency. Scarcity, doom, and gloom were prevalent motifs to that set of writings, notwithstanding the remarkable growth rate of the European economy throughout the nineteenth century. Economists worried about the onset of the stationary state, whereby the profit rate fell and capital accumulation came to a halt; overpopulation resulted in a world of 'standing room only.' It is now apparent that they underestimated the potential for technological invention and innovation, both in the form of labor-saving and capital-saving procedures. Even if they did not comprehend the full ramifications of the industrial revolution of the late eighteenth century, there had already been many indicators in the agrarian sector that new techniques of plant breeding, crop rotation, and fertilization could have dramatic consequences for the accumulation of wealth. The reasons for their pessimism are still not fully understood.

2. *Neoclassical Economics*

Despite numerous appreciations by the Classical economists of the importance of utility or use-value in the determination of prices, it was only in the 1870s that economic theorists supplanted the labor theory of value with that of utility. Inspiration came from Jeremy Bentham (1748–1832), who believed that utility could be quantified and all actions reduced to a calculus of pleasure and pain. This was accompanied by a recognition that economic phenomena stemmed from the deliberations of the mind, and thus the locus of economic agency shifted from that of classes to individuals. Insofar as all labor created utility, the Classical distinction between productive and unproductive labor no longer obtained. Herein lay the germ of the more optimistic tenor that characterizes the

Neoclassical period. Wealth is nothing more than the maximization of utility; it is mental not material and thus knows no bounds. The Classical preoccupation with scarcity and the stationary state were thus swept aside.

The leading instigators of this so-called 'Marginal Revolution' were, in Britain, W. S. Jevons (1835–82), F. Y. Edgeworth (1845–1926) and Alfred Marshall (1842–1924) and, in Europe, Léon Walras (1834–1910) and Carl Menger (1840–1921). In the United States, the banner was carried by John Bates Clark (1847–1938) and Irving Fisher (1867–1947). The British group explicitly dropped the adjective 'political' from the name of the discipline, and sought significant ways to enhance its professional standing, through the formation of the British Economic Society and the *Economic Journal* in 1891, and by expanding and upgrading the study of economics in the university curriculum. Economics already had a much greater standing in France, due to its close links with the study of engineering and law, but there too efforts were taken by Charles Gide (1847–1932) and others to consolidate its standing as a full-fledged science. In 1878, every French university established a chair in economics and, in 1887, the *Revue d'économie politique* was founded. In Vienna, Menger attracted a number of students, giving rise to a full-fledged 'Austrian School' that survived until the Second World War. American economists garnered recognition with the founding of the American Economic Association in 1885, and the creation of three journals, the *Quarterly Journal of Economics* (1887), the *Journal of Political Economy* (1892) the *American Economic Review* (1891).

The Classical theory of Smith and David Ricardo had looked more to long-run 'natural' prices than to those that fluctuate daily in the market place. With the new emphasis on utility and demand, economists such as Jevons, Walras, and Menger maintained that every observed price was the manifestation of individual mental deliberations. There was no underlying more fundamental price to discern over the long run. The price of a good was determined at the margin, at the point where a given economic agent chose to forgo an additional unit of one specific good, and spend her money on other goods. Similar tradeoffs were construed for labor and leisure, for investments and savings, and thus the wage and profit rates were equally seen to be the effects of deliberations at the margin.

Jevons's grounding of the theory of prices in a concept of utility paved the way for the mathematization of economics. Market purchases were conceived as continuous functions of the utility that accrued to each additional infinitesimal unit of a good. Price ratios were posited to be commensurate to the last additional increments of utility that would be gained by additional purchases of two different goods. Insofar as each individual achieved this level of satisfaction, subject to budgetary constraints, their income would be perfectly distributed. Edgeworth found the means to incorporate Lagrangian techniques, thereby bringing added rigor to the concept of maximization. He also devised the indifference curve and contract curve, thus enabling a clearer representation of the links between individual deliberations and market maneuvers.

Marshall enriched the analysis of the demand curve, with rigorous definitions of elasticity and consumer surplus. He preferred to focus on the case of partial equilibrium, thus invoking numerous *ceteris paribus* conditions so as to isolate cases of comparative statics. Money income, for example, was held constant, as were the prices of all other commodities. Such simplifications, while unrealistic, were nonetheless insightful. To Marshall's credit, he struggled throughout his life with the trade-off between theory and empirical veracity, and left numerous accounts of these inquiries.

Walras went further in that he posited an economy in general equilibrium, whereby a silent auctioneer would establish those prices which would clear all markets simultaneously. By depicting the economy as a series of equations, Walras was able to demonstrate that there was an equal number of unknown variables. Hence, an algebraic solution could in principle be found. More specifically, given n productive services (land, labor, and capital) producing m finished goods, individuals with specific endowments, budget constraints, and a given set of prices, would achieve the point where supply equals demand across the entire economy. Walras made a number of simplifying assumptions, for example, that input coefficients for production were fixed, and that prices could be defined in terms of a single good, serving as the *numéraire*. However, he was unable to demonstrate rigorously that there was such a general equilibrium. Important refinements of this theory were undertaken by numerous others, notably Eugen Slutsky (1880–1948), Gustav Cassel (1866–1945), Abraham Wald (1902–50), John Hicks (1904–89), Oskar Lange (1904–65), and Paul Samuelson. In the late 1950s Kenneth Arrow and Gerard Debreu provided the capstone for the theory of general equilibrium.

The most salient feature of economic theory since the 1870s is its systematic use of mathematics, particularly the calculus. Much of the original momentum to transform literary political economy into a mathematical discipline was drawn from the wish to emulate physics. Even in the eighteenth century, Adam Smith among others found ways to inject mechanistic imagery into economic theory, the tendency of prices, for example, to gravitate to their natural price. John Stuart Mill, in his *System of Logic* (1843), developed the first extensive argument for viewing political economy as a science much like Newtonian mechanics. Both sciences were primarily axiomatic and deductive, and nonexperimental. Verification came after one had

derived the central principles from commonplace assumptions about the behavior of bodies, both human and physical. But political economy, Mill argued, could not make predictions with the kind of numerical precision of astronomy, and hence was deemed an inexact science.

What motivated the early marginalists to develop a mathematical theory was the realization that the phenomena themselves were quantitative, and that the mind deliberated in quantitative terms. They drew inspiration from new developments in logic and psychology, notably the work of George Boole (1815–64), Alexander Bain (1818–1903), and Theodore Fechner (1801–87). Strong analogies to the science of physics, notably mechanics and thermodynamics, also motivated the recasting of economics into mathematical form. Jevons, Walras, Edgeworth, Clark, Fisher, and Marshall each independently arrived at mathematical renditions of the theory of value and distribution. They found ways to apply geometry, algebra, probability theory, and the calculus. Economists have since adopted other mathematical techniques, such as topology, set theory, and have even linear programming trants to Wassily Leontie (1960–99).

In the period 1870 to 1930, many economists began to undertake the collection of large quantities of data and to estimate key economic variables or arrive at patterns such as business cycles. Efforts to measure and estimate key variables reach back to Petty, and statistical societies and investigations were commonplace by the mid-nineteenth century. But the systematic application of statistical methods and probability theory—what has come to be known as econometrics—only got underway by the Neoclassical period. Jevons, Henry Moore (1869–1958), and W. C. Mitchell (1874–1948) all attempted to discern business cycles by the regression of price data. Other important contributors to econometrics before the Second World War were Slutsky, Udny Yule (1871–1951), and Ragnar Frisch (1895–1973). Efforts to manage and plan the economy after the Great Crash of 1929 gave a significant boost to econometric research in Europe under the aegis of Jan Tinbergen (1903–94) and Trygve Haavelmo (1911–99) and in the United States in the form of the Cowles Commission. But while the Econometric Society was formed in 1930 and, in 1933, launched its own journal, *Econometrica*, the field only achieved full academic standing in the post-war period, and has obviously been much assisted with the advent of electronic computers (see *Econometrics, History of*).

3. *Applied Economics*

The Classical economists frequently engaged in public debates on such subjects as taxation, unionization, and foreign trade, but they nonetheless viewed their theoretical claims as in a separate sphere from their more practical ones. The art of political economy, the application of economic principles, was grounded in theoretical reflection, but also drew upon other bodies of knowledge, such as history, legal theory, and moral philosophy.

With the early Neoclassical economists, theory and policy became more closely linked, even though, paradoxically, the theory depicted an ideal world that was ahistorical and apolitical. The bridge principles which would link the world of Walrasian general equilibrium to the world as we know it have yet to be fully spelled out. Nevertheless, the tools of marginal utility were incorporated by Edgeworth and A. C. Pigou (1877–1959) quite readily into a branch called welfare economics, which addressed among other topics the age-old questions of distributive justice. In the first decades of the twentieth century, Vilfredo Pareto (1848–1923) devised some important tools for the ranking of alternative allocations of resources. A given allocation was deemed to be a Pareto optimum if no alternative arrangement could make at least one person better off without worsening the state of another. A Pareto improvement is a step toward such an optimum.

Social welfare functions took utility to be additive and measurable, even though the early Neoclassists had cautioned against such assumptions. There is, as yet, no measurable unit of utility, a 'util,' and economists generally have abandoned such a search, despite the implicit use of cardinal measures in some areas of analysis. Furthermore, although appeals to utility attempt to locate judgments of the 'good' in the hands of individuals, welfare economics necessarily incorporates some ethical judgments, both in determining what is socially desirable and in making policy recommendations in a world of scarcity. The general stance, however, is one of ethical neutrality. As Pigou decreed, economic welfare is synonymous to the good.

Another important field in applied economics is money and banking. Here, the school in Sweden, notably Cassel and Knut Wicksell (1851–1926) stands out. Irving Fisher was instrumental in formulating in algebraic terms what came to be known as the quantity equation, and also undertook steps to measure the average velocity of money, the rate at which a monetary instrument passes from one hand to another in the course of a year. But the person to transform most fully our understanding of money and reluctance to spend was John Maynard Keynes (1883–1946), who unpacked the underlying motives for the demand for money in terms of precautionary, transactionary, and speculatory needs. Keynes revived the seventeenth-century concern for hoarding money as a primary cause of economic slumps, whereby interest and profit rates are so low as to deter any investment. To escape the 'liquidity trap,' Keynes recommended government intervention in the form of fiscal and monetary stimuli. He placed considerable faith in fiscal policy as the

means to redistribute wealth, alleviate unemployment, and eventually liberate humankind from its passion for money. Keynes envisioned a world of developed economies run by decentralized institutions, whereby individuals would no longer be confined by economic necessity and could thereby transcend the cupidity that characterized the system of capitalism.

4. Heterodox Economics

Although the Neoclassical theory became the dominant position by the 1930s, there were many alternative streams of thought, some of which still survive to this day. In Germany, for example, such thinkers as Friedrich List (1789–1846), Gustav Schmoller (1838–1917), Werner Sombart (1863–1941), and Max Weber (1864–1920) were adamantly historical and sociological in their approach to the study of economic phenomena. They saw the Neoclassical commitment to rationality and mathematical methods as misguided. Others, such as Karl Kautsky (1854–1938) and Rosa Luxemburg (1871–1919), followed in the footsteps of Karl Marx (1818–83), who had emphasized strife between economic classes and upheld the labor theory of value. Marxist economics had its longest lineage in Eastern Europe, in the works of Vladimir Lenin (1870–1924), Nikolai Bukharin (1888–1938), Oskar Lange (1904–1965), and Michal Kalecki (1899–1970). Nikolai Kondratieff (1892–1931), while working under the Soviet system, made insights on the long waves of capitalism that were seen to be antithetical to Marxism.

In late-Victorian and Edwardian England, new schools of thought were founded that were either historical or socialist in orientation. Under the inspiration of Thorold Rogers (1823–90) and Arnold Toynbee (1852–83), economic history secured a firm toehold in the university curriculum, where subsequently it has flourished in the hands of William Ashley (1860–1927), G. D. H. Cole (1889–1959) and Phyllis Deane. The Fabians—George Bernard Shaw (1856–1950), Sidney Webb (1859–1947), and Beatrice Webb (1858–1943)—were instrumental in founding the London School of Economics (1895), which soon abandoned its socialist roots. Built up by such eminent economists as Edwin Cannan (1861–1935), Lionel Robbins (1898–1984), and Friedrich Hayek (1899–1992), the LSE became a leading institution for economic research and education. Sir John Hicks was the dominant figure at Oxford in the mid-twentieth century. At Cambridge University, two students of Keynes's, Piero Sraffa (1898–1983) and Joan Robinson (1903–83), cultivated neo-Ricardian theories which drew attention to capital rigidities and imperfect competition. The contributions of Dennis Robertson (1890–1963), Richard Kahn (1905–89), and Nicholas Kaldor (1908–86), however, insured that Cambridge to this day is primarily aligned with Neoclassical thinking.

Yet another group drew inspiration from Carl Menger (1840–1921), whose *Principles of Economics* appeared in 1871, the same year as Jevons's most important economic treatise. In one respect, these works bore a strong similarity in that they both treated prices in terms of the utility theory of value. But Menger was steeped in the tradition of Immanuel Kant (1724–1804) and G. F. Hegel (1770–1831), and was most sharply opposed to the German historical school of the mid-nineteenth century. He did not appreciate utilitarianism, nor the turn toward mathematical techniques. Together with his pupils, Friedrich von Weiser (1851–1926) and Eugen von Böhm-Bawerk (1851–1914), the Austrian school made strong commitments to methodological individualism, to the heroic efforts of the entrepreneur, and to the efficacy of market mechanisms. Introspection and *a priori* reasoning were the main methods of inquiry, insofar as economic phenomena were the products of a logic of choice. The Austrians also drew attention to the role of information, the scarcity of time, and the importance of defining economic needs and wants.

Both Joseph A. Schumpeter (1883–1950) and Hayek harked from Vienna, but moved considerably past the teachings of Menger. Both also emigrated to America before the Second World War and, in Hayek's case, settled in England, so that their respective doctrines came to evince an interesting blend of Austrian rationalism and Anglo-American empiricism. Schumpeter's *Capitalism, Socialism and Democracy* (1942) and Hayek's *Road to Serfdom* (1944) are two of the most popular nontechnical works of the twentieth century. Like Keynes, they attempted to predict the fate of capitalism as an economic system and speculate on the political measures required to sustain the status quo.

In America, under the inspiration of evolutionary biology and Social Darwinism, a school that came to be known as Institutionalism took shape with the work of, most notably, Thorstein Veblen (1857–1929), John R. Commons (1862–1945), and Wesley Clair Mitchell (1874–1948). They viewed economic phenomena in evolutionary terms; for example, human rationality was but one step from animal instinct. Human institutions were replete with contradiction; human striving was in many respects futile. Economic phenomena were treated in broader sociological terms, as part of the government and legal system. Although the Institutionalists failed to generate a large following, they were a viable force in the economics profession right through the 1940s and, more recently, have made a second coming in the form of New Institutionalism, as expounded by Douglass North most notably. Here, the salient concepts are transaction costs and institutions, which are defined as rule-setting bodies that serve to minimize such costs. From a different standpoint, Ronald Coase's theorem shows

that there are no externalities given zero transaction costs and well-defined property rights.

5. *Postwar Developments*

Since World War Two, Neoclassical economics, particularly in the United States, has become a formidable edifice. American economists garner the majority of the Nobel prizes in economics, and many non-American economists find it essential to spend some period of their career studying or teaching in the United States. Paul Samuelson's *Foundations of Economic Analysis* (1947) provided the first mathematical exposition of price dynamics; Milton Friedman restored the monetarist doctrines of the pre-Keynesians and, more recently, John Muth, Thomas Sargent, and Robert Lucas have inspired a train of thinking known as the New Classicism. The efforts of Frank Knight (1885–1972) and Jacob Viner (1892–1970) made the University of Chicago the most prominent center for the study and dissemination of economic theory. More Nobel Laureates in economics have had an affiliation with that university than with any other.

Undoubtedly the most original and influential subfield to develop since the war has been game theory, which had antecedents in previous work, such as that of Blaise Pascal (1623–1662) and Augustin Cournot (1801–77), but which truly came into its own with the publication of John von Neumann (1903–57) and Oscar Morgenstern's (1902–77) *Theory of Games and Economic Behavior* (1944). Game theory has underscored the importance of uncertainty, of suboptimal outcomes, and of strategizing. It has also drawn attention to the significance of information as an economic resource. Similar kinds of analysis can be found in decision theory and rational choice theory, such as Arrow's impossibility theorem.

Economists tend to specialize in one branch, some of which have longstanding roots, for example, labor economics or public finance. Other significant postwar developments are cliometrics (Robert Fogel), experimental economics (Vernon Smith), and household economics (Gary Becker). As with all of the aforementioned, the predominate aim is model building driven by mathematical tractability. Economists rarely seek laws of a general nature. In contrast to the economists of the Classical era, which might even be characterized as the glorious age of universal principles—the law of diminishing returns, of the falling rate of profit, and Say's law, Neoclassical economists prescribe more limited generalizations, such as the Phillips curve or the Heckscher–Ohlin conditions for trade. The search for general laws seems like a task long forgotten. Nevertheless, the Neoclassical theory is assumed to be universal in scope, to apply not only to fully developed nations but to all human societies, past and present. The model of rationality that lies at its conceptual foundations is purported to capture human agency at its most fundamental.

Notwithstanding all of the mathematical refinement that has transpired in the past century or so, there remains a vociferous minority who point to severe limitations of the Neoclassical paradigm and call for more public ownership or social controls. Herbert Simon and, more recently, Amartya Sen have called into question the model of human rationality to which most Neoclassicists subscribe. Other prominent critics since the 1950s are Joan Robinson, Gunnar Myrdal (1898–1987), Kenneth Boulding (1910–93), Robert Heilbroner, and John Kenneth Galbraith. They desist from singing the praises of capitalism, but do not view socialism as a viable alternative. Criticism is done with full knowledge and understanding of the mainstream theory, and for that reason these economists, and several more, have won large audiences for their writings. The Neoclassical theory has been remarkably robust in the face of such criticism, but its longevity is by no means guaranteed.

Economics: Overview

Economics is often defined as the study of the production, distribution, and utilization of scarce resources. Although this description is a useful characterization of much economic analysis it is in some ways unsatisfactory. To many economists this definition confines the scope of economic analysis so that some subjects studied by economists, such as the determinants of occupational safety (see *Safety, Economics of*) or the determinants of health care (see *Health Economics*), may not be included. The history of economic analysis (see *Economics, History of* and *Political Economy, History of*) is a fascinating demonstration of how the topics that economists take up for study have changed systematically over the last two centuries.

More generally, economics is the study of social relations that result from the wants that people have. This broad definition no doubt encompasses most, if not all, of economics. However, even this broad definition of economics omits some important activities that economists undertake as part of their profession. Economists have been major contributors, for example, to the development of specialized software useful to economists and other social and behavioral scientists (see *Econometric Software*) and to the development of mathematical tools of broad applicability in the social and behavioral sciences (see *Game Theory: Noncooperative Games*).

Most broadly, then, some would simply define economics as the studies that economists do.

1. *The Subject and Method of Economics*

Economics is divided either by subject matter or by the primary method used for study. The subject matter of economics is often divided into the areas of microeconomics, the study of the behavior of individual agents, and macroeconomics, the study of the behavior of aggregate units.

The vast majority of economists who work in academia, business, or government are working on problems that would be called microeconomics. However, the discussion of the aggregate economy, and public policies related to the aggregate economy, often pique the public interest for prolonged periods far more than do the issues of microeconomics. Aggregate unemployment and its movement is always of interest (see *Unemployment: Structural* or *Monetary Policy*, for example), but Antitrust Policy or health care costs (see *Health Economics*) are only on the public agenda occasionally. To show the magnitudes involved, we may compare the number of university graduates of business schools (who almost certainly have studied microeconomics) with the number of graduates from economics departments (who almost certainly have studied macroeconomics). In the USA in the academic year 1995–1996, for example, there were 13 times as many business school graduates (227,000) as there were economics graduates (17,000).

Macroeconomic analyses often focus on key indicators like the unemployment rate, gross national product, or price inflation (see *Macroeconomic Data*). It is increasingly common for these analyses to be based on the aggregation of microeconomic analyses, although this is not always the case.

Microeconomic analyses often focus on the details of a particular market or organizational structure. The breadth of subjects taken up using the tools of microeconomics is truly breathtaking, ranging from art, culture, and sports (see *Art and Culture, Economics of* and *Sports, Economics of*) to housing and agriculture (see *Housing Economics* and *Agriculture, Economics of*). As such, these analyses often abstract from other analyses that may be relevant in principle, but are thought to be irrelevant in practice.

Economics is often also distinguished by the methods that are used. Very generally, economic studies are often said to be either theoretical or empirical, and sometimes both. Although the techniques of analysis may vary dramatically among theoretical studies, ranging from the purely verbal to the highly mathematical, these studies have in common the attempt to provide a general framework of analysis that is independent of the direct observation of economic behavior.

Empirical studies in economics are less concerned about generality and more concerned about the direct observation of economic behavior. In principle, it is a commonly held goal of many economists to provide both a theoretical framework and the observational analyses that serve to test the implications of the assumptions on which the theory depends. However, this is not always possible or desirable.

The editors of the *Journal of Economic Literature* have provided a useful and exhaustive set of categories for the literature of economics. The categorization was done after an exhaustive set of studies of the nature of the vast literature of economics and with the assistance of a number of distinguished economists. Broadly speaking, there are 18 broad categories and a residual category that contains a group of special topics. The 18 categories are General Economics and Teaching; Methodology and History of Economic Thought; Mathematical and Quantitative Methods; Microeconomics; Macroeconomics and Monetary Economics; International Economics; Financial Economics;

Public Economics; Health, Education, and Welfare; Labor and Demographic Economics; Law and Economics; Industrial Organization; Business Administration, Business Economics, Marketing, and Accounting; Economic History; Economic Development, Technological Change, and Growth; Economic Systems; Agricultural and Natural Resource Economics; and Urban, Rural, and Regional Economics. As this list demonstrates, the categories of economics are not really mutually exclusive and it is often useful to categorize a particular economic study under more than one heading.

It should be apparent from this list of categories that modern economic analysis covers a very broad set of topics. Indeed, the list of topics included changes continuously.

2. *The Profession of Economics*

One of the main changes in economics since around 1900 is the increasing professionalization of the subject. At the beginning of the twenty-first century many people earn their living directly or indirectly from economic research. This may be seen in the phenomenal growth in the volume of published economic scholarship. The first economics journal, the *Zeitschrift für die gesamte Staatswissenschaft* (Tübingen), was founded in 1844. It was 22 years before another journal, the *Quarterly Journal of Economics* (Cambridge, MA), was created. By 1900 there were still only seven economics journals. By 1962 the number of economics journals had increased to 76, a growth of about one per year, but only 24 of these were published in the USA.

In 2001 there are approximately 610 economics journals, of which 300 were published in the USA. The growth in the number of journals in the last half of the twentieth century was at a rate 10 times greater than was the case in the first half of the twentieth century. These journals today publish about 2,600 issues and contain over 350,000 printed pages each year.

The growth and professionalization of economics has led to a change in the way that economists organize themselves. The oldest professional organization of economists, the American Economic Association, was founded in 1885 with fewer than 200 members. By 1962 the membership had grown to 11,000, most of the growth occurring between 1940 and 1962. By 2001 membership had reached 22,000, but it had changed very little during the previous two decades.

Other general-purpose organizations of economists have not fared so well. The Royal Economic Society was formed in 1890 and by 1959 had 5,000 members. In 2001, however, the Royal Economic Society only has 3,300 members. At the same time, however, there has been considerable growth in the number of specialist organizations of economists. Worldwide there are now 257 economics associations, of which 77 are headquartered in the USA. Many of these organizations have small memberships, but they often remain viable because they serve the strongly focused interests of a special group.

O. Ashenfelter

Economics, Philosophy of

Like many of the social sciences, economics grew out of philosophy, and the concerns of economists continue to intersect with those of philosophers. Philosophical reflections on (a) scientific method and social ontology; (b) the nature of rationality, self-interest, and preference; and (c) welfare, justice, equality, and freedom are of abiding significance to economists and other social scientists.

1. *Economic Methodology*

Philosophical reflection on economics is ancient, but the conception of 'the economy' as a distinct object of study dates back only to the eighteenth century. Aristotle addresses some problems of economics mainly as problems of household management. Scholastic philosophers addressed ethical questions concerning economic behavior, and they condemned 'usury'—that is, the taking of interest on money. With the increasing importance of trade and nation-states in the early modern period, 'mercantilist' philosophers and pamphleteers addressed questions concerning the balance of trade and the regulation of the currency. Only in the work of the physiocrats and especially of Adam Smith do scholars begin to think of the economy as an object of study with its own principles and laws.

Eighteenth century philosophers wrote in the shadow of Newton's towering accomplishments. David Hume is unabashed about his hopes to develop

a science of mind and society in the image of Newton's science of the solar system. To that end, he seeks out general laws of individual thought and action, out of which larger-scale orderly relations will arise, in just the way that patterns in planetary motion arise from the laws of motion and gravitation governing individual bodies. Thus Hume traces the rise in prices and the temporary increase in economic activity that follow an increase in currency to the perceptions and actions of individuals who first spend the additional currency.

It then lay to Adam Smith to extend such a method to a systematic *Inquiry into the Nature and Causes of the Wealth of Nations* and to make explicit an implication of previous causal inquiries such as those of Hume, the physiocrats, and of many of the mercantilists. That implication (which is arguably the foundation for all social science) is that the social, aggregative implications of individual choices are often *unintended*. In spending their additional gold imported from abroad, traders do not intend to increase the price level. But that is what they do nevertheless. In this way unintended regularities that arise from the intentional choices of individuals can rule those individuals just as surely as the regularities of nature, and, like nature, societies can be objects of scientific investigation.

1.1 Classical Economics and the Method a Priori

Although Adam Smith made some general comments about scientific method in his *History of Astronomy* and other essays, he wrote little explicitly about the method of economics. The first extended reflections on economic methodology had to wait until Nassau Senior (1836) and John Stuart Mill (1836). Their essays must be understood against the background of the prevailing economic theory. Like Smith's economics (to which it owed a great deal) and modern economics, the 'classical' economics of the middle decades of the nineteenth century traced economic regularities to the choices of individuals facing social and natural constraints. But, as compared to Smith, more reliance was placed on severely simplified models. In David Ricardo's *Principles of Political Economy*, a portrait is drawn in which wages above the subsistence level lead to an expanding labor force, which in turn requires more intensive agriculture or cultivation of inferior land. The extension of cultivation leads to lower profits and higher rents; and the whole tale of economic development leads to a gloomy stationary state in which profits are too low to command any net investment, wages return to subsistence levels, and only the landlords are affluent. From the time Ricardo's *Principles* was published (1819), the data available to classical economists was never in accordance with the trends the theory predicted. Yet the theory continued to hold sway for more than half a century, and the unfavorable data were explained away as due to various 'disturbing causes.'

It is not surprising then that Mill's account of the method of economics would emphasize the relative autonomy of theory. Mill distinguishes between two main kinds of inductive methods. The method *a posteriori* is a method of *direct* experience. It is only suitable for phenomena in which few causal factors are operating or in which experimental controls are possible. Mill's famous methods of induction are detailed specifications of the method *a posteriori*. In his method of difference, for example, one holds fixed every causal factor except one and checks to see whether the effect ceases to obtain when that one factor is removed.

Unfortunately, such direct inductive methods cannot be used to study phenomena in which many causal factors are in play. If, for example, one attempts to investigate whether tariffs enhance or impede prosperity by comparing the prosperity with and without tariffs, the results will be irregular and unreliable because other causes besides tariffs will also differ across societies and times. So one needs instead to employ the method *a priori*. Despite its name, this is an *inductive* method, but it is an indirect inductive method. One first determines the laws governing individual causal factors in domains in which direct inductive methods are applicable. Having then determined the laws of the individual causes, one investigates their combined consequences deductively. Finally, there is a role for 'verification' of the combined consequences, but owing to the causal complications, this testing has comparatively little weight. The testing of the conclusions serves only as a check on one's deductions and as an indicator of whether there are significant disturbing causes that one has not yet accounted for. Mill gives the example of the science of the tides. One determines the law of gravitation by studying planetary motion, in which gravity is the only significant causal factor. Then one develops the theory of tides deductively from that law and information concerning the positions and motions of the moon and sun. The implications of the theory will be inexact and sometimes badly mistaken, because many subsidiary causal factors influence tides. By testing the theory one can uncover mistakes in one's deductions and evidence concerning the role of the subsidiary factors. Because of the causal complexity, such testing does little or nothing to confirm or disconfirm the law of gravitation, which has already been established.

Because economic theory includes only the most important causes and necessarily ignores many minor causes, its claims, like claims concerning tides, are inexact. Its predictions will be imprecise, and sometimes dead wrong. But it is possible nevertheless to develop and confirm economic theory by first establishing in simpler domains the laws governing the major causal factors and then deducing their con-

sequences in different circumstances. For example, statistical data tell a mixed story about the relationship between minimum wages and unemployment; and there is no data at all about what the consequences for employment would be of an extremely high minimum wage. On the other hand, everyday experience teaches one that firms can choose among more or less labor-intensive processes and that a high minimum wage will make more labor-intensive processes more expensive. Since one also has good reason to believe that firms try to keep their costs down, one has good reason to believe that a high minimum wage will increase unemployment.

According to Mill, economics is not only inexact and committed to the method *a priori*. In addition, he maintains that it is a *separate science*. What distinguishes economics as a discipline is not only its concern for a certain domain of phenomena, but also its limitation to a particular set of causal factors, which predominate in this domain. With respect to this domain, one can (at a certain level of approximation) ignore the myriad causal factors that influence all social phenomena and which are the subject matter for sociology and develop economics separately. In defending a view of economics as in this way inexact and separate and a view of economists as following the method *a priori*, Mill was able to reconcile his empiricism and his commitment to Ricardo's economics.

Although Mill's views on economic methodology were challenged later in the nineteenth century by dissident economists who believed that the theory was too remote from the contingencies of policy and history, Mill's methodological views dominated the mainstream of economic theory for well over a century. Mill's vision survived the transformation of economics from classical to neoclassical and is clearly discernable in the most important methodological treatises concerning neoclassical economics, such as John Neville Keynes' *The Scope and Method of Political Economy* (1891) or Lionel Robbins' *An Essay on the Nature and Significance of Economic Science* (1935). Indeed, Hausman (1992) argues that current methodological practice closely resembles Mill's methodology.

1.2 Twentieth Century Philosophy of Science and Economic Method

Beginning in the 1930s, mainstream economists began to have a bad conscience about their traditional methodology, which some saw as insufficiently empiricist. Robbins is a transitional figure, because at the same time that he clung to Mill's methodology (1935, Chap. 4) and to the identification of the domain of economics with the predominance of particular causal factors (the allocation of scarce means that have alternative uses—1935, Chap. 1), he also offered his apparently empiricist critique of interpersonal utility comparisons as untestable value judgments (1935, Chap. 6). Terence Hutchison argued that the propositions of pure theory were so hedged with *ceteris paribus* conditions that they were not testable (1938). Paul Samuelson argued for a need to separate the 'operationally significant' economic wheat from the chaff, and in his theory of revealed preference he provided a model for how to do so (1947). Other economists cited survey data to argue that the theoretical propositions of economics were false. The confusing methodological situation stabilized in the 1950s with arguments by Fritz Machlup (1955) and especially Milton Friedman (1953) that economists need be concerned to fit only data concerning prices and quantities and that the 'realism of assumptions' is irrelevant.

Although confused, mistaken, and inconsistent with the practice of mainstream economists—including his own practice—Friedman's views have dominated the methodological conceptions of mainstream economists over the past two generations. His views are confused because they conflate many different kinds of 'assumptions' and 'realism.' Basic generalizations, propositions concerning initial conditions, and antecedents of conditional claims are all called 'assumptions.' Assumptions are called 'unrealistic' if they are false, incomplete, or not approximately true. Friedman's views are mistaken, because (as Mill already emphasized) market data are generated by too many causal factors to provide effective tests of economic theory. The eclecticism that Friedman's official methodological position counsels—'don't worry about what theory says, just ask whether it fits market data'—contradicts the firm and narrow commitment to a specific theory that characterizes mainstream economics, including Friedman's own work. Nevertheless, Friedman's views were warmly embraced because they freed mainstream economists to ignore criticisms of their theories and to abandon all empirical work apart from econometrics.

In the 1970s and 1980s other streams of contemporary philosophy of science began to influence the methodological reflections of economists. Karl Popper's view that scientific theories must be falsifiable, which had been defended by Hutchison, was taken up and emphasized by Mark Blaug (1992). According to Popper, the hallmark of science is to formulate theories so that they can be exposed to empirical testing and to reject theories that fail tests. Hutchison and Blaug object that mainstream economic theories are not harshly tested and that mainstream economists are unwilling to surrender them when they fail the few tests they are subjected to. In his extensive publications, Lawrence Boland (1982) has also emphasized the relevance of Popper's views to economic methodology, although Boland's interpretation of Popper is rather different than Blaug's or Hutchison's.

Imre Lakatos' methodology of scientific research programs (which represented a wedding of some of

Thomas Kuhn's insights to Popper's philosophy of science) was for a while widely discussed (Latsis 1976, de Marchi and Blaug 1991). Although still emphasizing the importance of empirical criticism, Lakatos insisted that theories should not be abandoned until superior alternatives are found, and his emphasis on heuristics struck a responsive chord.

A spate of prominent contemporary writers on methodology: Roger Backhouse, Bruce Caldwell, Neil de Marchi, D. Wade Hands, and E. Roy Weintraub have a more ambivalent relationship to Popper's and Lakatos' philosophy. Caldwell wrote a series of searching though charitable criticisms of Popperian views. Backhouse, de Marchi, Hands, and Weintraub were all at one time enthusiastic about Lakatos' views, though to differing degrees all have moved away from them now. Backhouse and de Marchi remain the closest. Hands has become a proponent of the application to economics of new work on the sociology of science, while Weintraub's work on the stabilization of concepts in economics has been more influenced by literary theorists

More recently, alternatives to philosophy of science influenced by work in literary theory and sociology have also developed a following among economists. In a series of stylistically brilliant works, Deirdre McCloskey has criticized the whole project of exploring a normative methodology for economics and has urged instead that economists attend to their rhetoric—that is, to their ways of persuading one another (1985). This work has been highly controversial because many of McCloskey's formulations apparently reduce questions about the correctness or incorrectness of economic claims to questions about what most economists accept. Such a view would imply that minority views are always mistaken. McCloskey denies such a radical reading of her position, but it is not clear how to avoid it without incorporating normative methodological commitments into the rhetoric of economics.

Philip Mirowski's work on methodology is heavily historical and less radical epistemologically than McCloskey's. He has explored the influence on economics of the formal analogy between utility theory and physics (1989). More recently, his work has shown increasing concern with sociological influences. For other work that tests the boundaries of conventional methodology, see Mäki et al. (1993).

Over the last 15 years, economic methodology has become a large field. It has its own *Journal of Economic Methodology* and occupies a large part of the journal, *Economics and Philosophy*. Dozens of monographs on economic methodology have been published. Graduate programs in the field have been established (including a Ph.D. program at Erasmus University in Rotterdam), and there are regular sessions on economic methodology at meetings of economists and philosophers. The field is very diverse, and each of its leading figures has a distinctive approach. Although one can roughly identify Popperian–Lakatosian and sociological–literary schools, there is no easy way to categorize contemporary methodology.

Several methodologists have been particularly interested in the role of explicitly causal notions in economics (see *Causes and Laws: Philosophical Aspects*; *Causation: Physical, Mental, and Social*). Nancy Cartwright (1989), who is also a distinguished philosopher of physics, has (unlike most philosophers writing on economics) paid a great deal of attention to econometrics. She has defended the importance of specifically causal considerations in science, and has argued that econometricians have made important contributions to a philosophical understanding of causation. Cartwright holds that economists should be understood as attempting to identify causal *capacities* and that the work of econometricians can be understood as contributing to this task.

Daniel Hausman (1992) defends a modernized variant of Mill's methodology that depicts economics as inexact and permits the plausibility of the basic principles of economics to count in the assessment of economic theories. But he is skeptical of the view that a small set of causal factors do indeed predominate in the domain of economics and defends a greater attention to the results of experiments, surveys, and field work. He has increasingly emphasized the role of causal generalizations in mainstream microeconomic theory.

Kevin Hoover (2000)—unlike most methodologists—has written on problems concerning macroeconomics. Although he has addressed technical issues in econometrics, his main interest has been in causality. Like Cartwright, Hoover has placed particular emphasis on what one can learn about causation by studying the work of economists.

Tony Lawson (1997) finds his inspiration in the 'transcendental realism' of Roy Bhaskar. Lawson sees himself not merely as enunciating a distinctive approach to methodology, but as laying the foundations for a new economics. Crucial to the approach and to his methodological views is a strongly realist ontology (see *Realisms and their Opponents: Philosophical Aspects*) which takes the objects of scientific investigation to be causal mechanisms and tendencies that lie as it were 'beneath' the irregularity of phenomena. This realist ontology leads him, like Cartwright, Mäki, and increasingly Hausman, to regard economic theories as identifying causal mechanisms and tendencies.

Uskali Mäki is harder to categorize. Like Lawson, he is concerned with realism, but whereas Lawson attempts to redirect economics and its methodology on the basis of a specific realist ontology, Mäki elucidates versions of realism to which economists have been implicitly committed. Like Cartwright, Hausman, and Hoover, Mäki emphasizes the importance of causal notions in economics. Like Hands and Mirowski, Mäki also applies insights from the

sociology of science to the understanding of economics.

There is a great deal of other work, too. A number of economists and philosophers have attempted to apply to economics the structuralist view of scientific theories developed by Patrick Suppes, Joseph Sneed, and Wolfgang Stegmüller. (See for example Hands 1985 and Balzer and Hamminga 1989.) Alexander Rosenberg, who is also a distinguished philosopher of biology, has pursued a number of different themes. His *Microeconomic Laws: A Philosophical Analysis* (1976) was one of the first modern philosophical treatments of the methodological problems of economics. In that book Rosenberg argues that economics fits reasonably well within a standard philosophical model of the natural sciences. But shortly afterwards Rosenberg changed his views radically, and he now defends the position that mainstream economics is best understood either as applied mathematics or as a normative social and political theory (1992).

Contemporary economic methodology thus moves in many directions. Although some of it is directed toward the conduct of economics, one regularly finds a sort of methodological schizophrenia whereby in theory economists cling to positivist or Popperian philosophical views that are radically at odds with their practice, which is roughly Millian. Other work in methodology is oriented toward the philosophy of science, and it appears that the study of economic methodology has made significant contributions to philosophical investigations of causation and explanation. It is controversial whether methodology can or should be a distinct and relatively self-contained field rather than addressing itself toward economists or toward philosophers.

2. *Methodology, Rationality, Preference, and Self-interest*

The study of rationality, preference, and self-interest is a second area of overlap between economics and philosophy. Mainstream economic theory is built around a variant of 'folk psychology.' According to folk psychology, human actions are the consequence of beliefs, desires, and circumstances that determine the feasibility and consequences of actions. The same elements figure in economic theories of choice. Sometimes economists suppose that agents have complete knowledge and thereby avoid having to refer specifically to beliefs, but in other contexts beliefs are explicitly modeled—most typically as subjective probability judgments. In place of desires, economists postulate that economic agents possess stable, complete, and transitive preferences. Given additional technical conditions, such preferences can be represented by a continuous 'utility function' such that $U_P(A) > U_P(B)$ if and only if an agent P prefers A to B. 'Utility' is simply a way of indicating how an alternative is ranked by an agent. It is not a substantive object of choice, and indeed it makes no sense to regard an agent as seeking or preferring utility. Mainstream economic models relate choice to preference by maintaining that, subject to the constraints, agents maximize utility—which means merely that among the feasible alternatives agents choose whatever they most prefer.

The previous paragraph presents the standard theory of choice as an empirical theory purporting to describe, predict, and explain how agents choose in fact. But the same theory also functions as a theory of rationality. Preferences are rational if they are complete and transitive (and perhaps satisfy other axioms, too). Degrees of belief are rational if they satisfy the axioms of the calculus of probability. Choices are rational if they are utility maximizing. Given this model of rationality, the empirical claim of the standard theory of rational choice can be restated simply as the claim that economic agents are in fact rational.

According to this theory of rationality, it is irrational to choose one feasible option over another when one prefers the second and according to this theory of choice people will in fact never choose one feasible option over another if they prefer the second. Since according to these theories choice is and ought (rationally) to be determined by the agent's preferences, it is easy mistakenly to infer that these theories maintain that agents are and ought to be self-interested. But whether a choice is self-interested depends on the *content* of the preferences that lead to it, not on whether the choice is determined by preferences. People who prefer to sacrifice their interests to others are not self-interested, and the fact that their choices result from these preferences does not make their choices self-interested. Unlike the standard theories of choice and rationality, the views that it is rational to pursue one's own interest and that people in fact do so are 'substantive' theories of choice and rationality. Unlike the standard 'formal' theory, which merely specifies a certain *structure* of choice and preference, self-interest theories specify an objective that agents do or ought rationally to have.

Theories of rationality are normative theories. They *prescribe* what one ought to do—not, to be sure, as a matter of morality, but as a matter of rationality or prudence. (Irrationality is foolish rather than evil.) Incorporating as it does a normative theory, economics is unlike any of the natural sciences. The reason why economics incorporates a theory of rationality is that human actions, unlike the actions of oak trees or potassium, can be criticized or justified as well as explained. This fact has important methodological consequences and indeed (as just argued) establishes one important distinction between the social and the natural sciences.

The first and perhaps most important methodological consequence is that explanations of individual

choices cite the *reasons* why the agent acted. Although a number of philosophers in the 1950s, who were influenced by Wittgenstein, argued that such explanations that cite an agent's reasons could not be causal explanations, nowadays most philosophers are persuaded by Donald Davidson's argument (1963) that satisfactory explanations which cite an agent's reasons must also be causal explanations. Agents may have reasons for performing an agent that are not in fact responsible for the action. Davidson argued that the distinction between the reasons that are 'effective' and those that are merely rationalizations is that the first unlike the second are causes of the action.

So the fact that the explanations economists offer of individual choices cite reasons for those choices does not imply that economists are not giving causal explanations, and it does not imply a strong anti-naturalist distinction between the structure of the natural and social sciences. But the fact that the causal explanations economists offer also cite reasons is nevertheless of great interest. It explains why economists must hold that agents are to some extent rational. (If they weren't then they couldn't have reasons for their actions.) Furthermore, it implies that the actions of economic agents are subject to rational *appraisal*. Were the agent's reasons *good* reasons? Was the action *justified*? Once one begins appraising choices, one is just one step away from ethical questions. Readers should be aware that the standard theories of rationality and choice are controversial. For more detail on the theories and these controversies, see *Intentionality and Rationality: An Analytic Perspective* and *Rational Choice Explanation: Philosophical Aspects*.

3. *Welfare, Justice, Equality, and Freedom*

Economists have an ambivalent attitude toward ethics. On the one hand, many have been concerned to insist that mainstream economics is a 'positive' science, whose conclusions are entirely independent of any moral commitments. On the other hand, economists freely give out normative policy advice. Some of this advice is purely technical, like the advice that a civil engineer might offer on where to locate a bridge, but much of it is not. Most mainstream economists are in fact committed to a specific view of ethics that emphasizes welfare, and they also adopt a distinctive theory of welfare. (When economists emphasize *efficiency* they are virtually always concerned with efficiency at promoting individual welfare.) These features of normative economics are not entailed by positive economics or the theory of rationality, but they are heavily influenced by them.

There are a variety of different ethical bases for assessing social arrangements. In addition to considering the welfare of the members, one can also ask whether the rights of the members are protected and whether procedures and the distribution are just, whether the members are treated equally, and what sorts of freedoms and opportunities people enjoy (see *Rights*; *Justice: Philosophical Aspects*; *Equality: Philosophical Aspects*; *Freedom: Political*). All of these considerations are important, but in economic policy pronouncements and normative theory (which indeed is called 'welfare economics'), typically only considerations of welfare enter.

The reason for this narrow normative focus is that welfare can be tied tightly to the standard models of rationality and choice. Suppose that individuals are rational and—in addition—that they are self-interested. As already pointed out, the standard theory of rationality does not imply self-interest, but self-interest is also commonly assumed in most economic models. It follows that individuals will prefer alternative A to B if and only if they believe that A serves their interests better than B. If individuals have perfect knowledge, which is again a common assumption in economic models, it follows that individuals will prefer A to B if and only if A in fact serves their interests better. Finally, if one identifies an individual's welfare with whatever is in the individual's interest, it follows that A is better for and individual than B if and only if the individual prefers A to B—or in other words that welfare is the satisfaction of preference. This view of welfare has the additional advantage that it prevents concerns about paternalism—to which many economists are opposed—from even arising, since by definition it could never be good for individuals to overrule their preferences.

Most normative economics is thus doubly narrow. Not only is it characterized by an almost exclusive preoccupation with welfare, but it is also committed to a particular view of welfare as the satisfaction of preferences. This double narrowness is doubly unfortunate. The limitation to considerations of welfare means that in policy discussions economists treat nonwelfarist ethical criteria as exogenous constraints to be left for someone else to worry about. The commitment to a preference satisfaction view of welfare has the drawback that this view of welfare is false. Because individuals are not always self-interested and because their beliefs are not always true, individuals do not always prefer what is good for them. There are a variety of good reasons to be hesitant about paternalism, but the view that individuals are always perfect judges of their own good is not one of them. There is some work, particularly by Amartya Sen (1992), that stretches these limits on normative economics, but such work is the exception to the welfarist rule (see also Hausman and McPherson 1996; *Economics and Ethics Welfare: Philosophical Aspects*).

4. *Conclusions*

Mainstream economists, whether engaged with positive theory, the theory of rationality, or with normative and policy investigations, are overwhelmingly com-

mitted to an exaggerated simplification of a plausible view of individual agents as possessing stable and consistent preference rankings, which, given the constraints, determine their choices. Market outcomes are the unintended consequences of these choices. Rationality is defined by this structure of choice. Welfare, like choice, is determined by these same preference rankings. Although there are philosophical issues concerning economics that have no particular connection to this core commitment, most work in the philosophy of economics has attempted to comprehend and evaluate the basic model of choice and its applications in positive economics, normative economics, and the theory of rationality.

Ecotourism

Ecotourism is criticized for being a vague and elusive notion, but, as with *Sustainable Development* (SD) (see *Sustainable Development*) this may prove its strength as a unifying concept which varied interests can identify with. However interpreted, ecotourism has commanded a degree of attention out of all proportion to its market significance because it appeals to all stakeholders. Destinations welcome the prospect of non-destructive natural resource utilization; increasingly discerning and differentiated tourists turn more and more to alternative, specialist, vacation experiences, and the tourism industry recognizes market potential.

1. Defining 'Ecotourism'

It is no coincidence that much of the discussion about ecotourism parallels the weighty debate surrounding the definition of SD. This is because the high ground claimed by ecotourism is that it constitutes a form of sustainable tourism. The most commonly used definition of ecotourism is that coined by the Ecotourism Society as 'responsible travel to natural areas which conserves the environment and improves the welfare of local people' (Lindberg and Hawkins 1993,

p.8). How this pivotal definition has evolved, and is evolving, mirrors the SD debate. The principles that ecotourism should embody fluctuate somewhere between a strong and weak green stance.

The first of these principles is that ecotourism should be 'green', recognizing a two-way link with nature conservation. This is incorporated in early definitions, such as that of Ceballos-Lascurain in 1987 (credited with first coining the term and giving it its preliminary definition) who suggested that ecotourism 'consists in traveling to relatively undisturbed or uncontaminated natural areas with the specific objective of studying, admiring, and enjoying the scenery and its wild plants and animals, as well as any existing cultural manifestations (both past and present) found in these areas' (Weaver 1998, p.15). Orams suggests that this perspective is essentially passive, requiring only that the activity does not result in negative impacts on the physical environment (Weaver 1998, p.16).

The second principle, incorporated in the Ecotourism Society definition, is that ecotourism should be responsible. This implies a more active position, involving behavioral/lifestyle changes by participants together with actions that contribute to environmental conservation and local livelihoods (Weaver 1998).

The third principle, essentially pragmatic, is that in order to be sustainable, ecotourism must recognize the interests of all stakeholders, including the tourism industry and the tourists themselves. Tourism is an economic activity which must be capable of making a profit if it is to survive, and delivery of a successful product depends on tourist satisfaction.

If ecotourism embodies these principles, symbiotic relationships between the varying interests should follow, with environmental protection resulting both from and in enhanced standards of living for local populations, continued profits for the tourism industry, sustained visitor attraction, and revenue for conservation.

2. *The Ecotourism Spectrum*

The reality of ecotourism in practice is, more often than not, divergent from its conceptualization in theory. Inevitably, the identity of ecotourism as one of the fastest growing tourism market segments leads to the term's widest use, and abuse, in the travel and tourism trade. Tour operators frequently relabel their products as a marketing ploy. Many travel experiences prefixed with 'eco' such as ecotour, and eco-(ad)ventures are often little more than examples of environmental opportunism (Wight 1994). Ecotourism, thus interpreted, may be ecologically based but not ecologically sound. Furthermore, it is unlikely to incorporate sociocultural integrity or, especially in the longer term, economic viability, as it compromises the very resources upon which it is based.

It is therefore evident that ecotourists are not an homogenous group. Several writers have identified a spectrum of expectations, behavior, and consequent impacts. Lindberg suggests a fourfold typology, ranging from handcore, through dedicated and mainstream, to casual nature tourists (Fennell 1999, p.57). Orams suggests that the continuum of ecotourism paradigms is bounded by polar extremes representing high human responsibility on the one hand and low human responsibility on the other (Weaver 1998, p.16). Paralleling the deep:shallow ecology debate (see *Ecology*, *Deep*) distinctions have also been made between deep, ecocentric, and shallow, human-centric, ecotourism.

Clearly ecotourists differ over many dimensions, but the typical profile is an average age of over 40 years, higher than average income and educational attainment, and a slight preponderance of males over females (Fennell 1999).

3. *The Conservation/Development Link*

It has become increasingly recognized that unless the needs of host populations are considered ecotourism will not be sustainable, as there will be no incentive for local communities to conserve. The creation of National Parks and wildlife reserves may satisfy the viewing needs of tourists, the profit maximizing aims of the tourism industry, and, if properly managed, the requirements of conservationists, but frequently the local population not only may not benefit but also may actively lose out. Within such protected areas, particularly in developing countries, they may be physically excluded from the resources upon which their livelihoods depend. This has led to the accusation of ecotourism as ecoimperialism (see *Ecological Imperialism*). The essential link between conservation and development is part of the much wider Parks People debate, but ecotourism is receiving increasing attention from policy makers and nongovernmental organizations as a theoretically nondestructive operationalization of the 'use it or lose it' philosophy, simultaneously making conservation pay and paying for conservation. It has also captured the interest of development agencies as a pro-poor strategy to enhance local livelihoods, although there is little evidence to date that tourism interventions have been driven by poverty elimination objectives.

4. *Ecotourism into the Millennium*

4.1 *Growth and Change*

The general consensus is that ecotourism is here to stay and set to grow. This is because it is a reflection of

much wider trends. Its increasing popularity may be attributable to being 'new,' alternative tourism, a reaction against the characteristics of mass consumption inherent in conventional mass tourism. Also, as the World Tourism Organization recently suggested, such travel may be regarded as a primary antidote to high-tech living. As well as constituting a lucrative niche, tour operators can respond to pressures of green-consumerism, increasing market credibility by offering a more responsible product. Inevitably, growth brings change and one of the most controversial aspects of change concerns scale of operation.

Many protagonists maintain that ecotourism must be small scale, low volume. Their view is that growth undermines sustainable ecotourism economies. However, the notion of small-scale, limited, specialist visitation, invariably highly priced, draws accusations of elitism; indeed Wheeller refers to ecotourism as 'egotourism' (Lew and Hall 1998, p.28). More fundamentally, David Western, the former head of the Kenya Wildlife Service, maintains that 'the principles applied to the mass market can do more for conservation—and alleviate more harm—than a small elitist market. Ecotourism, accepted in this way, is shifting from a *definition* of small-scale nature tourism to a set of *principles* applicable to any nature-related tourism … Surely what matters is not scale or motive, but impact' (Lindberg and Hawkins 1993, p.10). Coincidentally, many are also skeptical of the minimal economic impact, local, regional, or national, if ecotourism is restricted to small scale.

The question of scale however, raises issues of the carrying capacity of a locality (see *Human–Environment Relationship: Carrying Capacity*). Certain problems arise if the scope of ecotourism is broadened to embrace all nature tourism.

4.2 Divergent Theory and Practice

The potential benefits of ecotourism are widely documented, but despite various guidelines (Lindberg and Hawkins 1993, Lindberg et al. 1998), there is a considerable gap between theory and practice. This is partly attributable to the inevitable lag 'between the cutting edge of theoretical discussion and the application of theory to real-world situations' (Lew and Hall 1998, p.202). However, the disappointing performance of ecotourism to date in achieving several of its goals, such as increased local involvement, indicates the need to identify not only the nature of this gap but also its cause.

4.3 The Context

One cause is the failure to recognize the wider context within which ecotourism is cast. As Butler (1998, p.34) asserts 'tourism is part of the global system and cannot be tackled in isolation, spatially, economically or temporally.' It is vital that a move is made beyond a tourism-centric view, as it is 'inappropriate to discuss sustainable tourism any more than one might discuss any other single activity … we cannot hope to achieve sustainability in one sector alone, when each is linked to and dependent upon the others' (Butler 1998, p.28). These linkages exist not only between sectors but also between levels and interests, but there are discontinuities. What is sustainable for one interest in one place at one point in time in unlikely to be so for another. Williams and Shaw (1998) suggest place as an integrative concept, whereby prospects for tourism sustainability are mediated by contingencies of place. However, such contingencies are shaped by economic, sociocultural, political, ecological, institutional, and technical forces which are endogenous and exogenous as well as dynamic. Witness, for example, the inextricability of the global and the local as priority tourism projects in the Mekong subregion were postponed by the Asian Development Bank because of the Asian financial crisis.

Not only does ecotourism need to be set into the much wider context, but also it is imperative that it is set into specific context with regard to tourism. Milne (1998, p.47) suggests that 'in attempting to achieve more appropriate forms of tourism, it is also essential that we steer away from creating a dichotomy between 'alternative' and 'mass' tourism. Such a division serves little real purpose and diverts our attention away from the interlinked nature of all types of tourism development.'

The essential requirement of not examining ecotourism in isolation is also evident when considering the needs of foreign and domestic tourists. These two groups may construct divergent 'imaginative geographies' of the natural and cultural resources of the destination. This is particularly evident where cross-cultural differences are great. In China, domestic tourists favor artificial site enhancement compared with preservation in a pristine state, and have a higher tolerance of crowding and litter. These characteristics are clearly an anathema to foreign ecotourists.

This question of ethnocentricity may even create schisms between seemingly consensual viewpoints. Hinch (2001) surmises that, at first sight, the ecocentric world view of 'true' ecotourists should be congruent with that of indigenous cultures who tend to see themselves as being one with the land. However, he highlights potential discord should the ecotourists witness the hunting or trapping of species that may be an essential component of traditional livelihoods.

4.4 Geographical Perspectives

The contextual aspect is all important as ecotourism both shapes and is shaped by the social, cultural, geopolitical and geo-economic milieux within which it is set. Human geography and ecotourism thus share many common research foci. These include global–

local relationships, and the constraining and enabling conditions according to scale and circumstance (Hall and Page 1999). It is evident that human geography and ecotourism can each inform, and be informed by, the other. Ecotourism is not insignificant as a face and force of contemporary tourism.

Ecumene

Ecumene (sometimes oecumene) is a rendition of the Greek word *oikoumene*, which the ancient Greeks applied to the inhabited (i.e., known to them) world. It conveys a sense of communion (as, notably, in religious ecumenism), a community of independent but interacting members, or a set of separate but interrelated societies and cultures. The notion is useful to anthropologists, geographers, historical sociologists, and world historians when they wish to indicate a large region that represents a sphere of persistent and effective interaction among a group of societies that have been influencing one another and have been shaped to some significant degree by a shared history. The concept of ecumene may thus serve to reflect the subdivision of the world into several separate spheres of culture-historical experience. More recently, with the growing interest in 'globalization,' the notion of a 'global ecumene' has emerged; the notion reflects the idea that the entire world is now becoming a single interaction sphere, and that processes (such as integration and constant cultural exchange) that used to characterize the more restricted ecumenes of the past now operate on a worldwide scale. This article will focus on the use of the term in anthropology, and to some extent in world history and historical sociology. The term has been most used by scholars interested in large-scale cultural dynamics over both time and space and who therefore tend to share in a common scholarly discourse.

1. Early Perspectives

Nineteenth century evolutionary anthropology (primarily Anglo-American) assumed that local societies were expressions of general cultural evolution; in effect, the ethnographic world was not mapped geographically but was viewed in terms of postulated temporal stages. By contrast, German ethnology (which was more firmly grounded in first-hand observation) emphasized the geographical distribution of cultural traits; it regarded cultural contacts and diffusion as the primary mechanisms of cultural dynamics. This fitted well with the commonplace experience that neighboring societies usually tend to be culturally similar, forming what German ethnology called 'cultural provinces'—a concept that stressed cultural continuities within regions.

Early twentieth-century American anthropology, whose worldview was derived from German anthropology by way of its founder Franz Boas, adopted this spatial perspective and saw the ethnographic world as being subdivided into 'culture areas' shaped by regional diffusion. This, however, was mainly true of the 'primitive' ethnographic world, which has usually been peripheral to the world centers of historically significant cultural developments. Even in the 'primitive' world, the diffusionist view raised some problems. The fact that North America, for example, had several culture areas rather than one, demanded some explanation of the cultural discontinuities between the culture areas (a problem that Ruth Benedict proposed

to solve by postulating distinctive regional patterns of culture). When one turned to regions of historically complex societies (such as Europe, the Mediterranean world, the Middle East, and South or East Asia) one found long-standing interactions in the midst of marked cultural heterogeneity.

The mounting dissatisfaction with the simplistic view of a world organized into a series of disparate culturally homogenous areas led Alfred Kroeber (1945) to draw attention to the existence on the world map of a central and culturally diverse area of 'civilization' ('a great web of cultural growth' stretching from Gibraltar to China). Within it, there were centers of consistent creativity, generating ideas and techniques that diffused through this area and sometimes to the peripheral areas beyond. Kroeber adopted the term oikoumene for it and his discussion may be seen as an early and prescient invitation to deal with the wider non-'primitive' world from an anthropological perspective. In this view, a culture area became a particular kind of ecumene—local and relatively, but not entirely, homogenous. As Kroeber (1936) had previously shown, such an area exhibited center-periphery relations through which diffusion throughout it took place.

However, Kroeber's 1945 invitation to expand the anthropological vision to worldwide cultural dynamics had scarcely any takers (for an unusual exception, see Hewes 1970). In the 1930s, anthropology began to abandon its regional ethnological perspectives in favor of a concentration on cultural dynamics. This turn took two directions. It either studied them within single societies or, when it dealt with contact, it studied it as it occurred between two neighboring societies. In the latter case, anthropology did develop a rich collection of ideas about cultural transmission, but the notion of the ecumene had no place in such a locally focused endeavor and it lay dormant in anthropology for some 30 years. In the meantime, the issues it raised came to the fore among world historians and historical sociologists (see Grew 1995).

2. *World History*

A 'universal history' had been a major project of the eighteenth century Enlightenment, and the idea was revived in the earlier twentieth century in the comparative analysis of civilizations by such historians as Spengler (1926–1928) and Toynbee (1934–1961). Though these comparative studies did not fashion a unified historical narrative on a world scale, they did bring to attention the existence of 'high' periods in the histories of non-Western societies. This undermined the Eurocentrism of world history of the time, in which the first ecumene of any importance seemed to have arisen only with the fifteenth century expansion of the West. Now, attention was being drawn to the dominance of preceding regional ecumenes, such as the Islamic world or China-centered eastern Asia, with the West being frequently peripheral to them. Some historians, notably McNeill 1963), began to frame world history in terms of a succession of dominant ecumenes, thereby wrenching it out of the complete grip of Western history.

The disappearance of the Western colonial empires after the Second World War reinforced the trend, for it raised questions about the very primacy of the West in world history, the reasons for it, its transience, and the lessons all this held for the immediate future. Here, post-colonial political and sociological concerns merged with historical ones, calling into being a historically oriented political science and political sociology. To be sure, the focus at first remained Eurocentric, as shown in one of the first formulations of these new perspectives—that by Wallerstein's (1974) 'world-system' analysis. Wallerstein took modern Western expansion to be a historically unique occurrence arising from specifically Western historical factors, such as the rise of capitalism. Nevertheless, the formulation was a first step toward an exceptionally fruitful debate and a series of analyses and reanalyses (e.g., Abu-Lughod 1989, Frank and Gills 1992, Smith 1991).

The debate brought to historical consciousness a variety of preceding smaller 'world-systems,' ecumenes that coexisted with one another in different patterns of integration, and that went back into prehistory. This new world history transcends the traditional national units and focuses on such interregional processes as long-distance trade, economic interdependence, interregional enterprise, large-scale imperial polities, and continent-wide cultural relations between centers and peripheries. It recognizes large areas of economic, political, and cultural interaction, their dynamics, and their periodic demise and reorganization into new ecumenes (Mazlich and Buultjens 1993). As is natural with any new paradigm, it has led to detailed examinations of local dynamics of economic, political, and cultural exchanges. This development represents, in some sense, a retreat from worldwide perspectives and it often provides correctives to the sweeping assertions of the grand picture. But many of these local studies take the world setting as a necessary context for their analyses and thus address the broader issues.

3. *Modern Anthropology*

Similar currents began to sweep anthropology in the later 1960s. The paradigm that had dominated anthropology since the 1930s and that dealt with the systemics of single cultures was lapsing. The demise of colonial rule made an ahistorical approach to ethnography increasingly unrealistic, and this called attention to the larger forces swirling around the anthropologist's supposedly isolated societies. With the introduction of

historicity into modern ethnography, it has become obvious that historicity is also necessary in dealing with the ethnographic past.

This new vision of former 'primitives' as being bounced about by the surrounding world was also reinforced by the popular journalistic discussions of 'globalization,' including large-scale international migrations, ethnic diasporas, world labor markets, economic integration, transnational economic and cultural flows, multiculturalism, cultural 'creolization,' the unifying role of the cyber net, and the divisive role of networks. These processes are sometimes seen as dismantling the separate old regional ecumenes that used to divide the world. What looms instead is a single community of interacting societies whose very borders appear increasingly to come into question—in brief, a single 'global ecumene' whose nature is being explored by anthropologists with the use of anthropological concepts (e.g., Foster 1991, Hannerz 1992). Thus, Kroeber's ancient oikemene has been transposed out of culture history and into the contemporary era.

In sum, the concept of the ecumene allows anthropologists to deal with interactions among disparate societies. Previously, the only concept that aggregated groups of societies was that of the culture area. But culture areas projected a homogenizing view of cultural interaction and it tied cultural diffusion to territorial continuities. The ecumene, by contrast, allows anthropologists a more realistic view of cultural dynamics—one in which very different societies interact and influence one another selectively and without ceasing to be different. As the mechanisms of such influence become better understood, it becomes clear that they can operate over discontinuous territory and thus encompass, in the modern age, the entire globe. At the same time, it should be noted that much of this new concern in anthropology has more to do with subject matter than theory, for it revives such old-standing anthropological interests as innovation, diffusion, culture contact, and selective acculturation.

Edgeworth, Francis Ysidro (1845–1926)

It is only recently that Edgeworth has become fully recognized as one of the greatest economists of his time, as well as one of its greatest statisticians—a unique combination. In both disciplines his best work was so subtle and profound that it took many years for its meaning to be understood. Edgeworth is thus a striking example of one whose reputation as an original thinker has grown ever since his death, slowly at first and then quite rapidly. After a century, Edgeworth's thought is only beginning to find an echo. *The future will no doubt acknowledge the profundity of his vision more and more* (Allais 1978, p. 191, referring to *Mathematical Psychics* (1881); original emphasis, as in all quotations here).

1. Life

Francis Ysidro Edgeworth was born on February 8, 1845 at the family home Edgeworthstown in County Longford, Ireland, the youngest of five sons. His father Francis Beaufort Edgeworth (1809–1846) was one of 22 children of Richard Lovell Edgeworth

(1744–1817), an inventor and educationist whose favorite child was the celebrated novelist Maria Edgeworth (1767–1849). Father and daughter were much interested in political economy and numbered among their acquaintance Bentham Malthus, and Dugald Stewart; after her father's death Maria also developed a warm friendship with David Ricardo.

Edgeworth's father, Francis Beaufort Edgeworth, was a favorite of both his elderly father and his half-sister Maria. His mother, 2 years younger than her step-daughter Maria, was Frances Anne Beaufort (1769–1865), of Huguenot stock and elder sister of the admiral who devised the famous Beaufort marine wind scale. Naturally averse to mathematics, Francis left Trinity College, Cambridge without a degree. After a brief courtship at age 22 he married Rosa Florentina Eroles (1815–1864), who was 16, poor, with 'beautiful eyes,' and daughter of an exiled Spanish general. After some years in Italy Francis struggled unsuccessfully as owner of a private school in Eltham near London, and in 1840 returned home to Edgeworthstown to run the estate. He died aged 37 after a long illness, in the worst year of the Irish famine.

Despite his disappointing career Edgeworth's father was not without talent. His writings on poetry and philosophy sufficiently impressed John Stuart Mill to lead him to enquire, in 1840, whether Francis might be available to tutor 'the eldest son … of a person of very high rank,' adding mysteriously that 'there is, probably, no situation of the kind in England in respect to which more important consequences may depend on its being well filled' (Mineka 1963, p. 439). Moreover, Francis's friendship was highly valued by the poets Alfred Tennyson and Edward FitzGerald and by the great mathematical physicist Sir William Rowan Hamilton.

Edgeworth himself was actually baptized Ysidro Francis Edgeworth, a form he sometimes used even as an adult. 'Marshall, remembering his mixed parentage, used to say: "Francis is a charming fellow, but you must be careful with Ysidro."' (Keynes 1926, p. 152). He was educated by tutors at home, committing to permanent memory whole books of Homer, Virgil, Milton, and Pope. A notable linguist, he was well-read not only in classical Greek and Latin but also in French, German, Italian, and Spanish literature. In 1862 he entered Trinity College, Dublin to read classics and in 1867 transferred to Oxford, where in 1869 he gained a First in the honors examination in classics and philosophy.

He spent the next 22 years in London, living on the heights of Hampstead in two bare rooms that he continued as a *pied-à-terre* after he moved to Oxford in 1891. Supplementing his slim private means by occasional earnings as a part-time teacher in further education, he studied law systematically (specializing in commercial law) until he was called to the Bar at the Inner Temple in 1877; he never practiced. He also read widely in mathematics and physics, his interests perhaps influenced by those of his father's friend Hamilton. Certainly, by 1877 he had gained 'a confident and creative mastery of the calculus of variations' (Stigler 1986, p. 306).

In 1871 he became an 'original' (and lifelong) member of the new Savile Club in central London, whose friendly and distinguished atmosphere apparently suited him well, so much so that during the years 1878–1882 he was quite active in the club's affairs as either a Committee member or an Honorary Secretary or both. Indeed, it was precisely then and not (as is sometimes alleged) as a reclusive Oxford don that he wrote and published *Mathematical Psychics* (1881). Two years later he began the many articles on probability and statistics whose quality carried him upwards through a series of appointments at King's College, London, until in 1891 he was appointed Drummond Professor of Political Economy at Oxford, tenable at All Souls. He retired from this post in 1922 but the College remained his principal home until he died (from pneumonia) in Oxford on February 13, 1926. As the last surviving male Edgeworth in Europe he inherited the family estate from his brother Antonio in 1911 but did not live there.

Although Edgeworth never married it was not for want of trying. He was smitten by the handsome and imperious Beatrice Potter who found him 'gentle-natured … excessively polite and diffident … pathetic … pedantic'—and boring, even though she glimpsed 'a hidden fire burning within.' Insufficiently discouraged, in June 1889 he published a glowing review of her early work and pursued her to a Co-operative Congress in Ipswich where, in spite of his 'agonized expressions of romantic regard,' she remained adamantly unimpressed (MacKenzie and MacKenzie 1982, pp. 283–4, 286–7). Three years later she married Sidney Webb.

The words diffident, excessively polite, and pedantic recur often in friends' descriptions of Edgeworth's character, which perhaps accounts for Heilbroner's remark that: 'Neurotically shy, he tended to flee from the pleasures of human company' (1999, p. 173). However, just as frequently those same friends also described Edgeworth as affectionate, humorous, and kind; 'in my house … few visitors were so beloved as he' (Bonar 1926, p. 652). Known for his hospitality to foreign visitors, he had 'the widest personal acquaintance in the world with economists of all nations' (Keynes 1926, p. 151). The young Joseph Schumpeter, visiting Edgeworth at All Souls, was memorably welcomed to breakfast by his host with 'rock pheasant' (presumably, cold roast grouse) and champagne (Samuelson 1951, p. 53n).

Edgeworth was twice President of Section F of the British Association for the Advancement of Science (1889, 1922), President of the Royal Statistical Society in 1912, one of the original Fellows of the British Academy (1903), and an honorary Doctor of Civil Law from the University of Durham (1889). The most

important of his few honors was his sole editorship of the *Economic Journal* (*E. J.*), which lasted from 1890 until J. M. Keynes succeeded him in 1911, whereupon he became Chairman of the Editorial Board. Keynes, busy at Versailles in 1919, co-opted Edgeworth to serve as Joint Editor and he continued active in this capacity 'up to the last day of his life' (Keynes 1926, p. 140).

No complete bibliography of Edgeworth's prolific writings in economics and statistics has yet been published but an incomplete count yields four very short books, about 300 articles and shorter papers, and more than 200 book reviews. Perhaps reflecting his position as editor of the *E. J.*, after 1890 his major papers in economics tended to be surveys, learned and complex and delighting in brilliant paradoxes, rather than articles on original themes. Many of these, especially the surveys of the theories of distribution, index numbers, international trade, monopoly, railway rates, returns to scale, and taxation, he gathered together and reprinted in Edgeworth (1925). All his many papers in probability and statistics (except (1887) and a few others) were reprinted in 1996.

2. *Mathematical Psychics*

Although subtitled 'An Essay on the Application of Mathematics to the Moral Sciences,' *Mathematical Psychics* actually contains *three* analytically distinct essays, all rather jumbled together. The first is on methodology and comprises pp. 1–16 (undated page references here are all to (1881)); Appendix I—'On Unnumerical Mathematics'; and Appendix II. It develops two separate themes, the first being a visionary stress on the importance of maximum problems for economics, at both the individual and social level. It goes on to argue that in many respects problems in economics are analogous to those of classical mechanics, so that '*Mécanique Sociale* may one day take her place along with *Mécanique Célèste*, throned each upon the double-sided height of one maximum principle' (p. 12). The second theme is less grandiose and develops in detail the importance of 'unnumerical mathematics' for positive economics. The emphasis here on second-order conditions for a maximum sounds very modern: 'the condition that a required curve shall be, or shall not be, convex … this very relation of concavity, not a whit more indefinite in psychics than in physics … quarried from such data as the law of decreasing utility, of increasing fatigue, of diminished returns to capital and labour' (p. 92).

Edgeworth wrote most of his second essay, on the *Utilitarian Calculus*, when he was primarily a mathematically inclined philosopher. It consists of pp. 56–82 (which essentially reprints (1879)); Appendices III and IV; pp. 116–8 and 122–5 of Appendix VI; and pp. 126–34 of Appendix VII. Earlier, pp. 35–79 of his monograph *New and Old Methods of Ethics* (1877) had applied the calculus of variations and the psychophysics or Fechner and others to Sidgwick's utilitarianism. The resulting 'exact utilitarianism' sought 'the greatest quantity of happiness of sentients, exclusive of number and distribution,' where 'sentients' explicitly refer not just to mankind but to the whole animal creation (1877, p. 35). After a pioneering and detailed variational analysis, employing Lagrange multipliers for both finitely and infinitely many constraints as well as the idea of a continuum of rational agents, he concluded that for modern humankind '(T)here is no indication that … a law of distribution other than equality is to be wished' (1877, p. 78).

The substance of some comments by Alfred Barratt on this monograph were incorporated in Edgeworth's article in *Mind* (1879), which enhanced his earlier analysis by considering the possible negative utility from work as well as positive utility from consumption; but also diminished it disastrously, by treating different individual capacities for enjoyment not, as before, as essentially random variations but instead as systematic differences in the sentient's position in the 'order of evolution.' This drastically modified his previous conclusions concerning the optimality of equal distribution, since now '*the more capable of pleasure shall have more means*' (1879, p. 398, 1881, p. 64), and led him to some startling arguments in favor of inequality.

When he wrote those indefensible passages Edgeworth was not yet an economist. But two years later, as virtually an apprentice in economics to his friend, neighbor, and mentor William Stanley Jevons, he wrote his masterpiece, the *Economical Calculus*. This third essay, entirely on positive economics, consists of pp. 16–56; Appendix V; pp. 118–22 of Appendix VI; and pp. 134–48 of Appendix VII. Its fundamental theorem asserts that: 'Contract without competition is indeterminate … Contract with *perfect* competition is perfectly determinate … Contract with more or less perfect competition is less or more indeterminate (p. 20). The wholly normative analysis of the earlier *Utilitarian Calculus* depended critically on two doubtful assumptions, the cardinal measurability of individual utilities, and their interpersonal comparability, but this theorem needs neither of them. Indeed, it is richly ironical that Edgeworth, the most uninhibited of utilitarians, should have produced in this third essay the most far-reaching (though implicit) ordinalist analysis of any neoclassical economist.

Few works in economics have been so misunderstood as the *Economical Calculus*. Over the years commentators have discovered there not what it actually contains but only what their own preoccupations have predisposed them to find. For example, those with the *déformation professionnelle* sometimes induced by Walrasian general equilibrium theory have tended to confuse the aims of Edgeworthian recontract with those of Walrasian *tâtonnement*, while those who believe neoclassical economics to be overly tender towards capitalism have found in

Mathematical Psychics 'a kind of Panglossian Best of All Possible Worlds' (Heilbroner 1999, p. 173). This is travesty. Edgeworth believed that *imperfect* competition, with its few competitors, occurs frequently in economic life. Hence, by the theorem, indeterminate contract should occur frequently too, with its 'characteristic evil' (p. 29) of '*deadlock*, undecidable opposition of interests, unceasing strife and tumult' (the last phrase a translation of Edgeworth's Greek quotation from Demosthenes). This impasse would then lead to 'a general demand for a *principle of arbitration*' (p. 51), a demand which Edgeworth proposes to meet by proffering the following utilitarian rule: the arbitrator should choose that contract which maximizes the total utility of all the parties concerned. 'Thus the *economical* leads up to the *utilitarian calculus*' (p. 56). In the theorem, *articles of contract* are whatever is subject to bargain, such as commodities or property rights, and parties may *recontract* away from any existing contract. *The field of competition* consists of *all* those parties (e.g., sellers and buyers) willing and able to enter into contracts for the articles in question. In these general conditions, which include 'the political struggle for power' (p. 16) as well as commercial exchange, there may well be neither prices nor markets for the articles. Hence, the theory of supply and demand in perfect markets, as already worked out by Jevons, Marshall, and Walras, does not apply to the general case of Edgeworthian contract and it becomes necessary to devise radically new concepts of equilibrium, appropriate to this general setting.

Edgeworth's first such concept is a *settlement*, 'a contract which cannot be varied with the consent of all the parties to it,' and the second *final settlement*, 'a settlement that cannot be varied by recontract within the field of competition' (p. 19). A settlement can, therefore, withstand any variation from it proposed by any party to the original contract, while a final settlement can withstand any variation proposed by any interested agent, whether an original contractor or not. A settlement is, thus, precisely an allocation that yields *maximum d'ophélimité*, a concept first defined 16 years later by Pareto and now known universally as *Pareto optimality*, its Edgeworthian origins long forgotten. Note that while settlement is a concept of positive economics, Pareto optimality belongs to welfare economics.

Edgeworth explicitly provides for coalitions, whose members may recontract between themselves in order to improve their positions under prevailing contracts. As pointed out first by Shubik (1959), from this perspective the set of final settlements is precisely the core of the relevant cooperative game. (While working with John von Neumann in late 1940, Morgenstern 'showed him the *contract curve*' (Rellstab 1992, p. 83), but their epoch-making book of 1944 has no reference to Edgeworth.)

When there are only two agents they are the only possible contracting parties, so all settlements are also final settlements. Now for Edgeworth, competition necessarily involves at least three agents (see 1894, p. 378), so two agents represent '(α) Contract without competition' (p. 19). For this case Edgeworth invented and deployed general utility functions and indifference curves to show that the final settlements form a continuous contract curve containing infinitely many points. Contract is, thus, completely indeterminate. (His analysis here remains central to standard microeconomic theory, which uses the 'exchange box' invented in 1906 by Pareto to amend Edgeworth's original exposition; by a delicious irony, economists usually attribute Pareto's device to Edgeworth!)

At the opposite pole to bilateral exchange lies perfect competition, where indefinitely many traders exchange infinitely divisible articles of contract among themselves. Here Edgeworth shows each resulting market equilibrium allocation to be a settlement (the first proof of the *First Fundamental Theorem of Welfare Economics*), as well as a final settlement. He conjectures the true result (proved rigorously 91 years later by Debreu and Scarf) that, in the perfectly competitive replica economy on which his analysis is based, every final settlement is a market equilibrium allocation of some initial endowment. Since the latter allocations are usually unique or at least finite in number, this shows that perfect competition is perfectly determinate.

Edgeworth next displays extraordinary technical virtuosity in dealing with the intermediate case of imperfect competition, where he proves that for a replica economy with $2n$ agents (where $1 < n < \infty$), the set of final settlements always shrinks in size as n increases, so that contract becomes less and less indeterminate as the degree of competition increases. The key property needed for this striking result is the strict convexity of individual indifference curves, which Edgeworth actually proves by using assumptions that imply cardinal measurability of utility, but which he could just as well have assumed directly, without need of cardinality.

This completes the proof of the theorem (for details, see Newman 1994). As a coda, Edgeworth joyfully and correctly proves that his arbitration rule always produces a settlement. But this has two grave difficulties. First, the rule itself depends on cardinal measurability of utility. Second, an acceptable rule should produce not just a settlement but a final settlement. Otherwise, for some agents the utilitarian allocation might require their allocated utility levels to be below their initial levels, and so its implementation would require compulsory redistribution.

3. *Works in Statistics*

Soon after *Mathematical Psychics* appeared, and possibly influenced by Galton, Edgeworth became attracted intellectually by the 'law of error,' i.e., the

normal distribution and the central limit theorem. For the next 10 years he devoted his formidable powers and energy to probability, mathematical statistics, and applied statistics, publishing over 30 papers and one brief monograph (1887). Although subsequently he split his creative efforts more evenly between statistics and economics, in those later years he published a further 75 papers in statistics. R. A. Fisher rated Edgeworth of 'equal eminence' with Karl Pearson in statistics, while a distinguished historian of the subject has judged him to be 'the leading theorist of mathematical statistics of the latter half of the nineteenth century' (Stigler 1987, p. 98).

Edgeworth set himself the task of adapting classical probability theory, developed originally by Pierre Simon Laplace and others for the physical sciences, to the problems of statistical inference in the social sciences. For example, regarding the returns of the Bank of England, 'to estimate the probability that the differences in the averages for different weeks and months are not accidental … under what circumstances does a difference in figures correspond to a difference in fact' (quoted in Stigler 1986, p. 308). In 1883 an early result of these efforts was possibly the first derivation of Student's *t* distribution (reprinted as McCann 1996, II, No. 1), followed in 1885 by a pioneering version of the analysis variance for a two-way classification (McCann 1996, III, no. 2).

His methodological views on statistical inference in the social sciences were given in his centrally important paper *Methods of Statistics* of 1885 (McCann 1996, II, no. 3—this reprint has quite illegible diagrams). Generally, Edgeworth took an undoctrinaire Bayesian approach but was quite willing also to use frequentist methods rather than inverse probability, as when in 1905 he used significance tests to compare means (McCann 1996, I, no. 26). In (1887) and elsewhere he stressed the importance of maximizing (expected) utility rather than probability in devising appropriate statistical procedures: 'what have we to do with probability or frequency, except as a guide to our actions?' (1887, p. 53). But that monograph has no hint of an axiom system that would unify probability and utility, such as those developed much later by Ramsey, de Finetti, and Savage.

He bequeathed his name to statistical posterity with his development in 1905 of a new series expansion—subsequently the *Edgeworth series*—as a means of adding correction terms to the central limit theorem in order to deal with skew distributions (McCann 1996, I, no. 26). Less eponymous but more widely known is his term coefficients of correlation and his demonstration in 1892 of their role in expressing the parameters of the multivariate normal distribution (McCann 1996, III, no. 16 and II, no. 21). A less appreciated novelty, anticipating R. A. Fisher, was his proof in 1908–9 of the asymptotic efficiency of maximum likelihood estimators (McCann 1996, I, no. 12).

Finally, as so often with Edgeworth, a pioneering contribution in 1888 to inventory theory (McCann 1996, III, no. 4) was ignored by economists and statisticians alike until very recently, even though it 'filled a gaping hole in orthodox classical monetary theory' (Laidler 1991, p. 184). This delightfully written essay on banking demonstrated rigorously and quantitatively what had been known to bankers intuitively and qualitatively for centuries, that a bank's prudential reserve level rises proportionately, not with its liabilities, but with their square root.

Education and Economic Growth

The manner and rate of *economic growth* among nations and its causes has been a topic for theory building, speculation, and investigation since the inception of the discipline of economics. Early economists such as Adam Smith and John Stuart Mill recognized that there must be a link between *education*, broadly defined, and economic growth. Explorations of the nature of the linkage did not seriously get under way until the early 1960s with the work of American economists Theodore Schultz (1961) and Gary Becker (1993), who developed a theory of human capital formation and then sought to analyze the rate of return of investment in education and training. The last half of the twentieth century has abundantly documented that linkages exist but that they are neither inevitable nor straightforward in their relationships and effects. Early naive theories of *human capital* that proposed strict linear relationships between formal education and economic growth at both the individual (micro) and societal (macro) levels have now been abandoned in the face of overwhelming evidence that only few and modest direct relationships can be obtained no matter what definition or method of analysis is used.

1. *Defining Growth and Education*

Reasons for this maze of complexity are not hard to find. First we have to consider that when we speak of 'economic growth' there are many different ways in which it can be conceptualized and measured. Changes in Gross National Product (GNP), Gross Domestic Product (GDP), import/export ratios, unemployment rates, and various indices of economic activity are just a few of the many ways, individually or in combination, by which economic growth can be operationally defined. The means by which rates of growth are calculated can also have a marked impact on whether 'growth' is discerned or not (e.g., year-to-year change, rolling averages, decade-to-decade change). Any growth also inevitably occurs within convoluted national, regional, and global contexts that includes substantial changes over time in factors such as population growth, immigration patterns, human capital, technological innovations, structural unemployment, evolving taxation and accounting policies, trade agreements and tariffs, 'hidden' or 'black market' economies, regulatory environments, and political leadership. The degree to which these changes are measured and factored into economic growth models to create 'value-added' or 'adjusted' rates varies considerably among economists and particular schools of thought within which they work.

We also need to consider that as the world economy changes over time, particular sectors of national economies may also alter significantly. Increasingly in many nations applications of knowledge and information drive economic indices of productivity rather than material goods. Changing production patterns that emphasize customization and just-in-time delivery have also significantly altered both our conceptions and means of economic growth. Large corporations within the highly interdependent global economy often have worldwide revenues that exceed the GNP of many nations, and the dispersion of corporate assets among many countries makes quantifying economic growth in any kind of reliable manner increasingly difficult.

Further complications arise when a particular model of economic growth (with its attendant assumptions and foci) is analytically and econometrically related to education. 'Education' is a broad concept that includes a variety of subcategories or sectors. The 'formal' system would include primary, secondary, college/university, and certification forms of education (e.g., secondary education equivalency examinations, specialized training programs, and examinations that lead to industry-recognized certification). The formal system can be further subdivided into public and private spheres. Economists and other researchers generally have scant information about the private sector. Virtually all models of economic growth include substantial data available from the public sphere and only modest amounts from the private sector. In some nations, this means that better than one-quarter of the formal education sector is ignored as 'missing' and frequently forgotten data. Formal education in many nations can also be divided into academic and vocational/technical in terms of its focus and once again differing results are seen when considering the impact of these different forms of education on the economy.

An 'informal' education sector embraces non-credit forms of education and peer-learning systems (operating without the knowledge of management) that occur on the job and within the culture generally (e.g., evening 'courses' offered to the local community hosted by a local secondary school but having no formal relationship to credentialing or degree-granting institutions). There also exists the arena of job-related training or education which can take the form of job-embedded education (internships, apprenticeships, union-led training, formal company programs)

and industry- or state-led training (e.g., vocational/technical education for adults) or retraining, often conducted under the guise of either economic competitiveness or ameliorating the effects of structural unemployment. Investment in these types of *informal education* schemes (over $3.8 billion between 1963 and 1986 in developing nations) are particularly difficult to optimize owing to the dramatic influence of economic policies within competitive markets. Success also requires a close match between labor market conditions and the kinds of training received.

Adult basic education and general efforts to teach *literacy* must also be considered as important sectors of education that generally operate in isolation from the world of primary and secondary education. The economic effects wrought by adult education are difficult to measure and vary considerably among nations owing to other factors. Adult basic education, for example, is fairly large even in highly industrialized nations such as the USA and may be a much larger sector than formal education in some lightly industrialized nations. Finally, we must also recognize at the individual level that there is much informal education that occurs as a person accumulates life experiences, reads, interacts with others, and thinks. The cumulative effects of these highly personal forms of education are unknown in their effects upon economic growth.

Models of economic growth that seek to document the impact of 'education' usually focus on one or at most two of the above subcategories and frequently employ different data sources. Not surprisingly, they sometimes come to dramatically different and frequently contradictory conclusions that arise due to the measures for economic growth adopted, the methodology employed, the scope of the inquiry, and the data sources consulted.

2. *The Continuum of Development*

Further complications arise when moving up and down the continuum of highly industrialized, information-intensive economies and minimally industrialized, information-modest economies (a growing North–South divide on the planet). Economic growth models generally focus on the capacity of a national economy and focus on measures such as global market share, employment in wage-related activities, income contributions (personal and corporate taxes) and redistribution schemes, and other factors that embody within them an implicit belief that these are the proper measures for 'growth' and 'progress' for all cultures, peoples, and nations. Movement 'up' the development continuum to greater industrialization and an intensification of the role of information within the economy are seen as valuable and essential for every nation. This view elevates economic considerations as defined principally by economists who live in particular types of economies into a global standard against which all nations are measured. It ignores noneconomic factors such as population growth (e.g., expansive growth is generally frowned upon by economists but may be viewed positively by noneconomists), political considerations (e.g., socialist regimes may view economic goals differently from the majority of economists who work within capitalist frameworks), sociocultural milieus (e.g., individual and group behaviors and class structures) and issues such as fertility, life expectancy, and child mortality.

Economists who have looked at some of these issues in relation to 'developing nations' routinely suspect that 'traditional growth accounting estimates are likely to underestimate the true contribution of education to economic growth and social welfare in general' (Woodhall 1994, p. 2646). Additional data sources not generally accounted for in approaches to data include the hidden economies revolving around the informal labor sector, black markets, and other exchanges of goods that are not quantified or quantifiable in many nations of the world. For example, it is estimated that only about half of the GNP in developing nations is comprised of the share of earnings from labor vs. a range of 60–70 percent in highly industrialized nations. Some economists have recommended that dualistic models be created to address adequately the many distinct differences between economies on the two extremes of the development spectrum. Others have suggested that really four distinct types of economies can now be found among the developing nations of the world: (a) newly industrialized nations in Asia, (b) relatively highly educated Latin American nations, (c) large continental economies such as India and China, and (d) marginal rural economies found in Asia, Africa, and Latin America.

A number of disparate findings have emerged when viewing the impact of education on earnings along the development continuum. Higher average levels of formal education are frequently associated with higher earnings in most highly *industrialized nations*, although notable exceptions are sometimes seen such as nations in Eastern Europe and Russia (Decker et al. 1997, Filmer and Pritchett 1999a, Baldi et al. 2000). Nations at the other end of the spectrum generally demonstrate negative associations with education at university level once educated labor is no longer scarce. This is probably due to the fact that the expansion of the educated *labor force* has far outstripped the supply of jobs requiring such high levels of formal education and this disequilibrium exacerbates civil unrest. Oversupply has led many economists to recommend that postsecondary education be scaled back in many developing nations and these resources be targeted to primary education interventions. Investments in the education of women (a key source of inequality in many nations) and in general education (as opposed to vocational education) yield returns equal to or better than their alternatives, although once again there are

notable exceptions based on differences in economic policies, social structures, and the distribution of education (López et al. 1998, Filmer and Pritchett 1999b).

3. Human Capital Theory

Economists classically view labor, land, and capital (human and otherwise) as the three principal inputs into production. Studies of the contribution of education to economic growth have been one line of investigation within the human capital dimension—often held in tension with inputs from the other two sectors in complex multidimensional models to tease out the residuals that can be 'explained' in a statistical sense by education as defined by the researcher. These 'growth accounting' models have generally shown a fairly modest effect of education on economic growth ranging from as low as 1 percent to highs of around 30 percent with a mean finding of around 10 percent since the 1970s. Perhaps not surprisingly, returns from primary-level education (basic literacy and numeracy) are generally found to be much higher than for other levels and the decline can be steep as one ascends the levels of formal education.

A working assumption that underlies virtually all human capital approaches going back to Nobel Prize winner Gary Becker (Becker et al. 1995) and others, is that people will invest at an individual level up to the point where they believe they are going to realize a full return on their investment. This is often driven by a belief that there are certain fundamental skills that one must acquire in order to compete or advance successfully in the labor market. (It is important to note that costs subsidized by the state or other entities rather than the individual, routinely result in most students choosing to go for a higher level of education or credential than they would elect if they had to bear the full cost themselves.) Schools serve as a powerful socializing influence both in reinforcing the value of education and in shaping the kinds of educational experiences and expectations that people hold. In many societies, schooling serves as a modernizing function whereas in others (e.g., strict Islamic societies), it may serve to restrict impulses frequently associated with modernization or open capitalist societies.

Formal education frequently acts as a filter or a screen that determines a threshold level that a job applicant must meet in order to be considered for an open position. One of the many reasons why there are such modest direct relationships between education and economic growth or even education and earning in a narrow sense is that market supply has a bearing on the level of education deemed minimally acceptable by an employer. In times of ample supply of applicants, employers often require a much higher level of education as a key screening tool. Adjusting education supply functions in the light of these changing demands in order to increase economic productivity is both conceptually and politically difficult and is generally discouraged. In part, this is because employers and policy makers recognize that education helps positively shape a variety of other aptitudes, dispositions, and motivation critical to work success (Woodhall 1994). It is important to note also that wages are affected by many other factors extrinsic to employees and employers, such as taxation, price controls, inflation, and state and local policies and regulations. For these reasons, the strong form of the screening hypothesis that argued that higher levels of education signals higher wages over one's entire career is no longer viewed as tenable. A weaker form of the *screening hypothesis* that views credentials and higher levels of formal education as a filter at the initial hiring stage with accompanying early wage differentials is generally accepted. Competing theories about the operation of labor markets have produced divergent explanations for why educational attainment and levels of lifetime earnings generally hold over time in many industrialized nations. It has been amply demonstrated that 'people with the same level of education do have different earnings depending on their race, gender, ethnicity, ability, and social background' (Cippollone 1994, p. 1655).

Human capital theory has been substantially modified from its early days when considering the impact of education upon the economy. Understanding of human capital has expanded exponentially beyond education *per se* to embrace issues such as age distributions within given nations, rurality vs. urbanity, and threshold factors to economic growth in some nations such as basic health, sanitation, housing, water supply, and nutrition. The modest claims for education's impact on economic growth advanced today are a reflection of both the complexities involved and what Theodore Shultz (1961) has called 'adjusting to economic disequilibrium.' The problems associated with the human capital approach have led to several competing theories about the relationship between education and economic development. One theory takes an institutional approach and argues that supply and demand in education is shaped by larger social behaviors within the society. It is these social conditions, rather than education *per se*, that is influential on economic growth. A second approach focuses on labor market segmentation and internal labor markets, which in turn influence both education and economic growth.

A comprehensive causative model for economic growth embracing all sectors of education has proven elusive. While the general premise of a link between education and economic growth appears sound, the complexities associated with explicating the exact nature of this premise challenge the best theories and economists.

Education and Employment

Schooling is a social mechanism which, as a rule, dissociates the learner physically for a certain life period from the regular world of work and other life spheres. This is undertaken in order to prepare learners in a more rational manner for coping successfully with the diversity of work and other life tasks through explanations, rules, general reasoning strategies, etc. The more efficient the industrial society became in producing wealth, the more the education system and generated competencies contributing to the production of goods and services expanded. Regarding the world of work, education has:

(a) a qualifying (in the French and German connotation) function of fostering the cognitive and possibly affective and sensorimotor capabilities which might be useful to cope with job tasks;

(b) a status-distributive function: the level of 'educational attainment' determines to a certain extent the monetary resources and the social recognition which will be available to individuals in their subsequent life; for education is a powerful factor—and has increasingly become so over the nineteenth and twentieth century—in opening up or closing access to prestigious occupations and providing the means for professional achievement and thus to remuneration and socioeconomic status.

These basic functions are undisputed. However, it is generally assumed that education is bound to be imperfect in preparing for the world of work, partly because rational learning through dissociation from practice has its price in less direct preparation for occupational tasks and because education is expected to serve broader functions. Also, other factors contribute to professional success, e.g., sociobiographic background, genetically determined abilities, specific dynamics of credentials, processes of transfer from education to employment, and finally lifelong learning and personal development. Thus views vary as regards to the actual ways education is and ought to be shaped as well as the actual impacts learning has and ought to have on subsequent employment and work.

1. Imperfections and Limits of the Linkages of Education and Employment

Even if education was expected to be closely geared to the 'requirements' of the employment system and particularistic social factors were in play there are

obvious imperfections and uncertainties which make close linkages unlikely. Available research and past debates for instance pointed out the following issues:

(a) Occupational dynamics: The employment system is very dynamic in terms of changes of job tasks within given occupations, and most people have to expect occupational mobility in terms of employers or occupations. This challenges the view that one should prepare for a very specific bundle of job tasks.

(b) Indeterminate work tasks for highly qualified workforce: The higher the educational level required for a certain occupational area, the more difficult it is to identify the competencies required.

(c) Planning gap: There is an unavoidable time gap between the identification of new job assignments and the provision of respective competencies on the part of school leavers and graduates, because years are needed for the revision of curricula, and the actual 'production' of new graduates.

(d) Generalists' vs. specialists' paradigms: Views vary among experts regarding the extent to which education should be general or specialized according to areas of knowledge or occupations.

(e) Emphasis on vocational education vs. recurrent education: Finally, views differ similarly on the extent to which the growing role of lifelong learning might reduce the need for pre-career vocational or professional education and training, on the change of learning abilities over the life course, job requirements in different career stages, and the economic and social conditions for lifelong learning (cf. Schuller and Tuijnman 1999).

In all societies, controversies can be observed as regards the extent to which education is viewed as instrumental in securing the individual's and the society's economic success. There are also strong national differences with respect to four areas of values.

(a) An 'educational meritocracy,' i.e., a strong impact of vocational educational attainment on subsequent career, seems to be realized most and highly appreciated in Japan, whereas lifelong opportunities for counteracting those links are emphasized in the USA.

(b) A general or specific approach of education and training: Where a generalist's view prevails, for example in Anglo-Saxon countries and in Japan, specialized training tends to be viewed as 'narrow' both in terms of restraining professional flexibility and personality development. Where a specialist's view dominates, notably in France and to a certain extent in Germany, the acquisition of specific knowledge is considered as a process of exemplary in-depth learning which ensures substantial transfer to other areas of expertise, and is viewed as compatible with a broadly cultured personality.

(c) Concepts of employment and work-related identity: In France and Germany, employment and work are generally expected to be a major force for individual identity. This tradition has reinforced a high level of pride in skilled workers in Germany. In contrast, sense of affiliation to one's own employing organization tends to be viewed as a major source of identity and pride in Japan. In the Anglo-Saxon tradition, identity linked to work seems to be a phenomenon confined to high-level occupations, as the distinction underscores between (high-level) 'professions' and other 'vocational' areas.

(d) The role policies actually play and should play in shaping the relationships between education and employment: In the Soviet Union and affiliated countries, strong efforts were made from the 1950s through the 1980s to plan education according to the perceived demands of a planned economy. In the USA, faith in the self-regulatory forces is most widespread as far as educational preparation for employment and work in a market-driven economy is concerned. In European countries, different degrees of macroplanning and steering of education are considered essential in order to strike the balance between economic and other social and cultural rationales of education in a predominantly market-driven economy.

The different values are so pertinent for the actual links between education and employment in the respective societies that interpretations of research findings and discussions of their policies are most likely to reinforce national characteristics of education–employment relationships.

2. *Trends of Educational Attainment*

Expansion of education seems to have been a perennial trend since World War II. On average, about one third of the adult population in industrial societies had at least some upper secondary education in 1960; this proportion reached two-thirds in the late 1990s (OECD 2000).

From the late 1950s through the early 1970s, optimism prevailed that the economy requires a substantial increase of labor with advanced levels of education and that educational expansion is instrumental to economic growth. Comparisons focused on general and full-time schooling, thus neglecting vocational training. Accordingly, full-time enrollment rates of 17 year olds were 86 percent in the USA in 1970, about three-quarters in Canada and Japan, but only ranged in Western Europe from about 60 percent in Sweden to about 20 percent in Germany (OECD 1977). Average years of schooling, measured in 1975, ranged from about 11 years in the USA and the UK to less than six years in France, Spain, and Portugal.

The 1973 'oil crisis' was a turning point of the political mood, and concern about unemployment in general began to dominate over problems of employability of youth and potential mismatches between education and employment due to an over-

Table 1
Percentage of population from select countries having attained at least upper secondary education and university-level education, by age group 1998

Source: OECD 2000, pp. 37–8.

supply of labor with higher or other advanced levels of education and training (OECD 1977). At that time, the OECD began to include part-time enrollment and apprenticeship training into their figures of upper secondary enrollment, thereby observing an average increase of the secondary education graduation quota from about 60 percent in industrial societies around 1970 to more than 80 percent in the late 1990s. Differences ranged from more than 90 percent in 1998 in New Zealand, Japan, and Germany to less than 60 percent in Portugal (OECD 2000).

Similarly, the proportion of the respective age group being awarded a university-level degree increased from less than 10 percent on average in industrial societies around 1970 to almost 20 percent at the end of the century. A comparison of the educational attainment (Table 1) shows that the differences between the age groups are small in the USA, where the major expansion of enrolment took place before the 1970s, and high in Spain, where educational expansion is most pronounced in recent decades.

3. *Income Differences by Education*

In all societies, educational attainment and income correlates. In European OECD member states, for example, those with upper secondary education earned on average in the 1990s about 1.3 times, those with nonuniversity tertiary education 1.5 times and those with university-level education about twice as much as persons without upper secondary education (see OECD 2000). Income differences according to educational attainment tend to be higher for women than for men, though they earn less than men. Differentials declined moderately on average over the last three to four decades of the twentieth century, though not consistently over time and across countries. Variations across countries cannot fully be explained by patterns of supply and demand; other social factors come into play which contribute to varying income inequality.

Calculations based on the human capital approach show that individual returns for higher education vary between countries from less than 5 percent to more than 20 percent. In some countries they surpass the interest rates of business capital whereas in others, they remain below that level.

4. *The 'Match' between Education and Employment*

The extent to which educational qualifications match the employment demands is a frequent topic of debate. One tries to establish—both for recent graduates and the total labor force—whether qualifications correspond to the occupational structure

(a) horizontally (links between subjects and occupational categories), or

(b) vertically (appropriateness of the level of education to the occupational status).

Altogether, concerns about a horizontal match are more pronounced in countries emphasizing specialization in education and employment than in countries considering education predominantly as a general preparation. They tend to be more pronounced as well regarding higher levels of education than lower ones: A substitution of a car mechanic by a baker seems to

be more acceptable than that of an engineer by a chemist. But more leeway for substitution exists than expected. For example, the fact that about half of the Germans having undergone an apprenticeship training are employed five years later in occupations not closely linked to the type of training does not tend to be considered as a major wastage, but rather as an indicator that in-depth specialized vocational training fosters substantial potentials for flexibility and transfer of skills.

More attention has been paid to problems linked to possible vertical mismatches. In the 1960s, concern was frequently voiced that countries with a low proportion of the population with advanced education might fall behind the others with respect to economic growth. From the 1970s through the 1990s, in contrast, the controversies on the agenda concerned whether a trend toward 'overeducation' or 'overqualification' could be observed. During the 1990s, a mix of concerns about overeducation in some areas and lack of competencies in other areas, e.g., qualifications required for new technologies, was prevalent in many countries.

'Overeducation' and in some cases 'undereducation' was analyzed with the help of various measures (cf. Hartog 2000, Paul et al. 2000):

(a) Educational and occupational statistics seem to suggest that the expansion of advanced levels of education clearly surpassed the demand of the employment system.

(b) Employers' expectations similarly tended to support the idea of substantial increase of 'overeducation' in the 1970s and 1980s, though they also point out lack of competencies in some domains.

Surveys of former students also show a higher frequency of education seemingly surpassing the level of job requirements than that of 'undereducation,' but they indicate that many graduates make use on the job of the higher level of competencies.

The progress of research notwithstanding, the issue of 'overeducation' seems to be perennial, because the tensions do not fade away between often steep occupational hierarchies and a relatively open access to the highest levels of education. However, concern tended to be voiced less dramatically in the 1990s than in the 1970s (Teichler 1999). This might be explained by widespread expections that a 'knowledge society' is likely to emerge. Also, research has shown that most persons seemingly overqualified acquired a position only slightly lower than they had strived for.

5. *Education, Unemployment, and 'Employability'*

Youth unemployment and various modes of precarious employment became a major concern in most industrialized societies since the mid-1970s and in most developing countries for long periods. The unemployment quota among youth is substantially higher than that of the total labor force in most countries. Also, in most industrial societies, the higher unemployment quotas are, the lower is the level of educational attainment. OECD calculations made in the late 1990s suggest that Europeans trained below upper secondary education have to expect four years of unemployment over their life course, those trained on upper secondary education somewhat more than two years, and those trained on tertiary education level somewhat more than one year.

This led to a growing attention to the education of persons not achieving advanced levels of education, called for example, 'the forgotten majority' or the 'forgotten half.' A discussion was triggered as to whether an expansionist education policy could strengthen the employability potentials of young people and whether certain types of education and training were more successful than others in preparing youth for the world of work.

Various models were suggested to classify modes of vocational education and training on secondary education level (cf. Tessaring 1998). During the late 1970s, the apprenticeship training model (Lutz 1994) became popular in international debates, because the youth unemployment rate in Germany and neighboring countries was not substantially higher than overall unemployment rates. During the 1980s, the pendulum of debate swung in favor of a general approach of vocational education combined with initial and further on-the-job training within the employment system, as customary in Japan (Dore and Sako 1989).

Efforts were also made to increase educational and training opportunities in countries previously characterized by a low enrollment rate at the upper secondary education level. Recently new mixes of education and work experience have emerged without any single model being regarded as clearly superior.

6. *Transition from Education to Employment*

In the 1990s, increased attention was paid to the processes of transition from education to employment. An OECD study defined transition as a period of up to 10 years when youth might be searching for a satisfying and well-paid job, orientation and efforts to supplement competencies might interact, and employment opportunities might differ from those for the older workforce (Werquin et al. 1997, OECD 1999).

Part of the respective research focuses on the job start as a major indicator of the relationships between education and employment. Other studies analyze the speed of transition and the frequency of unemployment and precarious employment over various years. A further type of analysis tries to examine whether the process of transition is facilitated by certain types of

prior education and training, e.g., a close 'coupling' of education and training to respective occupations, notably through the apprenticeship systems (cf. Shavit and Müller 1998), whereas others consider 'market' regulation, as observed notably in the USA, as most promising because it facilitates adjustments at any time in the career.

Various studies address factors other than educational achievement that might explain transition to employment and further career. 'Credentials,' for example, both certify and symbolically overemphasize educational achievements. Also, sociobiographic background comes into play not merely in terms of particularistic advantages in the transition processes, but also as in terms of social skills not taught through formal educational processes. Further, the terms of 'key qualifications' point out the importance of competencies in part fostered by education and training. Moreover, transition from education to employment also can be viewed as a moment under reduced meritocratic rule when young people can seek for chances through diligent search, smart tactics, and the demonstration of talents so far not rewarded in education. Finally, some analyses indicate moderate impacts of targeted measures of improving transition to employment, notably short training programs for 'at-risk youth' and occupational guidance and counseling as well as placement arrangements by public employment agencies, private recruitment, and placement firms, and by placement support on the part of educational institutions.

7. *Concluding Observations*

Education became increasingly an important determinant of employment and career in the nineteenth and twentieth centuries. By and large, long periods of vocational learning are rewarded by a higher status and more interesting and independent work. However, this is affected by labor market situations of demand and supply. Also, education becomes, in the process of expansion, more and more a prerequisite for career success, whereby other factors might gain weight with respect to the details of selection and allocation. Finally, the growing dynamics within the occupation system make the influence of vocational education less visible when life-long education grows.

International comparison has pointed out a striking variety of modes of education and training and of links between education and employment. The debates continue on the virtue of general vs. specific education, on hopes set in educational expansion vs. a closer match between education and the demands of the economy, on the advantages of a close coupling between training and work vs. open market regulations, etc. But international comparison also questions the beliefs widespread in the 1960s that one could identify the most successful, modern way of shaping the education system in a most promising way for serving economy, culture, and personality development. This did not necessarily lead to a dominance of relativistic approaches, but rather often stimulated the search for new mixes, e.g., in combining general education with work experience, opening up avenues for tertiary education while intensifying measures for educationally disadvantaged youth, improving education and concurrently measures that address the transition processes directly as well as 'employability' in other respects.

Even in a 'knowledge society,' one does not expect that a more or less pure educational meritocracy will emerge, because other factors might increasingly gain momentum. But education seems to remain the single most important determinator of career and other life chances.

Education and Gender: Historical Perspectives

Formal systems of education in the modern world have a two-way relationship with societal gender inequality: they reflect prevailing ideologies about gender roles and, under some circumstances, have ameliorated gender inequality in the larger society. This article traces major historical changes in gender inequality in education, primarily focusing on the United States from the period immediately prior to the creation of formal state-supported systems of schooling to the present. Changes in gender inequality in access to education have been dramatic: once largely denied formal schooling, in many parts of the world girls now have equal or better access to secondary and, sometimes even, higher education than boys. Former gender differences in curricular opportunities have been narrowed significantly, especially in the West, and gender bias in texts, social interaction, and school-based activities has been dramatically reduced as well. Gender inequalities and bias in education are institutionalized more deeply in parts of the world where women still are restricted largely to the private sphere.

1. Access

1.1 Education Before State-supported Systems

The story of gender and education in the West has to start in the years before formal state-supported systems of education were common. In the seventeenth- and eighteenth-century United States, for example, schooling was provided through a patchwork of arrangements and formal schooling opportunities were largely closed to girls. Some girls did receive instruction in town and private schools: girls who were 'smuggled in' after the boys had gone home for the day (Tyack and Hansot 1990, Sadker and Sadker 1994). Early 'dame schools'—schools privately subsidized by parents—did admit girls, and it was from the dame schools that public school systems later evolved. The exclusion of girls from early formal schooling in the United States reflected the prevailing ideology that women were destined for domesticity; public life was reserved for males.

1.2 Early State-supported Education

State-supported systems of education emerged in the United States by the first third of the nineteenth century (the last third of the century in the American South). One distinctive feature of American state-supported schooling, or 'common schooling,' as it was known, is that it was coeducational. Boys and girls were educated together in the same school buildings—often one-room schools in rural areas providing what we would today regard as an elementary education (Tyack and Hansot 1990). The early institutionalization of coeducation put limits on the forms that gender inequality in education could take and gave girls roughly the same access to schooling as boys. Coeducation was preferred in the American case

Figure 1
Female-to-male ratio of degrees awarded in the United States, 1870–1995 (sources: US Bureau of the Census 1975, 1998; US Department of Education 1998)

mostly because of the economies of scale it allowed rather than from an ideological commitment to educating boys and girls side-by-side. Single-sex school buildings were more common in Western Europe and Britain during this formative period of state-supported schooling in the nineteenth century, and the United States remained somewhat distinctive by allowing girls similar overall access to state-supported schools.

1.3 School Expansion, Access, and Attainment

Cities and townships started to establish secondary schools around the mid-nineteenth century, although secondary schools enrolled only a tiny fraction of eligible youth before the early twentieth century. From the outset of the establishment of secondary schools, girls actually outnumbered boys. The federal government started to keep statistics on the number of high school graduates in 1870; in that year there were 7,000 male graduates compared to 9,000 female graduates (US Bureau of the Census 1975). From the nineteenth century to the present, American women have maintained their advantage over men with respect to likelihood of high school graduation (see Fig. 1; a ratio greater than one indicates a female advantage).

Gender distinctions were embedded more institutionally in nineteenth-century higher education than in elementary and secondary education, perhaps because a large proportion of colleges and universities were private and higher education remained the province of the elite until after World War II. Nineteenth-century American women had many fewer opportunities to attend college than their male peers had; Oberlin became the first American college to admit women but it was one of the only university options American women had until after the Civil War (Sadker and Sadker 1994). The gender inequality in access to higher education was reflected in stark gender differences in degrees obtained: in 1870, male bachelor's recipients outnumbered female recipients by almost 6 to 1. The gap closed gradually; by 1920, the male advantage in bachelor's degrees conferred was slightly less than 2 to 1 and in 1982 women surpassed men in the number of bachelor's degrees conferred for the first time—an advantage that has continued to widen (see Fig.1). From 1890 on, trends in gender inequality in receipt of masters degrees basically mirrored the trends in baccalaureates. Inequalities at the doctoral level, however, took much longer to close to any significant degree and at this level the male advantage is still significant: in 1995, men were 1.5 times more likely to get doctoral degrees than women.

1.4 The United States in Comparative Perspective

The relatively early timing of rough gender parity, or even female advantage, in access to secondary and baccalaureate-level education in the United States is unusual, as is the relatively early expansion of secondary and higher education to non-elites, and there are some countries in which women still experience significant disadvantages in access to education. In Britain and other English-speaking democracies, most of Europe, and most of Latin America, gender parity at the secondary and baccalaureate levels was achieved far more recently than in the United States. Although gender inequality in access to education has declined over time from its once substantial levels in most Asian countries, including the rich countries of Japan and Korea, gender inequality remains greater there than in any European state. Finally, large differences in women's and men's access to education still exist in much of Africa and the Middle East, with Muslim countries exhibiting the most gender inequality in access (Brint 1998, Stromquist 1995). The overall pattern is that societies in which women have been most fully incorporated into the public sphere exhibit the greatest gender equality in access to education.

2. Gender, Curriculum, and Social Climate

Being in the same schoolhouse, or even the same room, with boys did not and still does not mean that girls received the same education as boys. Unlike access, in the case of curriculum and social climate the picture is not one of increasingly similar experiences for boys and girls; looking back at the last 200 years, gender inequality increased before it decreased.

2.1 The Nineteenth Century and 'Identical Coeducation'

By the mid-nineteenth century, when the common school was established firmly in American society, the available evidence suggests that boys and girls were by and large exposed to the same kind of curricular materials and were expected to gain similar things from schooling: basic literacy and numeracy, and appropriate political and moral values (Clifford 1982). By 1850, the relatively sizable male advantage in literacy that had existed at the time of the Revolution largely had been erased. Americans' reasons for supporting basic literacy and numeracy differed by gender: for boys for their future roles in the public sphere and for girls for their future roles as mothers of the republic (Tyack and Hansot 1990). One possible reason why a 'common' education generally was provided to boys and girls throughout the nineteenth century is that the ideology and practice of separate spheres was established so firmly in American society that educating boys and girls together for purposes of basic literacy and numeracy hardly challenged it. And the adult social roles depicted in their curricular materials, particularly the ubiquitous McGuffey

Readers, clearly reflected a world of separate spheres (Tyack and Hansot 1990). Further, it is likely that noninstructional activities, such as chores, were rigidly differentiated by gender.

2.2 The Progressive Era and Gender Differentiation

Throughout the late nineteenth century, attendance rates at the high-school level were low and the curriculum was almost entirely academic. High schools in some cities were single-sex, but as was the case for common schools the most frequent pattern was to have coeducational high schools. Available data suggest that girls and boys took quite similar courses (Latimer 1958). All that changed with the rapid expansion of the high school in the early twentieth century and its corresponding transformation from a primarily academic, or classical, curriculum to a vocational curriculum. Vocational education was proposed as a means to prepare students for adult life; in the case of gender, it meant preparing boys and girls for starkly different expected adult social roles. Progressive-era educational reformers increasingly called for differentiated education for boys and girls (Cremin 1961).

Instruction in the core academic subjects remained largely coeducational. But the core academic subjects occupied a decreasing portion of most students' time as the twentieth century unfolded. Gender-differentiated vocational education became much better established in public high schools. The new curriculum in home economics, for example, was targeted to girls. Industrial education, especially those courses providing 'manual training,' was almost entirely for boys. Girls were the ones who flocked to new courses in commercial education. And boys became more likely to take advanced elective academic courses, especially in math and science (Tyack and Hansot 1990, Clifford 1982). Further, physical education and the increasingly diverse opportunities for extracurricular activities, including sports, were differentiated by gender sharply. These transformations set the institutionalized gender parameters of American education until the 1970s, when the more extreme forms of gender differentiation lost their social legitimacy.

2.3 The 'Discovery' of Sexism in Schools

By the late 1960s and early 1970s, social science scholarship began to take a critical look at education and social inequality; this early work, however, focused primarily on class (see, e.g., Bowles and Gintis 1976). Gender bias in the formal knowledge conveyed by schools and in taken-for-granted social interactions in schools and classrooms was not 'discovered' until slightly later, when feminist scholars and activists turned their attention to classrooms, curriculum, and texts (for early examples, see Frazier and Sadker 1973, Stacey et al. 1974). The forms of gender bias and gendered social interactions identified in these works were not new social phenomena; what was new, however, was the definition of them as a social problem to be rectified. Note that the feminist critique of sexism in schools could not have been mounted successfully until a time, such as the 1970s, when a more general, society-wide ideology of equality between women and men was gaining legitimacy.

Early critics identified a number of ways in which American schools commonly exhibited bias against girls. As summarized by Tyack and Hansot (1990), the most important charges included: biased textbooks, favoritism of boys in classroom interactions, sex-typed counseling of students into courses and careers, a paucity of athletic opportunities for girls, the overrepresentation of males in high-level math and science courses, and male domination of educational administration. The cause of eliminating sex bias in schools got a boost in 1972 when the federal government passed Title IX of the 1972 Education Amendments, which prohibited sex discrimination in any educational program receiving federal funds. (In the United Kingdom, the 1975 Sex Discrimination Act similarly boosted the cause of gender equality in education (Arnot et al. 1999).) Title IX enforcement was slow and uneven, but the act itself, coupled with other antidiscrimination measures passed in the 1960s and 1970s, helped promote a social climate that made gender bias socially unacceptable and provided leverage for local activists and educators to implement change in schools. The major credit for the transformation in gender relations in schools, however, has to go to the rapid changes that took place in the family and the workplace.

It is difficult to evaluate the degree to which gender bias has been eliminated in the thousands of schools in a decentralized system such as that in the United States, but the most progress has probably been made with respect to biased textbooks, course and career counseling, and athletic opportunities. These forms of bias were institutionalized more formally and easier to change via centralized authority. A recent assessment of the schools' progress toward elimination of gender bias reports that girls are no longer underrepresented in some forms of science (e.g., biology) but remain underrepresented in courses in advanced math, computer science, physics, and calculus; the gender gap in sports participation narrowed in the 1990s but girls are still much less likely to participate in a team sport; and boys are more at risk of dropping out or repeating a grade than girls (American Association of University Women 1999).

Gender differences in vocational preference testing was eliminated long ago, and schools have no doubt made much progress toward counseling similar boys and girls toward similar future plans (Tyack and Hansot 1990). Although more difficult to gauge, recent

studies suggest that boys still get more attention from teachers and are more likely to be called on in class—forms of microinteraction that are not only difficult to change by policy decree but also are often unnoticed by those engaging in the practices (Sadker and Sadker 1994). In some important respects, however, the gender gap has been inverted. In the US and the UK, among other places, girls at the secondary level now outperform boys. In Britain, interestingly, this has caused not a public celebration over girls' success but a moral panic over boys' low achievement (Arnot et al. 1999).

3. Summary

Although in the West important gender differences in educationally-based opportunity structures remain, the institutionalized forms of gender bias that prevailed in the past have been greatly reduced. Nonetheless, those changes have not been sufficient to eliminate the significant gender differences in educational experiences or outcomes that are produced by daily microinteractions among students and between students and adults (Brint 1998). Further, some gender differentiation is the result of active choices made by boys and girls themselves that follow from gender socialization and, at the same time, are reinforced by the continuing sexism and gender differentiation common in other spheres of life, including the family and the workplace. Although at present significant forms of gender inequality and bias remain in schools, especially at the most selective levels, education is, at the same time, the most gender-neutral social institution in the contemporary Western world and in some important respects girls and women now outperform boys and men in selected Western countries. Educational gender inequality and bias remain more institutionalized in societies in which women are more restricted to the private sphere.

Education and Income Distribution

It is widely believed that income is differentiated by education, although the degree of the difference varies from country to country, from industry to industry, from occupation to occupation, and from individual to individual. Education contributes to raising an individual's productivity and thus to increasing his or her earnings capacity provided that workers' wages are paid according to their productivity. This is called the marginal productivity theory in economics.

We can point out five reasons why an individual productivity is raised by education:

(a) Individuals not only acquire skills through formal education but also through job training. The human capital theory is common in this approach where an individual skill in production process and thus earning capacity requires formal (i.e., schooling) and informal training.

(b) Why does formal schooling raise productivity? The answer is that it imparts fundamental skills and technologies such as reading, writing, mathematical calculation, physics, chemistry, engineering, etc.

(c) Educated people can use other resources skillfully such as machines and new technologies. Also, they can decide quickly whether these resources and information are useful in raising productivity or lowering cost.

(d) Education or schooling can socialize people into functioning effectively in society and economy. For example, schooling teaches people to be motivated, to be cooperative and patient, and to take roles in leadership, etc. This idea does not explain the increase in productivity through skill acquisition or knowledge of technique, but emphasizes mental and social aspects, which are likely to raise a group's productivity. In other words, it is useful in modern society where a team production is common, and concerned with an organizational explanation.

(e) The human capital theory emphasizes the importance of both formal schooling and training in the production process. The concept of trainability suggests that an individual who received formal schooling is ready to receive training because he or she can learn from training quickly, and adopt it efficiently in the production process. At the same time, it is likely that a company can provide educated employees with training at cheaper cost because of the above properties.

Education certainly contributes to higher productivity. However, empirical findings regarding points (a)–(e) are mixed. This is, in particular, true when we contrast between the developing countries and the developed countries. The difference in farmers' productivity in the developing countries can be verified by the degree of literacy rate and/or the enrolment rate in primary or secondary schools. However, nonagricultural jobs in the developed countries do not support the positive correlation between education and productivity. The reason is that more formal education raises the possibility that educated people may take jobs where productivity is higher. In other words, it is not easy to identify whether higher productivity in certain nonagricultural jobs can be explained by their higher educational attainment or that educated people take jobs where productivity is already higher.

There are similar problems in the relationship between education and income. Although it is true that education certainly raises an individual's earning capacity, its empirical verifications are very mixed. At the same time, it is possible that some reasons other than the fact that education raises earning capacity may be responsible for the positive correlation between education and income. The present entry reviews these two issues fairly extensively, namely empirical effects of education on income, and possible other causes to explain the positive correlation between education and income.

Before proceeding to these issues, it is necessary to make a distinction between income and earning. Income consists of earnings (labor incomes) and nonlabor incomes such as interests, rents, pensions, etc. 'Earnings' is a better terminology when we are concerned with the effect of education on income because earnings are direct rewards for working activities. However, since income is used throughout this entry note that here income normally implies (labor) earning.

The human capital income function is the most popular form of empirical studies, which was developed by Mincer (1974), and its form was applied to many countries. The fundamental form of the Mincer type of human capital function (i.e., log earnings of individual (i) is written as follows:

$$InY_i = a + bS_i + cT_i + dT_i^2 + u_i$$

where Y_i is annual income, S_i is years of formal education, T_i is the number of years an individual has worked since the end of formal schooling, and u_i is an error term. T represents potential labor market experience, which is supposed to indicate the influence of job training and of work experience. The reason why the squared form of T is introduced is that the influence of job training and of work experience has a quadratic form.

Empirical estimations based on this formula or its variations have been fairly successful in many countries. The implications and interpretations of this formula may be proposed in the following ways. First, if the estimated coefficient of b were positive with statistical significance, it would imply that the effect of education on income is positive. At the same time, the estimated magnitude of b would indicate the rate of return to education. Based on many empirical studies it is known that the estimated coefficient of b is positive and statistically significant, and thus that education certainly raises an individual earning capacity. The estimated rates of return to education are therefore different between countries, industries, and educational levels. Thus, it is risky to provide any conclusions about them. It is, nevertheless, possible to proclaim that they would be ranged between 0.05 and 0.25.

Second, the estimated R^2, which shows the degree of fit in statistical estimations based on this formula, indicates the degree to which the model is successful in estimating the variance of income. More concretely, it shows the degree to which education is able to explain the income inequality (i.e., variation of income). A large number of empirical studies suggest that about 10–40 percent of the variation in observed incomes can be explained by the model with a linear schooling term and a squared form in labor market experience.

Third, the relative importance of the schooling term and of the labor market experience term is different between countries, industries, occupations, etc. In other words, the influence of formal education is stronger than that of experience in one country, one industry, or one occupation in the determination of income, while the latter is stronger than the former in another country, another industry, or another occupation. It is nearly impossible to obtain a general feature about the relative importance of formal schooling versus labor market experience in the

determination of income. It is difficult to determine which variable is more important to raise an individual earning capacity between formal schooling versus job training (or learning by doing).

There have been several serious modifications or alternative ideas for the original Becker (1964) formulation of education and the Mincer-type human capital earnings function both theoretically and empirically. Some of them are explained here.

First, one modification was presented by Card (1995) who extended the idea of Becker. Becker (1964) originally considered a model in which an individual finishes his or her formal schooling before entering the labor market. In reality, an individual goes back to formal schooling either full-time or part-time after entering the labor market, and then goes back to work after completely their education. In other words, an individual moves back and forth between full-time or part-time schooling and part-time or full-time work.

Card (1995, 1999) developed a model, which incorporates the movements of an individual in and out of the labor force. Concretely, Card was concerned with individual heterogeneity in optimal schooling choice. There are two sources which affect an individual choice, namely (a) differences in the costs of (or taste for) schooling and (b) differences in the economic benefits of schooling.

In addition, there is an issue of a specification bias in the effect of education on income. More concretely, ability (innate ability) of an individual may affect the determination of income, and an exclusion of ability from an earnings function is likely to provide a biased estimation of the effect of education on earnings.

A more formal analysis gives the following result. Ignoring other variables, a simple earnings function can be written,

$$Y = \alpha + \beta S + \gamma A + u$$

where Y is income, S is education, and A is a measure of ability. When we ignore ability, we obtain a biased estimator of β as follows,

$$Eb_{Ys} = \beta + \gamma b_{AS} = \beta + \gamma \operatorname{cov}(AS)/\operatorname{var} A$$

where the return to education is estimated with a bias. Thus, it is necessary to include A when ability has an independent positive effect on earnings, and the relationship between the excluded ability and included schooling variable is positive.

The classical study by Griliches (1977) concluded that the ability bias caused by the excluded ability was minor. There is a consensus not only based on the study by Griliches' but also the subsequent studies that the exclusion of ability is not a serious problem. However, there remain several technical problems regarding the effect of ability on earnings. First, even if a popular variable such as IQ is included, there is a question about whether this indicates a proper measure of ability: a professional baseball player or a professional singer who receives a very high income does not necessarily do so because of a high IQ. Second, even if we assume that IQ is a relevant measure, it includes considerable measurement errors.

Another variable, which attracted many researchers in this field, is family background. It is observed that children's schooling achievements are highly correlated with the characteristics of their parents' status such as father's education, mother's education, parents' income, etc. This is called intergenerational transfer of family status, and some specialists such as Bowles and Gintus (1976) proposed that the effect of education on income must be understood. The positive correlation between education and income is superficial because the effect of family background on income is more intrinsic than that of education in the presence of the predetermined effect of family background on children's education.

A recursive type of an econometric model, which explains the causal relationships from family background to children's education, and from children's education to income, is capable of verifying this property. Griliches and Mason (1972) for the USA, Tachibanaki (1980) for France, Tachibanaki (1996) for Japan and Tachibanaki (1997) for the UK empirically support that the causal chain from family background to children's education and income is valid in the developed countries.

Econometricians and statisticians are enthusiastic about various estimation methods to identify the true effect of individual ability, family background, and measurement errors in income and educational attainment. They often use sibling and twin-data, offspring data, etc. In order to consolidate the analysis it is necessary to apply more sophisticated estimation methods to these data. Since their methods and techniques are beyond the scope of this entry, they are not described here (see Solon 1999, Card 1999).

Education and Learning: Lifespan Perspectives

For many people the likelihood of being able to retain the same job, or even the same profession, for the whole of one's working life is becoming increasingly remote. In these circumstances the idea of learning and education continuing to take place throughout life is a necessity, not simply a desirable goal.

There are and always will be good practical reasons for paying particular importance to learning and training during a young person's early years. The need to equip a person with the skills and capabilities that make it possible to have an independent life, and deal with the demands and responsibilities of a job sufficiently well to be employable, is most pressing in the early stages of life. It is understandable that once someone is capable of making a living and functioning as a mature adult, further learning and training may receive less priority. Even so, the chances are that at various times a man or woman will have to face new challenges and adapt to changing circumstances. For that reason it is highly desirable that individuals are encouraged to be aware that they may repeatedly be required to engage in learning and studying activities, throughout their whole lives.

1. *Do There Exist Fixed Periods for Learning?*

Because it is so important for adults to maintain their capacity to learn, it may seem odd that some people continue to regard learning and education as being activities that take place exclusively in the preadult stages of life. However, there are at least two reasons why that association continues to be made, if erroneously, even today. First, many people have been led to believe that a person's mental capacities are relatively fixed, and unchangeable. Second, it is widely assumed that there are certain critical periods for learning, and that these occur in early childhood. Both these assertions imply that learning and educational experiences that take place after a person has reached adulthood have at best limited effectiveness. Therefore, it is inferred, childhood is the proper time for learning.

In reality, neither the belief that mental abilities are fixed nor the idea that there are critical periods for learning is at all firmly founded on factual evidence. Although the view that every person possesses inherent mental abilities that cannot be changed is still widely shared (see, e.g., Herrnstein and Murray 1994), it is challenged by evidence from a variety of sources (Ceci 1996, Howe 1997). Proof that mental abilities can change, often very considerably, has been provided by several kinds of research findings. First, for instance, results obtained in adoption studies demonstrate that children adopted at birth into nurturing families tend to be more intelligent that their biological relatives (Schiff et al. 1982, Schiff and Lewontin 1986). That finding would not occur if it were true that people inherit a fixed intelligence. Second, the results of a number of intervention studies that were designed to provide compensatory educational experiences for young children reared in disadvantaged early environments, provide further evidence that substantial changes can occur in a young person's mental capacities (Ramey et al. 1984, Zigler and Muenchow 1992). That finding too would be an impossible one if it were really true that each person has fixed inherent mental abilities. Third, further evidence of the malleability of people's mental capacities has been obtained from studies in which average performance levels at intelligence tests is compared between different generations (Flynn 1987, Flynn 1991). Once again, the findings provide evidence of substantial rises, challenging the belief that a person's mental ability is fixed at an early age. Finally, findings obtained from a variety of studies assessing the influence of factors such as schooling provide additional proof that a person's mental capacities are indeed alterable rather than being fixed (Baltes and Reinert 1969, Cahan and Cohen 1989).

The notion of critical periods, which is the other phenomenon that seemed to provide support for the view that learning and training experiences are only fully effective when they take place early in life, has also been sharply criticized. In the case of humans, it does not stand up to scientific scrutiny (Bruer 1999, Gopnik et al. 1999). It is true that in certain nonhuman species there are restricted periods, at an early stage of life, during which certain forms of learning have to occur if they are ever to take place at all. In humans, however, that is broadly not the case, with a few minor exceptions. Generally speaking, the timing of learning is not so crucial.

In humans, the only circumstances in which delaying learning has disastrous consequences for a child are ones in which there has been massive deprivation. For example, language development can suffer permanently when a severely neglected child is deprived of any opportunities to experience language, and perceptual development may be disrupted permanently as a result of undetected pathological conditions that affect vision (Bruer 1999). But these very unusual and extreme critical periods in humans are largely nonexistent.

That is not to say that it does not matter at all when learning takes place. Some forms of learning are achieved more easily or effectively if they take place early in life. For instance, individuals who acquire a second language in childhood may learn to speak it without an accent, whereas people who do not commence learning the language until adulthood may never learn to speak without a detectable accent (Newport 1990). However, the fact that some forms of learning take place more readily or more efficiently earlier rather than later is no justification for believing in the existence of rigid critical periods.

The vast majority of skills and capabilities that typically are learned by children and young people can also be learned by adults: in healthy nonelderly individuals substantial age-related decreases in learning capacity are unusual. Consequently, there are few if any impassable barriers to learning across the whole life-span. However, adult learners may encounter various practical obstacles. For instance, the kinds of learning arrangements and learning contexts that are appropriate for children and young people may be less appropriate for older adults. In order to maximize adult learning opportunities it may be necessary to devise arrangements that are more flexible than the school-based schedules that have been designed for children tend to be.

2. *The Need for Flexibility*

One of the practical reasons why it is necessary to provide especially flexible arrangements for encouraging adult learning is that, compared with children, older people have more responsibilities, more demands upon their time, and more complicated lives. Although a man or woman with a job and a family may be just as capable of learning as a younger person, and equally keen to learn, in all likelihood it will be necessary for learning activities to be fitted in with all kinds of other activities. In children, it is realistic to assume that whole days and weeks may be almost exclusively devoted to learning, but in most adults that desirable state of affairs will only rarely occur. Partly for that reasons, the sheer number of hours that an adult can devote to learning will be restricted, in comparison with the amount of time that a younger person is likely to have available.

The fact that the sheer amount of time that an older learner can devote to studying may be restricted does not inevitably mean that the older person will make less progress. Even when, as at school or in a full-time college or university course, the whole day is nominally set aside for training and learning purposes, it does not always follow that young students will be engaged productively in learning activities throughout the day. For most young people, there is a limit to the extent that they can continue concentrating on learning tasks over lengthy periods of time (Csikszentmihalyi et al. 1993). Perhaps as a consequence of boredom or fatigue, or inability to concentrate, a school pupil may spend much of the time relatively ineffectively, going through the motions of studying but not giving learning tasks the sustained concentration that can be achieved by a more committed individual.

For these reasons, highly motivated adults who are especially committed to their studies and capable of sustaining their concentration on studying tasks may achieve more in a given amount of time than a younger person does. That is most likely to be the case if the training and studying arrangements are flexible enough to enable the adult to engage in study activities at the same time as meeting their other. A full-time course will be a viable option for some adults but not for others. Part-time courses in further education will be preferable for many adults.

Some older students will favor the especially flexible kinds of arrangements for learning that are offered by institutions such as Britain's Open University and also by comparable institutions in many other countries. Here the actual timing and scheduling of learning and studying sessions is largely decided by the student. For middle-aged and older students, there are also some 'Third Age' institutions, which typically combine an emphasis on flexibility with a lack of emphasis on factors such as competition and assessment. These can discourage older learners who may perceive them as irrelevant or aversive. For other learners, however, the extra flexibility on nontraditional courses is only achieved at a cost, because the individuals have to take more responsibility for structuring their time and also have to make decisions concerning how and when to engage in study activities. Broadly speaking, the more flexible the arrangements, the greater the demands that are made upon the person's maturity and independence as a learner.

3. *Problems Faced by Older Learners*

In comparison with school learners, older people will usually benefit from the major advantage of being able to decide on the particular course of study to be followed, rather than being expected to study at a particular subject simply because that is what the school requires. Broadly speaking, older students are

likely to be highly motivated to learn. On the other hand, there are certain problems that are more likely to be confronted by older than younger learners. The added responsibilities of an older person's day-to-day life may not only constrain the hours available for study activities but may also produce distractions at times that are nominally free for learning. Older people worry about their jobs and their relationships. Parents, in particular, are likely to be concerned about their children. Responsibilities like these may make it difficult for an adult learner, compared with a younger person, to concentrate fully on learning. Of course, children at school have anxieties, too, but the fact that older learners are likely to be responsible for other people as well as themselves may create distractions that are especially hard to ignore.

Another difficulty that is more prone to be experienced by older learners stems from the frustration that can accompany individuals' awareness of the slowness of their progress. For example, compared with a young child who is learning to play the piano and is perfectly content to keep practicing at the simple tunes that music teachers set for their child pupils, an adult beginner may have different expectations of what a learner ought to be able to achieve. An adult beginner at the piano may be anxious to learn to play the kind of music that they enjoy listening to. For older learners it may be frustrating to discover that it will be some years before they will reach a stage at which they can begin to play that music. They may be unhappy to perceive that in order to become able to do so it will be necessary to spend numerous hours painstakingly attempting to master easier musical compositions. These may provide few of the aesthetic satisfactions associated with more advanced music. For children, on the other hand, their actual rate of progress may be equally slow, but lacking either a knowledge of more advanced music or an adult expectation of the amount of progress that ought to be made, for the younger performer there may be no comparable frustrations or disappointments.

Similar frustrations may confront adult learners of a second language. Once again, an adult learner may actually be making just as much actual progress as a younger student. However, being more aware of the differences between one's goals and one's actual achievements, and being more conscious of how difficult it is to make progress, the adult is likely to experience more discontent than the child does.

Adult learners may be taken aback to find themselves experiencing other obstacles that less mature students encounter. For example, the activity of studying contains elements that make it a difficult one for many people to sustain, irrespective of age. Studying tends to be solitary, it requires concentration, and it takes effort. Many learners, young and old, find themselves inadequately equipped to meet the demands that are imposed upon a young learner by the necessity to function effectively in that combination of circumstances (Csikszentmihalyi et al. 1993) Put simply, a learner of any age may be unprepared for the sustained and sometimes lonely efforts that studying and learning demand.

Of course, to a considerable extent people are able to learn how to learn more effectively. In many countries 'how to study' courses, which attempt to meet the particular requirements of adults who are returning to education, are widely available. However, it takes time and effort for a learner to gain the kinds of habits that help make it relatively easy for a person to engage in continuous study sessions (Howe 1990). Those learners who do succeed in establishing firm study habits experience fewer anxieties than other learners, and are less likely to feel the desire for distractions, or for company, that is common in learners who have had relatively little experience at independent learning (Csikszentmihalyi 1993, Howe 1998).

Some learners of all ages are handicapped by experiencing a severe fear of failing (Covington 1998; Howe 1998). A person who fears failure may genuinely want to succeed, but be so anxious to avoid failing that they cannot make progress because of an unwillingness to engage in difficult learning activities that are not perceived as resulting in certain success.

Fear of failure is linked to a lack of confidence, and for a self-confident and experienced learner, the prospect of an occasional failure may be not at all threatening. After all, seen objectively, a failure to achieve something is nothing more than a sign that further progress is needed, or that more work must be done. However, a less confident student may perceive possible future failures very differently. Someone who has failed often in the past, and found the experience a humiliating one, and one that is a real blow to one's self-esteem, may easily start to feel that failure must be avoided at all costs (Covington and Omelich 1981). To such a person it may appear that the easiest way to avoid failing is to simply not try. After all, if one has not even tried to achieve something, one cannot really fail at it.

Unfortunately, of course, although not trying at all may be a good strategy for avoiding failure, it is certainly not a good way to promote learning. In order to become an effective student, someone who is suffering from fear of failure will need to learn to see possible failures in a different light—as mere signals that more work is needed rather than as proof of the individual's inadequacy. This may be a difficult process, and one that requires time and patience, and the support of sympathetic teachers.

The view of education as a life long process is increasingly being seen as a necessity rather than just a possibility. Undoubtedly, most adults are just as capable of learning as younger people are. There are differences between older and younger students, of course, and, as we have seen, there are both advantages and disadvantages of being a more mature learner. Because arrangements for learning need to be more

flexible when it is necessary for a student to deal with all the responsibilities of adult life, is not always easy for the adult learner to identify educational programs that are suited precisely to the individual's particular needs. However, in many cases the fact that older learners are likely to be especially strongly motivated to learn, and can make informed choices and decisions about the topics to be studied, provides ample compensation for any difficulties.

Education: Anthropological Aspects

The study of education would appear *prima facie* to be central to the anthropological project, and courses that cover anthropological aspects of education are taught in a number of universities, particularly in the USA. Educational anthropology, however, has yet to create as secure a niche for itself as a separate academic discipline as, for example, medical or legal anthropology, which have become increasingly influential in the study of technologically advanced, as well as pretechnological, societies. One reason for the lack of a clearly defined anthropology of education has been that its areas of interest and methodological approaches have overlapped so much with those of other disciplines, in particular social psychology, sociology, and, of course, the growing field of educational studies. Indeed, some of the most influential work in the study of education has been produced either in collaborative projects between anthropologists and those from other disciplines or by the latter bringing anthropological insights to bear in their own work. The influence of anthropology—in terms of scope, theory and methodology—on the study of education, therefore, is rather more than it may at first appear.

1. Scope of Study

For anthropologists, the study of education is far from confined to the examination of formal educational institutions such as schools or to the experiences of those who have not yet been defined as adults. Education, in an anthropological sense, includes the whole range of learning experiences of individuals from conception to death. Indeed, to avoid the narrower connotations of the word 'education,' anthropologists have tended to use much broader terms such as 'socialization' and (less often) 'enculturation,' both of which emphasize that an individual's knowledge of what it means to be a social being is constantly refined throughout their life. The underlying assumption in the anthropological project is that every society or subsociety has an idea of what constitutes an 'educated person' (Levinson et al. 1996), but that this concept differs between societies and changes over time. One classic distinction in the study of education that many anthropologists have made is

between verbal and nonverbal forms of teaching (Lave and Wenger 1991, Singleton 1999). The former generally takes place in formal settings, such as schools, the latter in informal settings, such as apprenticeships. In verbal forms of teaching, the responsibility for ensuring correct understanding lies with the teacher, while in nonverbal forms it lies with the student who learns through close observation of the teacher.

In order to study such broad concepts as 'socialization' and 'enculturation,' anthropologists need to look at many features of the particular society they are examining, from kinship and religion to political and economic systems. When anthropologists study formal educational institutions—such as schools, companies, military, religious and sporting organizations—they also take a holistic approach. They examine how these institutions reflect wider social values and attempt to inculcate them into students through formal and informal means. For example, culturally specific ideas about children and childhood in a society impinge on the educational environment in that society and lead to very different types of classroom experiences. At the same time, classroom activity in any society is presented as a 'natural' process, even though it is clearly historically and culturally contingent.

These characteristics of the anthropology of education can be understood more easily if we look at how they have developed historically and at some of their underlying theoretical and methodological assumptions.

2. *Anthropology and Education: A Historical Overview*

A history of the development of the anthropological study of education might be divided into four main periods. Ethnographers at the end of the nineteenth and early twentieth centuries generally included, in their accounts of the life-cycle of the peoples they studied, some description of how children were cared for, educated, and made full members of society, often through complex initiation rites. In many ways, these accounts differed little from those provided by travelers, missionaries, and social commentators over the previous centuries who documented their observations of the treatment of the young in the societies they visited or in their own societies. Indeed, some comparative educationalists trace their subject back to Herodotus and Xenophon in Ancient Greece and Cicero in Ancient Rome (Trethewey 1976). Only occasionally would the earliest Victorian anthropological theorists, such as Edward Tylor, draw on examples of educational practices from around the world in order to support their theories about how societies evolved from 'savagery' to 'civilization,' but this was never done in a systematic manner.

The beginning of what we now know as the anthropology of education and socialization, therefore, should perhaps most usefully be linked to the first attempts to theorize systematically about the socialization methods of different societies. In this project, Arnold Van Gennep, Franz Boas, and Bronislaw Malinowski were perhaps particularly important.

Van Gennep's work on rites of passage introduced the idea that, while the rituals that mark the transition between life-cycle stages within any society are often both arbitrary and flexible, the underlying pattern of ritual performance often shows a remarkable similarity across societies. At the same time, Boas in the USA and Malinowski in the UK were among the first to challenge Victorian theories of social evolution which equated the poor performance of certain groups in formal Western educational institutions with cultural or biological inferiority. They did this in part by showing how socialization practices are designed to meet the particular 'needs' of a society at a given point in time. Their ideas of cultural relativity—that intelligence can only be judged in the context of a particular culture and not on a universal scale—helped form the basis of a counterargument to the use of universal tests of intelligence in a debate which continues to rage vigorously today.

In Britain, students of Malinowski such as Raymond Firth, Phyllis Kaberry and Audrey Richards continued into the 1930s to include in their ethnographies detailed descriptions of how children became full members of society. Followers of the alternative structural-functionalist tradition of A. R. Radcliffe-Brown, however, steered away from the study of education; they considered it to be too close to psychology and the concept of 'culture' which they eschewed in favor of the study of 'society.'

The second major phase of the development of the anthropology of education was the establishment of the Culture and Personality School in the 1930s and 1940s. This School, which enjoyed by far its greatest influence in the USA, primarily involved the application of psychoanalytic principles to ethnographic material. It believed that by studying child-rearing practices such as feeding, weaning, and toilet training, it was possible to understand the basis on which personality types were developed in different societies. Many of the leading US anthropologists of the period (Ruth Benedict, Cora DuBois, Abram Kardiner, and Ralph Linton) produced work within this paradigm. The School is probably best known, however, for the work of Margaret Mead; her argument that sex roles were determined culturally, as opposed to biologically, played an important part in the re-examination of cultural assumptions about men and women in many industrial societies.

The Culture and Personality School probably hit its height of influence in the wartime period with the publication of, so-called, National Character Studies, such as Benedict's classic account of Japanese society, *The Chrysanthemum and the Sword*. In the postwar

period, however, such approaches became increasingly criticized for exaggerating the homogeneity of personality types within any one society and the link between early child-rearing practices and later adult behavior, for ignoring the significance of relationships which exist between societies, and for reifying society rather than regarding it as a social construction. The result of sustained criticism was a dramatic decline in the influence of the Culture and Personality School. Some remnants of its approach could be seen, however, both in the way data on socialization practices were collected in the Human Relations Area Files, and in the more quantitative studies of childrearing carried out cross-culturally by Whiting and Child in the *Six Cultures Series* (1966). Such research, however, in its quest for similarities that held across cultures, provided little insight into the culturally and historically contingent nature of socialization and educational practices and it had little influence in the UK where the study of children and education virtually disappeared from the work of anthropologists for the next 20 years (see Richards 1970).

What might be seen as the third phase in the development of the anthropology of education began in the late 1960s. This phase was linked, to some extent, with the growth of civil rights movements in North America and Western Europe. In the USA, it focused in particular on what anthropologists generally termed 'cultural discontinuities' in the educational experience of minority and immigrant groups within the US educational system. Detailed ethnographic studies which examined how children, who did not come from the mainstream, white, middle-class society, experienced education in the USA were drawn on to develop programs of multicultural education and greater sensitivity to the educational needs of children from different ethnic backgrounds. As John Ogbu (1981) pointed out, however, these new programs could sometimes be at the expense of essentializing—freezing in time—and stereotyping the 'culture' of minority groups.

In Britain, similarly detailed ethnographic studies were being undertaken on British schools but with the focus on issues of class rather than ethnicity. Several of these (Hargreaves 1967, Lacey 1971) were undertaken by members of the social anthropology department at Manchester University whose head at the time, Max Gluckman, was keen to see anthropological methods used in the study of industrial societies. Probably the most influential work in the UK in this period, however, was Paul Willis' (1977) study of working-class culture in a British secondary school. Significantly, while Willis described himself as a sociologist, he drew heavily on the ethnographic methods used by social anthropologists.

The research that probably had the most lasting influence on the field of educational anthropology from this period, though, was carried out by the French scholar, Pierre Bourdieu who developed the concepts of 'cultural capital' (which the elite in society pass on to their offspring) and 'symbolic violence' (which schools impose on nonelite students so that they learn to silence themselves when in the company of those with greater social standing). While Bourdieu is also often described as a sociologist, the original insights for his later work can be found in the mainstream anthropological research that he carried out among the Kabyle peasants in Algeria (see Bourdieu 1977).

At the same time as ethnographers were examining the ways in which education systems reproduced class and ethnic inequalities, feminist anthropologists in many Western societies became interested in studying the mechanisms whereby gender patterns and inequalities were reproduced through the same system (Okely 1978). Overall, therefore, by the end of the 1970s the anthropology of education could be described as one of the most politically active areas of the discipline as well as one of the few areas where Western anthropologists were actively making studies of, and becoming involved in, policy-making in their own societies.

From the end of the 1970s, anthropologists of education became rather more outward looking, although they often remained politically committed. In part this involved more applied work being undertaken by anthropologists in developing countries. This work often identified closely with the ideas of the anticolonial movement and was sometimes highly critical of the manner in which Western educational systems had been 'imposed' on developing countries and tried to show how this had sometimes led to social disintegration rather than integration (Foley 1977). Perhaps more influential for policy in the West, however, were an increasing number of detailed ethnographic studies by anthropologists of the operation of the education systems of societies whose economies seemed to be rapidly developing at a time when those of the USA and Western Europe seemed, in the late 1970s and early 1980s, to be stagnating.

A large number of works on the anthropology of Japanese education, in particular, began to appear in the light of Japan's astonishing economic growth during the 1980s which many commentators—both inside and outside Japan—believed could best be explained by its education system. While some politicians in the West seemed to suggest that Japan might provide a model for the reform of their own education—particularly preschool and elementary—systems, most anthropologists pointed out the problems inherent in the piecemeal importation of elements of a foreign education system and the impossibility of adopting a system wholesale. Instead, they urged policy-makers to use descriptions of foreign education systems as a mirror for examining the strengths and weaknesses of their own systems (Rohlen 1983).

The fourth major phase in the history of the anthropology of education involved a change of focus

from studying those who run and organize education and other socialization systems to looking at the cognitive worlds of those being educated (Amit-Talai and Wulff 1995). While there had been calls within anthropology since the 1970s, influenced largely by the work of Edwin Ardener, for children, along with women, to be given their own voice in ethnographies (see Hardman 1973), this really only began to emerge two decades later. An impetus for this development may in part have been the United Nations Convention on the Rights of the Child. The Convention certainly sparked intense debate in many countries throughout the 1990s about what constituted a 'child' and what were 'children's rights'. Ideas about the 'child' and 'childhood' were shown to differ greatly between societies with consequent implications for issues of punishment and control in the formal educational institutions in those countries; some commentators indeed felt that the Convention represented an overly Anglo-Saxon view of the child that was being ethnocentrically imposed on other societies (Boyden 1990).

3. *Assumptions*

There are two overlapping sets of assumptions that need to be examined in order to explain the (often unconscious) different approaches that anthropologists have taken to the study of education. The first set relates to whether the anthropologist's primary interest is in the way education systems structure the behavior of individuals or in the way individuals construct education systems. This dichotomy is often described as one between a focus on 'structure' or 'agency.'

The second set of assumptions relate to the ideas—held both by the researcher and the society being researched, though these may not be the same—about how the process of socialization actually operates. For example, in the case of socializing children, is the child a passive object waiting to be molded by society, or an already formed individual which just needs an environment in which it can naturally develop, or a person intent on pursuing its own interests and on whom society has to impose its will (see Jahoda and Lewis 1988)? Sometimes these distinctions are discussed in terms of the child as *tabula rasa*, the Apollonian child (the child as naturally good), and the Dionysian child (the child as innately wilful).

Approaches which concentrate on how socialization systems—particularly formal education systems—help to construct, disseminate, and legitimate a commonly understood and accepted ritual and symbolic language and system of meaning within a society—thereby structuring the experience of individuals who are often presented as *tabula rasa*—are often described as Durkheimian or functionalist. Such analyses have been particularly influential in the study of large-scale modern societies where it is impossible for all the individuals to know each other personally. Formal education systems have played a major role in the formation of the modern nation state; they have often been the main means though which a common language has been disseminated and a national identity constructed in a population. Through their interaction with the economic and religious elements of the social system, they have helped to develop a national work ethic and inculcate national spiritual values. The study of education, therefore, has clearly been important in the work of anthropologists of ethnicity and nationalism such as Benedict Anderson and Ernest Gellner.

Marxist theories have also focused on the way in which education practices produce social beings but rather than seeing these as aids to social integration they have concentrated on how they maintain and reproduce social difference. Marxist and neoMarxist approaches to the study of education largely replaced functionalist and Durkheimian approaches in the 1970s with studies of how class and ethnic inequalities were reproduced through the education system in the USA and UK. These studies showed how an education system can be systematically designed—by means of 'linguistic codes' or a 'hidden curricula'—to provide differential educational experiences for different class, ethnic, and gender groups in a society. While the structural effects of class reproduction could be examined quantitatively, the actual mechanisms of the 'black box' (as it came to be called) of education could be discerned only through intensive qualitative research undertaken by ethnographers.

Social action theorists have focused on how the individual actors in the educational setting help to construct or resist its formal structures. Unlike Durkheimians and Marxists, they do not see individuals in an education system as passive but as active participants in a process of 'cultural production'. Where active participation supports the integrative or the social reproductive functions of education, the analyses of social action theorists overlap with those of Durkheimians and Marxists. As Willis (1977) showed in his account of working-class youth in the UK, for example, the subcultures of resistance formed by these youths to the middle-class curriculum often only served to recreate the class structure of the wider society. Social action theorists, however, generally suggest that there is a range of reactions to the learning process in any educational setting as well as a range of teaching styles. In describing these, they often draw, implicitly at least, on Max Weber's concept of 'ideal types.'

Understanding the differences between the positions outlined above is important in the discipline of anthropology as anthropologists are generally themselves the main research tools. The assumptions on which anthropologists base their research effect not only what they look at but also the types of questions they ask and the conclusions they are likely to draw.

4. Methodology

While there are a number of antecedents to the ethnographic approach to the study of society, it was largely patented and systematized by Malinowski in the 1920s and became closely associated with the discipline of social anthropology. The application of this approach may be the most significant contribution made by anthropology to the study of education. Almost all anthropologists of education have relied on some form of field research, ranging from total participant observation to informal interviews (Woods 1986). Through all of these techniques, the researcher tries to gain an understanding of the participants'—teachers,' pupils,' parents,' officials'—views on the educational process. In its ideal form, indeed, the researcher becomes through participant observation socialized in the society or institution being studied and thereby subjectively comes to empathize with and understand its values.

While field research has been shown to be a very effective means of understanding how socialization works in the broadest sense, it has perhaps particularly been suited to the study of education in 'bounded' institutions—institutions with clearly defined boundaries in terms of time and space—such as schools, churches, and other environments where children are taught basic social categories formally and informally. When children start formal schooling in Western societies, for example, they learn how concepts of time—work time vs. play time, school time vs. home time, holiday time vs. term time—and space—public vs. private, male vs. female, safe vs. dangerous—are divided in the extra-domestic environment. Such institutions, therefore, provide an excellent setting in which to investigate what are considered to be, in a particular society at a particular point in time, its core social values and how these values are socialized—through teaching the meaning of dominant symbols and key ritual performance—and legitimated through reference to ideas of 'tradition' and 'culture.' Field research also allows the researcher to gain a sense of the extent to which these values are accepted, rejected or ignored by those being taught them.

5. Contribution to the Study of Education

The discipline of anthropology has brought a number of important points to bear on the study of education—a relativistic perspective of socialization practices, a holistic approach, an ethnographic method that allows for the simultaneous study of structure and agency in the educational process—which have all become standard practice in the field even if they are not always associated directly in researchers' minds with anthropology. At the same time, the study of education has become increasingly common in anthropological accounts, but often under the headings of the study of ethnicity and nationalism or cognitive and psychological anthropology or the growing field of the anthropology of children rather than as a distinctive field of educational anthropology. It may be that the systematic anthropological study of education has been too threatening to anthropologists many of whom, of course, are themselves full-time educators.

Education: Cultural and Religious Concepts

Because not everyone assigns the same meanings to education, culture, religion, and concepts of education, it is important to explain how those terms are intended throughout this article.

Education means intentional efforts to improve people's knowledge, skills, goals, or values. Culture means the beliefs, patterns of behavior, and physical objects shared in common by members of a group and passed from one generation to the next through education and daily experience. Groups that display particular cultures can be of various kinds—family, community, regional, national, ethnic, occupational, social-class, religious, and more. Religion, as a subcategory of culture, is typically an integrated system of beliefs about a supreme being or gods (theology); the origin and control of the universe (cosmology); the nature of existence (ontology); rules governing human relations (ethics, morals); knowledge and its proper sources (epistemology); and the goal of life (teleology).

Concepts of education are beliefs about what is worth learning and how people should acquire that learning. A group's concept of education can be inferred from the dominant educational agencies, objectives, curriculum content, methods of teaching, and techniques of evaluation found within that group. To demonstrate how different groups' concepts can result in variegated modes of education across cultures, the following discussion is designed to illustrate the proposition that all cultures pursue the same five basic educational goals, but cultures can vary in: (a) the specific learning objectives and curriculum content under those goals; and (b) their system for delivering instruction. The article closes with a brief interpretation of historical trends in cultural conceptions of education.

The examples cited in support of this proposition focus on three cultural categories—national, ethnic, and religious. However, it is apparent that those three categories are not mutually exclusive. For example, national, ethnic, and religious are essentially identical in such countries as Saudi Arabia (82 percent Saudi ethnic origin; 99 percent Muslim) and Portugal (98 percent Portuguese ethnic origin; 92 percent Catholic) (Calhoun 1999). However, in such multicultural countries such as Canada, India, Indonesia, and the USA, significant differences are found among national, ethnic, and religious cultures.

1. *Educational Goals*

By outright statement or by implication, all cultures direct education toward the same five general goals: (a) knowledge and support of cultural traditions; (b) citizenship; (c) moral conduct; (d) vocational preparation; and (e) physical and mental health. However, because of the sociohistorical differences among cultures, the specific learning objectives and curriculum content under each of these goals can vary from one culture to another.

1.1 *Knowledge and Support of Cultural Traditions*

The first goal is to teach each new generation the culture's dominant worldview and history, including the traditional language, social organization, explanations of phenomena (physical and social sciences), and arts. For example, to communicate within their group, Pakistanis learn Urdu, Tunisians learn Arabic, and Peruvians learn Spanish, Qechua, or Aymara. To understand social organization, Tongans learn the traditional chieftain structure of their society, North Koreans learn the country's version of communism, and South Africans study their republic's multiparty system and national assembly. In the realm of literature, India's youths study the epic poems *Ramayana* and *Mahabarata*, students in Taiwan read the *Analects of Confucius*, and those in Spain read Cervantes' *Don Quixote*.

1.2 *Citizenship*

A society's system of governance determines what people need to know about their own role as a citizen and about how their own role relates to the role of other people. Because societies' social systems often differ, citizenship education varies across cultures. The proper behavior of serfs in a feudal society differs from that of citizens in a socialist state or in a capitalistic democracy. The roles of leaders in the Roman Catholic hierarchy differ from the roles of leaders in Quaker, Presbyterian, and Buddhist cultures.

1.3 *Moral Conduct*

Moral education concerns proper ways to act toward other people and, in some cultures, proper ways to act toward supernatural forces (gods, ancestral spirits), nonhuman beings (animals of specified types), and physical surroundings (sacred forests, mountains, and waterways). All cultures teach such virtues as honesty, loyalty, respect, and courage. All disapprove of theft, deceit, and murder. Most usually prescribe additional moral rules not found in every other culture, e.g., obeying God's commandments is an essential moral rule in Judaic, Christian, and Islamic cultures but not in Chinese Taoism or international Communism (Thomas 1997).

Cultures often differ in how they identify the people to whom their moral rules should apply. For example, most cultural traditions teach, at least by implication, that moral rules should guide relationships with friends ('our kind of people' or 'members of our

group') but not with enemies ('those who threaten our welfare'). Therefore, one moral education objective can be that of identifying the social conditions (war, economic competition, and religious confrontations) under which the moral rules should and should not apply to selected groups. Furthermore, as social conditions change, the way moral principles affect personal-social relations often change as well. During World War II, the British and the Germans were enemies, so they were taught to hate, deceive, and slay each other. In contrast, a half century later the British and Germans, both members of the European Union, were taught to apply their common set of moral principles to each other.

1.4 Vocational Preparation

Societies vary markedly in the types and complexity of vocations for which each new generation is trained. Cultures that depend chiefly on hunting and gathering or on agriculture for obtaining food and clothing have far fewer types of vocations than do highly industrialized, occupationally specialized cultures. As a consequence, the detailed learning objectives and instructional content for occupational training can differ significantly across cultures. Furthermore, where vocational preparation is obtained can vary greatly. In dominantly nonmechanized agricultural societies, children learn their vocation through family apprenticeships—working beside their parents in the fields. In highly industrialized societies, most youths prepare for occupations in schools (learning communication, computation, social interaction, and technical skills) and in on-the-job programs away from their homes.

1.5 Physical and Mental Health

Variations from one group to another in the exact aims and content of health education can result from cultural differences in beliefs about: (a) what constitutes health, sickness, and deviant behavior; (b) what causes sickness and deviant behavior; and (c) how to treat sickness and deviance.

In their conceptions of sickness, cultures can disagree about the sorts of distressing conditions that call for healing measures.

Diviners, curers, oracles, shamans, and doctors the world over are not only consulted about bodily ills, but also about mental ills, social problems, and calamities of supernatural provenance which express jealousy, hatred, and suspicions emanating from conflicts over land, money, and inheritance, over marital and sexual disputes, and from political ambitions and rivalries. Further, the bodily ills are commonly taken to be mere epiphenomena: themselves material outcomes of immaterial forces and agencies that inflict punishment for social misdeeds (Worsley 1982 p. 327).

Contrasting cultural views of deviant behavior can be illustrated by a cluster of symptoms (impaired sociability, language, and communication which are accompanied by a constricted range of interests and activities) that are interpreted in typical Western industrialized cultures as indicative of autism, a regrettable malady that should be remedied. However, cultures that attribute autistic-like behavior to possession by spirits can elevate individuals who exhibit such behavior to a respected position reserved for enchanted members of society. Such is the case of individuals classed as *Nit-ku-bon* in West Africa, where an infant who would be diagnosed as autistic in Western cultures is said to be a 'marvelous child' (Ellenberger 1968).

2. Systems for Delivering Instruction

The term 'educational delivery system' refers to a society's manner of organizing the people and institutions that provide education for the populace. One way to identify differences between cultures in their delivery systems is by recognizing (a) the nature of systems' structures and (b) the manner in which components of systems acquire responsibility for particular educational goals.

2.1 Delivery Systems' Structures

A society's educational delivery system can be understood in terms of its institutions, personnel, and roles. An educational institution consists of a group of people (personnel) who together are pursuing the same educational objectives, with each person playing a particular role in the sense of assuming a specific part of the responsibility for achieving the objectives.

Types of institutions found in virtually all cultures are known by such general labels as family, school, church, youth clubs, and television programs. Subtypes that are committed to more specific objectives and roles are identified by more exact labels. Under the designation school there can be such subtypes as nursery school, secular junior high school, Islamic Koran school, junior college, Greek Orthodox seminary, military academy, Chinese language school, cooking school, etc.

In many institutions, roles are identified by titles that enable knowledgeable members of the culture to estimate the responsibilities and skills that those titles imply. Examples of titles and of national cultures in which such titles are used include *docent* (France), *imam* (Egypt), headmaster (England), *guru besar* (Indonesia), and superintendent of schools (USA).

Sometimes roles are traditional ones not overtly defined but learned informally by neophytes' copying the behavior of established members of the institution, with the neophytes then learning what is expected of them by their being praised for performing the role

Table 1
Learning opportunities in representative nations

Nation	Percent of children in school	Teacher/pupil ratio	Percent of population literate	Computers per 1,000 persons	Computers on worldwide network per million persons
China	99	24.3	81.5	2.1	1.8
Denmark	99	10.4	100	270	9,670
Germany	100	18.2	100	165	5,794
Morocco	72	28.3	43.7	1.7	8.6
Netherlands	99	15.7	100	200	11,110
Norway	99	12.5	100	273	19,289
Pakistan				1.2	0.1
Peru	91	27.4	88.7	5.9	35
Russia	100	12.5	98	18	140
Saudi Arabia	62	13.3	62.8	35	1.5
United Kingdom	100	21.2	100	186	7,513
United States	96	18.7	95.5	328	23,012

properly and being admonished for deviating from accepted practice. Cultural differences in informally learned educational roles within the family can be illustrated with parents' behavior in Tahiti and Nepal. Levy (1996, p. 134) observed that children in Tahiti were allowed to go about their business of growing up without much verbal direction by adults; and when Tahitian parents did apply directive verbal interventions, their remarks were primarily negative: 'don't do this' or 'stop doing that.' In Nepal, parents offered much verbal guidance to their offspring as the children were learning to perform a new task, and this guidance was usually in positive, encouraging terms. Only after a child had achieved a measure of mastery would negative remarks appear, and then in a moral form, such as 'it's not right to do that,' rather than, 'don't do that.'

In other instances roles are formally described, as in the description of duties included in a contract that a headmaster signs when employed by a school system. Role definitions may also assume the form of the curriculum in a teacher-education program or of the skills and knowledge individuals must display in order to receive a license to teach in an accredited school.

In sum, cultures can differ in the types and subtypes of educational institutions they include and the roles that personnel are expected to perform.

2.2 Institutions' Assignments

The responsibility for achieving educational goals is usually divided among a society's educational institutions, with this division of labor often varying from one culture to another. Typical variations can be portrayed for the realm of moral education.

Whereas every society depends heavily on the family for teaching moral values, cultures often differ in the institutions outside the family that are authorized to promote morality. Some nations mandate a separate class in public and private schools for teaching religion, with much of the subject matter stressing moral behavior. Such is the practice in Finland, France, Germany, The Netherlands, Italy, Norway, Spain, Thailand, and much of Latin America. Other countries, such as Indonesia and Taiwan, require a class in moral education that is not religious in character but includes an emphasis on citizenship and civic responsibility. Public schools in the USA are proscribed from teaching religion, and they rarely maintain moral education classes. However, as in other countries, teachers in all subject matter areas in US schools are expected to foster moral behavior by the way they routinely maintain discipline and encourage amicable social relationships in their classes.

Variations among cultures in the responsibility for achieving educational goals can also result from variations in learners' access to such educational media as schools, books, television programs, and computer networks. Differences in access are principally the result of the availability of such media in a society. Although the latter half of the twentieth century witnessed a marked increase in the availability of schools in virtually all societies, by the twenty-first century the opportunities for formal education still differed significantly among nations. Even more dramatic than the variations in access to schools were the differences among schools in the preparation of teachers, teacher/pupil ratios, and the quality of facilities—reading materials, television, computers, and access to the worldwide computer network. The extent of five such differences in 12 countries near the close of the twentieth century is indicated in Table 1, which reports: (a) the percentage of nations' school-

age children enrolled in school; (b) teacher/pupil ratios; (c) the proportion of the general population over age 15 that was literate as the result of available educational facilities; (d) numbers of personal computers per 1000 persons; and (e) numbers of computers connected to the worldwide network.

3. Historical Trends

Over the nineteenth and twentieth centuries, interactions among cultures increased at an accelerating pace and affected societies' educational practices. The most striking trend has been observed in traditional societies replacing their indigenous educational institutions and teaching methods with ones deriving from Europe and North America. The original purveyors of the European-style school were Christian missionaries who accompanied Western military and commercial forces that colonized much of the non-Western world. Even after most former colonies gained political independence following World War II, the expansion of Western educational practices continued, expedited by foreign-aid projects for developing regions and by advanced communication technologies, such as television and international computer networks.

By the early twenty-first century, the Western-style school—with its constant flow of technological innovations—continued to be the dominant mode of formal education throughout the world. However, this intrusion of European and North American culture into indigenous cultures has not gone unchallenged. Education at the family level has continued to follow long-established traditions in many regions. In addition, conservative forces in various societies have sought to stem the encroachment of formal Western education on non-Western societies' inherited schooling practices. Such resistance has focused particularly on curriculum content. The most frequent curricular changes have been in the fields of history, literature, and the arts. In numerous societies, history books have been rewritten to interpret events from the vantage points of ethnic and religious groups that have gained significant political influence. Indigenous literature and art have been widely encouraged. Less common, and more controversial, have been efforts to teach science and mathematics that reflect traditional cultural worldviews. For example, in India during the 1990s, Hindu nationalists of the Bharatiya Janata Party sought to replace Western science in schools by introducing Vedic mathematics and the ancient science of *vastu shastra*. Party spokesmen charged that Western science was a source of imperialism and rationalism that conflicted with Hindu tradition (Gutek and Thomas 1998). In Australia, curriculum developers sought to accommodate Aboriginal political interests by issuing science-curriculum directives that accorded equal importance to: (a) Aboriginal modes of interpreting natural phenomena; and (b) scientific methods deriving from European/American tradition and practiced internationally (Maratos 1995).

What has been referred to as 'the crises in Islamic education' is the controversy in Moslem societies over the teaching of a Western scientific perspective which includes such precepts as: (a) conclusions about 'truth' should be based on empirical evidence; and (b) all conclusions are tentative and subject to revision on the basis of additional empirical evidence and logic. In Islamic tradition, the sources of true knowledge are the principal holy book, the *Qur'an*, and the sayings of the Prophet Mohammed recorded in the *Sunnah*. In any conflict between the revelations in the Holy Scriptures and 'scientific' theories (such as Darwin's theory of evolution), the 'scientific' theories are judged to be wrong. However, matters not treated in the holy books—such as computer technology or the geology of petroleum production—can be settled by empirical, scientific means. Moslem educators thus face the challenge of convincing learners that they should: (a) limit the application of scientific precepts to issues not dealt with in the holy scriptures; and (b) accept on faith the authority behind the doctrines that bear on matters treated in the scriptures. This same challenge is faced in other religious persuasions as well—Judaism, Christianity, Hinduism, Buddhism, Taoism, and more. It seems likely that the foregoing trends will continue in the future, with education systems across the world becoming increasingly alike in form and content. At the same time, ethnic and religious groups will probably continue their efforts to imbue curricula with content reflecting their own cultural traditions.

Education, Economics of

The economics of education is conceptually very broad. It could logically cover all aspects of the demand for schooling and of the impacts of schooling on subsequent outcomes. This discussion, however, concentrates on the more limited range of issues related to the organization, funding, and performance of schools.

Many facets of the broader field overlap those of labor economics, public finance, and growth theory, and they can best be put into those contexts—leaving this discussion to the unique facets of schools. The economics of education also borrows from other disciplines such as sociology and psychology, but the underlying behavior perspective remains unique to economics.

The economics of education is naturally linked to the study of human capital. Human capital refers to the skills and productive capacity embodied in individuals. While implicitly part of economics for several centuries (Kiker 1968), this idea has recently developed into a central concept in both theoretical and empirical analyses with the foundational work of T. W. Shultz (1961), Gary Becker (1993 [1964]), and Jacob Mincer (1970, 1974). Nonetheless, while abstractly dealing with skills and capabilities of individuals, human capital—to be both predictive and testable—must be defined in terms of more concrete measures. This requirement most often brings up schooling as a clear, measurable aspect of human capital that can proxy for major skill differences. While an expansive view could include all research topics that touch on schooling, it is useful to define the economics of education more narrowly in terms of unique aspects not covered in other subdisciplines: namely, the education sector itself. This discussion is also limited by available data and analyses. Due to a dearth of reliable outcome data from higher education as well as schools in other countries, the economics of education has concentrated its study largely on American K-12 schools. (The study of the economics of higher education, largely lacking student performance information, has directed most attention to issues of access and attendance and particularly of the influence of financial aids and costs on these (see for example McPherson and Schapiro 1990 or Kane 1994). Because these analyses have such a different perspective from those related to primary and secondary education, they are not included in this discussion.)

1. *Outcomes*

It is natural for economists to think in terms of a production model where certain factors and influences go in, and products of interest come out. This model, called the 'production function' or 'input–output' approach, is the model behind much of the analysis in the economics of education. The measurable inputs are things like school resources, teacher quality, and family attributes, and the outcome is student achievement. Let us focus on the outcome, first, and then move on to inputs, where more controversy exists.

Table 1
Percentage of population attaining upper secondary education or more, by country: 1992

Source: NCES (1996).

Historically, the most frequently employed measure of schooling has been attainment, or simply years of schooling completed. The United States leads the world in investing in schooling. By the mid-1970s, three-quarters of US students completed high school, culminating a long national investment period that started with just 6 percent graduating from high school at the turn of the century. Many developed and developing countries, however, have recently mimicked this trend, as illustrated in Table 1, which displays the increasing completion of secondary schooling for more recent age cohorts. By tracing schooling across different age groups, the growth in attainment is readily seen. The value of school attainment as a rough measure of individual skill has been verified by a wide variety of studies of labor market outcomes. In the US, Mincer (1974) pioneered the approach that is now standard. Psacharopoulus (1985) has taken this analysis to the rest of the world. The estimation considers the relationship between earnings (viewed as a direct

measure of individual productivity) and schooling and labor market experience.

However the difficulty with this common measure of outcomes is that it assumes a year of schooling produces the same amount of student achievement over time and in every country. This measure simply counts the time spent in schools without judging what happens in schools—thus, it does not provide a complete or accurate picture of outcomes. Today, more attention is focused on quality outcomes, and the most common measure is tests for cognitive skills. To the extent that the productive value of schooling largely involves the ability to make decisions under uncertainty and to adapt to new ideas and technologies (cf. Nelson and Phelps 1966, Welch 1970), cognitive skills appear to be a valid measure of human capital. This conclusion is supported by recent studies that show a direct correlation between test scores and earnings in the labor market.

While early studies of wage determination indicated relatively modest impacts of variations in cognitive ability after holding constant quantity of schooling, more recent direct investigations of cognitive achievement find generally larger labor market returns to measured individual differences in cognitive achievement (e.g., Bishop 1989, 1991, O'Neill 1990, Grogger and Eide 1993, and Murnane et al. 1995). (A parallel line of research has employed school inputs to measure quality, but, while some controversy exists, this has not been as successful. Specifically, school input measures have not proved to be good predictors of wage or growth. The strategy faces the measurement problems discussed below and ignores the fact that families, peers, and individual ability also enter into the equation.) Similarly, society appears to gain in terms of productivity; Hanushek and Kimko (2000) demonstrate that quality differences in schools have a dramatic impact on productivity and national growth rates.

Attention to quality and cognitive skills also matches a growing policy interest. As countries have moved toward more universal access to schooling, they have turned to issues of quality of publicly provided schooling.

2. *Production*

Let us now look at the other side of the education equation—the inputs, or determinants, of student achievement. Because outcomes cannot be changed by fiat, much attention has been directed at inputs—particularly those perceived to be relevant for policy such as school resources or aspects of teachers.

(This is differentiated from the more common approach in educational research of 'process-outcome' studies where attention rests on the organization of the curriculum, the methods of presenting materials, the interactions of students, teachers and administrators, and the like. An entirely different approach–true experimentation–has been much less frequently applied, particularly when investigating the effects of expenditure differences. The best known is an experiment in class size reduction in the United States during the mid-1980s, Project STAR (Word et al. 1990).) 'Analysis of the role of school resources in determining achievement begins with the 'Coleman Report,' the US government's monumental study on educational opportunity released in 1966 (Coleman et al. 1966). The report was conducted in compliance with a mandate of the Civil Rights Act of 1964 to investigate the extent of inequality in the nation's schools. Although this was not the first such effort, it was much larger and much more influential than any previous (or subsequent) study.

The study's greatest contribution was directing attention to the distribution of student performance—the outputs as opposed to the inputs. Instead of addressing questions of inequality by simply listing an inventory of differences of schools and teachers by race and region, it highlighted the relationship between inputs and outputs of schools.

Unfortunately most of the attention the report generated focused on the report's conclusions rather than its innovative perspective. The controversial conclusion was that schools are not very important in determining student achievement; on the contrary, families and, to a lesser extent, peers are the primary determinants of performance variance. The findings immediately led to a large (but decentralized) research effort to compile additional evidence about input–output relationships in schools (There were also extensive analyses of the report's methodology and of the validity of its inferences. See, for example, Bowles and Levin (1968), Cain and Watts (1970), and Hanushek and Kain (1972).)

The underlying model that evolved as a result of this research is very straightforward. The output of the educational process, that is, the achievement of individual students, is directly related to a series of inputs. Some of these inputs—the characteristics of schools, teachers, curricula, and so forth—are directly controlled by policy makers. Other inputs—those of families and friends plus the innate endowments or learning capacities of the students—are generally not controlled. Further, while achievement may be measured at discrete points in time, the educational process is cumulative; inputs applied sometime in the past affect students' current levels of achievement.

The selected input measures have been fairly similar across studies. Family background is usually characterized by such sociodemographic characteristics as parental education, income, and family size. Peer inputs, when included, are typically totals of a student population's sociodemographic characteristics for a school or classroom. School inputs include teacher background (education level, experience, sex, race,

and so forth), school organization (class sizes, facilities, administrative expenditures, and so forth), and district or community factors (for example, average expenditure levels). Except for the original Coleman Report, most empirical work has relied on data constructed for other purposes, such as a school's standard administrative records. (As discussed elsewhere (Hanushek 1979, 1986), a variety of empirical problems enter into the estimation and the subsequent interpretation of results. The most significant general problems are the lack of measurement of innate abilities of individuals and the imprecise measurement of the history of educational inputs. Both the quality of the data and the estimation techniques are very important in interpreting specific findings, but, as discussed below, these findings have less impact on the aggregate findings illuminated here.) Based on this, statistical analysis (typically some form of regression analysis) is employed to infer what specifically determines achievement and what is the importance of the various inputs into student performance.

3. *The Importance of Measured School Inputs*

The state of knowledge about the impacts of resources is best summarized by reviewing available empirical studies. Most analyses of education production functions have directed their attention at a relatively small set of resource measures, and this makes it easy to summarize the results (Hanushek 1997). Table 2 provides a tabulation of estimates of the impact of school inputs. The 90 individual publications that appeared before 1995 and that form the basis for this analysis contain 377 separate production function estimates. The table indicates the sign of the estimated impact of a given resource on student performance; positive estimates imply that more resources are associated with higher student outcomes and the opposite for negative estimates. Additionally, information is provided about statistical significance, or our confidence that there is a real effect of the resources.

For classroom resources, only 9 percent of studies on teacher education and 14 percent of studies on teacher–pupil ratios found a positive and statistically significant relationship between these factors and student performance. (This summary concentrates on the results. Details of the underlying analyses and the selection of studies for this tabulation are found in Hanushek (1986, 1997). The first column provides a count of the total number of estimates addressing the impact of the given resource.) Moreover, these studies were offset by another set of studies that found a similarly negative correlation between those inputs and student achievement. Twenty-nine percent of the studies found a positive correlation between teacher experience and student performance; however, 71 percent still provided no support for increasing teacher experience (being either negative or statistically insignificant).

Studies on the effect of financial resources provide a similar picture. There is very weak support for the notion that simply providing higher teacher salaries or greater overall spending will lead to improved student performance. Per pupil expenditure has received the most attention, but only 27 percent of studies showed a positive and significant effect. In fact, 7 percent even suggested that adding resources would harm student achievement. It is also important to note that studies involving pupil spending have tended to be the lowest quality studies, and thus there is substantial reason to believe that even the 27 percent figure overstates the true effect of added expenditure.

Table 2
Percentage distribution of estimated effect of key resources on student performance, based on 377 studies available through 1995

Resources	Number of estimates	Statistically significant		Statistically insignificant
		Positive	Negative	
Real classroom resources				
Teacher: pupil ratio	277	14 percent	14 percent	72 percent
Teacher education	171	9	5	86
Teacher experience	207	29	5	66
Financial aggregates				
Teacher salary	119	20 percent	7 percent	25 percent
Expenditure per pupil	163	27	7	34
Other				
Facilities	91	9	5	86
Administration	75	12	5	83
Teacher test scores	41	37	10	53

4. Do Teachers and Schools Matter?

Because of the Coleman Report and subsequent studies discussed above, many have argued that schools do not matter, and that only families and peers affect performance. Unfortunately, these interpretations have confused measurability with true effects.

Extensive research since the mid-1960s has made it clear that teachers do indeed matter. The simple definition of teacher quality used here is an output measure based on student performance, instead of the more typical input measures based on characteristics of the teacher and school. High-quality teachers are ones who consistently obtain higher than expected gains in student performance, while low quality teachers are ones who consistently obtain lower than expected gains. When this approach has been used, large variations in performance have been uncovered.

In fact, the degree to which teacher differences affect performance is impressive. Looking at the range of quality for teachers within a single large urban district, teachers near the top of the quality distribution can get an entire year's worth of additional learning out of their students compared to those near the bottom (Hanushek 1992).

If teacher quality is central to the performance of schools, then research and policy quite naturally should focus on this. Unfortunately, it has been difficult to link quality—measured by impacts on student achievement—to labor markets. While considerable work has been done to assess the gross flows of individuals into teaching and how those are affected by economic conditions, this does not provide a reliable link to quality. Murnane et al. (1991), Hanushek and Pace (1995), and Ballou and Podgursky (1997) show how various characteristics of teachers including test scores and quality of college are related to labor market conditions and school choices in the United States. Similarly, Hanushek and Rivkin (1997) for the US and Dolton and van der Klaauw (1995) for the UK find that teacher supply adjusts to salaries and labor markets. Nonetheless, these leave open the essential concern about any systematic impacts on school performance. Accurate assessment of teacher labor markets requires reliable quality measures along with information about hiring, retention, and mobility of teachers, and such data have not been available.

5. Study Quality

The previous discussions do not distinguish among studies on the basis of any quality differences, so the results could be distorted by not adjusting the tabulations. While 'study quality' has a variety of subjective components, the available estimates can be separated by a few objective components of quality. First, while education is cumulative, frequently only current input measures are available, which results in analytical errors. Second, schools operate within a policy environment set almost always at higher levels of government. In the United States, state governments establish curricula, provide sources of funding, govern labor laws, determine rules for the certification and hiring of teachers, and the like. In other parts of the world, similar policy setting, frequently at the national level, affects the operations of schools. If these attributes are important—as much policy debate would suggest—they must be incorporated into any analysis of performance, but little progress has been made in identifying or measuring the relevant aspects of policy. Each of these problems potentially leads to biases in the estimated effects of educational inputs. The adequacy of dealing with these problems is a simple index of study quality.

The details of these quality issues and approaches for dealing with them are discussed in detail elsewhere (Hanushek 1997) and only summarized here. The first problem is ameliorated if one uses the 'value added' vs. 'level' form in estimation. That is, if the achievement relationship holds at different points in time, it is possible to concentrate on the growth in achievement and on exactly what happens educationally between those points when outcomes are measured. This approach largely eliminates prior inputs of schools and families, which will be incorporated in the initial achievement levels that are measured (Hanushek 1979). The latter problem of imprecise measurement of the policy environment can frequently be ameliorated by studying performance of schools operating within a consistent set of policies—e.g., within states in the US or similar decision making spheres elsewhere. Because all schools within a state operate within the same basic policy environment, comparisons of their performance are not strongly affected by unmeasured policies (Hanushek and Rivkin 1997). If the available studies are divided by whether or not they deal with these major quality issues, the prior conclusions about research usage are unchanged (Hanushek 1997).

An additional issue, which is particularly important for policy purposes, concerns whether this analytical approach accurately assesses the causal relationship between resources and performance. If, for example, school decision makers provide more resources to those they judge as most needy, higher resources could simply signal students known for having lower achievement. In such a case, the statistical results might reflect the impact of achievement on resources, instead of the other way around. One way to deal with this is to take into account explicitly the resource allocation process. When done in the case of class sizes, the evidence has been mixed (cf. Angrist and Lavy 1999, Hoxby 2000, Rivkin et al. 2000). An alternative involves the use of random assignment experimentation rather than statistical analysis to break the influence of sample selection and other possible omitted factors. The benefits of this approach are well demonstrated in other fields (e.g., medicine or agri-

culture). By randomizing who gets the treatment and comparing outcomes across treatment and control groups, it is less likely than is the case in standard statistical analyses that problems of model misspecification or of selection into treatment situations will bias the estimates of program effects. With one major exception, this approach nonetheless has not been applied to understand the impact of schools on student performance. The exception is Project STAR, an experimental reduction in class sizes that was conducted in the State of Tennessee in the mid-1980s (Word et al. 1990). To date, it has not had much impact on research or our state of knowledge. (While Project STAR has entered a number of policy debates, the results remain controversial (Krueger 1999, Hanushek 1999).)

6. *Investigations Outside the United States*

Researchers have conducted studies on student performance around the world, although with lower frequency. Because student performance data are much less readily available outside the US, most such studies have been special purpose studies that are frequently difficult to generalize. Nonetheless, the results appear qualitatively very similar.

In less developed countries, there is a slightly stronger correlation between resources and achievement, but the overall picture remains the same (Hanushek 1995). This similarity is surprising, because one might expect more impact of resources in schools that begin with very low levels of resources.

For developed countries, the evidence is even scarcer and more difficult to summarize. A review by Vignoles et al. (2000) points to a small number of studies outside the US and shows variation in results similar to that reported elsewhere. Nonetheless, the limited research makes any generalizations difficult.

7. *Efficiency*

Efficiency involves the relationship between inputs and outputs in a production process. The underlying notion is that production is efficient if given inputs produce the maximum output. The simplicity of this statement, however, obscures a variety of complexities that arise when the concept is actually applied.

Typically, economics does not devote much attention to the analysis of efficiency. If there are competitive markets, the behavior of producers and consumers tends to drive outcomes toward efficient production. Because of this basic theorem, it is common simply to assume efficiency.

In education, however, efficiency is never a given. First, education is generally publicly provided. Governmental organizations, which do not face the same incentives as private firms, cannot be expected to move toward efficient production. In particular, few school personnel are rewarded or punished based on the outcomes students obtain, making the incentives for performance minimal or nonexistent. Second, it is difficult to find information on school efficiency. With complete information, parents might be expected to pressure schools to use resources more efficiently—either through local political processes or through moving to districts that did better (Tiebout 1956). Because student performance is influenced by factors schools can't control—i.e., input from family and friends—simply observing student achievement does not accurately reflect school contribution. Thus, parental and voter pressures on schools are lessened by imperfect information.

The underlying political economy of schools that can preserve such apparently large inefficiencies in resource use deserves considerably more research.

8. *Competition and Incentives*

The lack of direct incentives within schools has led to investigations of circumstances where incentive forces may be stronger. While there have been a wide variety of proposed changes (e.g., Hanushek et al. 1994), most have not been implemented or analyzed sufficiently to draw any conclusions about their efficacy.

The classic argument for competition comes from Friedman (1962) with his arguments for vouchers. The well-known arguments suggest that separating the finance of schooling from the production of schooling by allowing students to choose the school they attend would improve individual satisfaction with the outcomes. Within the United States, this approach has been vigorously debated, but few examples of implementation have occurred.

The most celebrated application has been Milwaukee, Wisconsin, where vouchers have been available to a (constrained) number of poor children since 1990 (Witte 1999). A number of privately financed alternatives have also been offered (Howell et al. 2000). Most of the attention to these voucher programs has centered on the student outcomes of students in them compared to public schools. (A variety of controversies have developed in these analyses. Perhaps the primary analytical issue is dealing with a selection of students and an appropriate comparison group. See, for example, the discussions in Witte (1999), Rouse (1998), and Greene et al. 1998).) Because these programs have been very marginal to the education system, there has been little suggestion that the public schools have made any adjustments in response. Thus, these choice experiences have not provided information about how public schools might react to a larger, more institutionalized program.

Private schools offer one possibility for better understanding the effects of competition. They must

compete with the public schools in order to attract clients, and thus they are subject to stronger pressures to provide high levels of performance. The literature on Catholic school performance is summarized in Neal (1998) and Grogger and Neal (2000). The evidence has generally indicated that Catholic schools on average outperform public. This superiority seems clearest in urban settings, where disadvantaged students face fewer options than others. This evidence is, nonetheless, subject to some caveats. First, as recognized since some of the earliest work on the topic (Coleman et al. 1982), it is difficult to separate performance of the private schools from pure selection phenomena. Specifically, since private school students could have attended public schools but instead pay extra for private schooling, they are clearly different than the public school students with identical measured characteristics. A variety of alternative approaches have been taken to deal with the selection problem, and a rough summary of the results after those efforts is that there remains a small advantage from attending Catholic schools. (Grogger and Neal (2000) suggest, however, that there is no advantage to attending private elite schools—a surprising result given the extra cost usually involved in that. These results are possibly due to selection problems, but it not a simple relationship because most people would expect positive selection into these elite schools.) Second, this literature says little about the distribution of school quality within the Catholic sector. Within the public sector, it is widely believed that school quality varies considerably across schools, and one might suspect that the same holds true for private schools.

A related issue is the reactions of public schools to the private sector. Hoxby (1994) demonstrates that public schools in areas that have larger concentrations of Catholic schools perform better than those facing less private competition. This analysis provides the first consistent evidence suggesting that public schools react to outside competition.

Perhaps the most important potential element competition comes from other public school jurisdictions. Specifically, households can choose the specific jurisdiction and school district, à la Tiebout (1956), by their choice of residential location. While adjustment is costly, these choices permit individuals to seek high-quality schools if they wish. Residential location decisions are of course complicated, involving job locations, availability of various kinds of housing, school costs and quality, and availability of other governmental services. Given choice opportunities plus voting responses, this model suggests pressure on schools to use resources effectively. Otherwise one might expect housing values to be affected.

The simple choice model would suggest naturally that larger numbers of schools or school districts per student would offer more opportunities for residents and thus more competition across schools. This simple model motivates the empirical analyses of Borland and Howsen (1992) and its extension and refinement in Hoxby (2000) and in Hanushek and Rivkin (forthcoming). The simple inclusion of measures of concentration indicates that areas with less choice have poorer schools on average (Borland and Howsen 1992). Hoxby (2000) pursues alternative strategies to look at the causal impact of concentrations and finds a larger estimated impact of competition on the performance of schools. Similarly, Hanushek and Rivkin (forthcoming) find competitive impacts on performance of urban schools and that these are particularly important for low income students who have fewer mobility options.

9. *Finance of Schools*

Public finance economists have devoted considerable energy to the study of the finance of schools, largely from the viewpoint of traditional tax and expenditure policy. The educational policy component of this involves equity in the provision of education. These considerations are largely motivated by the many studies that show wide disparities in achievement by race and socioeconomic background (e.g., Coleman et al. 1966, Hanushek 2001). Nonetheless, the typical discussion of equity concentrates primarily on spending disparities across schools and districts.

Indeed, one of the most significant policy issues since the early 1970s in the United States has been the appropriate way for states to fund local schools. While most states have employed a compensatory aid formula to ameliorate some local governments' difficulty in raising taxes, these measures have only partially solved the problem. The issue became the subject of court action in the 1960s, with the case of *Serrano vs. Priest* in California. Suits in many other states followed. As a result, some significant narrowing of spending variations occurred (Murray et al. 1998).

However there has been surprisingly little analysis of the impacts of these suits. This is important to undertake, because the prior research discussed above does not show a clear link between increased funding and school quality or student performance. From the perspective of educational outcomes, then, the value of spending changes related to equalization court cases and the related legislative actions remains an open question (Hanushek 1991). To date, little research has focused on the achievement impacts of school finance policies. The one analysis of the impact of the Serrano case found no lessening of variation in student outcomes after spending was equalized across districts (Downes 1992). A broader, nationwide analysis of district spending on earnings outcomes also found no beneficial relationship between the two, except perhaps for black females (Hanushek and Somers 2001).

10. Some Conclusions and Implications

The existing research suggests inefficiency in the provision of schooling. It does not indicate that schools do not matter. Nor does it indicate that money and resources never impact achievement. The accumulated research simply says there is no clear, systematic relationship between resources and student outcomes. The persistence of this raises important questions about current education policy, as well as a real need for further research.

The main conclusion of this research is that policy decisions should not focus on school resources, because the impact of resources on student achievement is unknown at this time. The policy solution seems to be to establish incentives—rewards or consequences related to student outcomes—and then to permit local schools to develop their own game plans for meeting these goals. While a wide variety of incentives have been proposed—such as vouchers, merit pay, or contracting out—most have not been implemented or analyzed sufficiently to determine their efficacy.

A final major issue raised by these analyses is their implication for other kinds of studies (Hanushek 1996). Most studies involving human capital are interested in its effect on other aspects of behavior. For these studies schooling is largely tangential to other interests, and researchers are typically simply looking for an easy and readily available measure of school quality. The most common has been spending per pupil. However, the inefficient production of human capital introduces natural measurement problems. Direct spending is no longer a good measure of quality because it has no perceivable bearing on performance. Second, it is well known that families have considerable influence on student achievement, implying that school resources are only part of the equation. Both factors suggest that studies which measure student achievement just through resource investment have a high potential for distortion.

E. A. Hanushek

Education for Gifted and Talented Children

The term 'gifted' is used to identify children who are superior in mental ability or very high academic achievers. Generally they are children who learn easily and rapidly, reason or use logic fluently, think well theoretically and abstractly, are advanced in verbal and/or mathematical skills, and retain or remember information exceptionally well. Their cognitive precocity is exhibited in their ability to function mentally at levels far beyond what is typical or normative for their chronological age.

Intelligence test scores are often used, along with other indicators of ability such as achievement test scores and teacher rating scales, to identify gifted children. While an IQ of 140 or above has often been the cutting level for classification as gifted, following the lead established by Terman (1925) in his study of

gifted children, a broad range of IQs from 120 upward have been used in real practice.

The terms 'talent' or 'talented' have often been used as synonymous with 'gifts' or 'gifted,' and the phrase 'gifted and talented' was, and still is, widely used with little effort to distinguish the two terms. For some practitioners 'talent' has been used to denote special ability in the arts while for others it refers both to academic talent (verbal talent, mathematical talent, etc.) and to artistic talent (music, drama, visual art, etc.). Leadership has also often been identified as a form of special talent.

Pioneering research on gifted children began with the work of Lewis Terman at Stanford University in 1920. Using the Stanford–Binet Intelligence Scale that he had developed and published in 1916, he went on to identify 1,000 children with IQs above 135 (most had IQs above 140) who were then on average 12 years of age, and to study their lives in great detail. The first major finding of the study, published in 1925, was that the children overall were not, as commonly thought, a group of social misfits characterized by eccentric behavior, but rather were generally quite normal except for their academic superiority and very good health. While the sample was quite biased in favor of white middle-class families, the findings were widely accepted in educational settings and came to focus educators' attention on their special need for more high-level and challenging instruction.

Understanding of intelligence and its role in giftedness was enhanced a great deal by the discovery of factors of intelligence and the fact that people have differentiated and unique patterns of cognitive capabilities—numerical, verbal, spatial, fluency—all of which are really components of general intelligence. Later, the same analytical tools of factor analysis were used to show that some aspects of intelligence are quite purely genetically determined (fluid) and others acquired through the interaction of genetic disposition with learning opportunities (crystallized). Thus, reasoning is more closely a fluid aspect of intelligence, whereas mathematical ability may be learned capacity that in turn manifests itself in intelligent behavior.

The componential approach to understanding intelligence and giftedness in a sense ran amok when psychologist Guilford (1950), using new methods of factor analysis, seemingly found hundreds of factors or facets of intelligence. Guilford proposed a 'structure of intellect' in which there were three dimensions: content or input on which thinking operates; operation or thinking processes and skills; and products or outcomes of the operations. The model was widely embraced, especially because of its inclusion of divergent thinking as an operation. However, it lost favor in the 1980s and 1990s as Guilford's factor analysis methods were questioned.

A major conception of human ability and giftedness appeared in Sternberg's new theory of human intelligence (1985). His componential theory of human intelligence is a cybernetic model that involves selective acquisition of knowledge, complex thinking or processing operations, and the creative production of new knowledge. A first major aspect of intelligence is a set of metacomponents, or cognitive operations, such as recognizing and clarifying problems, designing solution strategies, and judging the solutions. Another aspect is knowledge acquisition components, how we encode, retain, and use knowledge. Finally, there are performance components that are pieces of knowledge or skills needed to perform specific tasks. Sternberg's theory is now widely recognized in the world of gifted education, but no good test has emerged from Sternberg's theory and no specific identification of gifted children is carried out in the field of gifted education based on the theory.

1. *New Focus on Talent*

Publications by Gardner (1983), Bloom (1985), Csikszentmihalyi et al. (1993), and Gagné (1999) have presented new research and theoretical conceptions of specific human abilities, and paved the way for increasing attention among educators to the nature, development, and nurture of youth talents. After five decades of research on intelligence and components or factors of intelligence, Gardner proposed a new theoretical formulation of multiple intelligences that posited seven discrete general abilities: linguistic, logical-mathematical, spatial, musical, bodily-kinesthetic, interpersonal, and intrapersonal. Gardner acknowledged that the list may not be definitive; there may be other intelligences. Furthermore any or all of the seven intelligences might well be broken down into subcomponents. Gardner also acknowledged that calling the seven abilities 'intelligences' was somewhat arbitrary and that they might well be called 'talents' or 'abilities.' Whatever they are called, it is clear that Gardner's conception of multiple intelligences has had a major impact on school practice in general and gifted education in particular, but not so much in the area of identification of specific intelligences or talents in children as in the area of instruction directed toward development of gifted children's intelligences or talents.

Bloom carried out research focused on concert pianists and sculptors as representative of the arts, research mathematicians and research neurologists representing cognitive or intellectual fields, and swimmers and tennis players representing athletics. The subjects had all achieved world-class recognition before age 35. From the extensive interviews conducted with 120 subjects Bloom concluded that finding or identifying a child's talent strength or potential early was essential for the long-range development of the talent, that both parents and teachers play critical roles in supporting the child's talent development, and that motivational encouragement was essential at each stage of the child's talent development.

Confirmation of the need to identify specific youth talents as a prelude to nurturing talents came in other research of multipotentiality among the gifted. Specifically it was found that the idea that gifted children have potential for many different fields of achievement was a false conception. Instead, by the time they reach middle school and high school they have a limited range of talent potentials.

Recent research by Csikszentmihalyi et al. (1993) in which they studied talent development among teenagers with special talents in mathematics, science, music, art, and athletics, also concluded that it is essential for long-range talent development that youths' specific talents be identified as a prelude to the nurture of talents. They also concluded that there is a long-range process of differentiation of youths' specific talents, and integration of those talents with other personal characteristics to arrive finally at high-level expertise, creative achievement, or occupational fulfillment.

Gagné (1999) proposed that, out of several basic and original factors of giftedness, specific talents emerge as special forms of aptitude or ability as a result of experiences at home, in school, with peers, and in the broader community surrounding a child. The basic gifts or forms of giftedness are intellectual, creative, socioaffective, sensorimotor, and other unspecified, genetically determined abilities. Gagné concluded that there are six talent fields (academic, technology, arts, leisure activities, athletics, and communications-business) and six aptitude domains (intellectual, creative, socio-affective, personal, sensorimotor, and nonconventional). This author also surveyed students ages 9 to 17 and found 10 talent categories represented among them: academic, artistic, cognitive, creative, communication, athletic-physical, games, language, personal-social, and vocational-technical. As talent development relates to and/or is carried out in schools Feldhusen (1999) summarized these conceptions as representing talents in four domains: academic-intellectual, artistic, vocational-technical, and interpersonal-social.

In summary, there is an urgent need in the field of gifted education to move on beyond the simple dichotomous conception of youth as 'gifted' or 'ungifted' to a multi-aptitude or talents view of human abilities. Recent factor analyses of tests of human abilities (Carroll 1993) revealed once more, and more definitively than ever before, that there is a diversity of human abilities, but at the most macro level they can be categorized as general intelligence or g, fluid intelligence, crystallized intelligence, general memory and learning, broad visual perception-space relations-visualization, auditory perception, cognitive speed, and memory-retrieval ability. These basic human abilities underlie differentially the domains or fields of human talent that grow in youth with the nurturing experiences of homes, parents, peers, school, and the general community in which they live.

2. *Identification*

The field of gifted education places great stress on the identification process and makes pretense of finding the 'truly' or 'really' gifted child. Although there is little research verifying or validating identification processes, there is much discussion in the literature on finding gifted children, and also on finding those who are less easily found—such as children from some minority racial groups, physically handicapped children, and youth from culturally impoverished homes. The essential question to be answered, but which is rarely addressed, is the reliability of the process and/or the ratio of false positives and false negatives to a hypothetical total population of gifted children in a community. False positives are those who are incorrectly identified as gifted and who therefore fail to profit from, or do not need, special educational programs. False negatives, the far more serious problem, are those children whose abilities are at the level where need for the program is evident, but they are not identified as gifted and eligible for the program.

Children may be identified for a gifted program using an identification system based on Renzulli's three-ring conception of giftedness: ability, task commitment, and creativity. While children who are very high achievers are often declared not to be gifted, simply very hard workers, the Renzulli conception recognizes what is called 'task commitment' as a major component of giftedness. Task commitment may represent high-level and sustained interest in a field or topic of study as well as readiness to work long and hard at a task.

The other two factors of giftedness—abilities and creativity—constitute quite different areas for assessment. While valid and reliable measures of youth abilities are readily available, assessment of creativity in the identification process is much more tenuous. While the tests developed by Torrance (1981) were designed to measure creative ability, their validity and reliability for the assessment of creativity remain highly questionable.

The best combination of measures for the assessment of youth talents seems to be intelligence tests like the Wechsler Intelligence Scales, that yield scores for information, comprehension, arithmetic, similarities, vocabulary, digit span, picture completion, picture arrangement, block design, puzzle assembly, coding, and mazes as basic aptitudes; or the Differential Aptitude Tests, that yield scores for verbal reasoning, numerical reasoning, abstract reasoning, perceptual speed and accuracy, mechanical reasoning, space relations, spelling, and language usage.

Beyond the basic aptitudes or abilities, standardized school achievement tests offer valuable assessments of talented youths' precocity or advanced levels of learning, especially when they are administered off level; that is, when advanced forms of the tests are used in relation to a child's age or grade level. The major

standardized achievement tests available in the United States are the Iowa Test of Basic Skills, Stanford Achievement Tests, Metropolitan Achievement Tests, SRA Achievement Series, California Test of Basic Skills, Sequential Tests of Educational Progress, and the Scholastic Aptitude Test. All focus on student achievement in basic school subjects. However, the only test that has been used widely for off-level testing is the Scholastic Aptitude Test that has been widely used in the ubiquitous academic talent searches.

A third and valuable type of assessment is rating scales, most often completed by teachers who have observed children in the classroom over an extended period of time. Widely used are the Scales for Rating The Behavioral Characteristics of Superior Students by Renzulli et al. (1998), and the Purdue Academic Rating Scales by Feldhusen et al. (1997). The Renzulli scales assess learning, motivation, creativity, leadership, artistic ability, musical and dramatic talent, precision and expressiveness in communication, and planning. The Purdue Academic Rating Scales assess competence in mathematics, science, social studies, English, and foreign language learning. It is a misfortune of the field of gifted education that rating scales are often developed locally and used in the identification process without any attention to the validity and reliability of the scales.

A fourth area of assessment for identification is evaluation of student products portfolios, and/or performance ratings by skilled observers. This method of assessment is most appropriate for the several domains of the arts. Winner and Martino (1993) delineated well the early signs and development of giftedness in visual arts and music, and presented a comprehensive inventory of assessment procedures including tests, portfolios, and observation of performance. Clark and Zimmerman (1998) have also studied the nature of artistic talent intensively over several decades, and they summarized their work concluding that the development and assessment of artistic talent is a long-term process, not the one-time evaluation often used by schools to identify academically gifted children. Identification of talent in the arts usually involves not only portfolio evaluation but also day-by-day observational assessment by knowledgeable teachers of students' work in progress in the art classroom, as is also the case of music teachers and student musicians in the music classroom.

Identification of cognitively gifted and academically talented youth is most often carried out by combining or summarizing the collected data and judging if a child has reached a criterion level for giftedness or talent designation. Schools assume that children who are designated 'gifted' need the special educational service offered, but there is little evidence that they profit from it more than they would from remaining in the regular classroom. Research on boredom among gifted youth in school indicates that while many are indeed bored, so also are many youth who are not identified as gifted (Feldhusen and Kroll 1991). However, the same research indicates that the boredom of gifted youth is due mainly to the slow pace and low level of teaching in regular classrooms, while less able youth are simply not interested in much of typical classroom subject matter.

In summary, the identification process for all areas of giftedness and talent should best be viewed as a long-range process of helping children, parents, and teachers come to understand children's unique aptitudes and talents as a basis for appropriate educational planning and programming. There is probably little value in one-shot designation of children as gifted. A wide variety of tests, observations, and product assessments can be used over time to identify the nature and levels of emerging talent.

3. *Developing Gifts and Talents*

There is no definitive educational plan or program known to be uniquely appropriate for the development of gifted and talented youth. Generally it is assumed that, because of their precocity and capacity to learn faster than children of low or average ability, they need accelerated instruction, at a higher level commensurate with their achievement levels as revealed in the identification process, and at a faster pace. Children with IQs of 120 and higher are generally ready for instruction at advanced levels of the curriculum, and they learn new advanced material much more rapidly than children of low and average ability.

A wide variety of strategies are used to provide appropriate and intensive educational services to gifted and talented students, including:

(a) full-time classes in all subjects at the level of grades K–6;

(b) special classes in particular subjects (e.g., honors);

(c) enrollment part time at a college while in high school or taking college-level courses offered in the high school program (e.g., Advanced Placement);

(d) early admission to elementary school, middle school, high school, or college; and

(e) enrollment in a special school for gifted or talented students at any, several, or all grade levels.

The above options are offered throughout the United States and in some other countries. More common, however, are the following, far less intensive, services:

(a) pullout, resource room, or withdrawal programs in which gifted children work for 3–6 hours a week on creative enrichment, problem solving, and other supplementary activities not in the regular school curriculum;

(b) cluster grouped in an otherwise mixed ability classroom with a teacher trained to do accelerated and enriched learning activities with children in the gifted cluster; and

(c) individualized teaching in a regular mixed ability classroom guided by an individual learning plan for the gifted or talented student.

There is widespread assumption, also, that gifted and talented youth need the social experiences of interaction with peers of similar levels and types of giftedness and/or talent, and that they need higher level models and mentors in their own areas of talent. Peer models serve to motivate talented youth to higher level achievements and often serve as friends for gifted students who are otherwise socially rejected by less able peers.

Mentors and/or achievement models provide gifted and talented youth with blueprints or images of their own potential and ultimate achievements in a talent domain. Mentors are really key educational tools or resources in the education of gifted and talented youth. They teach, they motivate, and they provide emotional support to gifted and talented youth. Haeger and Feldhusen (1989) described a program of mentoring for talented youth at Purdue University, in which university faculty and graduate students served as mentors for special experiences on Saturday mornings. All students who were assigned to mentors were first required to take a Saturday morning course for nine weeks in the subject matter area in which they would have the mentoring experience. Haeger and Feldhusen found that prior background knowledge in the mentoring area was essential for successful mentoring experiences. Pleiss and Feldhusen (1995) carried out an intensive review of the theory and research literature on mentors, role models, and heroes in the lives of gifted and talented students and concluded that there is abundant support for their value in nurturing talent and social development of precocious youth.

Communities vary in their educational resources and attitudes toward gifted and talented youth. The great educational movement for inclusion or heterogeneous grouping of all youth for common educational experiences has spread to countries throughout the world. It has generated opposition to programs and services for gifted and talented youth in many schools. While inclusion may be workable and desirable for students of low and average ability, there is ample evidence that precocious youth who are also fast learners and able to pursue learning at deeper and more abstract levels are best educated in special classes with peers of similar ability and teachers who have been trained to work with the gifted and talented.

4. Summary

Gifted students are those who have superior general intellectual ability as revealed by intelligence and achievement tests and teacher ratings of their classroom performance. Talented students excel in one or more areas, such as science, mathematics, writing, arts, leadership, or technology, and are identified with tests, rating scales, portfolios, and performance ratings. Identification of gifted and talented students is a long-range and continuous process leading to better and better understanding of youths' talent potentials.

Gifts and talents are present in students at varying levels, and thus in planning educational services for them, their levels of ability must be linked to appropriate levels and types of service. There is a wide variety of services available to use in programs for talent development. Intensive and accelerated classes and programs, mentors, and schools focused on particular areas of talent such as mathematics, science, art, music, leadership, or technology serve best to meet the developmental needs of talented youth and to help them achieve their full potential.

Education (Higher) and Gender

In this article I sketch the relative position of men and women in higher education. I examine three distinct aspects of the educational system: access, college experiences, and post-collegiate outcomes. Women fare relatively well in the area of access, less so in terms of the college experience, and are particularly disadvantaged with respect to the outcomes of schooling.

Higher education is defined as formal enrollment and degree acquisition at the college and university level. While educational systems differ across countries, most distinguish between primary (elementary), secondary (high school) and tertiary levels of education (see UNESCO 1998 for details). As elementary and secondary education become increasingly universal, higher education becomes increasingly salient as the basis for educational stratification.

1. *Access to College in the United States*

In the United States women now represent the majority of students in the system of higher education. In 1995, 55.4 percent of students enrolled in college were women. During the 1990s, women high school graduates were five percentage points more likely to enroll in college than were men (64.7 versus 59.7 percent, respectively). Women's share of degrees climbed steadily during the 1970s and 1980s, a period when the fraction of college-age young adults enrolled in school increased slowly but steadily. By 1982, women surpassed men in the number of bachelor's degrees earned. Women have garnered more bachelor's degrees than their male counterparts ever since. By 1995, 54.6 percent of bachelor's degree recipients were women. Women earned 59.5 percent of two-year degrees, 52.7 percent of master's and professional degrees, and 39.3 percent of doctoral degrees (National Center for Educational Statistics 1997).

Women remain slightly overrepresented in lower-ranked schools, as indexed by higher acceptance rates, higher student/faculty ratios, lower standardized test scores, and lower fees (Jacobs 1999). The small remaining sex gap is due to two factors: (a) the relative scarcity of women in schools with large engineering programs (engineering programs tend to be above average in selectivity); and (b) the tendency of women to enroll in school part time, since lower-status institutions are more likely to accept part-time students. Selected reports on admissions as well as enrollment from leading institutions indicate that women are well represented among recent entering classes, except in schools that prominently feature engineering programs. There is some evidence that some liberal arts colleges are worried that they are enrolling too many women, and are starting to take steps to recruit men (New York Times 1998).

The parity women have achieved in college completion is a recent phenomenon, but the 1950s and 1960s represented a historically depressed level. Women represented 41.3 percent of college graduates in 1940, slipping to 23.9 in 1950 and remaining at an historically low 35.0 percent in 1960 (US Bureau of the Census 1975). Goldin (1997) estimates, based on retrospective reports from the 1940 Census, that women's college enrollment rates exceeded 90 percent of men's from the late 1890s until the mid 1920s, although the inclusion of normal schools arguably inflates Goldin's figures.

For the entire twentieth century in the United States, women have comprised a large proportion of students in primary and secondary schools. Women's rate of enrollment among 5–19 year olds has exceeded 90 percent of men's rate since as early as 1850, and 98 percent since 1890. Women have represented the majority of high school graduates since at least 1870: in 1920 over 60 percent of high school graduates were women (US Bureau of the Census 1975, 369–70, 379). The median years of schooling completed by women exceeded men for most of this century until the G. I. Bill after World War II enabled men to surpass women.

2. *International Comparisons*

Women in the United States have surpassed their counterparts in other countries in access to schooling at both the secondary and tertiary levels for more than a century. Today, the United States enrolls more college students per capita than virtually any other country, and women's share of college enrollments in the United States exceeds that in most other countries. (Data for selected countries are presented in Jacobs

1996. See also UNESCO 1998.) In most of the advanced industrial countries of Europe, women's share of enrollments is quite high. But even here, substantial variation persists, with women's share ranging from 40 percent of college students in Switzerland and 41 percent in Germany to 55 percent in France and 61 percent in Portugal. Women fared well in terms of schooling in the socialist countries of Eastern Europe (Kelly and Slaughter 1991), and socialist regimes in developing countries typically emphasized schooling for girls in their initial years in power. The post-socialist experience warrants close scrutiny, as women's status is eroding in many spheres in these countries (Biaecki and Heyns 1993).

Women's share of enrollment in Latin American colleges and universities is often quite high: Brazil, 53 percent; Argentina, 47 percent; Chile, 42 percent. Asian countries follow: in both China and India one-third of college students are women. African countries include many with the lowest share of female enrollments in the world. Within each of these regions, there is substantial variation in the share of women's enrollment.

Gender disparities are highest at the tertiary level, as young men are typically the first to pursue college. Gender disparities in expenditures are greater than those in enrollments, because college education is more expensive than elementary or secondary schooling.

3. *The Educational Process*

Women and men experience college differently, and face markedly different outcomes. Of the many respects in which the college experience differs by gender, here I consider fields of study and faculty representation.

Women and men pursue different fields of study in college. In the United States, 30 percent of women would have to change fields of study in order to be distributed in the same manner as men (Jacobs 1995a). The sex typing of fields of study is a worldwide phenomenon yet it varies between countries. For example, 51.6 percent of engineering students are women in Kuwait, compared with 3.3 percent in Switzerland and Japan (UNESCO 1998). One of the most striking contrasts is within the divided Germany: in the former East Germany, 32.4 percent of engineering graduates were women, compared with only 7.5 percent in West Germany. In Poland, 62.7 percent of mathematics and computer science degrees went to women, compared with 35.9 percent in the US and 21.0 percent in Egypt.

In the United States during the early 1960s, women were concentrated in an extremely limited range of fields. Education drew almost half of women undergraduates, and over 70 percent of women graduates were concentrated in just six fields: education, English, fine arts, nursing, history, and home economics. Now business is the leading field of study for women. In 1995, women garnered 52.3 percent of life science bachelor's degrees, 46.8 percent of mathematics degrees, 48.0 percent of business degrees, but only 17.2 percent of engineering degrees. Segregation across majors declined substantially from the mid-1960s through the mid-1980s, but has reached a plateau since 1985 (Jacobs 1995a).

Women have not always been segregated into separate fields from men. Founders of the most prominent women's colleges tried hard to maintain curricula that matched or exceeded men's in scope. During the early years of land-grant schools, no separate curriculum for women existed. A peculiarly feminine curriculum began to emerge with the development of home economics. This development reflected an enduring emphasis on female domesticity, but also was promoted in part by women academics, who were excluded from other fields and sought to create a field of expertise and set of job opportunities for which they would be uniquely suited. At the same time, this development contributed to the emergence of a distinctively feminine college experience for young women that served to limit the career prospects of many female graduates.

Men represent the great majority of college and university faculty worldwide (see UNESCO 1998, Jacobs 1996). In the United States, 33.4 percent of faculty were women in 1993. Women's representation declines with the prestige of the institution: 45.3 percent in public two-year schools, 33.9 percent in the public comprehensive schools, and 23.3 percent in public research universities. The number of women also declines with faculty rank. Women represent 42.1 percent of assistant professors, 30.0 percent of associate professors, and 17.0 percent of professors (National Center for Educational Statistics 1997). The US record actually looks quite favorable by comparison with the professoriat in Britain and France, which were 2.3 and 8.7 percent female, respectively, during the early 1980s. Graham (1978) notes that women's representation on the faculty of US colleges and universities actually declined between 1930 and 1970, before beginning a sustained advance during the 1970s and 1980s.

There are many reasons why women's entrance into faculty positions is so low. Until recently women were a small proportion of Ph.D. recipients; women are concentrated in a limited number of fields; women entered academia in large numbers during a period of retrenchment, and pursued fields that were facing sharp declines in enrollments (Slaughter 1993). Nonetheless, women's progress remains far slower than would be expected. Viewed optimistically, if a sizable fraction of women who are currently assistant professors are granted tenure, then the sex composition of the faculty will change dramatically from 2000–2020. Parity is unlikely for quite a long time because of the

number of fields in which women Ph.D.s remains severely underrepresented (Ransom 1990).

Much research has examined the position of women faculty members (see Chamberlain 1988, Jacobs 1996 for reviews). Studies have examined gender inequality with respect to hiring patterns, promotion rates, publication rates, mobility between institutions, job satisfaction, turnover, salaries, and the sense of personal and professional marginalization.

The notion of cumulative disadvantage seems to be a reasonable summary of the underrepresentation of women in faculty positions. In other words, women have been disadvantaged to some extent in every stage of the academic career process. This would account for women's underrepresentation in the higher echelons of university administration, in higher ranks, and in higher-status institutions. Graham (1978) suggests that the extreme exclusion of women from Ivy League institutions undermined the position of all women faculty, because, with the emergence of the research university as the pinnacle of the higher education system, these schools came to set the pattern for higher education as a whole.

A number of researchers see the position of women faculty as evidence of a 'chilly climate' for women throughout higher education (Sandler 1986). But the effects of faculty composition on students continue to be debated. Tidball (1980, 1986) finds that the proportion of female faculty is strongly associated with the number of women high achievers, even in coeducational schools. This finding is probably less vulnerable to the lack of institutional controls than are Tidball's findings regarding women's colleges, and is a result that bears further scrutiny with longitudinal data. Rothstein (1995) finds that women students with female advisors are more likely to continue their education after college. Evidence on student satisfaction with same-sex advisors (Erkut and Mokros 1984) and faculty (Ehrenberg et al. 1995) is mixed. These issues require more detailed investigation of particular environments on particular groups of women, such as math and science majors. Sadker and Sadker (1993) make the case for gender bias in the classroom, but this evidence is principally based on research in high schools.

4. *Educational Outcomes*

Much of the discussion on gender inequality in the labor market has been written in response to the writings of the human capital school of economics which holds that gender inequality stems from inadequate investments on the part of women (Jacobs 1995b). As we have seen, this is no longer the case in the United States. England (1992) has noted that working women have surpassed men in median years of schooling completed for much of the century; only during the period since the G. I. Bill have men surged past women. By the 1990s, working women once again caught up with men in average educational attainment (author's estimate, based on the March 1993 Current Population Survey).

Gender differences in earnings persist despite the parity in education attained by women. The median annual income of female college graduates is approximately 70 percent of that earned by their male counterparts (Jacobs 1996). Women earn less than men even with the same level of education. Indeed, the sex gap in earnings within educational levels is similar to that in the labor force as a whole.

The economic benefits of college have increased since the mid-1970s. The gender gap in earnings has narrowed at all educational levels, due in part to the decline in men's earnings (Bernhardt et al. 1995). Yet the gender gap in earnings among college graduates remains similar to that at other educational levels.

A significant portion of the gender gap in earnings can be attributed to gender differences in majors. Majors play a larger role in early career earnings, although they may influence later career earnings indirectly through occupational tracking. Formal schooling does not exhaust the range of possible sources of skill differences between men and women. The gender gap in wages may be due in part to gender differences in skills acquired in on-the-job training and informal experience. Space does not permit an in-depth exploration of all the sources of gender inequality in the labor market. The point here is that the gender gap in earnings in the United States does not stem from the fact that women spend too few years in formal schooling.

Studies find that higher education results in more support for egalitarian gender role attitudes on the part of women, particularly if the students took courses related to women's roles in society (Pascarella and Terenzini, 1991, p. 316). Other authors suggest that education increases women's support for feminism. Freeman, for example, (1975) maintains that education raises women's expectations and creates a sense of relative deprivation, leading them to support feminism.

As noted above, economists distinguish between the private returns to schooling—such as higher wages and higher household income—and the social or public returns, which may involve improvements to health, welfare, and society. Two principal nonmonetary effects of schooling that have been extensively researched are improved infant health and lower fertility. In developing countries, women with more education marry later, are more likely to use contraceptives, desire smaller families, have their first child later (but breastfeed for fewer months), and have a lower total fertility rate than do less educated women (Schultz 1993a, 1993b). Much of the research described by Schultz compares girls with primary education to those with no education in developing countries, but the depressing effect of education on

fertility is a consistent finding in affluent countries as well.

The 1994 United Nations International Conference on Population and Development (1995), held in Cairo, stressed the importance of empowering women in order to promote sustainable economic development and population control. Women's education is a central element in this agenda. Education may thus have significant implications for women's status with respect to gender relations throughout society, but these effects are historically contingent and depend on the character as well as the extent of women's education.

5. Conclusion

I have suggested that access, process, and outcomes are distinct aspects of higher education that need to be examined separately. The trends in these areas often do not coincide with one another, and consequently separate explanations of these facets of higher education are needed. For example, women remain a minority of faculty, and are disadvantaged in terms of rank and institutional prestige. Yet as students in the United States, women represent a majority of students at nearly all levels of higher education, and are not distinctly disadvantaged in terms of institutional position. Clearly, treating women's standing among the faculty and in the study body as one phenomenon will not do, since the extent of women's progress differs between these two statuses.

In my view, the principal challenge facing research on gender in education is to go beyond documenting specific gender effects to developing a more theoretically motivated account of the status of women in the educational system. This perspective would have to account for the relative status of women in each aspect of the educational system, as well as accounting for variation across time and space. The challenge is to situate gender inequality economically, historically, culturally, and politically. The substantial research in various fields on women in education should set the stage for the next generation of researchers to tackle some of the fundamental issues regarding gender and the educational system. In particular, the relationship between gender inequality in education and that in the rest of society is a fundamental question for future theory and research.

J. A. Jacobs

Education, History of

'History of education' is an ambiguous term in at least two respects. First of all, the term has come to designate different levels of reality. On the one hand, it refers to education as a universal social practice, and to the manifold forms and successive transformations that this practice has experienced over time. On the other hand, it refers to a field of intellectual activity, namely a branch of historical study, devoted to describing, interpreting, and analyzing this practice. Obviously, both levels are not disconnected from each other. Rather, it was a crucial stage in the transformation of the former, namely the crystallization of education into fully institutionalized and increasingly inclusive 'national education systems,' which gave rise to the emergence, not only of educational theory in general, but also of the historical study of education in particular. This historical connection, however, gave rise to yet another ambiguity, an ambiguity inherent in the emergent field of study as such. From its very origins, this field has oscillated between different disciplinary orientations, namely Education and History, i.e., between systemic self-reflection committed to educational ideals and reform, and more detached research committed to the rules of historical method. Against this background, the article briefly describes the process of educational system formation and some of its key features (Sect. 1) in order then to set out the institutional conditions and disciplinary models that have contributed to shaping the history of education into either an adjunct to educational theory (in terms of, e.g., *Geschichte der Pädagogik* or *histoire de la pédagogie*) or into a specialized field of historical study (in terms of, e.g., *Historische Bildungsforschung* or *histoire 'historienne' de l'éducation*) (Sect. 2). The article then goes on to describe in greater detail the important renewal the field has experienced, especially from the 1960s onwards, as a consequence of the influx of concepts and methods stemming from innovations both in social and intellectual history and in the social sciences more generally (Sect. 3).

1. *The Rise of the Modern Educational System*

Although education has occurred, and continues to do so, in manifold forms and at all times—in families, through catechizing, at the workplace, in youth clubs and organizations, or in borstals—education in modern times has by and large become institutionalized in the form of large-scale public systems of education. These constitute the modern type of educational organization *par excellence* (Thomas et al. 1987). Processes of the formation and eventual consolidation of 'the modern educational system,' while starting towards the end of the eighteenth century, came to completion only towards the turn from the nineteenth to the twentieth century (Müller et al. 1987). Moreover, educational system formation was only possible as a component of more encompassing processes of social transformation, and of concomitant processes of state and nation-building, which lead to the specifically modern pattern of societal organization explained as 'functional differentiation' by recent social theory (Luhmann 1982). Drawing on related concepts, one may characterize educational system formation by key features such as *inclusion*, *nationalization*, the system's *internal articulation* as well as *systemic self-reflection*.

Inclusion refers to one of the central aspects of modern social structures, namely the access of a population as a whole to all of the functionally specific subsystems constituted at the level of society. More precisely, inclusion means the universalization, not of so-called 'service roles' such as those of a politician, a physician, or a teacher, but of the corresponding 'service-receiving roles' specific to each of society's subsystems, namely the roles of the electorate, of patients, or of pupils, respectively. Thus, the educational correlate to the inclusion process at the level of society at large was, in terms common to present-day debates on education and development, the 'universalization of primary education.' This process started in the Protestant countries of Central and Northern Europe as early as the seventeenth century; was largely achieved, in most of Western Europe, by the end of the nineteenth century; and came to an end, in some countries of Southern Europe, Latin America, and Asia, only in the middle of the twentieth century. And yet, it still constitutes an unmet challenge in large parts of the Southern Hemisphere. At the level of national legislation, important steps towards universalizing primary education often went hand in hand with measures undertaken to assure greater inclusion also in the political and legal systems. As illustrated by the historical experience, not only of England and

Italy, but in varying forms also of France and Prussia or to some extent Russia, such measures consisted in, e.g., the extension of the franchise or, more generally, steps designed to turn hitherto dependent subjects into national citizens. At the local level, however, national school laws were gradually implemented as an answer to the radically altered communication requirements that were attendant on social structures increasingly characterized by new patterns of differentiation, and ensuing processes of rationalization, mobilization, and industrialization. In this sense, the process of inclusion in the emerging educational system corresponded to the gearing of that system to its actual function, for this function consists precisely in laying the foundations of the capability for universal communication across all subsystems of society. In sociohistorical terms, thus, it was essentially the achievement of universal mass schooling that marked the decisive transition towards the constitution of institutionalized education as a modern 'system.'

Nationalization refers to another process that came to fruition from the eighteenth century onwards. To the extent that the traditional union of schools and Church(es) gave way to the differentiation between education and religion, which were more and more conceived of as distinct spheres of social action and meaning, it was the increasingly rationalized and secularized nation-state that was thought to serve as the natural support and guardian of the education of its citizens. This view was underscored by the fact that the eventual achievement and continuous running of an inclusive educational system presupposed organizational resources and required an administrative infrastructure which no corporate social actor other than the state was deemed able to provide. Alternatively, the state and state-supported agencies were ready to use compulsory mass schooling also for pushing through the realization of more general state-related goals, such as social mobilization and equalization, national integration, and collective identity-building, or political socialization and indoctrination. Thus, whether in Europe, in the Americas, or in Asia, the realization of an all-inclusive educational system by way of universalizing compulsory mass schooling went hand in hand with the increasing intervention of central state-agencies and the building of comprehensive administrative frameworks. Education Ministries were established for securing the financial resources and building up the administrative infrastructure necessary in order not only to guarantee generalized supply, but also to successfully run standardized networks of institutionalized schooling. Just like the realization of compulsory mass schooling, this process took more than a century to come to completion. It was a long way, indeed, from late-eighteenth-century programs of establishing a coherent state-run scheme of educational institutions modeled on Catholic Church organization (in the pioneering Italian principalities of Parma and Piedmont and, subsequently, in Imperial France) to the all-encompassing organization of institutionalized schooling as a 'public legal organism' (as this accomplishment was acclaimed in late-nineteenth-century social analysis).

The emergent system's *internal articulation* was the inevitable complement to inclusion. Since education systems in Europe were not created in a vacuum, their system formation processes started from quite an array of existing institutions which were stemming, on their part, from premodern establishments such as medieval Cathedral schools and Renaissance universities, church-run colleges and academies for the sons and daughters of the nobility, endowed grammar schools and *Gymnasien* established by enlightened princely rulers, as well as municipal petty schools and the nineteenth-century forms of drawing schools, science schools, higher-grade, technical and vocational schools. It was, then, a significant feature of the differentiation process that, during the initial stage of inclusion and due to such origins, the emergent educational systems were rather decentralized, uncoordinated, and open in their organization. The more the continuing process of inclusion advanced, however, the more acute the need for internal specification and rational articulation became apparent. Specification, on the one hand, implied the removal of ambiguities and unregulated competition between institutions that were to become clearly defined alternative tracks or types of schooling. The systems' articulation, on the other hand, raised the issue of connecting hitherto uncoordinated institutional components with the aim of constructing a rational 'sequence,' or 'ladder,' of successive levels of education. The outcomes of such processes of defining educational systems' institutional structures can then be conceived of as ways of coping with divergent expectations and requirements: with inclusion (by organizing universal access to primary schooling for an entire age-group) and selection (by consecutively channeling pupils into different tracks and levels), or with qualifying for universal communication across all fields of society and inculcating differential 'habitus' as appropriate to particular groups, trades, and areas of activity. As a consequence, the issue of defining an educational system's career sequence has always been closely associated with a nation's public policy in general, and with its social and economic policy in particular. This applied especially to the construction of sequence between the 'lower' or vernacular schools (e.g., the so-called 'English' or 'German' schools) and the 'learned' or Latin-based establishments, or between, to take up a graphic phrasing coined by Prost (1968), *l'école du peuple* and *l'école des notables*. Thus, from the late nineteenth century 'systematization' of the major Western European education systems; over the definition, during the first half of the twentieth century, of examination-based transition procedures from the primary to the secondary level of education;

up to the successive introduction, from the 1960s onwards, of comprehensive types of schooling in many, but not all, countries throughout the world, contrasting models and programs for educational sequencing have been at the very core of educational policy debate. At the same time, these models and programs have fostered again and again the production of both educational reflection—particularly reformative reflection—and educational research.

2. *History of Education in Connection with Systemic Self-reflection*

It is a significant feature of modernity that in subsystems of society that have crystallized in connection with the far-reaching transformation processes explained in terms of 'functional differentiation,' system-specific self-descriptions intensify to such an extent that they take the form of explicitly stated reflection theories. This common pattern of self-referential theories *of* a societal subsystem developed *within* that system holds true also for educational theorizing pursued within the emergent educational system (Luhmann 1982). The tremendous increase, from the late eighteenth century onwards, in the production of educational ideologies, educational theories, and educational knowledge more generally has to be seen in connection with the growing acceptance of programs and policies fueling the establishment of state-run 'national systems of education.' In particular, the conceptual model of systemic self-reflection intrinsic to the major subsystems of society makes intelligible the institutionalization of educational theory as a field of academic study in close temporal and ideological connection with the passing of the decisive laws on compulsory schooling in most of the Western European nations. The historically unprecedented scale of universal mass education, its inclusive character, and, especially in the Catholic countries of Southern Europe, its secularized organization not only presupposed an administrative infrastructure of a previously unknown magnitude, but also required the intensification of reflection in new and more sophisticated forms. Moreover, the transition to universal mass education also entailed the need for public legitimization of the new system, not least in the form of throwing into relief distinctive national traditions of education and schooling. Salient examples include the foundation of the *Musée Pédagogique* in France (1879) and of its counterpart in Spain (1882) which were meant to serve as depositories of their respective nation's educational memoirs; the virtual invention of national educational tradition in monumental works such as Gabriel Compayré's *Histoire critique des doctrines de l'éducation en France* (1879) and Ferdinand Buisson's *Dictionnaire de pédagogie* (1887–88); or the launching of the *Monumenta Germaniae Paedagogica* meant to collect 'the materials, scattered over archives and libraries, that are relevant to the history of German education and schooling' (1886–1938).

In addition, the necessities of systematic teacher training, and attendant considerations of social utility and responsibility, impinged heavily on the emergent forms of the historical interpretation of educational traditions. These necessities and considerations favored a genre of educational history that remained subordinated to the categories and problematiques of systematic—i.e., philosophico-reflective—theorizing, a genre in other words which gave preference to narratives of the great educators and philosophers of the past, and to interpretations of their respective doctrines realized in terms of normative hermeneutics. Interestingly enough, this genre has been common to most European countries. It can be traced from early British works over, for instance, Dutch and Scandinavian examples as well as the impressive range of, in particular, German and Italian histories of educational thought up to recent specimens in quite a number of countries (Heinemann 1979–85). This genre as well as a good many of the studies commonly assigned to the history of education have aimed at producing—and in fact continue to produce—not primarily historical research in the manner of historians, but, instead, justification and legitimization, the construction of enlightened norm consensuses and the reinterpretation and reactualization, with respect to issues of present-day educational reform, of the normative and theoretical substance contained in historical texts, models, or institutions. In other words, this tradition of an 'educational' history of education—of *Geschichte der Pädagogik* or *histoire de la pédagogie*—has not aimed at a detached historicization of lines of educational thought or of past experiences, but at certain forms of theoretical and normative 'traditionalization.'

Thus, seen from the vantagepoint of sociohistorical analysis, the history of education closely associated, in terms of institutional and disciplinary affiliation, with educational theory has from its origins shared the ambiguities proper to the latter field. Just as educational studies in general, history of education has oscillated between rigorous research and systemic self-reflection. Accordingly, the field has given room to a considerable variety of constructions of reality, the varying presuppositions of which ensue from their being related to distinct system logics and problem perspectives: to either issues of objective method and explanation as debated from the vantage point of social science research, or to issues of meliorism and reform immanent in the dynamics of modern education, and to attendant needs for interpretation, orientation, and professional knowledge. The respective proportions, however, in which these component modes of reasoning have given shape to historical studies on education arise from an intricate interplay of institutional conditions, intellectual traditions, and disciplinary models (Schriewer et al. 1993). Thus,

recent analyses of the state of the art have—on the grounds of reviews of substantive interests, research topics, and methodological approaches that are given preference to as well as of the field's disciplinary status, specialized journals, and associations—contrasted two major models. These are, on the one hand, the German model, which is well represented also in countries such as Switzerland, Austria, and Hungary as well as in Italy and Scandinavia, and, on the other hand, the institutional-*cum*-epistemological model prevalent in France and the United Kingdom, respectively (Compère 1995). In the former model, due to a long-standing tradition of educational-*cum*-philosophical theorizing as well as to the institutional and intellectual integration of the history of education into education as a discipline firmly established in academia, the system-reflection style of educational history described above has by and large prevailed up to the 1970s, and still has a strong impact up to the present. By contrast, the tradition of education conceived as a philosophico-hermeneutic field of theorizing gave way to educational studies based on the social and human sciences both in France, from the 1930s onwards, and in the United Kingdom, in the aftermath of World War II. Consequently, these developments also facilitated the alignment of historical studies on education with history and sociology proper, and the intellectual opening of such studies to wider sociological and anthropological frames of reference. Thus, in France and the United Kingdom, just as in the United States, history of education has turned into an academic discipline in its own right which is fairly independent of educational studies in general, based on its own specialized journals, and elaborated by scholars who are (also) trained as historians. This *histoire 'historienne' de l'éducation* has in turn encouraged initiatives leading to the emergence of a social history-related *Historische Bildungsforschung* also in countries traditionally influenced by the German model.

3. *History of Education as a Field of Social Science Study*

Fueled by debates on a 'new history of education' which arose in the United States at the beginning of the 1960s, conceptual models and methodological approaches heavily influenced by modern social history (see *Social History*), intellectual history (see *Intellectual History*), and the social sciences more generally have since then considerably altered the field. The publication, in 1960, of Philippe Ariès' *L'enfant et la Vie Familiale sous l'Ancien Régime* and Bernard Bailyn's *Education and the Forming of American Society* can be seen as a turning point. A stimulating and intellectually demanding period was about to begin. From the 1960s to the 1980s, the 'new history of education' brought a critical perspective into a discipline that had been dominated by parochialism and myths of progress. Ever since its repertoire has come to include the *longue durée*, a focus on structures and mentalities, a special attention to serial and quantitative methods, and the ambition of 'total history.' These changes, moreover, are reflected in corresponding shifts from narrative history to problem-centered history, from descriptive to explanatory approaches, and from conceptions of unilinear evolution to a vision of historical processes that emphasizes their often conflict-laden, asynchronous nature. While accomplishing such shifts, scholars like Michael Katz and David Tyack, Antoine Prost and Dominique Julia, and Lawrence Stone and Harold Silver have been deeply influenced by social history perspectives. They have turned the legitimizing narratives of the past upside down, providing new arguments about the emergence and development of educational systems, the role of schooling in social reproduction, the educational strategies of various social classes, and the action taken by the nation-state in establishing mass schooling. They accordingly shifted the attention from the evolution of educational ideas to the relationships between education and society.

While in the early 1980s a sense of accomplishment was shared by a majority of the researchers involved in rewriting the history of education, only a few years later, the resources of the 'new' history of education seemed to be exhausted. The accumulation of data, the considerable increase in well-conducted studies based on extended series of archival sources, and the growing specialization of historical inquiry nevertheless left the impression that educational historians had fallen short of addressing actually meaningful issues. In addition, efforts meant to raise new questions, related for instance to minority and gender issues, did not lead to an epistemological breakthrough, but rather to an even wider fragmentation of the field. Innovative solutions were to be found, then, in the adoption of theoretical frameworks and methodological approaches that focus not only on the organization of practices and discourses over time, but also on the elucidation of how these practices and discourses have constructed and reconstructed the individual lives of people and, thereby, social reality. In this sense, educational historians are facing the same challenges and dilemmas like social scientists more generally. To the extent that the difficulties of coping with the plurality of meanings henceforth present in the analysis of social phenomena became apparent, the 'new' complexity of historical work has nourished old suspicion as far as theory is concerned (Lagemann 2000). The transition from 'History' to 'histories' implies a reconfiguration of the field that invites educational historians to reconceptualize their work and to adopt a more comprehensive approach, shifting from a social history of culture to a cultural history of society (Chartier 1998). Still, there is no consensus regarding the changes that are occurring in historical

studies in education (Cohen and Depaepe 1996). Nevertheless, drawing on an often used conceptual division between educational actors, school practices, educational ideas, and educational systems, it is possible to identify major tendencies that have come to shape historical research in education (Nóvoa 1998).

3.1 The History of Educational Actors and the Rediscovery of Experience

For a long time, historians have described the history of educational institutions rather than that of educational processes or interactions. Consequently, the history of educational actors has been one of the most neglected areas of research. The rediscovery of the concept of 'experience' opened new possibilities, well illustrated by numerous texts on autobiographies, teachers' professional careers, or students' life stories. One of the reasons why feminist theories have been so powerful in educational history is that they help to reveal histories silenced by traditional narratives. From these points of view, modernity dispossessed the actors of the educational process from their subjectivity through the imposition of a structural logic and a populational reasoning. People were classified as categories (the teachers, the learners, the children at risk, etc.) and managed as populations. However, after a long tradition of conceptualizing the world in terms of structure and representation, time had come to see the world as 'experience.' This implied a new 'epistemology of the subject' which, by dissolving the 'natural' divisions between public and private, discourse and practice, or between text and context, prepared the way for a shift toward a self-conscious study of pupils and teachers, and for bringing the individual actor in education back into the historical portrayal. Moreover, new conceptions of the subject and of experience allow attention to be paid not only to living experience, but also to the way people elaborate it. Finally, the concept of 'experience' has to be seen not only at an individual level, but also in its collective dimension, which is characterized by a redefinition of identities and belongings through the participation of people in different communities of meaning.

3.2 The History of School Practices and a New Concept of Culture

The history of school practices is another field that has traditionally been neglected by educational historians. Explanations of this 'black box' phenomenon are directly related to the concept of 'culture.' Schools have always been regarded as places of culture: at first, in an idealistic vision of putatively universal values and knowledge to be transmitted to the young generations; afterwards, in a critical perspective of ideological inculcation and social reproduction. In both cases, educational historians failed to look at the internal production of a distinctive school culture that is not independent of social struggles and conflicts, but cannot be explained as being merely determined by the external world either. More recent conceptualizations, in contrast, have defined school culture as both an ensemble of norms (which organize the branches of knowledge and behaviors that must be brought into schooling) and an ensemble of practices (which allow the transmission of such knowledge and the integration of such behaviors). Moreover, it is possible to identify tendencies of historical research that successfully try to refocus historical inquiry onto the internal functioning of the school by providing thoroughgoing analyses of organizational structures, curriculum issues, school subjects, and day-to-day realities. Thus, one of the most interesting lines of work tries to understand the permanence of a 'grammar of schooling' that resists changes and reforms. Another line of research focuses on the history of the curriculum, viewed as the outcome of a complex interplay of competing values and traditions. Several authors are voicing the need for deconstructing a 'natural-history' conception of the curriculum, and therefore seek to problematize the curriculum as text and historicize its evolution over time. A third strand of recent research worth mentioning is concerned with the history of school subjects. Historians are asking salient questions regarding the formation of school subjects, the institutionalization of school knowledge, and the ways in which it helps to organize our understanding of the world. Finally, one should not fail to point out a research trend concerned with the 'silence' observed within the traditional history of education about meaning and culture of classrooms, or the everyday education practice (Grosvenor et al. 1999, Ruiz Berrio 2000).

3.3 From the History of Educational Ideas to a Sociohistory of Knowledge

In contrast to traditional histories of educational ideas, the 'new' cultural history of education is interested in the production, diffusion, and reception of educational discourses throughout time and space. In other words, it is interested in 'a historical imagination in the study of schooling that focuses on knowledge as a field of cultural practice and cultural production' (Popkewitz et al. 2001). Therefore, the research interest has shifted to the discursive practices that regulate schooling, especially in situations of conflict or rupture. In this sense, several authors are calling for a historiography, not of the general terms, but of the conceptual structures that determine edu-

cational discourses, and for analyses, not of prominent ideas, but of fields of historically defined discursive problematiques. Such an approach is also important for analyses of the roles played by educational experts in providing 'legitimate' or 'scientific' interpretations of school realities. It helps to understand the original institutionalization of educational studies, not as a narrative of intellectual progress, but as a form of 'governmentality.' The question is not how to identify different ideas, but how to apprehend the rise of expert systems of knowledge (Drewek et al. 1998). The same holds true for the analysis of the complex transformation procedures that change academic subjects (integrated into their distinctive conceptual spaces) into school subjects (integrated into the arena of schooling), or for the study of the production and diffusion of textbooks that are not simply 'delivery systems' of factual information, but the results of cultural constructions imposing particular ways of seeing and interpreting the world. In this sense, knowledge has increasingly come to be taken as a text that redefines subjectivity and identities, that elaborates rules and behaviors, and that configures meanings and beliefs.

3.4 Comparative-historical Research on Education

The publication of Fritz Ringer's *Education and Society in Modern Europe* (1979) heralded a virtual breakthrough of yet another paradigmatic approach to the field, namely the comparative-historical research on education. Although some forms of cross-national analysis or international account had not completely been missing in previous periods, the programmatic views expressed by Ringer laid claim to new and ambitious objectives: 'There is simply no other means of arriving at explanations, and not just descriptions, of change in education than the comparative approach.' Substantive research inspired by such views has remarkably increased from the 1970s onwards. It covers, for instance, quasi-experimental investigations of the relationships between education and economic growth; large-scale theory-based analyses of the varying processes of educational system formation; as well as cross-national analyses of the emergence and varying discipline formation patterns of education as an academic field of study in the context of European university systems and the emerging social sciences more generally. Comparative-historical research has also shed new light on the role that nation-specific social meanings, widely accepted interpretative schemes, or 'symbolic structures' deeply rooted in a particular civilization have played in shaping distinctive academic cultures and educational institutions (Archer 1979, Müller et al. 1987, Schriewer et al. 1993).

Not always, however, have attempts at providing convincing explanation through the combination of historical research and cross-national, or cross-civilizational, analysis been successful. Consequently, much debate has been devoted to issues of explanation (see *Comparative History*). While traditionally, and to some extent up to the present, mainstream models of explanation have followed lines of reasoning as defined in the orthodox philosophy of science, far-reaching shifts in both problem-awareness and conceptual models have taken place in the wake of recent theory developments (Schriewer 2000). Among these are, for instance, world-system models and analyses which, by drawing on Braudelian concepts, not only reintroduced a macrohistorical perspective into comparative research, but also tended to replace the latter by analyses of global diffusion processes and of the working of an emerging 'world polity' (Thomas et al. 1987). New forms of reconciling history and comparison are also suggested, however, by insights from historical sociology as well as by interdisciplinary developments discussed under headings such as 'self-organization,' 'morphogenesis,' or 'evolutionary complex systems research' (Gulbenkian Commission 1996). Thus, comparative-historical research on education informed by concepts and models of this kind seems to be particularly suited, not only to radically historicizing educational phenomena, but also to linking historical analysis up with insight relevant to social theory.

Education in Old Age, Psychology of

1. Introduction

From an educational perspective lifespan development can be described as a continuous and active process of coping with developmental tasks, i.e., demands, challenges, and chances that depend on people's environment and life situation in given phases of the aging process. Specific developmental tasks are conceptualized as a consequence of the interaction between biological maturity, normative conceptions of 'successful' aging or development in society and individual plans, aims, needs, and values. The significance of environment and life situation for lifespan development is twofold: first, coping successfully with demands of the environment and life situation increases the potential for coping with future demands and initiates further development; second, chances offered by environment and life situation contribute to the realization of specific developmental gains.

The here intended understanding of development as a process of personal growth (focusing on stable, not only temporary gains) is connected closely to a concept of education that implies two meanings: the process of being engaged in educational activities (person educating himself) and the result of this engagement (the educated person). Education does not only lead to the establishment of differentiated knowledge systems, but also facilitates a broader understanding of own experience and action; two developmental gains of high significance.

The insight that developmental gains are possible even in very old age is essential for lifespan developmental psychology. Human development is to be understood as a lifelong process characterized by multidimensionality and multidirectionality (Baltes 1987). Aging implies different processes of change in different dimensions of the person; in each dimension gains and losses can be observed simultaneously; changes in one dimension are a poor predictor of changes in other dimensions. Accumulated and organized experiences, knowledge systems, and strategies for coping effectively with familiar problems and tasks are important developmental gains (in the sense of psychological growth) in older adulthood; important developmental losses do occur in physiological and neurophysiological functions and processes, c.f. cognitive flexibility, coping with unfamiliar problems and tasks, and speed of information processing (which itself decrease performance of short-term memory) (for an overview see Kruse and Rudinger 1997).

From the perspective of this article, education is a precondition for reaching developmental gains as well as for the opportunity to compensate for developmental losses (e.g., via the process of selective optimization with compensation) and for individual abilities to maintain or re-establish a personal satifying perspective on life in old age.

The first part of this article focuses on the importance of lifespan developmental psychology for understanding education in old age. In the following parts the competence-maintaining and competence-enhancing functions of education are discussed in the context of three topics: life competencies of the old as a human capital for society, productive life in old age, and potentials for development in old age.

2. Life Span Developmental Psychology and Education

Four conclusions for the understanding of education in old age can be drawn from the results of lifespan developmental psychology.

(a) Accumulated and organized experiences, differentiated knowledge systems as well as effective strategies for coping with tasks and problems and for taking the chances offered by environmental conditions and life situation must be understood as a consequence of education processes in earlier phases of the lifespan, i.e., active coping with tasks, demands, challenges, and chances in younger years. In this context the considerable continuity of lifelong development becomes clear, since achievements in earlier years extent to later years as long as they are used sufficiently.

(b) The use and further improvement of experiences, knowledge, and strategies for effective action is essential for the realization of developmental gains in old age. This fact points to the importance of education in old age. Generally, there is a sufficient amount of plasticity, i.e., capacity to learn and change. As a consequence, education in old age, aiming to contribute to the use and further improvement of experiences, knowledge, and strategies for effective action, should be able to contribute to effective coping with developmental tasks and 'successful' aging. From our perspective, there is a demand for education in old age, since people cannot cope successfully with developmental tasks or realize the potentials offered by cultural innovation (e.g., in the technical field) in old age without engaging in a process of coping with self, life situation, and environment.

(c) Education in old age must not be analyzed only in terms of possible gains, depending on development in earlier phases of the lifespan. Possible developmental losses are of equal importance here. In this context, two aspects should be considered: first, gerontological research could show that cognitive training has an impact on the decline in the 'mechanics' of human intelligence, i.e., the basic processes underlying intellectual performance (Kliegl et al. 1989). Moreover, through cognitive training the compensation of specific impairments and losses can be encouraged. Intellectual performance and everyday competence can be improved by new learning and memory strategies that compensate at least in part for deficits in sensory and motor functions. The 'selective optimization with compensation,' i.e., the choice (selection) of well-developed functions, skills, and strategies and their differentiation (optimization) with the aim of compensating for losses in other functions, skills, and strategies forms an important basis of 'successful aging' (Baltes and Baltes 1990).

(d) In the context of possible developmental losses—especially in very old age—decreases in health status and social integration as well as limitations of life expectancy should be mentioned. However, empirical findings do show that even in very old age most people are able to cope effectively with developmental losses and to maintain or re-establish a personal satisfying perspective on their life, pointing to resilience in old age. It should be noted that resilience is established through personal and environmental resources (for an overview see Kruse and Wahl 1999, Staudinger and Fleeson 1996). Concerning environmental resources, gerontological studies show that the opportunity to participate in cultural and social activities that offer stimulation and support promotes effective coping with developmental losses. These findings can be interpreted as support for an educational perspective that points to the significance of education for coping with critical life events, e.g., via providing information about effective coping strategies or institutional services. In the case of definite losses in certain functions and skills (e.g., visual impairment as a result of macular degeneration), compensation (e.g., use of cassettes or touch-typing) as well as increased engagement in interests and activities where these functions and skills are not necessary can be interpreted in two ways: first, as a process of education, second, as encouraged by educational activities. Several intervention studies show the possible impact of educational opportunities on the effectiveness of individual coping processes (see the overview in Wahl et al. 2000).

From the here intended understanding of education and its effects, the close relationship between education and competence becomes clear. The latter is defined as the skills and abilities to maintain or re-establish an independent, task-oriented, and personally meaningful life in a stimulating, supportive (physical, social, and infrastructural) environment, encouraging self-responsible coping with problems, developmental tasks, and challenges (Kruse 1995).

In old age education has competence-maintaining and competence-enhancing functions, i.e., the rationale of providing educational programs and services for the old is to offer opportunities for using and further improving competencies. In the following, our discussion will concentrate on three topics that proved to be important for gerontological research as well as for societal perception and valuation of old age: (a) life competencies of the old as a human capital for society; (b) productive life in old age; (c) potentials for development in old age.

3. Life Competencies of the Old as a Human Capital for Society

The term life competencies refers to experiences, strategies, and knowledge systems that people have acquired in earlier phases of the lifespan (i.e., our understanding of education as a result of active coping

with the challenges and demands of the environment and life situation in a given period of life). Life competencies are built up in the context of effective coping and enable people to maintain or re-establish a personal satisfying perspective on their life when confronted with serious problems, tasks, and challenges in later years. Building up life competencies in earlier years is a basic requirement for successful development in advanced age, i.e., effective coping with demands of life in old age. Such demands include practical and psychological as well as interpersonal and ethical demands. Consequently, our understanding of life competencies is not limited to the experiences, strategies, and knowledge systems acquired in the context of occupational activities.

Life competencies are also reflected in ethical judgements, voluntary activities for other people, as well as in the willingness and readiness to take responsibility for oneself, for others, or for society. In this context it should be mentioned that empirical findings show that active coping with developmental tasks and the chances and limits of life can lead to the establishment of 'expert knowledge' or 'wisdom' with respect to questions of life (see Smith and Baltes 1990). Expert knowledge or wisdom is not limited to old age, it can be developed in earlier years as well. The only prerequisite for the development of expert knowledge or wisdom is the conscious and responsible preoccupation with a multitude of problems, tasks, and challenges in different periods of life and different contexts of development. Therefore empirical findings support a perspective on lifelong educational processes that accentuates the development of the person rather than the cultivation of specific knowledge and skills (Kruse 1997).

With the term human capital we refer to the significance of life competencies for society and culture, i.e., processes of initiating societal and cultural change and the extent to which societal and cultural change is determined by life competencies of the old. Societal and cultural development depends on the possibility to use individual life competencies. It is here necessary to establish the respective infrastructural conditions, e.g., opportunities for volunteers to qualify and to use given experiences, strategies, and knowledge systems effectively.

The contribution of specific educational services to the realization and use of life competencies of the old, i.e., the conversion of individual life competencies into human capital, is of interest for educational research and practice. In a later part of this article we revert to educational services in which (a) an intergenerational perspective is put forward (i.e., members of different generations are addressed) and (b) individual experiences, strategies, and knowledge systems are made explicit and used by stimulating a dialogue or discourse. At this point we are content with stating that, for example, stimulating an exchange between the young and the old by inviting older people to visit schools, to participate in specific lessons (e.g., on history), and to engage in the transmission of experiences and knowledge is appreciated equally by the young and the old. In establishing intergenerational contact which enables people to realize and use specific life competencies, the challenge for educational practice is twofold: first, experiences, strategies, and knowledge systems must be explored and integrated systematically; second, discussion or discourse must be initiated and guided with methodological competence.

4. *Productive Life in Old Age*

Even if productivity is commonly associated with the making of things (production) and material values, and—consequently—speaking of productive life in old age generally refers to societal productivity, i.e., enrichment, promotion, maintenance, and relief of social systems, the term productivity is neither restricted to participation in the labor market or voluntary activities nor confined to manual expression (Baltes and Montada 1996). Instead, an adequate definition of productivity must also consider intellectual, emotional, and motivational expressions of productivity. Using an extended definition of productivity, several possibilities of leading a productive life in old age can be distinguished: being interested in development, living conditions, and vital interests of younger people, the transmission of information to younger generations and the (self-)responsible reflection of experiences and knowledge systems of younger generations are examples of intellectual and emotional productivity in old age, since intergenerational discourses can initiate emotional and intellectual differentiation in older and younger participants. Moreover, by leading an independent and responsible life, even when confronted with serious problems or borderline situations, older people can give a good example of how to cope with problems and difficulties to younger people, i.e., build a productive context for others: an illustrative example of emotional and motivational aspects of productivity (see Kruse 1995, Baltes and Montada 1996).

From this context it becomes apparent that even the dialogue between young and old can be understood as an educational process in which young and old people can enrich each other by exchanging specific experiences and knowledge as well as general life competencies (see examples in Wahl et al. 2000). For our understanding of education in old age, two conclusions can be drawn: first, older people are able to fulfill educational functions for others by offering skills, experiences, and knowledge or by leading an independent and responsible life which can be regarded as exemplary for younger generations. However, it should be mentioned that for fulfilling educational functions for others it is essential that the transmission

of experience and knowledge is free from prejudiced beliefs which presuppose that own knowledge is superior to knowledge of other people and that—therefore—others have to be instructed to adopt their experiences and knowledge systems. Second, dialogue and discourse with younger people can initiate further development. In our view, intergenerational discourse is an important means to realize potentials for development. From the reports of services and institutions concerned with education in old age, it seems obvious that intergenerational encounters—either informal or in the context of formal educational settings—do have significant impact on developmental processes in the young and in the old and therefore should be promoted intensively.

5. *Potentials for Development in Old Age*

Cognitive training programs and programs for maintaining and improving everyday competence (i.e., skills and abilities for leading an independent and responsible life and for coping effectively with problems, tasks, and challenges of environment and current life situation) have proven to be effective in numerous empirical studies (for a review see Wahl and Tesch-Römer 1998). Findings do indicate an apparent cognitive and behavioral plasticity which can be explained by functional and morphological changes in neuronal networks. Functional plasticity refers to the increased resting potential of neurons (on the basis of which cellular excitation processes can be speeded up), morphological plasticity refers to the production of new synapses and enrichment of dendrite growth in continuous activation processes (Kruse and Rudinger 1997). However, if there is a lack of continuous stimulation in sensory, sensorimotor, and cognitive functions, the probability of losses in cognitive and everyday competence—especially in very old age—increases dramatically. This special risk is caused by increased vulnerability of physiological and neurophysiological systems in old age. Baltes (1984) refers to developmental contexts characterized by a lack of stimulation and training of functions as 'intelligence-decelerating' environments.

Losses resulting from insufficient stimulation and training can be traced back to a loosening of neuronal switch-off mechanisms, to reduced capacity of the synapses, and to a reduced number of dendrites. For this reason the statement can be made that a certain amount of stimulation and activation as well as a certain amount of training cognitive and everyday competencies is a necessary condition for maintaining an independent and responsible life in old age. In this context it should be mentioned that even an independent, responsible, and personally meaningful organization of daily activities alone can offer a sufficient amount of stimulation, activity, and training of cognitive and everyday competencies; this leads us back to the former statement that informal educational activities (such as continuous use) contribute to education in old age. Therefore intervention measures for maintaining and enhancing competencies in old age should not only be restricted to the improvement of individual skills and abilities but also consider the importance of environmental conditions for the relationship between competencies and actual performance.

Education in Psychiatry

1. Introduction: Medical Education in General

Medical education worldwide is in a state of creative ferment, greater now than at any time since the early twentieth century. (The *Flexner Report* of 1910 had initiated groundbreaking reforms.) International consensus, reached by intensive global consultation conducted by the World Federation for Medical Education, is expressed in the *Edinburgh Declaration* (1988) and the Recommendations of the *World Summit on Medical Education* (World Federation for Medical Education 1994). These global mandates have been instruments for change worldwide, and the major impetus for reform.

Medical education currently is the driving force in many sectors of professional administration in medicine. To cite a few examples: postgraduate Deans administer salaries of doctors in postgraduate training; physicians in training are posted only to academically accredited hospitals; and many countries require continuing medical education credits for doctors to hold hospital appointments.

The contemporary managerial revolution in health care and the medicine-for-profit ideology have imposed an unanticipated educational limitation. Since ancient Greece the vocation of Medicine has been hallowed as a calling; to foster learning has always been esteemed. Now even born teachers can have their investment in teaching curtailed by their institution, if their educational zeal is judged to intrude on the potential for generating income through clinical work.

1.1 Reform and Stasis

Efforts to reform medical school curricula commonly fail because, as medical education research demonstrates repeatedly, the institution omits to change the committee structure (governance) of the medical school to be congruent with new educational goals. A curriculum left in the hands of departmental heads inevitably remains static. A Curriculum Committee, given autonomy and its own resources such as budgets, answerable to the Dean and not to departments, is essential. Departments are then still free to pursue their specific noneducational goals, such as research and clinical work, to which in any case they give greater priority (Abrahamson 1996).

Medical education has long derived crucial research impetus from the social sciences. Pioneering sociologists, most fortunately for medicine, elected to study medical education (Merton et al. 1957) when they started investigating the professions to determine why professionals do not exploit their clients more than is the case. The classic New York study at Cornell, *The Student-Physician*, followed by the investigation of Kansas medical school by Chicago sociologists, led to the conspicuous leadership which (Becker et al. 1961) medicine has provided in higher education generally. Sociologists, by studying the medical school as a social organization (Bloom 1988), have also explored obstruction to educational innovation. The resistances to curricular change in medical schools derive from apathy on the part of some medical teachers; the necessary critical mass of teaching staff, educationally informed, interested, and involved in the education of medical students, is not achieved. Medical teachers, in common with their counterparts in the rest of academia, commonly assume they are equipped to teach simply by virtue of their expertise in their research or specialist discipline: they are ignorant of the medical education literature, and do not know or respect the findings of medical education research (Miller 1980). They have very often not had personal instruction about how to teach.

Medical students learn best, they repeatedly convey when surveyed, when active student participation is encouraged; when the emphasis is on applied problem-solving (rather than learning of factual materials); when instruction is student-centered; and when teachers are humanistically oriented.

The shibboleth that everybody must learn the same syllabus has proved amazingly resilient. Emphasis on memorization of fact, resulting in information overload, has been the age-old obstacle to active learning. Teaching and learning methods are being revolutionized by electronic information technologies, problem-based learning, and simulated (standardized) patients. Scope is being given for critical thinking, and the development of clinical competence made a priority. Time has been freed for special interest options of students. Educational leadership is essential, often not provided by Deans deflected by administrative priorities; and students have to be valued partners as change agents at every level, participating actively in monitoring the quality of their education.

1.2 The Applicant Pool and Selection

There is now considerable attention being given to widening the range of entrants to medical school, to avoid discrimination according to gender (male and female entrants are now equal numerically), ethnicity, social class, etc. Applying to enter medical school,

given the great social desirability of the profession, is much documented and potential entrants are assiduously briefed and groomed (Iserson 1997).

Selection procedures have been investigated intensively. Entry criteria have centered on cognitive abilities unduly (e.g., school-leaving examination results), with nonintellectual attributes (e.g., motivation, empathy, humanism, drive, and determination) neglected. Once admitted, the student in a good medical school is responsibly respected and fostered (Merton et al. 1957, Coombs 1998).

2. *Basic Medical Education*

Medical education must be viewed as a continuum, with three constituent components: (a) basic medical education; (b) specialist training; and, (c) continuing education to maintain professional competence throughout professional life.

The medical school curriculum is the preparation for ensuing specialist training. The medical school phase results in a generic doctor, who can enter further training appropriate to a particular specialty. No doctor, in *developed countries*, relies any longer on his or her medical school education as the basis for his or her professional competence: all doctors, general practitioners as well, enter specialist training.

2.1 *Psychiatry in the Medical School Curriculum*

Psychiatry is a specialty in the field of medicine. All psychiatrists, in the first place, are medical doctors. Education in psychiatry starts, therefore, with entry to medical school, and basic medical education provides the start of the professionalization process.

In psychiatry specifically, the World Federation for Medical Education and the World Psychiatric Association in partnership have planned and instituted *The Core Curriculum in Psychiatry for Medical Students* (1999), the first ever global specification in any specialty, of the knowledge, skills, and attitudes which every doctor worldwide needs to learn about that specialty while at medical school. The *Core Curriculum in Psychiatry* specifies the minimum psychiatric instruction required by all medical students before proceeding to further training as specialists or as general practitioners.

Teachers of Psychiatry must concern themselves with the total curriculum of the medical school, and be involved with the governance of the medical school, serving on the educational committees that plan and implement the overall curriculum. Psychiatrists in medical schools must concern themselves with, and contribute to, all the canonical components of medical education in general: access (application to medical school, selection procedures, dropout, and wastage); curriculum; teaching methods; educational objectives; assessment and examinations; and evaluation and accreditation. Moreover, the departmental teaching of psychiatry must accord with the general institutional objectives of the medical school.

All branches of medicine, psychiatry of course also, are urgently confronted by the necessity to reorient the curriculum, to ensure not only curative medicine is taught, but also prevention of illness and promotion of health. Because of the great variation existing among countries and different cultures, any description of the program for psychiatry is of necessity schematic, but general principles can be set out which will apply in any setting.

Psychiatry must have a major place in the basic medical curriculum. (a) Understanding body–mind interaction, the unity of the person, is pertinent to the whole of medical practice, constantly advanced by research in the neurosciences. (b) Skills that are learned in psychiatry (e.g., the ability to form a good relationship with a patient, to assess the mental state, and to impart distressing information) are important for all doctors. (c) Psychiatric illness is common among patients seen by specialists in the other branches of medicine: among general medical outpatients, for example, about 15 percent given a medical diagnosis also have an associated psychiatric disorder; up to 40 percent of those given no specific diagnosis in fact have a psychiatric disorder. Psychiatric disorders are even more frequent among patients seen in general practice (Clare and Lader 1982). (d) Psychiatrists treat only a small portion of any nation's psychiatric morbidity; a great bulk of psychiatric disorder is managed, adequately or otherwise, by doctors whose psychiatric training often is confined to their exposure to psychiatry as medical students. All medical students require the psychiatry program, regardless of the branch of medicine they are destined to practice in the future.

2.2 *Broad Goals in Teaching Psychiatry*

When surveyed, teachers of psychiatry make clear the educational outcomes they consider the psychiatric program should achieve (Walton 1986).

(a) *Psychological-mindedness*. Communication skills and empathy with patients' emotional responses, and capacity for the interpersonal relationship between clinician and patient—the basis of the medical interview.

(b) *An objective approach to behavior*. Behavioral science teaching (notably psychology and sociology) provides students with scientific knowledge about behavior, augmenting their common-sense understanding with empirical knowledge.

(c) *Contact with psychiatric patients*. Relating clinically to patients, with a wide range of psychiatric illness and disorder, permits students to dispel their own anxieties about mental patients, and to overcome the prejudices and preconceptions customary in their society; they need therefore to develop skills in history-

taking, in examining the mental state, and in psychiatric interviewing of a patient repeatedly over a period of time.

(d) *Descriptive psychiatry*. Theoretical instruction about symptoms, signs, and syndromes, dealt with in the psychiatric textbooks, augments the clinical training when medical students are given proper access to patients.

(e) *Treatment methods*. A great proportion of all ill health being psychiatric, general practitioners and specialists in branches of medicine other than psychiatry inevitably deal with much the greater part of the mental health needs of the community. Knowledge about the main psychiatric treatment methods and skills is therefore essential for all future doctors.

2.3 Psychiatrists as Medical School Teachers

Psychiatrists have to overcome traditional disadvantages. Medical school teachers in general tend to view psychiatry as a backward branch of medicine. These nonpsychiatrist colleagues are further dismayed and confused by the doctrinal differences among psychiatrists (one a biologically oriented doctor favoring the medical model, the other a humanist concerned with psychodynamic processes, and practicing some or other form of psychotherapy). Medical school teachers in general are disconcerted when these contrasting ideologies come to be applied to the patients they refer to psychiatrists. It can sometimes seem relatively arbitrary how any patient will be diagnosed and treated—too much appears to depend on the outlook of the individual psychiatrist. Coterie positions are struck (see Coyle and Mollica of Harvard in *Current Opinion in Psychiatry* 1998, who have iconoclastically advocated that psychotherapy skills be 'deferred' to psychologists, social workers, counselors and clergy, whom they view as better suited for attending to the 'local taxonomy of human suffering').

Medical students acquire their professional values and outlook, in large measure, by modeling themselves on leading and respected teachers in the medical school. Investigations by sociologists, classically those of Merton(1957) at Cornell medical school in New York and Chuval (1980) in Israel have demonstrated that the status of psychiatry, of teachers of psychiatry, and of psychiatric patients in medical schools is not at the level of, say, medicine or surgery, with a seriously adverse effect on the teaching of psychiatry.

2.4 Medical Student Attitudes to Psychiatry

'Psychologically minded' medical students showed a greater interest in and a more positive attitude towards psychiatry than students scoring on tests as 'organically oriented.' Medical students' preference for psychiatry as a future career is stable, the same before as after psychiatric instruction. Certain learning experiences, particularly the clinical clerkship in psychiatry when in particular types of unit, can change students' attitudes towards psychiatry in a positive way. Only a very few percent of medical students choose psychiatry as a future career (see *Mentally Ill: Public Attitudes*).

2.5 The Science Base of Psychiatry

The sciences in the medical curriculum related to psychiatry include the biological sciences and the behavioral sciences. Science teaching in medicine has long been censured: a customary practice worldwide, instead of extending the 'basic' sciences throughout the curriculum, has been to compartmentalize the sciences in a so-called preclinical phase. Medical schools have imperatively to examine their entire educational program, in order to integrate science teaching properly with clinical instruction.

2.6 The Biological Sciences

Competing departmental interests fragment the sciences relevant to medicine into separate subjects (e.g., anatomy, physiology, pharmacology, etc.) at a time when integration of knowledge is the hallmark of advance (Eisenberg 1988). The *new biology* calls for an integrated view of whole structures, whether at molecular or macroscopic level. Medical schools have not responded sufficiently to the paradigm shift in science. Traditional basic science teaching in the medical schools stands charged with being outmoded, simplistic, and responsible for much of the information overload that mars medical curricula. Reform is a matter for the medical school as a whole, and is not to be left to the science disciplines in isolation from the clinical subjects.

2.7 Behavioral Science Teaching

Psychology and sociology in relation to medicine are viewed by departments of psychiatry as essential subjects in the curriculum. Despite this endorsement, behavioral sciences teaching remains problematic. Medical teachers in general are skeptical about the 'human sciences' and not sympathetic to such issues as Kant's fourth question: *Was ist der Mensch?*

Medical students and medical teachers alike are critical about the widespread failure in behavioral science teaching, given in the first or second year. Too

often a condensed general psychology and sociology course is provided, which inevitably is perceived as lacking medical relevance. Equally misguided is to include behavioral science as an optional subject in an otherwise compulsory curriculum. Experience has shown that both clinically experienced medical (psychiatrists) and nonmedical (psychologists, sociologists) teachers must be actively involved in the planning and delivery of behavioral science courses, clinical cases included throughout, to avoid implications of irrelevance or discordance with students' concerns as future doctors (see *Behavior Therapy: Psychiatric Aspects*).

2.7.1 Psychology. Students should acquire a basic overall knowledge of the findings, methodologies, and theories of psychology which are relevant to the practice of medicine; be aware of how patients' emotions, attitudes, values and experiences influence their response to illness and to its treatment; have a knowledge of learning processes and their relevance to medicine; possess knowledge about the main aspects of psychological development of humans from birth to old age; possess skills relevant to effective doctor–patient communication and particularly to interviewing; have knowledge of techniques of assessment used to test the reliability and validity of investigation procedures and therapeutic trials; and attain attitudes to development that will enable them as doctors to comprehend each patient as a complete person living in his or her own social environment.

2.7.2 Sociology. By the end of the course each student should understand: the various methods for defining and measuring health; know the importance for health and medical practice of social institutions such as the family, the community, the economy, and the law; understand the problems of equity and inequality in the provision and utilization of health services, related to age, gender, social class, and religion; grasp the changes in society and in the practice of medicine which have affected health and disease and the development of social policy; comprehend welfare provisions, the advantages and disadvantages of a country's health service, and problems of planning for change within a health service; know about the social (and sociological) factors that influence the process of becoming ill and the doctor–patient relationship, and the effect that ill health and hospitalization have on the lives of patients and their families; be able to discuss critically the role of preventive medicine and health education, and the role of self-help groups; the process of medical professionalization; and describe some of the research methods used to evaluate health and medical practice (see *Psychiatry and Sociology*).

2.7.3 Biostatistical sciences. The aims of courses in the probabilistic and information sciences are: to explore ways of making valid deductions from medical data; familiarizing students with the basic statistical terminology as found in the medical literature; to introduce the concepts necessary for designing as well as analyzing comparison and experimental studies in medicine; and methods of accessing and organizing medical knowledge; and computer literacy.

2.8 Clinical Psychiatry in the Curriculum

Instruction in clinical psychiatry must be integrated with the other main clinical subjects of the medical curriculum. The main teaching and learning methods in use are threefold: (a) lectures; (b) small group teaching; and (c) the clinical clerkship, a full-time attachment to a unit providing psychiatric care, in a general hospital psychiatric unit or in a psychiatric hospital, for six to eight weeks.

2.8.1 Objectives for clinical psychiatry in medical school. The knowledge, skills, and attitudes to be achieved by the end of study (educational outcomes) are general, deal with organic and with functional syndromes, and with treatment and management:

(a) *General*. The student should be able to: conduct a diagnostic interview including a mental state examination; relate patients' symptoms to their past experiences, personality, and social circumstances; give an account of his or her emotional responses to patients of different kinds and the way in which these reactions can influence judgment and hence the patient's management; understand patients' emotional responses to doctors and the way these can influence the presentation of illness; grasp the main principles of, and indications for, counseling and psychotherapeutic intervention.

(b) *Organic psychiatry*. The student should be able to: distinguish between organic and nonorganic psychiatric disturbance; recognize common organic mental disorders, including confusional states and dementia in different age groups; and management of organic syndromes in and out of hospital.

(c) *Functional syndromes*. The student should, for example, be able to describe: the management of depressive psychoses; schizophrenia and related psychoses; recognize common symptoms of neuroses; define and recognize the signs and symptoms of psychiatric illness; and the social services available for their management.

(d) *Treatment methods and agencies*. The student should be able to outline: the drugs commonly used; the principles of behavior modifications and their main clinical applications must be known; also important concepts in psychodynamic approaches, for example unconscious conflict and defense mechan-

isms; and the main agencies for the care and rehabilitation of the psychiatrically ill and those with learning disabilities in the community.

(e) *Examinations*. It is necessary to stress the importance of examinations, because examinations drive the curriculum. Students learn to pass examinations, whatever more high-minded educational emphasis teachers may seek to convey when specifying learning objectives. The assessment methods used should always be congruent with the objectives of the course. Only too often the methods of assessment are discordant. The professional examination needs to be composite: e.g., essay questions; short answer questions; an oral examination; continuous assessment during the clinical attachment, etc.

2.9 The Generic Medical Graduate

The product of basic medical education is a young doctor not yet equipped for independent practice on graduation. The goal of medical school is to produce a pluripotential doctor, who must then have postgraduate training to acquire the abilities needed for specialist (or generalist) practice. Prior to beginning such postgraduate training, the graduate is in the phase of transition from medical student to doctor.

The *junior hospital doctor* becomes a member of a consultant team in hospital. The notorious defects have been insufficient clinical supervision, insufficient feedback from consultants, excessive hours, and poor training standards with inadequate educational provision. Unless the general hospitals in which they work have psychiatry liaison services or psychiatric units, junior doctors receive no psychiatric instruction, and little incentive to consider training as a psychiatrist.

3. Specialist Training in Psychiatry

Training to become a specialist is the sector of medical education of particular significance to the specialty organization in each country (e.g., the American Medical Association, the American Psychiatric Association, etc.). General practice (family medicine), requires training that has a substantial psychiatry component, because of the epidemiological fact that the majority of psychiatric patients are seen not by specialist psychiatrists but by generalists.

Postgraduate training is in transition at present, not only nationally, but also worldwide. In part, this process of re-evaluation and reform results from the altering roles, responsibilities, and relationships of doctors, an upheaval so extensive and multifarious that the *World Summit on Medical Education* was designated: 'The Changing Medical Profession' (World Federation for Medical Education 1994).

Local context is crucial. Culture and history of each country are critically important in determining patterns of health care. Appropriately therefore each country continually reviews and reorients postgraduate medical education. Moreover, there are major differences between countries in their organizational frameworks for funding, delivering, and assessing postgraduate medical education. The professional nomenclature of psychiatric diseases and disorders varies: e.g., in North America the *DSM-IV* is used (American Psychiatric Association 2000) while in countries of Europe *ICD-10* is the diagnostic system (World Health Organization 1992).

3.1 Structure and Implementation of Specialist Training

Postgraduate training in almost all countries is the concern of the *Ministry of Health*, and takes place mainly in the hospitals of the country's health service. Universities are associated with health services in the postgraduate training programs, e.g., twenty psychiatric hospitals in The Netherlands have psychiatric training approval, eight of which are university hospitals. Psychiatry is one of the medical specialties now undergoing profound change (Caldicott 1996).

Specialty organizations customarily set standards and hold examinations in postgraduate education. Their particular role differs considerably among countries. In the United Kingdom, taken as an example, the Royal Colleges and their Higher Training Committees have major responsibilities. Each College (including the Royal College of Psychiatrists) through its Higher Training Committee produces its own assessment standards. The Colleges set formal competitive examinations to regulate entry into higher specialist training. During specialist training in the UK the Higher Training Committee vets the quality of the training posts and the progress of each trainee specialist, through inspection visits and regular formative assessment of the trainee.

3.2 Clinical Training

Postgraduate training in psychiatry involves a *sequence of posts*, providing a wide range of clinical experience and making up a rotational training scheme, usually in one geographical area and often in one approved hospital complex. The *rotational training scheme* includes a university department or hospital, and allows experience in the various *subspecialties* of psychiatry, including in addition to adult general psychiatry: child and adolescent psychiatry, mental retardation, geriatric psychiatry, psychotherapy, general hospital (liaison) psychiatry, and other special fields.

3.3 Theoretical

The *academic content* of postgraduate training in psychiatry should include an introduction to general

psychopathology, pharmacology, genetics, interviewing, diagnosis and classification, organic disorders, drug and alcohol dependence, schizophrenia, mood disorders, neurotic disorders, personality disorders, learning disability, psychiatric disorders of childhood and adolescence, old age psychiatry, forensic psychiatry, drug treatments, counseling and interpretative psychotherapies, behavioral and cognitive therapies, rehabilitation and community care.

3.4 Assessment Procedures

The *specialist examination* is taken at differing stages of training in different countries, and is also phased differently in the various specialties in each country. In order to sit the UK Royal College of Psychiatrists examination, trainees must have completed three years of psychiatric training and must be in a training post. After such general training, they may choose either to become general psychiatrists, or to enter additional training for a psychiatric subspecialty: e.g., in The Netherlands an additional two years in child psychiatry is required to obtain the Certificate of Completion of Specialist Training in Child Psychiatry.

In addition to the specialist examination, which as indicated above may be during the course of training, a number of countries have also introduced formal *summative* assessment at the end of specialist training. Equally important to trainees is feedback about performance, specific help about any weakness, and planning of future training.

3.5 Psychiatry Among the Medical Specialties

Countries differ in the separate specialties they identify. Psychiatry is not uniformly recognized, not even in all the countries in the European Union, regulated by law: the European Specialist Medical Qualifications Order, 1995. When psychiatry is one of the recognized specialties in a country, there are differences in training requirements including duration, e.g., it has been said that psychiatric training in the UK takes six to seven years, but four years in Portugal, Greece, or Belgium (with no formal examination in Belgium).

3.6 Subspecialties in Psychiatry

After general specialist training, young psychiatrists elect to undergo further training in subspecialties, and in professional life are designated according to the branch of the specialty in which they work. Adult psychiatry, child and adolescent psychiatry, geriatric psychiatry, forensic psychiatry, addiction psychiatry, etc. are differentiated, the range of categories varying to some extent in different countries.

3.7 National Differences in Standard Setting

In broad terms, five different patterns of responsibility for standard setting can be identified worldwide.

(a) National medical associations, as in Norway and Portugal, take the leading responsibility. In other words, the medical profession itself provides and dispenses the postgraduate training in the country. This is also the case in Germany, and in certain Central European countries.

(b) Designated professional bodies, distinct from the national medical association, may have major responsibilities, as in the United States where the specialty Board of Psychiatry, and in the United Kingdom where the Royal College of Psychiatry approve training posts as well as assess the competence of doctors in training.

(c) The government (Ministry of Health) together with the regional medical administration may take the main role. Sweden is an example of this arrangement.

(d) Universities may be the chief responsible bodies, as in Finland and southern Europe.

(e) Postgraduate Institutes in some countries are, or were, the chief postgraduate authority, as in Central and Eastern Europe.

3.8 New Developments

In Europe, within each country, there has been steady evolution of postgraduate training over the past 20 years, with formal definition, recognition, and support given to the educational programs. *International legislation* controls important aspects of medical education in the European Union, in the interests of free intercountry movement of doctors among the member states.

So that women, in particular, are not penalized, training arrangements for *doctors with domestic or other special responsibilities* have to be specified, or parents who have interrupted their training for family reasons are precluded from re-entering medical practice. European Union directives on postgraduate medical education now also specify that the minimum number of hours of work in part-time training (for general practice, at least 60 percent of the hours worked by those employed full-time). Similarly, doctors training part-time in hospital specialties will be required to extend their already lengthy training on a pro-rata basis in order to qualify for specialist registration.

Postgraduate medical training has secured the *confidence of the public* in the medical care provided by accredited specialists. To cite the UK again simply as an example, the statutory basis for the medical education infrastructure has been long regarded as a major strength of the national system, the General Medical Council, the body responsible for the register of qualified medical practitioners, held in high repute. However, malpractice and legal infringements have

recently undermined the long-standing confidence in self-regulation by the medical profession.

Doctors in postgraduate training have other professional needs which training programs must cater for. They require, for example, to learn the limits of their own competence, to identify and remedy deficits in their knowledge and skills, to learn when and how to seek the assistance of others, and to develop effective working relationships with professional colleagues and others. Structured training programs are therefore obligatory, which incorporate modern educational practice (Borman and O'Grady 1997).

4. *Continuing Medical Education (Professional Development)*

As a third great sector of medical education, maintenance of competence throughout professional life is now obligatory, and accepted as such by employing authorities, doctors themselves and the general public who require quality medical care and accountability by doctors for the clinical service they provide. Continuing medical education (CME), or professional development, consists of those educational activities undertaken by practicing doctors to maintain and update their clinical competence.

Medical journals and other medical scientific publications always were and continue to be paramount in disseminating new knowledge and promoting best clinical practice (Vysohlid and Walton 1990). Special continuing education courses were first introduced, in some middle European countries, for doctors practicing in state health services in 1878. As increasing numbers of countries introduced social insurance, furthermore, continuing improvement of their employees' professional competence also came to be expected. This direct intervention and involvement of the state, to a lesser or greater extent, in promoting new knowledge and experience for doctors in the public health service is the original model of CME.

As pertains to all specialists, so also it is the personal responsibility of every psychiatrist to remain competent. This ultimate obligation of individual physicians calls for proper means to assess constantly the quality of their work and effectiveness of their professional services, such as a system of performance review. Agreed standards are necessary, and computerized medical records greatly enhance *audit*, the process of examining one's clinical performance in relation to peers.

Being performance related, CME goes beyond information and knowledge, and focuses on the carrying out of actual clinical responsibility and services. The material included in CME, over and above lectures, case presentations, conferences, scientific meetings and conferring among clinical colleagues and their hospital firms or clinical teams, must be based on understanding of how adults learn: adults are oriented to tasks they undertake themselves, and to the personal interests they pursue. CME material must be relevant to the practitioner's own daily responsibilities. Old-style courses, in which doctors were brought together to sit through series of lectures haphazardly given by outside experts, are not congruent. Mere attendance at CME courses for which credit is given cannot be assumed to improve professional competence.

There is widespread agreement that the CME system in a country must be closely integrated with the health care system, and related to the health needs of the population. Some countries are already imposing sanctions on doctors who do not engage in approved CME activities. Self-evidently, differences in the CME system between countries are to be expected and, indeed, greatly varying patterns are compounded by national realities in the health care services, the varying professional bodies with authority for medical education and training, and the forms of statutory regulation of the medical profession.

Since the Second World War, opportunity was provided for CME in practically all North American and European countries. CME is now always adapted to identified and actual needs of the health problems of the population, and to the health services, particularly in relation to primary health care and ambulatory settings. Coordination between medical school programs and subsequent specialty training programs has powerfully consolidated the provision for continuing medical education.

The provision of clinical information made available by modern information technology is the basis now needed for CME. Distance learning can combat the relative unavailability of CME for doctors working in rural areas and distant from the main teaching center.

All doctors have now to accept personal responsibility for maintaining professional competence throughout their working lives through CME. In addition, regular monitoring and revalidation are increasingly advocated. This third, and longest, phase of medical education is the most important, and both basic medical education and postgraduate training must now be planned and implemented as preparatory for lifelong CME, to ensure professional competence of all medical doctors throughout professional life. The imperative charge, on all nations, is for provision of effective medical services by sufficient, responsible, ethical doctors.

Education: Phenomena, Concepts, and Theories

1. Classical and Christian Traditions

The Latin verb *educare* can be translated as 'to pull up,' and it is in this sense that it is understood to mean 'to educate': a person is pulled upwards. As both a concept and a play on words, 'education' entails a difference in height, and a process by which this difference is overcome. In Western literature, the concept of the 'teacher' and 'educationalist' has been associated with asymmetry ever since Homer's *Iliad*, and the direction of this asymmetric relationship cannot be reversed at any point in the educational process (Homer 1987, Book 9, p. 430ff.). 'Teachers' are appointed to train 'pupils,' who in turn are to learn what the teacher knows and represents. Education is subject to the person of the teacher, who is equipped with limited authority, the purpose of which is to make him- or herself superfluous upon successful completion of the educational process.

With regard to the terminology, a distinction is to be made between *educatio* and *eruditio*. The first area is that of moral education—in the wider sense a training of the body and the senses—whereas the second area is concerned with scholarly education and instruction. The two areas are often understood as opposites, as was the case in ancient Sparta, and later in the theory of Rousseau. The fundamental friction between the two has remained to this day, and educational discourses typically lend weight to one side or the other. This was also the case in Graeco-Roman times. A key question was how positive education should or must be. The question was answered by means of two consequential concepts, relating to rhetoric and public teaching on the one hand, and self-education on the other. Sophist teachers, who—as portrayed in the dialogs of Plato—publicly announced truths and virtues, were juxtaposed with Socratic dialogs, in which Socrates guided his untutored interlocutors to formulate answers to the problems he posed. Finding the solution to the problem required the 'pupil' to engage in independent thought with the maieutic (or Socratic) assistance of the 'teacher'; the teacher does not present a positive truth in a didactic manner.

The fundamental question of whether virtues can be taught is posed by Socrates in Plato's dialog *Meno*. The question is not answered, however, at least not in the expected sense. The first historical negation of the 'teacher' (of virtues; Plato 1999, 96a–c) is accompanied by a rejection of the teaching of virtues in favour of 'divine providence' (Plato 1999, 100a). This links education with Plato's theory of the soul (1999). Education is not simply rhetoric because—according to Socrates—truth cannot be taught in public. Knowledge is innate in the soul, rather than learned from experience. It is the teacher's task to encourage pupils to think for themselves, thus becoming aware of these timeless ideas. In other words, pupils need to be goaded into conscious reflection.

The relationship to psychology is of fundamental importance to the theory of education and the demands made of it. Without the concept of the soul, education cannot be considered to have lasting 'inner' effects. Yet Platonic theory rejects the notion that the soul can be easily affected by education. Education is

not merely the imitation of nature. Its two main areas, morality and knowledge, require pedagogical efforts going beyond imitation. The means of education, i.e., dialog, admonition, models, or guidance towards new insights, are not given simply on the basis of nature. At the same time, pedagogical efforts are limited. Education imparts knowledge and skills, but it cannot reach all of mankind. The Socratic wariness of 'teachers' who independently and publicly pronounced truths remained intact on into Christian times.

2. *Modern Aspects of Educational Theory*

With the Renaissance it became possible to forge a conceptual link between human dignity and education, i.e., to keep education free from doctrines of humiliation. In this sense, education (*eruditio*) became humanistic, but without the canon of classical teaching being lost. However, the adoption of Platonism in the Italian Renaissance, particularly in Florence (Hankins 1991), allowed the theory of 'inner' education—related to innate ideas, rather than doctrines or text books—to be strengthened. In the seventeenth and eighteenth centuries, new Platonic theories of education determined cultural life, i.e., literature, art, music, and key aspects of philosophy. Education was the aim and the expression of lasting ideas which, in turn, were intended to be understood in a manner which was independent of certain Christian doctrines. In England, in particular, the independence of education and the consequent fight against orthodoxy in the seventeenth century amounted to a political force in which new Platonism and the natural sciences were allies.

In this respect, a distinction is to be made regarding the education of children. Since the Reformation, education has concentrated on the minds and souls of children. This was strengthened by post-medieval catechisms which stipulated the form of learning, and emphasised the necessity of education beyond the parish and the church (Bast 1997). It was envisaged that the establishment of elementary school education in the eighteenth century would supplement education at home, without too much weight being attached to knowledge during lessons. The focus on Christian morals was of fundamental importance. These were supposed to become spiritualised, i.e., more closely related to the Augustinian 'inner teacher.' Moreover, the pietistic conception of the child resulted in the pedagogical dissemination of the Christian (particularly New Testament) view of the child as a paragon. Only adults whose inner being could once more become that of a child were close to Christian mercy. With pietism, education became a missionary power with the goal of bringing forth 'new people' and subsequently a 'new world' of belief.

In contrast to esthetic education, which determined the concept of 'the educated' and made it independent of teachers, the education of children has typically been seen from the perspective of educational methods. With the introduction of printing, instructional theories on the education of children could be disseminated for the first time. Thus, expectations were established, examples of which can be found in Christian pedagogy as early as the seventeenth century (e.g., Mitternacht 1666). Education was reduced to a methodological basis. In the eighteenth century, sensualistic psychology strengthened the trend for education to be understood as a target-oriented effect. The Platonic concept of 'innate ideas' became less influential, and was replaced by theories of learning. These stated that the inner world is established by processes of learning, and that learning can be guided by education. Hence, education, and subsequently morals, would make the person what he is, and what he becomes (D'Holbach 1770/1994, p. 346ff.).

The aspect of the inner being was further developed by Rousseau (1969), who combined earlier notions about the 'nature' of children (Mercier 1961) with Buffon's theory of human development. Basically, Rousseau proposed a solution to the problem of mercy that was widely discussed in French educational circles during the seventeenth and early-eighteenth centuries. His approach was that if the Augustinian theory of initial sin can be rejected, and if children can be assumed to develop on the basis of their natural goodness, education can be understood to be a new form of mercy. It cannot be taken as given; it occurs together with the development of nature, subject to the proviso that nature is protected against abuse by society. Rousseau therefore refers to *éducation negative*, in which virtues and reason are not imparted in a positive manner. The Socratic nature of *Emile* also becomes apparent in that the teacher (governor) is an omniscient authority. In contrast to the teacher in *Meno*, however, Rousseau acts as if he were simply allowing matters to take their course. The key concept for childhood—'*laisser meurir l'enfance dans les enfants*' (Rousseau 1969, IV/p. 324)—has Augustinian features, but the 'inner master' is not intended to, and should not, be a representation of the outer one.

Rousseau also embraces a certain version of the two-world theory: in childhood, nature is this life, and society the next world. The only difference is that the roles are played in reverse order, and do not follow the same sequence as in the case of Augustine. It is envisaged that a good education will engender a good society, conditional on the ability to keep the existing society out of education. At the same time, natural education is supposed to abstain from influencing the child's future (Rousseau 1969, IV, p. 301ff.). It would be 'barbaric' if it were geared towards the citizen (*le citoyen*) rather than the man (*l'homme*). One can speak of the education of *men* if nature is intact, and one can thus develop in accordance with one's own potential. In other words, Rousseau embraces the theory of

development. Education is not only concerned with the mind or learning, but with the whole of nature and its development. This presupposes that childhood is a world of its own (Rousseau 1969, IV, p. 319). This doctrine is far-reaching, and has constantly attracted new followers who understand learning as genetic and relate it to the autonomous child 'developing' from within (Oelkers 2000).

3. Educational Phenomena and Pedagogical Theories

There is a high degree of historical continuity in educational theories. Theories of childhood are just as dependent on the history of the concept as theories of education are. This holds even if they relate to societies which are in stark contrast to that of the eighteenth century, or to new media which neither Rousseau nor Locke could have foreseen. Hence, educational theories are not randomly constructed; they refer back to historical principles which are flexible enough to be applied to various situations and environments. At least, this is the case if very general statements or theories stipulating what can and cannot be deemed a valid educational phenomenon are discussed and accepted.

General theories of education are those which do not refer to certain environments, such as Plato's Athens, to certain doctrines, such as Augustine's Christianity, or to certain practices, such as catechism lessons. It is possible to generalise education by referring to doctrines of the soul, concepts of society, nature, progress or universal morals. It is almost always the case that theories mix these elements, frequently by shifting the relations between them and utilizing their immanent dualisms. The 'mind' of a child can be seen as the result of 'natural development'; such 'natural development' can oppose 'society'; 'morals' and 'nature' can be seen as either complementary or opposing forces; education can serve to impart society's morals or to oppose them, etc.

Educational theories only become specific when they do more than simply develop dualisms. They must at least differentiate between inner and outer, between process and product, between children and adults, between intention and effect and between objective and experience. These elements must be capable of being linked together, and cannot be understood as opposing forces if a positive theory of education is to be created. Such a theory is normative, rather than merely descriptive. It is geared towards practice and aimed at bringing about improvement. This demands the definition and justification of the pedagogical intent, as well as the prediction of outcomes. The demands placed on education can only be limited if the theory can differentiate between inner and outer. Objectives do not immediately constitute effects; educational processes are controlled by means of target-oriented rhetoric and experience, without the two ever being identical.

When the above is applied to the sphere of anthropology, the following statement can be made: children are not adults. Moreover, they do not simply become adults in accordance with the intentions of their educators—they also gather their own experience, independent of educational targets. In a literal sense, children are not the 'product' of education, primarily because each educational outcome can be changed by subsequent experiences. A pedagogical intent is necessary, but it is not the only causal factor. Education is a permanent and hazardous attempt to adapt to each new child. The subjects or themes of educational theory emerge in response to educational phenomena which may be of a moral, esthetic, or pragmatic nature. This is conditional on the identification of a certain need or deficit which requires pedagogical processing.

In contrast to the classical theories, modern educational theories are unlimited. They extend beyond the interpersonal relations of 'masters' and 'pupils,' and may relate to the 'world' or 'society'; they allow for a generalisation of the child as well as for abstract objectives such as 'emancipation'; they are no longer bound by religious theories. Accordingly, educational phenomena are general. In other words, they determine both the object and the responsibilities of education. The term 'education' may relate to literature and the arts, philosophy and all areas of knowledge, as well as all kinds of beliefs, but it may also relate to morality and mores, societal development or the general betterment of mankind. To this end, there are several competing theories allowing for very little standardisation.

In view of the interrelations between the theories, however, educational theories should not simply be equated with the names of their authors. The classification of theories according to names, or schools and directions associated with these names, is the most frequent lexical form of organisation. Definitions of this kind are not only obscure, they fail to produce real classifications, because the grouping principle barely allows any exclusions to be made. Ultimately, everything that can be related to the abstract relationship between humankind and the world can be described as 'humanistic,' 'dialogical,' 'progressive' or 'critical'—or indeed the opposite.

However, one can only speak in terms of 'educational theories' if primary criteria are used, allowing for differentiation and suggesting definitions. It is not sufficient merely to confirm the doctrines of certain pedagogical authors. However, part of the reflection on education is determined by this very desire for approval with respect to historical parameters perceived as archetypes. In this sense, educational theories should—and can—educate in their own right. They focus reflection on and perception of educational phenomena to the area of validity of doctrines.

When reflecting on the topic of 'education,' however, one is forced to consider the following unavoidable problems: observation of children reveals not only a 'natural development,' but a complex world of perceptions that must constantly link the inner and outer aspects without being able to rely on stages or supports. Accordingly, the concept of 'education' cannot contain the dualism of 'development' or 'impression.' Both concepts are helpful in the politicisation of education: 'development' is understood in the sense of siding with children, whereas 'impression' is understood as a means of strengthening educational authority. However, this alone does not constitute an educational theory. A distinction must be made between educational theory and the public rhetoric about education. A theory of education cannot merely confirm general aims by reference to preconceived doctrines, nor can it rely on 'education' being seen merely as a moral suggestion.

4. *Educational Theories*

Against this backdrop of theoretical tradition, at least five types of educational theories can be distinguished. This differentiation is made on the basis of the theories' underlying approach, which may be related to theory systems or general models of reflection as widely varying as philosophy, psychology, social theory, or anthropology. They can be grouped into idealistic, pragmatic, cultural, individualistic, and political approaches to educational theory, at the very least. These are not different aspects of one approach, but different ways of reflecting on the general theme of education. The methods used vary, and include analytical, empirical and historical approaches. The main topic of 'education' is outlined in terms of a normative core which, as far as is possible, is justified by hard facts. The theory itself is a construct which in some cases tends more towards *educatio*, and in other cases leans more towards *eruditio*.

Idealistic theories of education are based on moral aims or principles, which can be justified in an ideal or 'transcendental' manner. The two most influential approaches in the history of the theory are those of Plato (1999) and Kant. In the first approach, education serves to organize the state in accordance with the philosophical ideas of goodness and justice. The second approach is characterized by a form of education that centers on personal morality in accordance with the categorical imperative of action. Individual liberty is limited by law, and action is guided by strict virtues. The idea of the general good justifies the ideal state; practical reason justifies moral action. Consequently, educational theory has its normative core in the notions of goodness and morality, both of which are to be transmitted to children and citizens.

Pragmatic theories of education emphasise the paramount importance and hazardous nature of one's own actions. Since Darwin, these have been justified by an evolutionary-theoretical approach, in the sense that education is understood to be a continuous readjustment to changing worlds of experience. Against this background, Dewey (1985) sees education as 'a process of the continuous reconstruction of experience.' There is no morality that is formulated outside or independent of experience; the general public and democracy represent the regulative bodies for moral exchange. Similarly, Mead (1970) does not see education as an isolated chain of events between the inner and outer aspects. According to Mead, the 'organized self' (1970, p. 162) learns and gathers experience within the framework of its group, i.e., subject to the proviso of continual exchange processes (1970, p. 265). Education 'is' nothing else.

Cultural theories regard education as Bildung or initiation (Peters 1965), and are justified in a 'transcendental' manner. The process of initiation opens regulated ways of learning to culture and society. Those who intend to assess education must become involved with it. The educated man/woman is a normative ideal that develops within the process of education, i.e., does not exist independent of it. This is conditional on the historical existence of culture, i.e., the major fields of knowledge and ability into which the student is initiated. The individual personality develops in the process of this initiation. According to Bruner (1996), education itself can also be perceived as a 'culture' which, by means of specific institutions, ensures that education is provided for successive generations, with constant or increasing levels of performance. Schools and universities and, in a broader sense, the educational media are institutions for the continual transfer of knowledge and learning which can also be described in terms of general systems theory (Luhmann and Schorr 1988).

Individualistic theories of education, such as that advanced by Herbart (1808), focus on morals, understood to be a characteristic or potential of the personality. 'Morals' are based on practical ideas with the intention of determining moral education. Since Herbart, it has been possible to draw up a concept of morals on the basis of esthetic judgments, i.e., as an immediate and involuntary assessment of the excellence or impropriety of an occurrence or an action. This judgement is not simply subject to the law, it occurs spontaneously. The concept of spontaneity means that individualistic theories are in stark contrast to all theories which expect education to be a fixed inner result. Since Kierkegaard (1980), there have been different attempts to lessen the friction between the ethical and the esthetic, but the conflict between duty and affection in education has never really been resolved. The conflict recurs regularly: today's constructivist educational theories stress the spontaneous creation of one's own world, while moral theories refer to the 'inner' results of education, which are not supposed to change spontaneously.

At the beginning of the twenty-first century, political theories of education are primarily geared towards democracy. The totalitarian theories of the twentieth century have largely disappeared. It is no coincidence that a new reception of the eighteenth century civic society emerged after 1989, and that Dewey's *Democracy and Education* (1916) has become the focus of international pedagogical discussion. In contrast to Dewey, new approaches to a political theory of education include expanding its scope to involve the deliberative public (Gutmann 1999), and specifying its tasks and subjects to involve civic virtues (Callan 1997). The fundamental friction has survived: on the one hand, political democracy educates by means of its problems and procedures; on the other hand, education is intended to promote democracy. Citizens must be equipped with the capacity to participate actively in public life. Yet even the best school is not an embryonic society, anticipating on a small scale what later occurs on a much larger scale. The object of the theory is determined and non-determined at one and the same time.

5. *Educational Criticism*

Educational theories are simultaneously positive and critical. They draw attention to deficits which are to be made up or avoided in the future. This calls for a critical approach to present and past education. The underlying objective is for the future to be better than the past, and this would seem to be feasible if and inasmuch as education can be improved. Criticism of education *per se* is different. This sort of criticism rejects the claims that a theory of education is able to group, describe, and control an object or a range of subjects pertaining to 'education.' The normative alignment of most of the educational theories is seen as an illusion, their expectations of effectiveness are related to technological deficits in educational practice, and the identification of the 'child' as the object of education is subject to criticism on both the moral and psychological levels.

Education as an illusion was the subject of the psychoanalytical criticism of the 1920s in particular (e.g., Bernfeld 1925). According to this critical approach, the theory of education reflects ideals and thus expectations which can be understood as reflections of the subconscious, i.e., which refer back to the authors of the theory. Their illusory nature of this discourse means that it does not need to take note of educational realities. The critique of education advanced within the framework of general systems theory refers to the fact that the education system does not have access to any technology which might guarantee its objectives, it is referred to as a fragile form of communication which needs to be self-directing. Similarly, constructivist approaches to educational criticism underline the autonomy and self-organization of learning which cannot be incorporated by educational theories in which adults decide and act vicariously for their children. Furthermore, these kinds of theories tend to regard children, or learners in general, as the objects of education, i.e., to impose a certain course of action on them irrespective of their approval.

This was the very problem with Kant's ethics which, for good reason, stipulated that persons should not be treated as objects. However, Kant could not eliminate compulsion from education. The problem is insoluble as long as the school of thought is determined by dualisms such as compulsion or liberty. The general criticism of education uses the dualisms rather than avoiding them. For example, 'inner' is played off against 'outer,' 'self-organization' is confronted with 'outside determination,' and the discrepancies between the aims and the realities of education are exposed. Educational theory, in contrast, requires relations which allow for graduation, and which can be related to ongoing experiences in changing situations. The objects of the theory are those who act, i.e., those who can grant more or less liberty, use more or less compulsion, realize better or worse objectives, adapt precisely or less precisely to realities, relate to a child's personality in a more or less appropriate manner, etc.

It is necessary for a happy medium to be found in each case. Educational theory must be adjusted to a temporal and social succession of situations which are in constant flux. In this respect, educational theory represents a continual learning experience which needs to be able to correct its aims and intentions. Most of the educational theories mentioned above are not geared towards self-correction, primarily because their basic premises are not supposed—or allowed—to be modified. Their expectations are geared towards public rhetoric; education is supposed to achieve general targets, and is not understood as an experiment that may succeed or fail, but can only succeed if its approach can be corrected in response to experience. This experimental understanding of education has been embraced in the theory of Dewey (1985), in particular. However, it had only a very inconsistent effect on his own efforts to formulate an educational theory.

This is no coincidence. On the one hand, 'education' is a normative expectation which precludes modifications; on the other hand, it is a fragile practice which adjusts expectations, bringing them into line with possibilities. Educational theories should take account of this differentiation and process both levels. Expectations regarding education can be understood and rationalized in a manner which distances itself from public rhetoric (Siegel 1988); the practice of education can be formulated in terms of contractual theory (Gauthier 1990) or action theory; reflection on pedagogical matters can respond to uncertainties about the paradoxes of the educational field and pick out unavoidable dilemmas as its central theme. In this way, 'education' will no longer be an object, but a series of subjects and themes geared towards public

understanding, with no more than disciplined reflection at their disposal. In contrast to the popular reform pedagogy, educational theories are no longer perceived as guarantees for success. This also applies to the attempts to infer the nature of 'education' from general models of philosophy, psychology or other disciplines. In view of the high level of competitiveness between the general theories, their mere existence is no guarantee for their application in practice.

The normative type of pedagogical tradition still determines the field of reflection to a considerable extent. It suggests generalizations and tends to preclude practical or empirical differences. The concept of 'education' survives in public rhetoric, as do its suggestive powers and standards of argumentation. This explains why it can be so easily called into question and is constantly coming under fire. In this respect, education is nothing more than the belief in it. In fact, educational expectations are renewed irrespective of periodic or even chronic crises, meaning that better theories do not simply replace poorer ones. Progress does not occur in the form of a general increase in knowledge; the theories exist in a complex field of public expectations, tough competition, unrelenting demand, and high moral conformity.

The theoretical dynamics created between science, philosophy, and practice cannot be understood without this field of expectations. On the one hand, they are subject to very long-term historical assumptions; on the other hand, responses are expected on a short-term basis, because 'education' is a priority in the public perception, calling for immediate explanation and action. Because societal expectations are so high, educational theory has neither the time nor the distance to subject itself to self-assessment. It does not simply react to a scientific problem, it reacts to public demand. As such, it is and remains attractive, but at the same time creates its own particular difficulties.

Education (Primary and Secondary Schools) and Gender

Since the 1970s, the number of empirical studies on differences in the academic performance and social

development of boys and girls in elementary and secondary school has escalated. In 1992, the American Association of University Women Educational Foundation (AAUW) estimated that over 1,000 articles and studies on girls and their education in kindergarten through 12th grade had been reviewed for their comprehensive report, *How Schools Shortchange Girls*. Gender studies of this type typically show how societal structures, primarily schools, distribute resources inequitably among boys and girls and what effect these distributions have on various outcomes such as achievement, self-esteem, educational attainment, and occupational choice. It now appears that the distribution of resources is changing, and assumptions about the treatment and consequences of certain actions are being challenged as the gender gap between boys and girls closes along several key dimensions.

Recent US data indicate that the achievement test score gap between girls and boys has been steadily declining during the 1980s and 1990s, and girls now perform as well as boys on most national tests.

In 1996, girls outperformed boys on tests in subjects such as reading and writing, and performed nearly equal to boys in mathematics (Campbell et al. 1998). In light of these findings, the question has been raised if schools are still 'shortchanging girls.' Kleinfeld (2000) argues that the idea that girls are victimized at school is wrong; girls receive higher grades in school, perform better than boys on standardized tests in many subjects, and enter and complete college more frequently than young men. Males are more likely to be placed in special classes for learning disabilities, are more difficult for teachers to handle, and are given less encouragement by their teachers to succeed.

As differences in the academic performance and educational attainment of boys and girls continue to decrease in magnitude, increasingly researchers are suggesting that girls and boys are a great deal more similar than they are different. This is not to say that there are no gender differences, but they appear when examining specific knowledge and skills in particular samples of females and males. Gender research has moved from assumptions of homogeneity within the sexes to a more detailed examination of intra-gender differences among girls and boys. Focusing on race, ethnicity, and social class has made recent research on gender more complex, and allowed for more fine grained distinctions of the academic and social challenges facing boys and girls as they progress through school.

1. *The Elementary School Years*

When they enter kindergarten, most young children have clear ideas about gender and strive for conformity with gender-stereotyped roles. Boys are committed more rigidly to sex roles than girls, consistently choosing and preferring sex-typed toys and activities. By age 10, there appears to be more flexibility in sex-segregated behaviors, although most children continue to prefer to spend time with same-sex peers (Thorne 1993).

Large-scale studies show that females are more likely to start their formal schooling at an earlier age than males and are less likely to fall behind academically and repeat a grade. Girls typically enter kindergarten with education-related skills such as small muscle development and language competence, abilities that are highly valued by their teachers. Mastery of these skills often eases the transition for girls from preschool into kindergarten. Boys, on the other hand, tend not to be as proficient in these capacities when they enter school and receive more attention than girls from their teachers, who give them specific and helpful feedback and challenge them with more complex and abstract questions. Teacher–student interaction studies in elementary school reveal that teachers tend to view boys' academic problems as motivational, but when girls exhibit similar problems they are seen as lacking ability (Sadker and Sadker 1994).

2. *Middle School*

The differential treatment by teachers of girls and boys continues through middle school where, it has been argued, girls' sense of competence is undermined and they become silent in the classroom (Brown and Gilligan 1992). Findings by Eccles et al. (1998) indicate that gender differences are more likely to be observed where gender stereotypes are endorsed by girls and boys. Girls who believe the stereotype that boys are more competent in a subject like math will be more likely to lack confidence and to avoid challenges in that subject.

Beginning in early adolescence, females consistently report greater dissatisfaction with their appearance and bodies than males. This phenomenon appears to have intensified over the last several decades. Perceptions of one's attractiveness are correlated with self-esteem for both males and females. Some claim, however, that females are more susceptible to the influences of the media, their teachers, parents, and peers, and have substantially lower self-esteem than males (Orenstein 1994). A more cautious view of these findings and other studies are discussed in two major meta-analyses conducted by Kling et al. (1999) and Feingold (1994), which show small but statistically significant gender differences in self-esteem favoring males for both cross-sectional and longitudinal studies.

In middle school, girls continue to demonstrate an academic advantage over boys, outperforming them with respect to grades in academic and nonacademic

subjects. However, there appear to be no significant differences in test performance between boys and girls (Willingham and Cole 1997). Females at this age are more likely than males to report talking to their parents about selecting courses, school activities, and their classes. Boys continue to skip school and get into trouble more often than girls. At home, however, there appear to be few differences in how parents monitor behavior. Males and females are likely to report similar levels of parental control regarding television viewing, reviewing homework, and limiting the time they can go out and be with friends (US Department of Education 1995).

3. Secondary School

Despite growing support among the general public and supplementary federal funding for the development of nonsexist curricular materials and programs in the 1970s, gender equity issues continued to plague American secondary schools well into the early 1980s. Although in high school girls consistently received higher grades than boys, boys tended to perform better than girls on standardized tests. In trying to discover what contributed to these results, researchers examined several different factors, including educational expectations, course-taking behaviors, gender bias of standardized tests, peer group interactions, and extracurricular participation. Results of their efforts encouraged the development of a number of different programs and activities to increase teacher and parent awareness of the problems facing girls in school (AAUW 1995). In the 1990s, it appears that these initiatives have been effective, and gender differences are slight or nonexistent in some domains.

4. Educational Expectations and Occupational Aspirations

Educational expectations and occupational aspirations, which have been shown to be highly sex-typed, have tended to be predictive of adult occupational attainment (Marini and Brinton 1984). Today, however, most adolescents expect to attend college after high school graduation, and these expectations do not vary by gender (Schneider and Stevenson 1999). Comparing large-scale longitudinal data from 1972 to 1992, Green et al. (1995a) show that in 1972 males were more likely than females to expect to complete college. However, by 1992, females and males were equally likely to expect to complete their education with at least a bachelor's degree. In 1992, for the first time, females were more likely than males to expect to earn a graduate degree. These results do not hold across all groups: Hispanic females are the least educationally ambitious and are least likely to expect to complete college or earn a graduate degree.

Males and females both aspire to professional occupations that require higher education degrees. However, gender differences continue to persist among certain occupations. Females are more likely than males to aspire to careers in education, health, psychology, and cosmetology, whereas males are more likely than females to aspire to careers in engineering, auto mechanics, and electronics. No gender differences are apparent for career aspirations in computer programming or business.

5. Course-taking Patterns

The courses students choose to take in high school have a significant impact on their lives after high school graduation. Students who take advanced courses in science and mathematics are more likely to attend selective colleges than those who do not. In the 1980s, girls lagged behind boys in the number of mathematics and science courses they enrolled in. In the 1990s there has been a change, with girls now taking nearly as many mathematics and science courses as boys (Wirt et al. 1999). However, a gap still exists with respect to the types of courses girls and boys take in these subjects. Females are less likely than males to take a fourth year of mathematics or science, which includes calculus and physics. Even females who earned high grades in previous mathematics and science classes often elect not to take these courses. Boys are more likely than girls to take physics as well as biology and chemistry. Girls outnumber boys in humanities and social studies; they are also more likely than boys to be enrolled in basic data entry and word processing courses.

Advanced placement (AP) and honors courses are geared to help students prepare for advanced placement tests for college entrance, where a scoring within a specified range allows a student to earn college credit for a specific subject. Consistent with their general course-taking patterns, females are more likely than males to take honors courses in foreign languages, English, and social studies; take about the same number of honors classes as boys in science, and slightly fewer in mathematics (Dwyer and Johnson 1997). In the 1990s, the number of girls taking AP exams increased more rapidly than the number of boys. By 1996, the number of males and females taking AP exams in the natural sciences and mathematics also increased, with the number of females increasing slightly more than males. Although more females were taking AP exams in the 1990s, the relative performance of girls and boys in most subjects was very similar (Willingham and Cole 1997).

6. Other Tests of Academic Performance

The small sex differences observed on the AP exams can also be found on other standardized tests. Recent results from the National Assessment of Educational Progress (NAEP), a nationally representative exam of student knowledge in selected subjects, show that the highest standardized test scores in reading and writing across all sampled grade levels were earned by girls. Boys earned higher scores on average in history, geography, mathematics, and science (Campbell et al. 1998). Males' test scores are about 10 percent more variable than females' which means that men are likely to outnumber women at the top and bottom of the scale, even though there are no sex differences in the mean scores (Hedges and Friedman 1993). Therefore, if the cutoff for admission to a highly selective program is scoring in the top 5 percent, fewer than half as many women as men may be admitted.

7. Experiences in School

Gender differences also characterize many aspects of adolescents' peer relationships. Adolescent girls' peer networks are often larger than those of adolescent boys, include more opposite-sex friends and fewer close friends. Nevertheless, girls' friendships are characterized by greater intimacy than are those of boys (Connolly and Konarski 1994). Females and their friends are more likely than males and their friends to have positive values and attitudes regarding their schooling experiences. While 43 percent of females say their friends think studying is very important, only 29 percent of males believe studying is very important to their close friends. Nearly 56 percent of females compared to 41 percent of males believe that their friends value receiving good grades (Green et al. 1995b).

8. Extracurricular Participation

There has been an increasing awareness that much of gender socialization occurs outside of the classroom in the extracurricular and informal activities of the school (Eder and Parker 1987). Data from the National Education Longitudinal Study of 1988–94, a nationally representative longitudinal sample of over 20,000 adolescents, show differences in gender participation. Girls were more likely to participate in artistic, religious, social, and service activities. White females were more likely to participate in most extracurricular activities than Hispanic, African–American, or Asian–American females. Male high school graduates were more likely than females to have taken at least one year of physical education, and outnumbered girls in team sports. Girls outnumbered boys in performing arts, school government, and literary activities, but boys were more likely than girls to occupy positions of leadership in some of these activities. As for activities outside of school, girls were more likely to take classes and be involved in activities with their parents than were boys.

9. Single-sex Schools

One of the responses to the negative implications of gender bias in schools has been a movement toward creating more single-sex schools (US Department of Education 1993). Research on the advantages of single-sex schools is mixed, particularly when taking into account selection bias issues. However, as more parents and educators become concerned with issues of harassment, differences in self-esteem, and the academic performance of females, the number of female single-sex schools may increase, even though there is not overwhelming evidence that girls fare better academically in these environments.

10. Leaving School before High School Graduation

Although dropout rates have been declining steadily, there are some important distinctions with respect to gender. Dropout rates are especially high among Hispanic girls. In 1995, 30 percent of Hispanic females aged 16–24 had dropped out of school and not yet passed a high school equivalency test. In contrast, dropout rates for white and African–American females declined, and those for white, African–American, and Hispanic males remained stable (US Department of Education 1995). One of the most frequent reasons teenage girls give for leaving school is being pregnant. Teenage pregnancy is linked with poor school performance, and is also distributed differentially among girls of different race and ethnicity, with Hispanic girls the most likely to become pregnant and leave school. Typically, across all racial and ethnic groups, males tend to take less responsibility than females for decisions about child bearing and childcare.

11. Transitioning from High School

Most young people will enter some type of postsecondary school following high school graduation. Today, females are slightly more likely than males to obtain some form of postsecondary education. In a recent study by AAUW (1999), among those high school students who entered the work force after

graduation, males were significantly more likely than females to describe their employment as a career rather than a job, to say they never seriously considered attending college, and to believe that they could get a decent job without a college education. Females in this group were more likely to feel that lack of money was a barrier to education and that better information about financial aid would have influenced their chances of attending college.

Even though there have been substantial gains in closing the gender gap in elementary through high school, there are still small differences that can have substantial implications. For example, low self-esteem may encourage a girl or boy to take less challenging courses, which can ultimately affect future plans after high school. Young people, regardless of gender, have talent and ability in particular areas when given the opportunity to succeed. The life paths that young people choose need to be constructed on the basis of their talents and efforts not their gender.

Education: Skill Training

1. Introduction

More than 200 years ago, Adam Smith argued that the incentives to invest in workers' skills are similar to the incentives to invest in physical capital. Workers or their employers invest in skills if the benefits or

'returns' from this investment exceed its cost. These investments manifest themselves in increased worker productivity. When workers receive the returns from investments in skills their wages, salaries and fringe benefits rise. When employers receive the returns from these investments their profits rise.

This article describes how the concept of 'human capital' anticipated by Adam Smith applies to decisions to acquire more schooling or to invest in vocational skills on the job. The idea is that workers and their employers act as if they evaluate investments in skills using the same cost-benefit calculus that they would use when assessing the net benefits from any other investment. The familiar forces of supply and demand influence these decisions. As more individuals acquire schooling, the supply of better-educated persons increases. All other things being equal (i.e., holding demand constant), the number of better educated persons employed increases, as does national output, but wages or salaries for this class of workers decline. Similarly, as more persons become educated, the supply of less educated persons declines and this group of workers' wages tends to increase.

An important difference between investing in workers and investing in new plants and equipment is that individuals can move. An employer that provides generous training opportunities to its employees may find that it has provided generous training opportunities to other employers' workers. This problem creates an important disincentive for employers to train their employees. Accordingly, this article focuses on the incentives for workers to acquire vocational skills either while in school or on-the-job and then discusses the evidence on the incidence, duration, and costs of training. The last section of this article comments on circumstances where these incentives may be insufficient and where the public sector might productively influence private training decisions.

2. *Incentives to Invest in Education and Training*

Economic theory predicts that competitive markets provide workers and employers with incentives to invest in training (Becker 1980). Individuals acquire more schooling because the value of future benefits associated with that schooling exceeds its costs. For the individual who decides to go to school, the benefit from schooling is the difference between her earnings with the schooling minus what her earnings would have been without the additional schooling. Individuals realize these earnings gains from schooling during each year of their working lives. Because individuals reap these gains in the future, they should be appropriately discounted to account for the 'time value of money.'

Most analyses of the cost of schooling focus on the direct costs and the opportunity costs of schooling. The former costs consist of the value of resources used to teach students new skills. The value of these resources to society is the value of what they would produce if they were used in some other activity. Analysts often estimate this amount by the (unsubsidized) cost of tuition, supplies, and transportation associated with attending school.

Opportunity costs are another important cost of schooling, especially for adults. This cost arises because when a person is in school they may not be working, or if they are working, they are likely to be working in a job in which their productivity is relatively low or they are working fewer hours. Consequently, schooling is associated with lost earnings for the individual and lost output for the economy. Analysts usually measure this cost by a person's wage times the number of additional hours that she would work had she not gone to school. Because older workers are more productive, the opportunity cost of schooling is higher for them than it is for teenagers and young adults.

The decisions of individuals about whether to attend school depend on the relative magnitudes of these varying components of the benefits and costs of schooling. A simple model of this decision process is instructive for its empirical implications. Suppose the earnings gain due to schooling is constant throughout a worker's working life and is denoted by B_i. The subscript associated with the term B_i indicates that the benefits from schooling vary among individuals in the population. If an individual is contemplating attending and completing college, then we can think of the term B_i as being the college wage premium. Suppose further that the worker's career has N years remaining, future gains are discounted at a rate of r, the direct costs of schooling are K, and earnings during the schooling period would have been Y_0. Under these conditions the decision to attend school depends on whether the benefits exceed its costs as is summarized by the following expression:

$$B_i\,(1-(1/r)^N)/r > K + Y_0 \qquad (1)$$

This expression implies that people who attend school (a) anticipate higher gains than those who do not attend; (b) anticipate working longer after completing school; and (c) face relatively low direct and opportunity costs of schooling (Heckman et al. 1999).

The foregoing expression explains why more academically able persons attend school and acquire more years of schooling than do their less able counterparts. These persons acquire new skills more efficiently and as a result experience a larger increase in their productivity as a result of their education. Young people also should be more likely to attend school than older persons for two reasons. First, they have more years left in their working lives during which they can realize a return on their investment. Second, they have less labor market experience and can not

earn as much if they were to go to work. The expression given in (1) also implies that public subsidies of education should increase enrollments in schooling because they lower an individual's cost of schooling. Such subsidies should encourage persons to enroll in school who would not have otherwise attended school, because their anticipated gains from schooling, B_i, are relatively low, or they are older, or they face a relatively high opportunity cost of schooling.

The familiar forces of supply and demand for workers with differing levels of schooling influence the decisions of individuals to attend school. If schooling is a good investment (i.e., the inequality given by (a) holds), more persons attend school. Because of the increase in the supply of better-educated workers, the prevailing wages for these workers decline and therefore so does the gain from schooling, B_i. As the gain from schooling declines, enrollment rates also decline. In this way, market forces determine school enrollment.

We observe an example of this adjustment process in the United States during the 1970s, when young college educated workers experienced a marked decline in their relative earnings. These individuals were from a large, well-educated birth cohort that entered the workforce at the same time that labor force participation rates for women were increasing rapidly. The increase in supply pushed down their earnings. A similar pattern was observed in Korea and Japan during the 1980s, when the ratio of college-educated to high school educated workers' earnings declined (Kim and Topel 1995).

The decision to invest in skills on-the-job involves the same cost-benefit analysis as that given by expression (1) above. The difference between the decisions to invest in schooling and in on-the-job training is that employee and employer interests are not necessarily the same. When the skills that workers acquire on the job are easily transferred to other employers, the incentives of firms to invest in their employees' skills are greatly diminished. The employer can profit from its training investments only if the employee stays with the firm. In order for an employer to have sufficient incentive to invest in employee skills, it needs some device that ties the worker to the firm. One way that companies can foster long-term relationships with their employees is to offer them some form of deferred compensation.

Another solution to the problem of providing on-the-job training to employees is for the worker to pay for the training. In principle, an employee could sign a contract in which she agrees to compensate the employer for training costs if she were to leave prior to some specific date. But another way to achieve this outcome is for the employee to pay for the training by accepting a lower salary during her early years on the job. This outcome would occur if essentially two market transactions take place when a firm hires a worker. The first transaction is the familiar one in which an individual sells her time for a wage. The second transaction results because workers seek training opportunities from employers (Rosen 1972). They buy this training from employers by accepting lower pay. Accordingly, the wages and salaries that we observe workers receiving are the difference between the value of their time and initial skills that they bring to the workplace minus the cost of the training provided by the employer.

3. *Sources of Training in the Private Sector*

There is a great deal of information about the amount of schooling obtained by people in countries throughout the world. In the United States, the web pages for the US Departments of Education and of Labor include a wealth of information on school enrollment, educational attainment, and academic performance by different groups in the population. By contrast, much less is known about sources of training outside of school. Estimates of the amount of training acquired on-the-job usually are imprecise.

There are several reasons why we do not know enough from existing data sources about the incidence and intensity of vocational training received by the workforce. First, most data sources contain only unrefined measures of the incidence, the source, and duration of training as reported by the employee. These data sources do not include measures of the costs of training other than the employee's wage. Even less common are employer reports of training activity that are representative of the experiences of the workforce. Further, if more effort were made to survey employers about their training expenditures, there remains the problem that many firms do not keep separate accounts on the resources spent on employee training.

A second reason that we do not know as much about on-the-job training as we do about schooling is that such training is conceptually difficult to measure. If firms provide training in the context of a formal program, it is relatively easy to characterize the content of the program and to measure the number of hours spent in training and the dollars spent on the program. However, much private sector training is provided informally, especially in the United States (Lynch 1994). Employees acquire new skills by trial and error, by watching their peers and supervisors perform their jobs, or while they are mentored by other employees. Such training represents an investment, because the employer incurs the costs associated with a new employee's lower productivity. These costs include the wages employers pay employees to shadow other workers, the lost output associated with the time that other workers spend away from their jobs, and the lost output associated with employee errors.

In one of the few large surveys of employers, US employers reported that only 12 percent of the training

that they provided their most recent hires during their first three months on the job occurred in a formal setting. The majority of time in training occurred while the employee was on the job (Barron et al. 1989). Surveys of representative samples of the US labor force also underscore the importance of informal training in the workplace. Among individuals who responded to special supplements of the US Bureau of the Census' Current Population Surveys (CPS) and who said that they needed specific skills in order to qualify for their current (or last) job, 47 percent reported that they acquired this training informally either on another job with the same employer or from a previous employer. Further, among those reporting that they had acquired training while in their current jobs, 37 percent said that those skills had been acquired informally while on the job (Ashenfelter and LaLonde 1997).

4. *The Incidence of Skill Training in the Workplace*

In spite of existing data sources, do we know roughly how often and how much training workers acquire after they leave school? Vocational training is relatively common. In the US for example, the CPS indicates that a majority of workers are employed in jobs that require specialized training. Among these workers, 41 percent reported that they had received additional training while in their current job.

An important and consistent finding in the literature on the incidence of training is that there is a strong positive correlation between an individual's formal schooling and whether she reports having received on-the-job training (Lillard and Tan 1992; Lynch 1992; Altonji and Spletzer 1991). This relationship between worker skills and the propensity to receive training is not unique to the United States. Studies of worker training in Great Britain and Germany also reveal a positive correlation between employees' formal schooling and whether they have received formal on-the-job training (See Nickell 1982; Greenlaugh and Stewart 1987; Booth 1991; and Pischke 1996). These findings hold especially for formal company programs, and training received off the job but paid for by the employer. The relationship between schooling and the incidence of skill training appears to be less strong when the training is provided informally. But, this result may simply underscore the difficulty we have in identifying and measuring informal training.

The positive relationship between schooling and the receipt of training suggests that training is more productively provided to more skilled or academically able people. In the context of expression (1), research indicates on-the-job training is more productive when firms provide it to individuals with larger gains (B_i) from schooling. Studies show that even among persons who have attained similar levels of schooling, the better educated among them receive more training (Altonji and Spletzer 1991). One nationally representative US survey found that less than 12 percent of young economically disadvantaged persons reported receiving vocational training during the previous 18 months. By comparison, the percentage of young adults in the population at large that reported receiving training during the same period was approximately 25 percent (Lillard and Tan 1992).

The strong complementarity between workers' prior skills and on-the-job training also has implications for workforce policy. People with limited or poor quality schooling are likely to receive limited additional training once they enter the labor force. Governments can not expect that private firms will compensate for deficiencies in the public education system by providing training in basic skills to their employees. Instead, research suggests that employers would increase the incidence of skill training if the educational attainment and general skills of the workforce rose.

5. *Estimates of the Amount Invested in Training*

Although the available measures of training investments are not very precise, it is still possible to estimate the amount invested in training each year. The most direct approach is to add together the value of the time that workers spent being trained or training others plus the resource costs associated with providing the training (Mincer 1994). This approach requires detailed information on the employees' use of time. On occasion such information is collected from workers in the form of a diary, in much the same way that government statistical agencies collect information for consumer expenditure surveys. Given the costs of gathering this type of data it is not often used to estimate the cost of training on an economy wide basis.

A less expensive approach for estimating the annual cost of on-the-job training is to infer the amount of training received by employees from the rate of their earnings growth during their careers (Mincer 1962). This inference relies on an important empirical regularity. The wages and earnings of individuals rise with the amount of labor force experience that they have acquired, but rise at a decreasing rate. When individuals are young, their wages and salaries rise relatively rapidly as they acquire more work force experience. But as they move into middle age the rate of growth in their earnings slows and for some groups stops all together. This rise in earnings indicates that young workers become more productive as they get older.

If we assume that all of the increase in workers' earnings results from training received on-the-job during their careers, and if we assume that investments

in training earn a 'normal' rate of return, then we can infer the total investment in private training each year from the growth in workers' earnings. In keeping with these assumptions, several studies report that employees' wage growth is largest when they report that they are receiving training in their current positions. As they begin to report that they are receiving less training in their current jobs, their wage growth also slows (Brown 1989). Mincer's and Higuchi's (1993) study of US and Japanese manufacturing industries finds that workers in industries in which firms provide more training also have earnings that rise more rapidly with years of service. In another study of professional employees in a large US manufacturing firm, about 18 percent of the growth of employees' earnings is explained by participation in the company's formal on-the-job training programs (Bartel 1992).

If workers receive training that raises their general skills, the foregoing approach probably overstates private investments in skill training. There are other reasons that workers' earnings grow during their careers besides training. For example, workers change jobs frequently, especially early in their careers, in order to obtain better pay. This 'job matching' process leads to higher worker productivity as workers' skills become better matched with the tasks demanded by employers. But the resulting rise in worker productivity does not come about from investments in training, but rather from investments in 'job search.'

By contrast, the indirect approach to estimating annual training investments could understate the total investment in training if some of the skills that workers acquire are 'firm-specific.' These are skills that raise workers' productivity with their current employer, but not elsewhere. Because workers can not transfer these skills to another firm, it is more likely that the employer is willing to invest in training. Under these circumstances, the wage gains from training should be smaller than the productivity gains. This gap between workers' wage gains and their productivity gains indicates that the employer receives a return on its investment in training. Among the few studies that examine the relationship between training and productivity, at least two of them suggest that the effect on worker productivity of training received during the first few months on the job is twice as large as its effect on wages (Barron et al. 1989; Bishop 1994). This finding suggests that a significant component of vocational training may involve 'firm-specific' skills provided by the employer.

Studies of on-the-job and vocational training in the United States suggest that both the direct and indirect approaches yield similar estimates of annual investments in training. According to these studies, the annual cost of vocational training amounts to between $150 and $200 billion per year. By comparison, the annual costs of formal schooling in the US, including the forgone earnings while individuals are in school, have been estimated at around $500 billion dollars.

6. *The Impact of Training on Workers' Earnings*

Many studies find a significant positive correlation between the incidence and the amount of training received by employees and their wages. This correlation might indicate that on-the job training yields positive returns. But it also could simply indicate, as discussed above, that individuals who are more productive and highly paid also are more likely to receive training from their employers. Distinguishing between these two hypotheses is difficult. Employers do not provide training randomly to their employees nor do workers randomly acquire training on their own. However, studies that attempt to address this difficulty continue to find a positive relationship between measures of the incidence and duration of training and workers' wages. Research suggests that the gross returns to wages from a year's worth of vocational training is approximately 10 percent per year or more (Mincer 1994).

This evidence on the impact of skill training suggests that the returns from on-the-job training are comparable if not larger than the returns from formal schooling. One explanation for this finding is that despite analysts' best efforts, they still have not satisfactorily accounted for unobserved attributes that simultaneously influence wages (or productivity) and the propensity to receive training. There are several reasons, however, to expect that the returns from skill training to be larger than the returns from formal schooling. First, the returns from formal schooling may be lower than the returns from training because some schooling costs probably are better characterized as consumption instead of as an investment. Second, because workers acquire some specific skills and at the same time may leave the firm, the returns from training need to be larger than the returns from schooling in order to compensate both the worker and the employer for the risk associated with turnover.

Finally, as new technologies are introduced some skills may become obsolete. One study suggests that the value of workers' vocational skills may depreciate by as much as 10 percent per year (Lillard and Tan 1992). As a result, if workers' skills are likely to depreciate, the returns from vocational skills must be larger in order for there to be sufficient incentive to invest in training.

7. *Concluding Remarks*

Increased interest in the incentives to invest in vocational skills has coincided with several economic developments during the last two decades of the twentieth century. First, the rise in earnings inequality in the United States and Great Britain appears prompted in part by a decline in employers' demand for the services of relatively unskilled workers (Katz and Murphy 1992). The long-term prospects of many

of these individuals is poor because students in these countries appear to end their formal schooling less skilled and ready to learn than their counterparts in other industrialized nations (Berg 1994). Second, a large number of workers displaced from traditional sectors of industrialized economies have suffered long-term earnings losses (Jacobson et al. 1993). As these displacements spread to the services sectors, interest in the feasibility of retooling such workers has increased. Finally, the low unemployment rates during the late 1990s in North America have pressured employers to put greater emphasis on training their existing workers rather than to expect to be able to hire employees with the required skills.

Some commentators and researchers argue that these developments require attention from the public sector because employers and their employees lack adequate incentives to invest in skill training (Lynch 1994). To be sure, as this article has described, a well functioning competitive labor market provides incentives for workers to acquire and their employers to provide skill training by compensating workers with higher wages and firms with increased profits. Individuals face similar incentives when deciding whether to acquire more schooling. But there may be instances when these incentives are insufficient. Imperfect capital markets may restrict access to funds, which prevent individuals and firms from making otherwise productive investments in skills. These instances also arise when vocational skills can be easily transferred from one employer to another. The possibility that employers can poach other firms' employees diminishes incentives to invest in employee training. Likewise, imperfect or asymmetric information about workers' skills also may reduce incentives to invest in vocational training. Few studies address this possibility, but one that does suggests that skills are not fully 'portable' at least during the first year on the job (Bishop 1994). If it is difficult for workers to reveal their skills to a potential employer, employees may invest less in new skills than they would otherwise.

The merits of policies that require the public sector to play a role in private training decisions depend on whether companies and their employees underinvest in training. Such a view remains open for debate. As discussed above, there are several reasons why such a debate will be difficult to resolve. First, measures of vocational training tend to be unrefined and often not comparable among studies of firms in the same country, much less studies of different countries. Second, some components of training, especially informal on-the-job training, are conceptually difficult to measure. Evidence discussed here indicates that such informal training is an important source of training, especially in the United States. Finally, even if researchers concluded there has been too little investment in vocational training in industrialized economies, the conceptual difficulties associated with measuring different types of training indicate that it will be hard to enforce employer mandates to provide more training (Brown 1990).

Educational Assessment: Major Developments

The role of assessment and evaluation in education has been crucial, probably since the earliest approaches to formal education. However, change in this role has been dramatic in the last few decades, largely due to wider developments in society. The most dramatic change in our views of assessment is represented by the notion of assessment as a tool for learning. Whereas in the past, we have only seen assessment as a means to determine measures and thus certification, there is now a realization that the potential benefits of assessing are much wider and impinge on all stages of the learning process. In this article, we will outline some of the major developments in educational assessment, and we reflect on the future of education within powerful learning environments, where learning, instruction, and assessment are fully integrated.

1. *Definition of the Concept*

Much has been written about assessment, measurement, and evaluation in educational practice. However, there are different meanings and it is necessary to draw as clear a distinction as possible between these three different concepts. In this context, semantic distinctions embedded in the literature are considered. What measurement, assessment, and evaluation have in common is the operation of testing. Each commonly (but not always) makes use of tests, but none of the three operations is synonymous with testing. Moreover, the types of the instruments used for each of the three operations may be different (Fig. 1).

Figure 1
Relationships between the most commonly used different concepts in educational assessment

Worthen and Van Dusen (1991) define 'measurement' as the process of making observations about some attribute or characteristic of a person, a behavior, an event, or even an object, using clearly specified procedures to translate those observations into quantifiable or categorical form. Educational measurement is broader than educational testing. In addition to the fact that measurement frequently employs tests, it can also employ instruments, checklists, and other methods that are not considered as testing tools. However, measurement is rarely undertaken for its own sake. It is a basic research procedure that may be a component of both assessment and evaluation. Measurement itself places no value on what is measured or on the results of the measurement process.

In evaluation, quite the opposite is the case. The major attributes studied in evaluation are precisely chosen because they represent educational values. Objectives are educational values and they define what is sought to develop in learners as a result of exposing them to a set of educational experiences. Evaluation literature provides multiple perceptions of evaluation, differing in level of abstraction and in their descriptive or judgmental character. At the most general level, evaluation has been defined as a formal appraisal of the quality of educational phenomena (Popham 1988), as a determination of goal achievement, or as a measurement of merit (Scriven 1967). These definitions can be characterized as judgmental. More elaborated definitions are given, describing evaluation as 'data-collection of education materials for providing information for decision-makers.' These definitions have a more descriptive character. The definition of evaluation as 'an act of collecting systematic information regarding the nature and quality of educational objects' (Nevo 1995) combines description and judgment.

Closely related to the notion of measurement and evaluation is the term 'assessment.' According to Worthen and Van Dusen (1991), 'assessment' refers to

the process of transferring test scores—or results of alternative means of appraising learning outcomes—into statements about student performance. Such learner assessment is built on the bedrock of measurement's value neutrality, but its capstone is evaluation whenever the assessment data contain implicit judgments of the merit or worth of the performance of individuals or groups of students.

The difference between assessment and evaluation is also made clear by Scriven (1967). 'The goal of evaluation is that of providing answers to significant evaluation questions (e.g., assessing student performance), whereas its roles refer to various ways in which those answers are used (e.g., using these achievement data to determine the adequacy of the curriculum).' The distinction made by Nevo (1995) between 'primary' and 'secondary' functions of student evaluation is relevant here. Primary functions of assessment are those in which the student is the object of the evaluation and it is intended to provide information for the improvement of learning to certify individual accomplishment. Secondary functions of student assessment are those where the object of evaluation is not the student, but rather the teacher or the school or some other object, and the results of the evaluation are used for school accountability, or to control students or motivate them. Nevo uses the British synonym of 'student assessment,' for student evaluation. He also points at the difference between this British use of student assessment, and the recent distinctions between 'student testing' and 'student assessment,' referring to performance testing and authentic testing.

2. *Functions and Criteria of Student Assessment*

One of the main issues in student assessment is clarity about the type of instructional decision that is supported by the assessment procedure. Nitko (1989) identifies four types of instructional decisions that are supported by tests. These are discussed below.

2.1 *Placement Decisions*

This is deciding in which instructional sequence or at what level in the instructional sequence a student should begin in order to avoid unnecessary repetition of what is already known, and to allow the more rapid attainment of new goals. Placement or prior knowledge state tests are given before a student begins a unit of instruction. They may focus on the prerequisite knowledge and skills for proposed learning or on the outcome knowledge and skills to determine whether students have already attained the desired outcome of the instruction. Thus, instructors use prior knowledge state tests to place students in instructional modes by (a) determining the degree to which prerequisite entry behaviors or skills are present or absent, (b) determining entering mastery of course objectives, and also for (c) matching students to alternative instructional modes, based on student characteristics.

2.2 *Monitoring Decisions*

This is deciding (a) whether students are learning appropriately, and (b) whether the assigned learning activity is working effectively, or a different activity should be assigned. So-called progress assessments or assessments of growth are the instruments for the assessment of a student's progress toward the final learning objectives. Progress assessments provide feedback to students on how their learning is progressing and can lead to the (formative) decision that there is a need to remediate or relearn a certain instructional unit. Progress assessments, taken during instruction, are used by instructors to (a) choose or modify subsequent learning activities, (b) prescribe remediation of group or individual deficiencies, and (c) provide on-going feedback to the student for the purpose of directing advanced or remedial study.

2.3 *Attainment Decisions*

This involves deciding, at the end of a particular instructional segment, whether a student has attained the desired instructional goals. Final tests are used for certifying student learning and evaluating teacher effectiveness.

2.4 *Diagnostic Decisions*

This is deciding which learning outcomes a student has not acquired and the probable cause(s) of the failure to acquire them, in order to remediate or correct incomplete or erroneous prior learning. Diagnostic assessments are designed to provide specific information on individual learning deficiencies and misunderstandings. When prior knowledge state assessments, progress assessments, and final assessments are designed and interpreted properly they can also provide information of a diagnostic nature since students and teachers can use this information in order to regulate learning processes.

Another issue in student assessment relates to criteria setting. A distinction can be made between norm-referenced and criterion-referenced tests. Norm-referenced tests determine the level of students relative to some groups (e.g., class, school, age-group), whereas criterion-referenced tests determine the level of a student relative to some predetermined criterion set by the curriculum, the teacher, or some authority. Nevo (1995) mentions that while norm-referenced tests are suitable for selection procedures, criterion-referenced tests are the tests schools predominantly need.

3. Innovations in Assessment

3.1 Consequences of the Developments in Society

Economic and technological change, bringing with it significant changes in the requirements of the labor market, poses increasing demands on education and training. For many years, the main goal of education has been to make students knowledgeable within a certain domain. Building a basic knowledge store was the core issue (Dochy and McDowell 1997). Students taking up positions in modern organizations in the twenty-first century need to be able to analyze information, to improve their problem-solving skills and communication, and to reflect on their own role in the learning process. People increasingly have to be able to acquire knowledge independently and use this body of organized knowledge in order to solve unforeseen problems. As a consequence, education should contribute to the education of students as lifelong learners.

3.2 Paradigm Change: From Testing Towards Assessment

Many authors (Dochy and McDowell 1997) have pointed out the importance of instruction to promote students' abilities as thinkers, problem-solvers, and inquirers. Underlying this goal is the view that meaningful understanding is based on the active construction of knowledge and often involves shared learning. It is argued that a new form of education requires reconsideration about assessment (Dochy et al. 1999). Changing towards new forms of learning, with a status quo for evaluation, undermines the value of innovation. Students do not invest in learning that will not be honored. Assessment is the most determining factor in education for the learning behavior of students. Traditional didactic instruction and traditional assessment of achievement are not suited to modern educational demands. Such tests were generally designed to be administered following instruction, rather than to be integrated with learning. As a consequence, due to their static and product-oriented nature, these tests not only lack diagnostic power but also fail to provide relevant information to assist in adapting instruction appropriately to the needs of the learner. Furthermore, standard test theory characterizes performance in terms of the difficulty level of response choice items and primarily focuses on measuring the amount of declarative knowledge that students have acquired.

This view of performance is at odds with current theories of cognition. Achievement assessment must be an integral part of instruction, in that it should reflect, shape, and improve student learning. Assessment procedures should not only serve as a tool for crediting students with recognized certificates, but should also be used to monitor progress and, if needed, to direct students to remedial learning activities. The view that the evaluation of students' achievements is something which happens at the end of the process of learning is no longer widespread; assessment is now represented as a tool for learning (Dochy and McDowell 1997).

Birenbaum and Dochy (1996) describe this movement as a paradigm change between two cultures in the measurement of achievement and relate this to developments in the learning society. In the traditional so-called testing culture, instruction and testing are considered to be separate activities. Instruction is the responsibility of the teacher, whereas testing is the responsibility of the psychometric expert, who can use elaborate procedures for test development and sophisticated psychometric models for the analysis of test responses. The work of such experts within testing agencies was stimulated by the demand for objectivity and fairness in testing and a high level of standardization where important decisions were to be based on test scores. Stemming from such demands, common tools for assessment in education were easy-to-score items such as multiple-choice items and true/false items. The testing culture fits well with the traditional approach to education where teaching is seen as an act of depositing the content which students receive, memorize, and reproduce. The most efficient way of testing this process is by standardized tests delivered by external testing agencies.

The changing learning society has generated the so-called assessment culture as an alternative to the testing culture. The assessment culture strongly emphasizes the integration of instruction and assessment. Students play far more active roles in the evaluation of their achievement. The construction of tasks, the development of criteria for the evaluation of performance, and the scoring of the performance may be shared or negotiated among teachers and students. The assessment takes all kinds of forms such as observations, text- and curriculum-embedded questions and tests, interviews, performance assessments, writing samples, exhibitions, portfolio assessment, and project and product assessments. Several labels have been used to describe subsets of these alternatives, with the most common being 'direct assessment,' 'authentic assessment,' 'performance assessment,' and 'alternative assessment.'

3.3 New Methods of Assessment

Investigations of new approaches (e.g., Birenbaum and Dochy 1996) illustrate the development of more 'in context' and 'authentic' assessment. Nisbet (1993) defines the term authentic assessment as 'methods of assessment which influence teaching and learning positively in ways which contribute to realizing educational objectives, requiring realistic (or "authentic")

tasks to be performed and focusing on relevant content and skills, essentially similar to the tasks involved in the regular learning processes in the classroom' (p. 35).

Assessment of such 'authentic' tasks is highly individual and contextualised. The student gets feedback about the way he or she solved the task and about the quality of the result. Evaluation is given on the basis of different 'performance tasks,' performed and (reviewed) assessed at different times. The evaluation criteria have to be known in advance. When students know the criteria and know how to reach them, they will be more motivated and achieve better results. This form of evaluation gives a more complete and realistic picture of a student's ability (achievement). It not only evaluates the product, but also evaluates the process of learning. Students get feedback about their incorrect thinking strategies. Within the new forms of 'new assessment,' much attention is paid to authentic problem-solving, case-based exams, portfolios, and the use of peer and self-assessment. (Birenbaum and Dochy 1996).

In traditional education, the question 'who takes of the exam and who defines the criteria?' is seldom asked. Most of the time, it is the teacher. New forms of education do pose this question. Student themselves, other students, or the teacher and students together, are responsible for assessment. The type of student self-assessment referred to most frequently in the literature is a process which involves teacher-set criteria and where students themselves carry out the assessment and marking. Another form of student self-assessment is the case where a student assesses herself or himself, on the basis of criteria which she or he has selected, the assessment being either for the student's personal guidance or for communication to the teacher or others. According to Hall (1995) there are two critical factors for genuine self-assessment: the student not only carries out the assessment, but also selects the criteria on which the assessment is based. Similarly, peer assessment can indicate that fellow students both select the criteria and carry out the assessment. Any situation where the tutor and students share in the selection of criteria and/or the carrying-out of the assessment is more accurately termed co-assessment (Hall 1995). However, it is still frequently the case that teachers control the assessment process, sometimes assisted by professional bodies or assessment experts, whereas students' assessments and criteria are taken seriously but considered to be additional to the assessment undertaken by the teacher or professor rather than replacing it. Implementing forms of self-, peer, and co-assessment may decrease the time-investment professors would otherwise need to make in more frequent assessment (Dochy et al. 1999). In addition to that advantage, using these assessment forms assists the development of certain skills for the students, e.g., communication skills, self-evaluation skills, observation skills, and self-criticism.

4. *Assessing New Assessment Forms*

Judgments regarding the cognitive significance of an assessment begin with analyses of the cognitive requirements of tasks as well as the ways in which students try to solve them. Two criteria by which educational and psychological assessment measures are commonly evaluated are validity and reliability. One can say that based on these criteria the results above are not yet consistent and, depending upon the assessment form, there is a larger or smaller basis to state that the evaluation is acceptable.

It is however important to note that Birenbaum (1996) mentions that the meaning of validity and reliability has recently expanded. Dissatisfaction with the available criteria, which were originally developed to evaluate indirect measures of performance, is attributed to their insensitivity to the characteristics of a direct assessment of performance. The most important element of new assessment models is the reflection of the competencies required in real-life practice. The goal is to ensure that the success criteria of education or training processes are the same as those used in the practice setting. Hence, as notions of fitness of purpose change, and as assessment of more qualitative areas are developed, the concepts of validity and reliability encompassed within the instruments of assessment must also change accordingly. This means that we should widen our view and search for other and more appropriate criteria. It should not be surprising that a new learning society and consequently a new instructional approach and a new assessment culture cannot be evaluated solely on the basis of the pre-era criteria.

5. *Validity-related Issues*

Although performance assessment appears to be a valid form of assessment, in that it resembles meaningful learning tasks, this measure may be no more valid than scores derived from response choice items. Evidence is needed to ensure that assessment requires the high-level thought and reasoning processes that they were intended to evoke.

The authors of the 1985 Standards define test validity as 'a unitary concept, requiring multiple lines of evidence, to support the appropriateness, meaningfulness, and usefulness of the specific inferences made from test scores' (AERA, APA, NCME 1985, p. 9). All validity research should be guided by the principles of scientific inquiry reflected in construct validity.

Within the construct validity framework, almost any information gathered in the process of developing and using an assessment is relevant when it is evaluated against the theoretical rationale underlying the proposed interpretation and inferences made from test scores (Moss 1992). Thus, validation embraces all the experimental statistical and philosophical means

by which hypotheses are evaluated (Messick 1994). Validity conclusions, then, are best presented in the form of an evaluative argument (Cronbach 1989) that integrates evidence to justify the proposed interpretation against plausible alternative interpretations.

Kane's argument-based approach is in line with Cronbach's view on validity. According to Kane (1992), to validate a test-score interpretation is to support the plausibility of the corresponding interpretative argument with appropriate evidence (a) for the inferences and assumptions made in the proposed interpretative argument, and (b) for refuting potential counter arguments. The core issue is not that we must collect data to underpin validity, but that we should formulate transparent, coherent, and plausible arguments to underpin validity.

Authors like Kane and Cronbach use validity principles from interpretative research traditions, instead of psychometric traditions, to assist in evaluating less standardized assessment practices.

Other criteria suggested for measuring validity of new assessment forms are the transparency of the assessment procedure, the impact of assessment on education, directness, effectiveness, fairness, completeness of the domain description, practical value, and meaningfulness of the tasks for candidates, and authenticity of the tasks. According to Messick (1994), these validation criteria are, in a more sophisticated form, already part of the unifying concept of validity, which he expressed in 1989. He asserted that validity is an evaluative summary of both evidence for and the actual as well as potential consequences of score interpretation and use. The more traditional conception of validity as 'evidence for score interpretation and use' fails to take into account both evidence of the value implications of score interpretation and the social consequences of score use.

Messick's unifying concept of validity encompasses six distinguishable parts—content, substantive, structural, external, generalizability, and consequential aspects of construct validity—that conjointly function as general criteria for all educational and psychological assessment. The content aspect of validity means that the range and type of tasks used in assessment must be an appropriate reflection (content relevance, representativeness) of the construct-domain. Increasing achievement levels in assessment tasks should reflect increases in expertise of the construct-domain. The substantive aspect emphasizes the consistency between the processes required for solving the tasks in assessment, and the processes used by domain-experts in solving tasks (problems). Further, the internal structure of assessment— reflected in the criteria used in assessment tasks, the interrelations between these criteria, and the relative weight placed on scoring these criteria—should be consistent with the internal structure of the construct-domain. If the content aspect (relevance, representativeness of content, and performance standards) and the substantial aspect of validity is guaranteed, score interpretation based on one assessment task should be generalizable to other tasks assessing the same construct. The external aspect of validity refers to the extent that the assessment scores' relationship with other measures and non-assessment behaviors reflect the expected high, low, and interactive relations. The consequential aspect of validity includes evidence and rationales for evaluating the intended and unintended consequences of score interpretation and use (Messick 1994).

In line with Messick's conceptualization of consequential validity, Frederiksen and Collins (1989) proposed that assessment has 'systematic validity' if it encourages behaviors on the part of teachers and students that promote the learning of valuable skills and knowledge, and allows for issues of transparency and openness, that is to access the criteria for evaluating performance. Encouraging deep approaches to learning is one aspect which can be explored in considering consequences. Another is the impact which assessment has on teaching. Dochy and McDowell (1997) argue that assessing high-order skills by authentic assessment will lead to the teaching of such high-order knowledge and skills.

With today's emphasis on high-stakes assessment, two threats to test validity are worth mentioning: construct under-representation and construct-irrelevance variation. In the case of 'construct-irrelevance variation,' the assessment is too broad, containing systematic variance that is irrelevant to the construct being measured. The threat of 'construct under-representation' means that the assessment is too narrow and fails to include important dimensions of the construct being measured (Dochy and Moerkerke 1997).

5.1 Special Points of Attention for New Assessment Forms

The above implies in our view that other criteria suggested for measuring validity of new assessment forms will need to be taken into account, i.e., the transparency of the assessment procedure, the impact of assessment on education, directness, effectiveness, fairness, completeness of the domain description, practical value and meaningfulness of the tasks for candidates, and authenticity of the tasks.

Authentic assessment tasks are more sensitive to construct under-representation and construct-irrelevance variation, because they are often loosely structured, so that it is not always clear to which construct-domain inferences are drawn. Birenbaum (1996) argues that it is important to specify accurately the domain and to design the assessment rubrics so they clearly cover the construct-domain. Messick (1994) advises the adoption of a construct-driven approach to the selection of relevant tasks and the development of scoring criteria and rubrics, because

it makes salient the issue of construct under-representation and construct-irrelevance variation.

Another difficulty with authentic tasks, with regards to validity, concerns rating authentic problems. The literature reveals that there is much variability between raters in scoring the quality of a solution. Construct under-representation in rating is manifested as an omission of assessment criteria or ideosyncratic weighting of criteria such that some aspects of performance do not receive sufficient attention. Construct-irrelevance variation can be introduced by the rater's application of extraneous, irrelevant, or idiosyncratic criteria. Suggestions for dealing with these problems in the literature include constructing guidelines, using multiple raters, and selecting and training raters. However, even within communities of problem-solvers, there is no common sense about the solution to an ill-defined problem. Since universally accepted (objective) criteria do not exist, argumentation can be an important means to judge the quality of solutions for an ill-structured problem. Therefore, product and process quality criteria need to be identified, defined, and communicated to candidates and raters (Dochy and Moerkerke 1997).

6. *Reliability-related Issues*

Reliability in classical tests is concerned with the degree in which the same results would be obtained on a different occasion, in a different context, or by a different assessor. Inter- and intra-rater agreement is used to monitor the technical soundness of performance assessment rating. However, when these conventional criteria are employed for new assessments (for example using authentic tasks), results tend to compare unfavorably to traditional assessment, because of a lack of standardization of these tasks.

The unique nature of new forms of assessment has affected the traditional conception of reliability, resulting in the expansion of its scope and a change in weights attached to its various components (Birenbaum 1996). In new assessment forms, it is not about achieving a normally distributed set of results. The most important question is to what extent the decision 'whether or not individuals are competent' is dependable. Differences between ratings sometimes represent more accurate and meaningful measurement than would absolute agreement. Measures of inter-rater reliability in authentic assessment, then, do not necessarily indicate whether raters are making sound judgment and do not provide bases for improving technical quality. Suen et al. (in press) argue that the focus on objectivity among raters as a desirable characteristic of an assessment procedure leads to a loss of relevant information. In high-stake decisions, procedures which include ways of weighing high-quality information from multiple perspectives may lead to a better decision than those in which information from a single perspective is taken into account. Measuring the reliability of new forms of assessment stresses the need for more evidence in a doubtful case, rather than to rely on making inferences from a fixed and predetermined set of data.

In line with these visions on reliability is Moss' idea (1992) about reliability. She asserts that a hermeneutic approach of 'integrative interpretations based on all relevant evidence' is more appropriate for new assessment because it includes the value and contextualized knowledge of the reader, than the psychometric approach that limits human judgment 'to single performances,' results of which are then aggregated and compared with performance standards.

7. *Conclusion: Future Research and Developments*

The assessment culture leads to a change of our instructional system from a system that transfers knowledge into students' heads to one that tries to develop students who are capable of learning how to learn. The current societal and technological context requires education to make such a change. The explicit objective is to interweave assessment and instruction in order to improve education. Although promising results have been reported, the first attempts to introduce new assessment procedures have not been entirely positive. Madaus and Kellaghan (1993) reported problems with the organization, time, and costs of assessment programs. A number of lessons can be learned from the early applications of new assessment programs.

Firstly, one should not 'throw the baby out with the bath water.' Objective tests are very useful for certain purposes, such as high-stake summative assessment of an individual's achievement, although they should not dominate an assessment program. Increasingly, measurement specialists recommend so-called balanced or pluralistic assessment programs, where multiple assessment formats are used (Birenbaum 1996). There are several motives for these pluralistic assessment programs: a single assessment format cannot serve several different purposes and decision-makers; and each assessment format has it own method variance, which interacts with people.

There is a need to establish a system of assessing the quality of new assessment and implement quality control. Various authors have recently proposed ways to extend the criteria, techniques, and methods used in traditional psychometrics (Kane 1992). Others, like Messick (1994), oppose the idea that there should be specific criteria, and claim that the concept of construct validity applies to all educational and psychological measurements, including performance assessment.

Further, there is a need for well-designed and well-evaluated heuristics, which would help teachers to implement and design high-quality new assessment procedures. Teachers need clear criteria for the development and use of assessment procedures, and easy-to-use techniques for quality improvement and quality control.

Surely, there is no one ideal assessment format for all cases. All assessment formats can have negative effects on teaching and learning. From this perspective, Frederiksen's criticism (1984) can be more broadly interpreted than simply as an exposure of the negative effects of multiple-choice items; it also shows that some aspects of any assessment may have negative as well as positive educational consequences. However, new assessment forms with their potential to develop and assess learning achievements which are congruent with contemporary views of the nature of knowledge and the needs of society for educated persons, is an avenue which we must continue to explore.

Educational Evaluation: Overview

In goal-directed human behavior, choosing between alternatives requires the assessment or the 'evaluation' respectively of the different possible behaviors. A rational choice can only be made when there is at least some factually based appraisal of each alternative's consequences. Thus an evaluation of former consequences of behavior ('experience') should always be the basis for rational decisions to keep the risks of unwanted consequences as low as possible. Trying to minimize the risks is also a question of ethics if other persons are affected by the consequences of an action as well. However, educational evaluation is realized in systems which are so complex that most evaluation attempts meet fundamental difficulties. Dealing with these problems requires not only scientific knowledge but also practical experience. This article can only give a general insight into some fundamental and methodological questions.

1. Fundamental Questions of Educational Evaluation

1.1 Definition of Evaluation

It is difficult to give a complete definition of an empirical construct. Rossi and Freeman (1993, p. 5), however, offer a formal definition: 'evaluation is the systematic application of social research procedures for assessing the conceptualization, design, implementation, and utility of social intervention programs.' Put differently, evaluators 'use social research methodologies to judge and improve the ways in which human services policies and programs are conducted, from the earliest stages of defining and designing programs through their development and implementation.' (Rossi and Freeman 1993, p. 5) This is a definition close to science. The more one gets involved in the everyday business of evaluation, the less important become special methods of the social sciences. Often, simple questionnaires or interviews can be helpful. Generally speaking, evaluation is about the systematic appraisal of alternative options of behavior. Anything beyond that depends on the respective field of application and the emphasis chosen by evaluators working there.

1.2 Concepts of Evaluation

Due to the many forms of evaluation, different concepts of evaluation have been developed; for an overview see Scriven (1991).

The following forms of evaluation can be distinguished:

Microevaluation (the focus is on individual aspects of the evaluated program) vs. *macroevaluation* (global results are of interest);
Internal evaluation (those responsible for the scheme evaluate the program themselves) vs. *external evaluation* (development of the program and its evaluation are separate);
Summative evaluation (the review of the results takes place after a scheme/program has been completed) vs. *formative evaluation* (a measure and its effect are constantly checked in order to optimize it).

All these models (as well as others) can be used as general schemata to prepare evaluation studies. However, in each individual case it needs to be considered which aspects are especially relevant. 'Model' in this sense means aid for structuring and can offer a first orientation. In practice most evaluation studies (and most of them are focused on practical issues) cannot be completely described with just one model because of the complexities in real life. Therefore several dimensions and evaluation criteria are required.

1.3 Aspects and Problems of Practical Evaluation

Instead of an 'ideal' definition (which would be impossible) or an ideal classification scheme, the multifaceted aspects and problems of real evaluation attempts are outlined. The following questions are discussed: What is evaluated where and with what purpose? Which direct and indirect costs arise during the evaluation? With what are the results compared?

Exemplary answers (see Table 1) are given to these questions for the Third International Mathematics and Science Study (TIMSS), where the mathematical and scientific achievements of students from selected years in primary schools and secondary schools have been compared internationally.

1.3.1 What can be evaluated? As evaluation serves to optimize both actions and decisions, the consequences of both need to be compared with each other, i.e., evaluated. Concerning the alternatives in the educational field, the following are especially important:

Objectives: e.g., the consequences of different curriculums for a school subject or a vocational training (see *Curriculum Evaluation*);
Conduct of individuals: e.g., different didactical approaches in one seminar;
Techniques and procedures: e.g., comparison of different teaching methods;
Programs: e.g., the results of a new program to reduce unemployment in young people;
Systems: e.g., international comparison of school achievement (see *School Effectiveness Research*).

Different aspects are often intertwined. If, for example, techniques are to be evaluated then different individuals (e.g., teachers) use these techniques. This

Table 1
Basic evaluation questions for TIMSS

1. **What?:** International comparison of the efficiency of schools with regard to the achievements of students in mathematics and science
2. **Where?:** Schools; more or less randomly chosen schools from the 45 participating countries
3. **Objectives?:** International comparison of school systems and evaluation of the national school system with regard to the international results
4. **Cost/Benefit?:** No explicit statements, but large expenses are justified if the evaluation improves political decisions that affect many people
5. **Comparisons?:** Curriculums, school lessons, students' achievement

makes separating the effects problematic and may even raise the question of an interaction between the teachers' personalities and the teaching methods. It might get even more complicated when some of the aspects mentioned above vary systematically, e.g., when different educational programs have different objectives. Consequently, the results have to be interpreted keeping that in mind.

1.3.2 Where can evaluation take place? Generally speaking, all educational and educational-psychological measures can be evaluated. These evaluation studies can take place at very different locations. Each confronts the evaluator with very specific problems:

Laboratories: e.g., a model school can be introduced to test different forms of tuition. This makes the work for the evaluator easier as both teachers and parents are more motivated. Nevertheless, it is problematic how far the results from the laboratory situation can be transferred to the real life situation. This is a methodological problem as internal and external validity cannot be maximized at the same time (see Scriven 1991).
Educational Institutions: e.g., schools, universities. They are most often the place where educationally relevant evaluation takes place. Often the psychologists need to be able to communicate and cooperate well as they are dependent on the support of the other people involved.
Educational Systems: the evaluation of larger reform models or the comparison of whole educational systems like TIMSS (see Beaton et al. 1996 and Mullis et al. 1998 for a US account, Baumert et al. 1997 and Baumert et al. 2000 for a German account). Even more than with individual organizations one has to anticipate that the objective of the measures might encounter opposition from some of the people involved.

1.3.3 What objectives can an evaluation have? Other than in science, evaluators cannot choose the objectives of their evaluations in practice themselves. Evaluations in practice usually aim at improving existing 'systems' (see *School Improvement*). The evaluator has to consider the needs of those affected by the consequences of the evaluation. Additionally, the evaluator can only help the principals and those affected by the evaluation's consequences to clarify the objectives. The evaluator might draw attention to facts that have so far not been considered or point out contrasting interests of different subgroups. Nevertheless, evaluators need to remain neutral to all parties as well as all alternatives that are to be evaluated (for further information see e.g., American Psychological Association 1992).

1.3.4 What costs arise? Evaluations are expensive. Those evaluations that are carefully planned, carried out, and appraised especially require full commitment from all those involved. 'Costs' in addition to the cost of financing include:

Doubts concerning the present situation: The fact of an evaluation being carried out might be seen as criticism and depreciation of the present teaching efforts;
Unrest for all those involved: The examination of measures one has got accustomed to and the introduction of new measures can often disturb the implicitness that is important for the success of teaching;
Impairment of the personal situation: A control of the effectiveness among the employees of an institution can upset their self-esteem and reputation;
Additional workload for all those involved;
Delay in time: especially if a measure could be implemented immediately without the evaluation and without the risk of a negative outcome;
Possible damage for those affected by the implemented measure, if for example a new way of teaching languages does not prove to be as effective as the old method.

These costs and disadvantages of evaluation are only acceptable if they are outweighed by the benefit. Thus evaluators do not only need to be competent in their field but also in convincing others of their project. Still, it would be asking too much to assume that society needs to finance evaluations for every important new measure—even if the outcome of the cost–benefit analysis is positive.

1.3.5 Comparing the results. The basis for evaluations is always the comparison of different alternatives. If there are several independent alternatives then their consequences can be compared directly with each other. In this case a *summative* evaluation is possible.

If just one action alternative can be evaluated then the appraisal can have different criteria:

Expectation of the participants ('the students have been satisfied with my classes');
Former situation ('my intervention has been a success as the climate in the class has improved');
Personal objective ('I have reached XXX');
External objective ('the desired improvement in mathematics was achieved by the new teaching method');
Standard with group-reference ('with this learning method results were achieved that are better than the average of the last course').

In all this cases a functional appraisal is possible, especially with the objective of a *formative* evaluation. It lacks, however, the possibility of deciding that this option is better than another one (and which one). The alternative chosen might even have been the comparatively worst option under the circumstances. Without an alternative this cannot be decided, even if the outcome was positive (this class was better than last year's).

Which methodological approach is chosen (appraisal of one alternative or a comparison of groups as in experimental designs) depends on the objectives of a study. Causality can only be demonstrated when different groups are compared. If the cost–profit relationship is assessed it might be sufficient to focus on one alternative, even if the result is less meaningful.

2. Science's Contribution to Evaluation Studies

2.1 Reasons for Employing Scientifically Trained Evaluators

Evaluations of all kind are present in work situations, e.g., a school principal giving a judgment about a teacher. Evaluations like this are frequently done and many professionals believed (and sometimes still do) that the use of science for evaluations is superfluous. In contrast to this stands the rising figure of scientists and graduates actually working in this field. The reasons for this should lie primarily in the aspects of technical competence and objectivity.

Experts should have at least some knowledge in critical areas like basic research as well as in methodology (for planning the design and editing the results statistically). In addition to that they should have a higher ability of analyzing the often complicated connections found in most evaluation studies.

The image of objectivity plays an important role especially in critical evaluation studies, e.g., the evaluation of politically significant reform plans which only get financed if there is a massive dissension between the different political groups. Even though scientists are usually independent of political programs and ideas, they still have their own social convictions as well as preferences for certain theories. Consequently, politicians tend to assign those evaluators to the task who they assume to be on 'their' side. This may lead to the image of evaluators who can be bought. Different evaluation studies of the same project leading to different results can make the situation even more difficult (a famous example was the discussion about the effects of the comprehensive school, see Leschinsky 1999).

2.2 Planning and Designing an Evaluation Study

A significant advantage scientists have is their familiarity with the design of studies that allow a comparison of the relevant groups. For the planning and implementation of scientific evaluation studies, it is furthermore important that before the data is ascertained it is clear how it will be analyzed.

The design should try to exclude as many disruptive factors as possible. As studies differ so much there is nothing like an 'ideal' design. Other than in pure research it is not always helpful to stick to the original design throughout the whole evaluation. Whenever a program that is being evaluated shows serious shortcomings then it needs to be corrected in the interest of those concerned, even if it might go against scientific principles.

Another difficulty may arise with the sample. For being able to generalize the results, it needs to be representative. It is, however, also the psychologist's duty not to deceive participants about the purpose of the study (see e.g., American Psychological Association 1992). The truth might deter some people ('The new method is probably only ideal for the very weak children but we also need good pupils in the study') which then has serious statistical consequences.

2.3 Evaluation Reports

Mostly, evaluation results only present a basis for further discussion for those having to make a decision. Thus it is especially important how the decision-making groups learn about the results.

Usually, scientists are not used to informing laypersons (politicians, journalists, teachers, etc.): Only short summaries can be easily understood and scientific jargon (e.g., using the subjunctive and avoiding clear positions) is not accepted. The report has to be written in such a way that laypersons can comprehend the results and recommendations by the evaluators.

Even more problematic are oral reports, especially when controversial issues are concerned. The evaluator can easily be turned into the agent of one position. At the same time, it ought to be part of the professional ethics of an evaluator that although one attacks the scientific position of a colleague, personal integrity should remain untouched.

For guidelines on scientific evaluation reports see, for example, Fink (1995).

3. Present State of and Outlook for Evaluation Studies

In the last years there has been a renewed evaluation trend; this also holds true for the educational sector. In both schools and universities, new projects have been realized. In times of recession and tight budgets no one is prepared to pay for something of which the benefit is unknown. The public experts want to be informed about the efficiency of these costly institutions. In the universities, evaluations so far have been national. Some countries have an established ranking system as can be found in the USA (for an overview see House 1993) or the UK, others, like Germany, do not. For schools this has been the TIMSS study on the international level.

Realistically, evaluation studies in the educational sector cannot have the same degree of meaningfulness as pure research studies. However, this is not the intention of these studies either. Evaluation has served its purpose when it has provided discussions about a 'best' measure or the 'ideal' design with a rational basis. For this objective, there is no better alternative.

Luckily, the demand for evaluation studies is rising. The acceptance for evaluations is increasing in the whole educational sector. Nevertheless, they are limited by tight public budgets.

Educational Innovation, Management of

Managing innovation in education (especially in schools) is a complex task for the principal, and also the staff, and often includes collaboration with outside partners. Innovations demand learning and are seldom neutral in the eyes of stakeholders, therefore they imply the understanding and handling of intertwined technical, political, and cultural perspectives.

1. Management

Management and leadership are not exactly the same thing, but many have noticed that for school leaders they tend to overlap. Leaders engage in mobilization, vision building, problem solving, and learning, whereas managers do the goal setting, facilitation, coordination, monitoring, and rewarding business. Both roles are clearly needed to facilitate innovation and change. There is a growing interest in that teachers now engage more in leadership roles among their peers.

2. Innovation

Innovations are programs, material, schemas, structures, etc., that promise to be new and better than the old ones. They denote the technical content of improvement. However, the generation, diffusion, and use of innovations are also political and entrepreneurial processes governed by their special rationalities (Fullan and Stiegelbauer 1991). Research had to learn by its own mistakes that there are technical, political, and cultural perspectives on innovations. Neglect of one or two of these still causes school reforms to fail (House and McQuillan 1998).

2.1 Technical Implementation of Innovations

Innovation as a technical concept originally belonged to the research, development and dissemination strategies of change (RDD) and a related approach advocating 'planned change,' both especially strong from the 1950s. Belief in expert-based, top-down change was founded on scientific positivism and models of rational decision making for implementation. It sometimes simplified the technical problem to ideas of 'teacher-proof' innovations. More sophisticated work within this tradition was synthesized in early work by Havelock (1969) in a system analysis-based view of the linkages and linking roles between providers and users of innovation. Out of this research about change, agent characteristics and training evolved. Increasing interest in the social psychology of organizations culminated in the organization devel-

opment movement of the 1950s–1970s. RDD strategies also incorporated T-groups and other group dynamic devices in order to change the climate of organizations, making staff more receptive to innovations. Teams or departments can still be sent to 'temporary systems' (Miles 1964), resorts where the regular system's norms and hierarchies cannot easily dominate and thereby allow the training of more creative relations. The problem of how learning from temporary systems can survive in the regular system always remains.

2.2 Political and Cultural Competition

The negotiation of interests and the legitimacy of authority are the focus of the political perspective. Strategies used by individuals or groups to serve their interests within an organization are called micropolitics. A school is fairly often informally run by a dominant coalition of teachers and the principal may be lucky to belong to it. Micropolitics is almost inevitably a part of management as a principal strives to achieve control of and commitment from the staff. When it is done with a hidden agenda, including, e.g., cooptation, and control of information flows, it is even more micropolitical. Micropolitic tensions often imply a gender aspect.

The cultural perspective rests on an image of community where values and shared meanings hopefully merge into cultural integrity. Contrary to issues within the political perspective, cultural issues are hardly negotiable, as their meaning may have deep roots in ideology or group identity. This is one of the reasons why control of the recruitment of organization members greatly facilitates common action.

The political definitions of outcomes from innovations are stressed by Cuban (1998), who isolates five important criteria by which the success or failure of them are judged in the USA. Three are favored by the policy elite—effectiveness, fidelity, and popularity, and two by practitioners—adaptiveness and longevity. The effectiveness and fidelity criteria are connected to a bureaucratic concept of top-down authority guarding control and technical rationality, which is preferable for elites.

There are professional and popular movements working from a bottom-up perspective with agendas of their own, reflecting differing views about, e.g., learning and teaching. Movements engage in contests over professional culture. Often they are recruited as partners to elite initiatives.

Simola (1998) named a certain blend of utopian and rationalistic ideas 'wishful rationalism.' It gives educational reformers 'self-created problems,' a most important component for group identity to build around. It can be added that wishful rationalism probably has one of its most fruitful seeding grounds in the literature of management and leadership.

3. Solutions and Problems of Mixed Character

Teacher efficacy illustrates nicely the need to use several perspectives in searching for solutions to problems of innovation and change. Teacher work is basically characterized by technical uncertainty, which makes high self-efficacy hard to achieve. Rosenholtz (1989) found that receiving positive feedback on performance and collaborating with other teachers were among the most important sources of teacher efficacy. This is in line with general theory on self-efficacy, which predicts that mastery experiences is the most important determinant, but that also social persuasion (pep talk and general feedback), and vicarious experiences (e.g., modeling by peers) are important. It is suggested that the implementation process should contain early and strong support because of its vital importance for teachers' feelings of practice mastery and which also increases user commitment.

Networking between teachers from different schools (but with the same interest in subjects, children of a certain age, etc.) is seen as a powerful instrument for professional development and change. It frees participants from limitations in institutional roles and geographic isolation, and builds a kind of temporary system. Networks are organizationally flexible. They support 'just-in-time learning,' learning that is tied to the actual work teachers do. Networks stimulate teachers to take leadership roles among peers. Within them, more egalitarian and sustained interaction between researchers and practitioners may be built (Lieberman and Grolnick 1996).

There have, however, been warnings against networking as just fostering a discussion culture. Some think that the tendency to talk together instead of working and learning together is already too strong within the teaching profession.

Great efforts are made to disseminate complex concepts of constructivistic instruction in science and mathematics to teachers using a 'systemic reform' design. Measures at several levels will conjoin: teacher education, curriculae, testing, accountability systems, information, support, etc. Strong coalition building at regional and local levels is needed to achieve this and still the result is highly dependent on the capacity of single schools. High-capacity schools have cohesive staffs developing 'collegial learning communities' and using professional networks to scan their environment for innovations and models. Low-capacity schools lack a critical mass of teachers willing to or used to work like this (Knapp 1997).

A 'learning community' in the sense just mentioned is about teachers learning together at the same school, and another term for that might be a 'learning organization.' However, Leithwood and Seashore Louis (1996, Chap. 13) point to different conceptions inherent in those terms. Organizational learning implies deep change of norms and repertoires, a process

which can be highly stressful for participants and which is by no means linear or harmonious. They find that this transformational change must be balanced by evolutionary changes. 'Breakthroughs' have to be complemented by 'small wins.' The small adaptions of everyday life help to shape continuity and stability in relations and routines, and thus the possibility to build a professional community. So schools need both, and the challenge is to get them into a positive dynamic. There is some evidence that community building preferably foregoes deep organizational learning. Leadership that is simultaneously authoritative and supportive is strongly associated with professional community. So is trust among staff and between staff and leaders, and it also fosters risk taking, which is good for learning.

Louis and Miles (1990) found that successful urban schools struggling to change in hard environments used evolutionary planning; i.e., iterative processes of learning through experience. This must be clearly distinguished from the strategy of 'muddling through,' which is to take advantage of any hopeful events that might occur under severe constraints. Evolutionary planning demanded strong coordination by cross-role groups or steering groups which must be legitimate in taking control over the process. Legitimacy came both from the principal and from power sharing. Vision building was important, but contrary to many assumptions it did not depend especially much either on formal data collection or on the leaders' charisma. It was rather an interpretative act making the staff realize a common task and a common fate. 'Deep coping' involved measures such as rolling planning, substantial restaffing, attempts at increasing school control over the environment, etc. Actions aimed at building system capacity, such as coordinators and task forces, were more effective than actions aimed at personal capacity building.

However, for ambitious change within schools, another, competing concept is also recommended, i.e., 'strategic planning,' which is a revitalized planned change approach. In the version of Kaufman and Herman (1991), it is a bold adventure in which the school interacts with its constituencies in making missions for the future and deriving long-term goals and strategies from them. Involving stakeholders means that the approach uses its political in addition to its technical potentialities. The whole idea of strategic planning has, however, been criticized for being contraproductive in using too formal and technocratic planning methods.

4. *Models from Industry and Markets*

The 1980s–90s saw a great inflow of innovative ways of organizing schools coming from the business sector. This marks a change of control over schooling as both professional and political judgements are circumscribed by administrative and economic models. Total quality management (TQM) is such a broad concept, geared to market mechanisms. It has one line of thought focusing on the tight steering of processes ('doing it right from the beginning'), and another focusing on the capacity to control the environment. The latter may mean that schools are recommended to influence their input by putting up their own preschools and parent training programs, and by controlling publishers of school books. It should also engage in consumer research, as 'in enterprises that depend on public support for their existence, perception is truth' (Bradley 1993, p. 4).

Educational Institutions and Society

The analysis of relationships between educational institutions and society presupposes at least minimal conceptions of institutions and societies as social systems

1. Educational Institutions

1.1 School Systems as Institutions

There is widespread agreement in sociological theory that institutions are social creations that serve to solve basic problems of society—e.g., to produce essential goods (economic institutions), to regulate sexual needs and biological reproduction (marriage and family), to resolve conflict (legal and political institutions), etc. Educational systems can also be regarded as large-scale problem-solving institutions. Confronting human genetic plasticity and the ability to learn to meet the complex needs of social life reveals the necessity of cultural reproduction via educational institutions. Educational systems form the highly institutionalized and organized part of the total educational service of a society for the new generation.

Given this background, the question arises as to which societal problems an educational system responds in a highly complex society and what it contributes as an institution for society at large. The answer is that above all educational systems solve cultural reproduction problems, i.e., problems of reproducing the culture and social structure of a society in the light of the biological exchange of its members. Each new generation, for instance, must learn to read and write if the society is not to decline into a more primitive state. A certain technology can only be maintained if we also have future technicians and engineers who, for instance, can build and repair television sets, cars, and computers.

To solve these problems of reproduction, school systems have been created during long historic processes of intentional 'institution building.'

1.2 School Systems as Places for Socially Controlled and Organized Learning

Content and ways of learning are structured and arranged in educational institutions on behalf of outside authorities. They express the power of social groups interested in specific content and processes of education.The socially desired learning processes are enforced in school systems by legal procedures and sanctions, by providing learning material and personal resources, and by systematically developing teaching know-how via elaborated training procedures.

1.3 School Systems as Socialization Agency

The third and central element of our concept of schools characterizes them as socialization agencies. Any process is labeled socialization if it at the same time constitutes psychological structures and reproduces cultural and social structures. School systems socialize children and adolescents via training qualifications and teaching values, without which the individual would be unable to function in society. At the same time, social reproduction and societal functioning is perpetuated. School systems are thus subsidiary arrangements; they emerge when mere participation in the social life of the family and kin group no longer suffices to teach all that is required for the functioning of society.

It is evident that reproduction is the main function of school systems, but school systems are also instruments of social change, proposed by social groups in charge of educational government.

2. The Structural-functional Approach: Society and Institutionalized Education

In the 1960s, two sociological theories became prominent as frameworks for the formulation of the relationships between educational institutions and society: first the structural functionalism of Parsons, and secondly the framework of English social anthropologists (Halsey).

Here for the first time the basic idea is formulated rigorously:

> (a) All societies maintain themselves with the help of a culture, i.e., with a complex set of attitudes and skills which are not contained in the genetic constitution of an individual but must be learned. This social heritage must be transmitted by social organization. Education has this function of cultural transmission in all societies.
> (b) Individuals' personalities must be formed so that they fit into a culture. Everywhere, education has the function of forming social personalities. As culture is transmitted by influencing personality, education contributes to integration of society whereby society can be seen as a mechanism which enables humanity to adapt to its environment, to survive, and to reproduce. (Halsey 1973 p. 385)

In his famous essay 'The school class as a social system,' Parsons (1959) explicated two functions of modern educational systems, namely socialization and selection.With socialization Parsons conceptualizes the process of passing skills on to each new generation, thus allowing them to fulfill tasks in an occupation and as a citizen. The function of selection leads to an allocation of students to occupational positions matching their abilities and interests. The structure of the school class is ideally suitable for fulfilling these tasks by modeling the processes of qualification and allocation. Dreeben (1968) continued these lines of

reasoning by contrasting the social structure of the family and the school and by explicating the corresponding norms and values. Thereby the family represents a particularistic institution where each member occupies a unique status. In contrast, the school is seen as a universalistic social system where students are treated as equals and difference is attributed by universalistic norms of achievement.

An influential analysis of the relationship between school system and society originates from the French language area. The sociologists Bourdieu and Passeron (1977) became the first since the important work of Durkheim (1956), to provide internationally recognized contributions clarifying relationships between the educational system and social class (Bourdieu and Passeron 1977). Using the example of the higher educational system in France, they postulated the split between the official ideology of achievement based on upward mobility and the actual rules for social reproduction. In reality, students with the correct cultural 'habitus,' belonging to the family culture in the bourgeoisie and the upper class, have greater opportunities. These strata reproduce their privileged positions via the school system. The ideology of achievement as the basis for social mobility serves to veil the real process. Thus the school system does not pass on a society's cultural heritage. Instead the culture of the ruling class makes primary use of it to maintain its privileged position.

3. *The Dual Function of Educational Systems in Modern Societies*

Beyond a more affirmative or critical view on the social functions of educational systems in modern societies, the schooling process can be analyzed from two perspectives: one with the view on reproducing and changing society, the other on constituting individual qualifications and orientations.

To see the social functions of 'human processing' via schools is indispensable for an adequate understanding of schooling. In a historical perspective, this becomes especially evident. From an individual perspective, school represents the most important cultural context for learning and the development of competencies and values. At the beginning of the twenty-first century, the relationships between educational institutions and society can be characterized as follows:

(a) Reproduction of cultural systems, which are often characterized as knowledge and skills, is institutionalized within the school system. This involves mastering basic symbolic systems ranging from language and writing to acquiring specific professional qualifications. Accomplished by instruction, this function is referred to hereafter as the *qualifying function*.

(b) The second function refers directly to the society's social structure. Social structure is defined as the distribution of positions in the occupational and social area. By way of school-based learning of qualifications, verified by a detailed system of examinations, the young generation is allocated to stratified occupational positions (*allocation and selection*).

(c) School systems are instruments of social integration. Reproduction of norms, values, and belief systems serve to reinforce prevailing power relationships (see Bernstein 1996, for contemporary theory on the relationship between knowledge and control). This accounts for the central political function of the socialization process in educational institutions (*integration and legitimization*).

In Fig. 1, the three reproduction functions of educational systems in modern societies are summarized. They appear as contributions to a defined

Figure 1
Social functions of schooling

social system which are necessary for its survival. To those involved, functions appear as tasks and goals. Therefore, reproduction can be converted into social change via educational institutions.

The school's societal references are shown on the left in Fig. 1. Systemic problems may arise which can only be solved adequately by educational institutions. This may be the case with regard to necessary qualification patterns for the occupational system, the legitimate structure of social mobility and social reproduction, and the legitimacy of the societal power structure or the political system.

The educational mechanisms through which societal problems are solved are shown on the right in Fig. 1. Instructional processes, examinations, and the institutional structure are differently involved in the process of fulfilling societal functions.

4. *The Historic and Action-theoretical Approach: The Evolution of Relationships between the Educational System and Society*

From the background of the functional analysis above, the economic, social, and political significance of educational systems is clearly visible. At the same time it becomes evident that the functional relationships between educational institutions and society are at work only in modern societies. Because educational systems do not follow a path of social determinism, their historic evolution can be traced back to observable processes of their creation. They are the result of human agency and social interaction and thus distinguish themselves fundamentally from natural evolution, as do all other areas of social reality (Archer 1995).

Educational systems in the European culture have emerged in the context of religious movements and interests. Until the eighteenth century it was the church, particularly, which provided personnel for schools, maintained buildings, selected curricula, set the definition for instruction and access to education, and shaped opportunities after graduation. In comparison to the multifunctional relationships between educational institutions and societies in modern times, this represented a case of mono-integration. The primary goal of educational institutions consisted in the cultural reproduction of religious knowledge and thereby maintained a monopoly in the Christian way of understanding human existence. As a book religion, Christianity depended on the training of religious experts. During the Reformation, providing direct access to the Bible became an essential part of the Christian way toward salvation. Therefore everybody should be able to read. This belief became an important impetus for teaching reading and writing to everybody. The practice of teaching was conceived along the lines of preaching and roles of teachers ran parallel to those of priests. Thus they determined the definition of knowledge in terms of pedagogical practice and the types and quality of educational output which seemed necessary.

Naturally, the typology in Table 1 fails to represent the total variety of historic phenomena covering educational institutions. There existed important national variations (see Archer 1979 for France, England, Russia, and Denmark) and particularly variations by religious faith. During the sixteenth century the Reformation was crucial for the emergence of alphabetization and literacy. It was also an important basis for the rise of national educational systems at the end of the eighteenth century.

In order to understand the emergence of national educational systems in European countries after the French Revolution, three historic predecessors have to be kept in mind: (a) it could build on advanced literacy

Table 1
Typology of relations between educational institutions and society (mono – integration vs. multiple integration)

	Mono-integration	Multiple integration
Functions	Maintenance of religion, of a monopoly in interpreting the meaning of human existence	Relation to political systems Relation to economic systems Relation to the social structure
Resources	Provided by the church	Provided by the state
Personnel	Integrated role of priest and teacher	Professional staff with defined autonomy
Content	Religious content selected and controlled by the church	Pluralistic content, as a result of democratic bargaining
Control	Ownership	Democratic and bureaucratic control
Hierarchy	Subordination and domination	Bargaining power of corporate actors
Access	Elective access	Universal access by ability and interest
Promotion rules	Conformity to religious convictions Suitability for expert positions	Achievement in defined subject matters
Careers	Positions in the hierarchy of the church	All divisions of the labor market: Dependent on qualifications

(for Switzerland, see Messerli 1999), (b) there existed scholarly communities at universities since the middle ages, communicating in one common language (Latin), (c) private schools served the need for commercial and industrial qualifications in the cities. Accordingly, there had been scattered possibilities of education in the cities since antiquity. The universities represent a complex history in which the conflict between reason and faith arose early as a heritage of antiquity. Development of scientific thinking has been an important motivation for establishing public education since the Renaissance and the rise of humanism.

The rise of modern education became an essential part of the emergence of state structures from the nineteenth century onward. This process turned out to be a historic struggle for power in which identifiable actors and interest groups proceeded within the framework of historic and structural conditions. Their activities during a process of structural elaboration led to educational institutions, which only gradually assumed the characteristics of a coherent system in the course of the nineteenth and twentieth centuries. Speaking of an educational system means that pathways through the school system were systematically linked to each other, that a professionally trained staff emerged, and that coherent curricula were developed. During this process, the 'meritocratic' principle was established as the only legitimate way of promotion.

The three main social functions described above developed along this historic route. At the individual level they implied that long-term learning became a universal instrument of individual life planning. A parallel process could be observed at the social level. It implied the increasing inclusion of all social classes in the educational system. During the nineteenth century the struggle for social participation in education took place at the primary school level, in the twentieth century at the secondary and tertiary level. Thus discussion about the role of education reflects the political discourse of society. Yet it is embedded within the political rules of the society and the real power structure, which becomes visible in historic and comparative perspectives (see Heidenheimer 1997).

5. *Empirical Analysis of the Relationship between the Educational System and Society*

Historic analysis of the relationship between the educational system and society is not limited to the topic of how the educational system evolved parallel to and as part of the developing welfare state during the last two centuries.

5.1 *Educational Expansion*

Beyond system development, the factual educational participation at various educational levels can be described. Doing this, it becomes apparent that all parts of the population had become literate in most European nations toward the end of the nineteenth century. Expansion of secondary education and particularly tertiary schooling occurred cyclically, yet it was only during the 1950s that it began in large numbers. The sharp increase in educational participation from the 1950s to the 1970s began to level off from the 1980s.

Opinions vary greatly in the discussion of causes for this educational expansion. Doubt exists primarily about the thesis that it resulted from conscious planning and pressure by political decision makers. Actually it followed a complex interrelationship of supply and demand, of system-building processes on the supply side and accumulating consumer demand. Pressure from parents and students emerged in the twentieth century through perspectives on qualification-related life planning. These focused on the perception of opportunity structures influenced by economic developments in an era of rapid technological change and economic globalization. On the political level, a highly productive educational system turned out to be a key factor for successful global competition.

5.2 *The Educational System and Social Structure*

The nineteenth and twentieth centuries reflect the struggle over participation in education by privileged and disadvantaged social groups. Efforts were exerted to achieve a classless society by education, by implementing the principle of meritocracy, and by forcing the nobility to take examinations. Educational expansion brought about egalitarian effects and strengthened the role of the equal rights of all citizens (Müller 1998). Moreover, parallel to expansion the twentieth century saw an observable increase in educational opportunities for the farming sector as well as for workers and employees. Yet relative inequality of opportunity (Fend 1982) still existed in all industrialized nations at the end of the twentieth century.

The greatest progress in educational participation during the second half of the twentieth century could be observed among girls and women. They profited most from educational expansion (Blossfeld and Shavit 1993, Dahrendorf 1965, Müller and Karle 1993, Schimpl-Neimanns and Lüttinger 1993).

6. *Practical Questions*

Linking a theory of educational institutions to historical processes of their creation opens up the perspective that humans are responsible for shaping educational institutions for the demands of future developments. Questions of quality in the educational systems and their effectiveness in the light of limited resources have top priority in the political agenda. At

the opening of the twenty-first century one central issue deals with the problem of how to shape the qualifying function of educational institutions within the framework of international economic competition. Answers to questions about equal opportunity and the principle of meritocracy will shape the acceptance of education in the coming years. Questions concerning democratic control of knowledge and values will be of great significance for the peaceful coexistence of people in a global civil society.

Educational Institutions, History of

1. Origins

Any attempt to specify a starting point for the history of educational institutions is necessarily arbitrary. This is due to the uneven and contingent distribution of early historical sources across time and space, as well as to the fuzziness of the term 'educational institutions.' Broadly speaking, the term refers to a set of rules that govern the aims and activities of the adult generation in socializing the young generation into more or less age-graded roles. Knowledge about how to profit from the extended period of human infancy in order to further physical and moral/cognitive development must have been part of the everyday wisdom of the older generation long before precepts concerning education appeared in religious texts. And even after the introduction of educational institutions in a more narrow sense of the term (schools), these rule-sets governing everyday socializing/educational practice remained of prime importance since these formal institutions were highly specialized and, for centuries to come, reached only a small minority of a population.

The boundaries between religious or general cultural practice and educational practice and the respective institutions in these fields are not clearly marked. Thus, for ancient Jewish education the basic set of texts is identical with the literature guiding religious practice: the Pentateuch, the oldest part of the Old Testament, i.e., the books Moses 1–5. Of course, those parts of the text referring directly to education are clearly recognizable as such but, obviously, their interpretation (e.g., in the Talmud) depends on the religious context and vice versa (Schwenck 1996, pp. 153–77).

For example, we are most familiar with an educational practice that is not primarily channeled through educational institutions in the narrow sense of the term but rather builds on participation in cultural, social, and political activities in a highly dynamic society, namely that prevailing in ancient Greece during the classical period (for the following, see Marrou 1948, Schwenck 1996). This does not hold, of course, for Sparta, where the male child left the family at the age of 7 years to join a state-controlled educational system for the next 12 years bent on producing fearless and obedient warriors.

Athens at that time had not developed a public system of schools; military training of 2 years' duration was introduced only in the late fourth century BC. Education of the young (boys) was the responsibility of the family, which availed itself of the services of private teachers. Boys of fathers having full citizenship had the right, at age 10 years, to be present at most cultural events. Although the works of the poets and historians were available in writing and many of the (male) citizens must have been literate to be able to

fulfill their public duties, Greek culture of the classical period was to a large degree an oral culture. Festivals, the theater, and competitions in presentations of dance, music, poetry, drama, and athletics provided ample opportunity to familiarize the young generation with the rich heritage of Greek civilization. This experience was understood to be more than a means to achieve esthetic refinement; it exposed the young to reflections on human destiny and justice, concepts of virtue, models of conduct and of good governance. It was preparation for citizenship and moral education. Physical education and music education, too, were considered fundamental for the formation of the free citizen. Especially the former was seen as part of the preparation for military service, and the communes were responsible for providing and controlling localities for athletic activities. The growing prestige of the Panhellenic games may, however, have served to weaken the nexus with military training.

Many elements of the (nonformal) curriculum of the classical period reappeared in the curriculum of the public schools provided by the larger communes during the Hellenistic era, normally dated from 338 BC when Philipp II of Macedonia defeated Athens and their confederates in the battle of Chaironeia. In both periods the curriculum is strictly oriented towards general as opposed to vocational education. The adult role emulated in the schools is not that of the skilled professional but that of the citizen potentially responsible for different general tasks in and for his community and in need of general moral as well as cognitive competences.

Educational institutions of a more restricted vocational orientation had already been introduced long before the apex of Greek civilization in the Sumerian city states of the third millenium BC. These were highly differentiated societies facing complex administrative challenges and had important trading relations. To document and control their diverse activities they needed systems of book-keeping for the different administrative fields and functions. Considering the state of development of the sign system for writing, mastering this task required systematic learning. Consequently, writing schools for trainees of the administration were established (Feldbusch 1988, pp. 1473ff). Comparable institutions specializing in the education of scribes, administrators, and probably also artisans had already existed in ancient Egypt (Craig 1981, Adick 1992, pp. 164ff).

The Hellenistic system of postelementary education which prospered not only in the Greek communes but also in many regions bordering on the Aegean and Mediterranean Seas, and which functioned in the eastern part of the empire until the fall of Byzantium in 1453, is important for further developments during the Middle Ages in Europe in several respects: it provides the context in which early Christian concepts of education are developed in close contact with classical pre-Christian educational theory. The curriculum of the Enkyklios Paideia/Septem Artes liberales remains a point of reference in the debate on the contents and objectives of postelementary education, even gaining in importance with the growth of first-hand knowledge of the classical texts in central and western Europe.

2. *The Middle Ages*

The cathedral schools first founded towards the end of the eighth century and spreading throughout the Carolingian Renaissance provide evidence of this type of long-term curricular continuity (Verger 1986). Although their primary purpose was the education of the clergy via an in-depth study of the Holy Scripture, they also introduced their students to a version of the trivium grammar, rhetoric and—around the end of the tenth century—dialectic. Thus, these schools offered a relatively broad general education, including the study of classical nonreligious texts, as a basis for the professional preparation for the clergy. Some of these schools developed into universities in the first half of the thirteenth century, the largest and, with respect to the quality of its liberal arts and theological faculty, perhaps the most important among them the University of Paris, which attracted large numbers of students from England, the German-speaking regions of Europe and Italy. Among its famous teachers were Albertus Magnus (1240–48), Bonaventura (1248–57) and Thomas of Aquino (1252–58 and 1268–72) (Verger 1986, p. 421). Their names, like Duns Scotus, Roger Bacon and Occam, also point to the importance of the Christian orders, foremost among them Dominicans and Franciscans, as centers of the rich intellectual life and scholarly learning of the twelfth and thirteenth centuries. The attractiveness of the University of Paris was comparable to that of law schools in northern Italy (e.g., Bologna and Pavia), which served as models for the rest of Europe. The hierarchical relation between professional schools of theology, law (Orléans) or medicine (Montpelier) at the top and the ancillary and preparatory functions of the liberal arts faculty, typical of the university up to the end of the eighteenth century, is already discernible in some of the French cathedral schools of the eleventh and twelfth centuries. This may have helped to preserve the idea that higher education should be more than just a rather restricted professional training. When, by the late Middle Ages, much of the knowledge acquired in classical antiquity and preserved in the centers of learning of the eastern part of the Roman Empire had been recovered, this offered the opportunity to widen the scope of scholarly learning to approximate the full range of the classical liberal arts curriculum by including parts of the quadrivium: arithmetic, geometry, music, and astronomy. To be sure, this was already the vision of Alcuin—teacher and close counselor of Charlemagne, learned author of textbooks on the seven liberal arts and very active in

the propagation of cathedral schools in the early ninth century. In most of the French cathedral schools, however, teaching of the liberal arts seems to have been restricted to the trivium.

When the first German universities were founded in the second half of the fourteenth century (beginning with Prague in 1348), they followed the organizational pattern developed in the older European universities: the liberal arts faculty was by far the largest but ranked lowest. The faculties of theology and law enjoyed the highest prestige and the best remuneration of their teachers. In most of these universities, however, the arts faculties covered the full range of the arts, including natural science on the basis of Aristotle's writings (Paulsen 1919, Vol. I, Rüegg 1993/1996, Vol. 1).

The larger and more successful European universities were international in the composition of their student bodies and teaching faculties, which, of course, was rendered possible by the use of Latin as the lingua franca of higher learning. Students were attracted by famous teachers and these, too, traveled much in search of better conditions for their work. Thus, knowledge spread fairly quickly, but was accessible only to that small minority who mastered the medium of communication. Schools that could have transmitted the necessary skills were small and widely dispersed. Demand for this type of instruction was low for a host of reasons. Until the end of the eighteenth century there was no clear demarcation between the respective functions and objectives of schools and universities.

By the end of the fourteenth century, most European towns of some importance had one or more schools. They were attached either to a parish, a convent, or a chapter, or directly sponsored and controlled by the communes. The latter form, with the supervision of the town's council, seems to have prevailed in Germany. But here, too, the relation between school and church remained a tight one. In many cases the minister of the church was himself the teacher or he may have acted as rector of the school, responsible for the selection of a teacher who, in turn, chose his own teaching assistants. The pupils were taught in two or more groups formed on the basis of age and learning progress. The main objective of the town school was to teach the pupils to read and to write Latin. It seems remarkable that these schools took in not only the children of well-to-do families but sometimes also a sizable proportion of poor children living on charity (Paulsen 1919, Vol. I, 18ff).

3. *The Humanistic Movement and the Reformation*

Around the turn of the sixteenth century, universities and schools were shaken by two interdependent events: the humanistic movement, originating in the Italian Renaissance, and the Reformation (Rüegg 1993/1996, Vol. 2). The humanistic movement was a polemic revolt against the culture and learning of the Middle Ages, which it condemned as a dark, narrow, uninspired, mechanistic, unnatural and bookish educational tyranny; and it was a movement for a fresh reading of the poets and philosophers of classical antiquity in their original language—Greek, Latin, Hebrew—a re-reading freed from the pressure to prove this literature's compatibility with Christian values and dogma. It was, last but not least, a plea for a study of (human) nature, unfettered by the authority of classical literature (for a contrasting evaluation, compare Paulsen 1919, Vol. I, Chaps. 3–5 and Garin 1964, pp. 25ff).

The movement's immediate effect on the schools seems to have been rather limited, depending on the conditions encountered locally: the prestige of the classical languages was raised, new textbooks written or recommended by devotees of the movement were introduced, some schools hired a poet to teach the basics of Latin poetry and eloquentia. In a small number of schools, Greek was introduced as a new subject. The long-term effects, on the other hand, were important to both schools and universities: The curriculum of the liberal arts faculty was considerably extended to include Greek language and literature which was, like Latin literature, to be represented in a fairly wide selection of poetry philosophical, historical, mathematical, and other scientific texts. Most arts faculties also offered courses in Hebrew. This increase in service functions opened teaching positions for humanists and doubtless raised the prestige of the arts faculties. In the larger schools created in the course of the sixteenth century by combining several smaller Latin schools, too, Greek was offered as a new subject; in some of them even an introductory course of Hebrew was taught. Several of these larger academic schools in fact covered areas of knowledge that were traditionally part of the curriculum of higher education

As for the effects of the Reformation on the development of educational systems, only two aspects will be mentioned here: it supported the relatively fast spreading of literacy in the mainly Protestant areas of northern Europe (the concept of universal priesthood combined with the accessibility of the sources of faith translated into the vernacular to every literate person). Sweden seems to have been most successful in this respect. Already in the seventeenth century, admission to full church membership was tied to the ability to read. Prussia was the first state to initiate steps towards compulsory elementary education early in the eighteenth century. Other Protestant states followed suit early in the nineteenth century. Fairly reliable quantitative data on the development of attendance at primary schools and on the spreading of literacy are available only for the decades from about 1830 onwards. In both respects, they show a considerable

advantage for the Protestant territories (Flora 1975, Flora et al. 1983).

In central Europe, in particular, the Reformation changed the relation between the university and the polity. The universities became part of a territorial state with a distinctly denominational character that assumed control over the reorganization of the religious system and of the educational institutions still closely connected with it. This process entailed a loss of autonomy on the part of the universities, a loss which increased with the growth of the central state administration This is clearly visible in the Protestant territories, where the ruling dukes and princes were actively engaged in the process of reorganizing the universities and of creating a new type of academic school (Landesschule, Fürstenschule), financed directly by the state and recruiting its students more or less statewide. The control of the elementary schools, financed by the communes with few additional resources provided by the state, remained mostly in the hands of the church. Towns continued to be responsible for the establishment and financing, mostly via fees, of Latin schools or different types of intermediate schools without foreign language instruction for children of well-to-do families (Leschinsky and Roeder 1976). To remit (partly) fees for motivated pupils from poor families seems to have been widely practiced.

In England, the impact of the Reformation on school development may have been even stronger than in central Europe: 'modernization of the educational system dates from the Reformation. It was during this period—from the early mid-sixteenth to the mid-seventeenth century—that grammar schools were established in most market towns, with separate school buildings being erected and teaching being developed as a profession, and a systematic approach to the structuring of the content of education … took root' (Simon 1987, p. 93).

Despite the changes observable in the schools and universities during the sixteenth century, they still had more in common with their precursors of the late Middle Ages than with the modern system of education which slowly evolved at the end of the eighteenth century and which developed with increasing rates of change and growth from the middle of the nineteenth century onwards. The main function of the university still is the transmission of a cultural tradition legitimized by traditions. Where such traditions were not established as in the case of Protestant theology, this led to bitter and fruitless quarrels between adherents of dissenting factions of Protestantism, who had their strongholds in different universities.

There seems to have been little room for creative minds in the fields of philosophy, mathematics, and natural science. Descartes, Spinoza, Newton, and Leibnitz stayed out of its bounds. Hopes for the progress of knowledge and for innovations with the potential of improving the lot of mankind concentrated not on the university but on the Academy, an association of men of proven ability, especially in mathematics, science, and technology (Stichweh 1984, pp. 67ff). That the academies established in Germany did not pose a threat to the position of the universities is mainly due to the fact that the latter, from the start of the eighteenth century, had embarked on the road to an ambitious reform.

4. *Reforming the University*

The University of Halle, founded in 1694, acted as forerunner and model in this development. It succeeded in attracting a number of outstanding teachers, among them August Hermann Francke, one of the heads of the Pietistic movement and an original pedagogical thinker, Christian Thomasius, a jurist influenced by Grotius and Pufendorf, who also taught and published in the German language, Christian Wolf, mathematician and an eminent advocate of rationalistic philosophy, who also published textbooks in German, and J. S. Semler, a theologist (1752–91) who was among the first to introduce the historical–critical method into the study of the Holy Scripture. The curriculum of the faculty of philosophy was extended to include history, geography, mathematics, and the natural sciences; the law school offered lectures on, among others politics and natural law. Halle clearly pointed the way to a modern university that was no longer just a teaching institution but had begun to accept systematic research as a major function and service to society.

The second model university of the eighteenth century was that at Göttingen, founded in 1734. Its focus was on the modern disciplines: political sciences, history, law, mathematics, and natural sciences; however, it was equally important for the development of the study of the civilizations and literature of classical antiquity. Lectures were given regularly in German. There existed something like a common understanding that it was an obligation of the university to extend knowledge in the respective disciplines by doing original research. Like A. H. Francke in Halle, both Gesner and Heyne, the dominant figures in the field of classical studies in Göttingen, were influential in improving the preparation of teachers and the educational practice in schools.

Whereas in France the universities and colleges of the Ancien Régime were suppressed by imperial order in 1793 and, in their stead, a series of professional schools were organized (Verger 1986), universities in Germany consolidated their dominant position in higher education and succeeded in safeguarding a sphere of autonomous decision making in the organization of their teaching and research. The pattern of the further development throughout the nineteenth century and beyond was already clearly discernible in

the conceptual framework elaborated by Fichte, Schleiermacher and W. v. Humboldt for the foundation of the Berlin university in 1810: the traditional ranking of the faculties was to be abolished; a central role was ascribed to philosophy, in the sense that a philosophical spirit ought to pervade work in all fields of study. The mission of the university was defined as science in the service of truth, i.e., doing research to extend the boundaries of knowledge. This mission explicitly included the students. They were expected, fairly early in the course of their studies, to choose topics of interest where they could do original work on a restricted scale, the results of which were to be presented and discussed in the seminar. The seminar provided a new setting for teaching and learning, adapted to the new mission of the university: a regular meeting of a professor with his more advanced students for the purpose of discussing original research presented either by the professor or by a student.

A growing specialization of both teachers and students and the formation of subdisciplines was one important effect of these developments, regarded as ambivalent by those concerned with the preparation of teachers for academic secondary schools, that profession to which most students of the philosophical faculty aspired (Paulsen 1919, Vol. II, pp. 259–78). For a comparative perspective on the 'transformation of higher learning … expansion, diversification, social opening, and professionalization in England, Germany, Russia and the United States' see Jarausch (1982).

5. *Schooling in the Eighteenth and Nineteenth Centuries*

The first decades of the nineteenth century were not only a period of change for the universities. They also saw the evolution of the dominant type of academic secondary schools (Gymnasium), the curriculum of which centered on the classical languages Latin and Greek and, to a lesser degree, on mathematics and German, without completely neglecting the study of history, geography, and science. Relations between secondary schools and universities were clearly articulated with the introduction of the final examination (Abitur) and the examination of teachers qualifying for employment (Müller and Zymek 1987). Parallel developments are observable in France with the evolution of the Lycée and the introduction of the Baccalauréat in 1820.

With respect to the development of elementary education, wide regional variations in the actual enrollment of that age group for which compulsory education was mandated are observable in the first half of the nineteenth century. The highest proportions of enrollment around 1820 was reached in Saxony, totaling more than 80 percent. An average for the whole of Prussia in 1816 was (probably over-) estimated at 60 percent. Three decades later, the least developed province of Prussia topped this mark with 70 percent of the age group under compulsory schooling actually enrolled. Obviously, there must have been a rather steady growth of the provision of elementary education over the period (Leschinsky and Roeder 1976, pp. 137ff). The expansion of the provisions for teacher training seems even more remarkable: 17 new seminars for the education of elementary school teachers were established during the period, raising the total number to 38. Their yearly output of qualified teachers seems to have been sufficient to meet the growing demand.

In England, compulsory attendance was not introduced until the final decades of the nineteenth century. But there, too, a rapid increase in literacy throughout the century is to be observed, much of it due to the willingness of working-class parents to pay for the education of their children in one of the many local private schools, which they often preferred to the cheaper schools established by the churches or by associations crusading for the education of the lower classes, as Thomas W. Laqueur contends (Stone 1976, pp. 192ff).

6. *The Emergence of Educational Systems*

At the start of the twentieth century, coherent systems of education emerged in the more developed European nations. The elementary schools no longer stood apart from the rest of the system, but developed their function as feeder institutions for the secondary schools. Within the secondary system or between secondary and primary schools, new types of schools were established, varying in curricular focus prestige and entitlements conferred upon them. Well into the twentieth century, the classical academic secondary school with its clear focus on Latin and Greek languages and literature—lycées, collèges in France, grammar schools and, of course, the small number of highly prestigious boarding schools, the so-called 'Public Schools,' in England, and the Gymnasium in Germany—succeeded in defending its top position. Below this type ranked secondary schools that did not offer Greek or neither Latin nor Greek but, instead, taught modern languages and reserved more hours of instruction for the sciences: enseignement spécial in France, higher-grade schools in England, Realschulen, Oberrealschulen, Realgymnasien in Germany. Many of these schools emerged owing to the activities of local pressure groups convinced that the classical curriculum did not meet the educational needs of their children. The ambitious blueprints for their modernized curricula, integrating elements of vocational and of general education, however, had already been proposed from the second half of the seventeenth

century onwards (Leschinsky and Roeder 1976, pp. 168–208). Some of these types of secondary schools eventually achieved parity with the classical academic secondary schools—if not in prestige, at least in entitlements to matriculation (Prost 1969, Müller et al. 1987, Müller and Zymek 1987). Central and regional bureaucracies, responsible for the development and functional control of the system, were expanded early in the nineteenth century in France and Germany. This happened considerably later in England, where an effective substitute had been developed in the form of the Royal Commissions 'with the brief of examining and making recommendations for the reform of all levels of education' (Müller et al. 1987, p. 88). Curricular frameworks and standards of examinations for different types of schools and teacher training were specified by the central administration, traditionally leaving most leeway for curricular decisions on the level of the individual school in England. The inclusion of females had progressed considerably throughout the nineteenth century, although parity was not achieved until the second half of the twentieth century.

7. *A Global Model of Schooling*

In reviewing the long-term evolution of educational institutions in the more developed countries of western, northern and central Europe and in the USA, one gains the impression that, despite national peculiarities and the weight of regional traditions, the systems emerging at the turn of the twentieth century are basically similar in structure and functioning. They seem to represent what has more recently been termed a 'global model of schooling.' The thesis that we are witnessing the 'formation of a world educational system' (Adick 1995) implies that the dynamics fueling the development of systems of mass education presupposes the existence of the modern nation state and the concept of citizenship but that it is to an important degree transnational. This thesis has received substantial support in empirical research conducted by John W. Meyer, one of its principle proponents, and his collaborators (Meyer et al. 1992). Thus, an analysis of constitutions enacted since about 1870 shows that practically all of them include statements concerning the individual right of access to education and the authority and obligation of the state to provide and regulate the educational institutions (Boli-Bennet in Meyer and Hannan 1979). The Prussian constitution of 1794 (Allgemeines Landrecht) can, at least in some respects, be cited as an important early precursor of these later developments. A study of primary school curricula enacted between 1920 and 1986 also reveals a high degree of communality with respect to, e.g., the subjects taught, hours of instruction per subject, and basic changes in the content of subjects across a large sample of countries (Meyer et al. 1992). Further support comes from case studies of educational developments in colonial and postcolonial West Africa (Adick 1992, 1995) that document autochthonous initiatives in the course of the nineteenth and early twentieth centuries to establish a school system for the native population. The problem of whether the curriculum should cultivate native African traditions or emulate the best international models was, and still is, openly debated (see Reichmuth (1995) for the influence of Christian and Muslim communities on education in Nigeria and Wiegelmann (1999) for the development of schooling in Francophone Senegal, with special attention to the problem of the language of instruction, afflicting many of these countries).

More recently, the evolution of a global model of schooling has been actively promoted by international agencies: OECD's 'Reviews of National Policies for Education' are based upon a continuously refined set of common criteria and standards used in the evaluation of national educational systems. The European Union, too, may induce a further rapprochement between educational systems of member states; mutual recognition of qualifications certified in schools and universities can be viewed as a step in this direction. Large international quantitative studies of school achievement presuppose communalities in the curricula of primary and secondary schools, their success in constructing achievement tests, developed in international groups of researchers and valid in countries otherwise different, offers proof that such communalities exist in fact; and decisions of national educational administrations taken in reaction to test results may again push the trend towards globalization.

To be sure, the global model still leaves room for variation between countries, e.g., with respect to ensuring elite education for minorities of high achievers, in the degree of comprehensiveness of higher secondary education, in the organization of different types and levels of vocational and higher education, and in the importance assigned to specific subjects like, for example, religion.

A final remark addresses the problem of large gaps in the global model: both the quality and the inclusiveness of educational provisions are far below accepted international standards even on the level of primary education in a number of developing countries, despite considerable progress achieved in the decades between 1960 and 1980. The report prepared for the 1990 'World Conference on Education for All' presents a long list of deficiencies in, e.g., equity of access, completion of primary cycle preparation of teachers, quality of instruction, availability and quality of instructional materials, and managerial competences of personnel at the central, regional, and school level (Lockheed and Verspoor 1990). The recommendations, elaborated in the report, for action to overcome these deficiencies may have been effective in some countries. In others, the situation may well have deteriorated further in the course of the 1990s. This, at least, is the impression gained from a survey of the

conditions of primary schools conducted in 14 of the least-developed countries in 1995 (Postlethwaite 1998). In significant parts of our world primary education for all still constitutes a vision rather than a reality.

Educational Leadership

The quality of education provided in schools and colleges is commonly thought to be influenced by the quality of the leadership directing these organizations. But the meaning of leadership, how it differs from everyday management and administration, and how it is manifested in educational organizations are matters of considerable dispute. Differing views of the forms and effects of leadership in education are central to this article, as is the question of what, if anything, is distinctive about 'educational' leadership. Issues of power, ethics, democracy, and the consent and empowerment of organizational participants are central to the exercise of leadership. They are particularly salient in educational organizations, because of their formative and symbolic role in shaping a society's future. Such issues lead to disagreements about how

educational leadership should be conceived and researched, and ensure that it will remain a highly contested concept.

1. Generic Leadership Versus Educational Leadership

Scientific research on school administration and educational leadership began in the late 1950s and early 1960s, when researchers in the 'theory movement' began utilizing the techniques of the social sciences to examine these topics (Willower and Forsyth 1999). Although researchers recognized that schools and colleges were totally different from business and industrial organizations, little attention was given to differences among types of organizations in the early research. Instead, leadership and administration were treated as generic organizational issues for many years, with few questions asked about what might be distinctive about these functions or processes in educational settings. To the extent that a generic approach is considered sufficient, one only needs to look at the generic literature on leadership and administration in organizations. The main argument in this article, however, is that generic approaches, although valuable, are insufficient for comprehending effective leadership in educational organizations.

Many definitions of leadership exist, but most acknowledge that it involves the ability to influence others—often defined as the ability to get them to do what they otherwise would not do—coupled with the ability to get people to accept a mission or vision of the goals or purposes a group, a team, or organization should follow (Hoy and Miskel 1996, Leithwood and Duke 1999). To distinguish between leadership and management, some definitions emphasize that leadership involves bringing about change or innovation, while management involves maintaining the smooth operation of the existing organization. Research on leadership has evolved from early studies that focused on the traits or abilities of effective leaders, to recognition of the importance of the situation or context that leaders face. Thus, a 'contingency' approach asks what traits in what situations are important for effective leadership (Hoy and Miskel 1996).

1.1 The Importance of Context

The organizational structure of typical schools and colleges involves a context in which teachers are solo practitioners doing discretionary, professional work. This workplace impedes direct supervision and fosters the autonomy of employees (Lortie 1975). This context thus reduces the effectiveness of a directive, 'command and control' style of leadership and seems conducive to a more collaborative approach. This raises the question of how leaders can best improve the effectiveness of schools and teachers. The early research on educational leadership emphasized strong, directive leadership by school administrators, but more recent research suggests that a more participatory and collective approach to leadership is needed, to obtain the consent of employees and to build a sense of 'professional community' in schools (Newmann and Wehlage 1995). Some of the contextual aspects of schools, such as the tension between their bureaucratic and professional features, create what Ogawa et al. (1999) call the 'enduring dilemmas of school organization.'

How much teamwork and democracy are really needed in schools seems to be both a cultural and philosophical question. In the English-speaking democracies, cultural values press for a democratic approach, even if it is seldom fully achieved. In other societies, for example many Asian nations noted for high student achievement, schools are usually run in a more traditionalistic, 'top-down' manner. The Asian nations show that, in a cultural context supportive of student effort, traditional values, and the importance of learning, traditionally structured schools, utilizing top-down management and teaching, can be very successful. In more pluralistic Western societies—less supportive of effort, traditional values, and learning—effective schooling is more difficult to achieve. Firestone and Louis (1999) provide an interesting discussion and set of references on these themes.

To the extent that schools, wherever they are located, can be instructionally effective through some combination of high academic standards, strong teachers, and a milieu supportive of learning, they may not need to undertake school improvement efforts. But many, if not most schools lack these qualities and need systematic improvement efforts. Research has shown repeatedly that teachers in these more typical schools often lack the motivation and/or the skills or capacity to successfully implement new programs or teaching approaches (Fullan 1991). The need to enlist their involvement and effort in school improvement ventures creates a demand for educational leadership, i.e., leadership primarily focused on facilitating and improving the core function of educational organizations: teaching, and learning. The need for school improvement also calls for leaders adept at motivating and managing the change process in organizations.

1.2 Models of Leadership

In a comprehensive review of the research literature on school leadership, Leithwood and Duke (1999) delineate six models of leadership as predominating in the articles published since 1988 in four leading English-language educational administration journals. Of the three most frequently mentioned models,

'instructional leadership' led with 13 mentions, followed by 'transformational leadership' (11 mentions), and 'contingent/leadership styles' (nine mentions). The other three leadership models uncovered were 'moral leadership,' 'managerial leadership,' and 'participative leadership.' Instructional leadership is close in meaning to the broader concept of 'educational leadership' explicated here. Transformational leadership involves leadership that inspires and heightens the commitments and capacities of organization members toward the attainment of organizational goals. In contrast, 'transactional leadership' involves the exchange of valued things between leaders and followers in a more extrinsic relationship that lacks the quality of a mutual pursuit of higher purposes.

Leithwood and Duke (1999, p. 54) state that the contingent/leadership styles approach focuses on 'how leaders respond to the unique organizational circumstances or problems they face as a consequence, for example, of the nature and preferences of coworkers, conditions of work, and tasks to be undertaken.' Moral leadership (see Hodgkinson 1991) focuses on 'the values and ethics of the leader, so authority and influence are to be derived from defensible conceptions of what is right or good' (Leithwood and Duke 1999, p. 50). Managerial leadership 'focuses on the functions, tasks, or behaviors of the leaders' (p. 53) in the belief that competent performance of these functions will facilitate work within the organization. Participative leadership emphasizes the group's decision-making processes and collective involvement. As argued earlier in this article, it represents the kind of leadership increasingly in demand in democratic societies.

1.3 Democratic or Shared Leadership

Fearing that leaders tend to abuse their power—in education as elsewhere—critics call for more democratic, shared or collective governance arrangements (Chapman et al. 1995). Advocates of educational leadership, while recognizing the possibility of negative leadership, emphasize the importance of leadership for organizational improvement and extol the value of leaders capable of communicating an inspiring vision of a more dynamic and effective organization. However, whether educational leadership should be viewed, normatively or empirically, as the property of one or a few individuals or as a collective organizational property is an increasingly important question, both in research and practice.

Since the 1970s, scholars embracing critical theory and post-positivist orientations have mounted a sustained critique on mainstream approaches to social science, organizational theory, and leadership (Heck and Hallinger 1999). As Leithwood and Duke (1999, p. 63) note, three features of the theory movement in educational administration have come under attack: 'a positivist orientation toward knowledge, a structural–functionalist conception of organizations, and a control-oriented, managerial view of leadership.' Arguing that knowledge is actually 'socially constructed,' that hierarchical relationships in organizations reinforce unjust inequalities in society, and that a control orientation toward leadership and administration impedes reform and empowerment, critics such as Foster (1989) contend that educational leadership must focus on social justice and emancipation.

Along with concerns for democracy and justice, pressures for more shared or participative leadership also increasingly flow from demands for higher performance and better student achievement. The case for 'high-involvement' management for high-performance schools is well stated by Darling-Hammond (1996, pp. 146–7).

Efforts to invent nonbureaucratic twenty-first-century organizations tend to use incentives and structures that motivate through collaboration rather than coercion; build strong relationships rather than rely solely on rules for governing behavior; encourage quality by structuring work around whole products or services rather than disconnected piecework; and create information-rich environments that support widespread learning and self-assessment among workers rather than rely primarily on hierarchical design and supervision of work routines. Such organizations aim to stimulate greater thoughtfulness and creativity rather than focusing largely on enforcing compliance with predetermined procedures. Their success, then, depends on the creation of new opportunities for teacher and school learning, new modes of accountability, and new kinds of incentives for continual improvement and problem solving.

Research on school improvement efforts and, particularly, on the professional development of teachers to facilitate these efforts, shows how the theory and practice of educational leadership can move toward approaches that are more participatory and democratic. Smylie and Hart's (1999) perceptive synthesis of research on school leadership and teacher learning and change illustrates this well. Building on work on human and social capital development, they show how teacher collaboration in improvement initiatives and teachers' sense of membership in a professional community can be fostered through more participative and distributed forms of leadership. Smylie and Hart (1999, p. 428) contend that, rather than a hierarchical, bureaucratic style of leadership, 'from social and human capital development perspectives, attention is drawn toward relational and interactional aspects of school leadership. These perspectives call for a broader conception of school leadership, one that shifts from a single person, role-oriented point of view to a view of leadership as an organizational property shared among administrators, teachers, and perhaps others' (p. 428). This view 'sees leadership as participative and inclusive, as infused throughout the social system of

the school in ways that foster collective responsibility, mutual trust and obligations, and joint accountability' (p. 436).

Smylie and Hart emphasize that school principals still have vital roles to play in this shared approach to leadership, for example, in creating opportunities for interaction, fostering social bonds, and establishing support systems. Further, they stress that efforts to move to this participative model always encounter resistance because they 'challenge deeply entrenched patterns of isolation and autonomy that define teachers' work' (p. 430). Leadership and improvement strategies for pulling teachers out of these deeply engrained norms and habits are the subject of extensive research and writing (Sykes 1999), some of which cautions against manipulating teachers against their will.

2. School Culture and Change

Firestone and Louis' (1999) review of research on 'schools as cultures' emphasizes that the shared culture of isolation and autonomy among teachers in many schools frequently inhibits change and improvement efforts. Nevertheless, they argue that, within some limits, leaders can begin a process to change a school's culture toward one more conducive to participation, professionalism, and improvement. This can be done, in part, through the effective use of 'symbolic leadership,' in which the leader uses symbolic language and ceremonies, highlights key values and shared meanings, and reinterprets events to renew or redirect the organization's culture. A related strand of research, in the broad field of school improvement and organizational change literature (Louis et al. 1999), involves the growing interest in leadership approaches to foster 'organizational learning' in schools (Leithwood and Louis 1998). The well-known 'continuous improvement' and 'total quality management' approaches represent views of how organizational learning can be institutionalized in organizations.

Differences in national cultures associated with such core values as 'equality versus inequality, collectivism versus individualism, masculinity versus femininity, and uncertainty avoidance versus tolerance for ambiguity' are among the factors that affect leadership and the culture of schools (Firestone and Louis 1999, p. 302). At the same time, the increasing forces of globalization produce pressures and trends that tend to reduce national differences and 'internationalize' or standardize the character of education systems and educational administration (Chapman et al. 1999). For example, growing international pressures to honor diversity and end discrimination based on race, religion, gender, etc., are changing the culture of schools worldwide and opening the doors of school leadership to people from all backgrounds. Thus, effective educational leadership is likely increasingly to require more inclusive and collaborative approaches that foster collective responsibility and commitment, thereby promoting professional development and school improvement.

Educational Learning Theory

1. Introduction

There are distinct traditions in education that derive from differing perspectives on the phenomena of the domain. We organize our discussion around three general perspectives that have developed in educational research. We recognize that other organizing principles could be chosen, and that many of our colleagues would characterize the field in different terms. Our version groups together many research contributions that could be distinguished in important ways. We have arrived at this grouping in our own effort to understand broad trends in educational research.

The perspectives correspond to three general views of knowing and learning, which following Case (1992) we refer to as *empiricist*, *rationalist*, and *pragmatist–sociohistoric*. (Case used the simpler term 'sociohistoric.') Empiricism, typified by Locke and Thorndike, emphasizes consistency of knowledge with experience. Rationalism, typified by Descartes and Piaget, emphasizes conceptual coherence and formal criteria of truth. Pragmatism, typified by Dewey and Mead, and sociohistoricism, typified by Vygotsky, emphasize that knowledge is constructed in practical activities of people as they interact with each other and their material environments. Current manifestations of these three perspectives are the *behaviorist* perspective, the *cognitive* perspective, and the *situative* perspective.

All three of these perspectives have contributed, and continue to contribute, important insights to fundamental scientific knowledge and understanding of cognition and learning, and have influenced educational practices significantly. While each perspective is valuable, they frame theoretical and practical issues in distinctive and complementary ways, somewhat in the way that physics, chemistry, and biology frame issues surrounding genetic replication in different ways. This essay is drawn from an extended discussion of the three perspectives in Greeno et al. (1996).

2. Overview of the Three Theoretical Perspectives

There are three thematic issues that characterize the perspectives:

(a) The nature of knowing.
(b) The nature of learning and transfer.
(c) The nature of motivation and engagement.

In the behaviorist/empiricist view, knowing is an organized accumulation of associations and components of skills. *Learning* is the process in which association and skills are acquired, and *transfer* occurs to the extent that behaviors learned in one situation are utilized in another situation. Motivation is a state of the learner that favors formation of new associations and skills, primarily involving incentives for attending to relevant aspects of the situation and for responding appropriately. There are three traditions that we consider contributed to this view. *Associationism*, which goes back to Locke and David Hume, viewed knowing as the associations between ideas, and learning as building new associations. *Behaviorism* took the position that knowing could be characterized only in terms of observable connections between stimuli and responses, and learning in terms of forming and strengthening or weakening and extinguishing those connections through reinforcement or non-reinforcement. *Connectionism* (or neural networks) treats knowledge as the pattern of connections between neuron-like elements, and learning as the strengthening or weakening of those connections.

The cognitive/rationalist perspective on knowledge emphasizes understanding of concepts and theories in different subject matter domains and general cognitive abilities, such as reasoning, planning, solving problems, and comprehending language. There are three traditions of research that we consider to be branches of the rationalist perspective. The oldest of these is *gestalt psychology*, which emphasized the structural nature of knowledge and the importance of insight in learning. A second tradition, *constructivism*, was originally developed by Piaget and is focused on characterizing the cognitive growth of children, especially their growth in conceptual understanding. The third tradition, *symbolic information processing*, was developed in cognitive science by Chomsky, Simon, Newell, and others, and is focused on characterizing processes of language understanding, reasoning, and problem solving. All three traditions emphasize the importance of organized patterns in cognitive activities. The constructivist and information-processing traditions also focus on procedures and operations for representing and reasoning about information. Learning is understood as a constructive process of conceptual growth, often involving reorganization of concepts in the learner's understanding, and growth in general cognitive abilities, such as problem solving strategies and metacognitive processes. Discussions of motivation often emphasize that much learning occurs without the need for extrinsic incentives, as in the case

of learning one's first language, and focus on ways to foster the intrinsic interest of learners in ideas and concepts.

The situative/pragmatist–sociohistoric perspective views knowledge as distributed among people and their environments, including the objects, artifacts, tools, books, and the communities of which they are a part. Analyses of activity focus on processes of interaction of individuals with other people and with physical and technological systems. Several research traditions have contributed to the situative perspective. The best established of these is *ethnography*, including the study of cultural practices and patterns of social interactions, as well as discourse analysis and conversation analysis in activity theory, sociolinguistics, anthropology, and sociology. Another research tradition is *ecological psychology*, which studies behavior as physical interaction in which animals, including people, participate in physical and technological systems. A third research tradition is *situation theory*, in logic and philosophy, which analyzes meaning and action as relational systems and is developing a reformulation of logic to support these relational analyses. Knowing in this perspective is both an attribute of groups that carry out cooperative activities and an attribute of individuals who participate in the groups. Learning by a group or individual involves becoming attuned to constraints and affordances of the material and social systems with which they interact. Discussions of motivation in this perspective often emphasize engagement of individuals with the functions and goals of the community, including interpersonal commitments and ways in which individuals' identities are enhanced or diminished by their participation.

3. *Acquiring and Applying Associations: The Behaviorist/Empiricist View*

When people's knowledge is viewed as having associations between ideas or stimuli and responses, learning is the formation, strengthening, and adjustment of those associations. The research on basic associative processes of learning has important implications for teaching and learning. One is the importance of individual students having opportunities to give responses of the kind that they are to learn, and of feedback that is contingent on the individual student's responses.

Researchers in behavioral conditioning also found that effective learning usually requires significant preparation, or *shaping*, in which the learner becomes oriented to the general conditions where learning will occur. In conditioning experiments with animals, shaping involves a period in which the trainer attends carefully to the animal's activity in the learning environment, first providing reinforcement for being near the goal (e.g., a disk that a pigeon can peck), then for orienting toward the goal, then for touching it, and finally only for pecking it; the response that is desired. This kind of instruction by approximation has clear parallels in school learning, where skilled teachers attend to students' progress and provide encouragement for students' efforts as they achieve better approximations to the behaviors they need to succeed.

Analysis of complex tasks into learning hierarchies (Gagné 1968) has been used in designing instruction sequences and computer-based systems for learning routine skills. The hypothesis that smaller units of behavior need to be mastered as prerequisites for more complex units provides a basis for arranging sequences of instruction in which students are able to succeed by learning in small steps. This *decomposition hypothesis* is currently being questioned by many in the cognitive community (e.g., Resnick and Resnick 1991), based on a concern that instruction limited to components can result in mechanical knowledge without sufficient development of the conceptual basis for procedures that are learned.

In the view that knowing is having associations, learning in a new situation depends on how many, and which kinds of, associations needed in the new situation have already been acquired in the previous situation. The idea of *transfer* in conditioning involves *gradients* of similarity along stimulus dimensions, so that a response learned as an association to one stimulus generalizes more strongly to other stimuli that are similar to it in all respects, and less strongly to stimuli that differ from it in one or more dimensions. Thorndike (1903) expressed this as a theory of transfer based on common elements.

4. *Acquiring and Using Conceptual and Cognitive Structures: The Cognitive/Rationalist View*

Research on children's *learning* has been a significant topic in developmental psychology. Piaget's influence on educational practice has been considerable, especially informing efforts to organize science learning in a way that involves students' discovery of principles and concepts. Current research is developing accounts of the rich intuitive conceptual understanding by children, which undergoes significant change as they grow older. The research emphasizes that children's learning must be viewed as transforming significant understanding that they already have, rather than as simple acquisitions written on blank slates.

Information-processing models characterize learning in terms of procedures that represent task information, set goals, and transform symbolic expressions to satisfy the main problem goal. As an example, Anderson (1983) simulates three kinds of learning processes: proceduralization, tuning, and automization. Researchers have also investigated reasoning and

understanding that depends on mental representations, called *mental models*, that provide a kind of simulation of events, rather than descriptions of events (Gentner and Stevens 1983). In reasoning with a mental simulation, a model represents properties of the system, and operating on the model changes some of those properties in ways that correspond to changes in properties of the system.

An important theme in the cognitive view of learning is the concept of *metacognition*, the capacity to reflect upon one's own thinking, and thereby to monitor and manage it. These strategies have been studied under many labels, all pointing to the importance of self-conscious management of one's own learning and thinking processes. This theme was introduced by developmental psychologists (e.g., Brown 1978, Flavell and Wellman 1977) who noted that a reflective, self-monitoring capacity discriminated developmentally advanced children from their less advanced peers.

In the cognitive perspective, *transfer* is assumed to depend on acquiring an abstract mental representation that is invariant across situations. A large body of research has found that students often fail to transfer their learning. Brown (1989) pointed out that in research about children's ability to transfer, the deck is stacked in favor of finding that transfer does not occur. Children are asked to solve a problem, then a new problem is presented, and the experimenter observes whether the new problem is solved in a way that uses the initial solution. Usually, experimenters do their best to hide the relation between the two problems when the second problem is presented, so that if children do transfer, we can be sure they did so spontaneously. More importantly, for Brown, the potential generality of the initial solution is not made clear. When Brown and Kane (1988) taught solutions of problems and asked children to explain why the solutions were examples of general themes, thus calling attention to their potential generality, the children in their experiments transferred much more successfully.

There is an important theoretical and educational principle in these results about transfer. The manner in which solutions of problems are presented can make a major difference for the generality of what is learned. If students understand the solution as an example of a general method, and if they understand the general features of the learning situation that are relevant to use of the method, the abilities they learn are more likely to apply generally.

5. *Becoming Attuned to Constraints and Affordances through Participation: The Situative/Pragmatist–Sociohistoric View*

When *knowing* is viewed as practices of communities and of the abilities of individuals to participate in those practices, then *learning* is the strengthening of those practices and participatory abilities. Systems in which individuals learn to participate in social practices are very common, and include apprenticeship and other forms of being initiated into the practices of a group. Lave and Wenger (1991) reviewed several studies of learning involving apprenticeship and concluded that a crucial factor in the success of such a system is that learners must be afforded legitimate peripheral participation, which involves access to the practices that they are expected to learn and genuine participation in the activities and concerns of the group. Lave and Wenger characterized learning of practices as processes of participation in which beginners are relatively peripheral in the activities of a community, and as they become more experienced and adept, their participation becomes more central. A crucial issue in the nature of learning is whether, and in what ways, the peripheral participation of beginners is legitimate. For an environment of apprenticeship to be a productive environment of learning, learners need to have opportunities to observe and practice activities in order to progress toward more central participation.

The view that learning occurs through participation is at the root of the practices of apprenticeship, where apprentices are guided and supervised by masters. In successful apprenticeship learning, masters teach by showing apprentices how to do a task (modeling), and then helping them as they try to do it on their own (coaching and fading). Lave and Wenger (1991) emphasized how an apprentice's identity derives from becoming part of the community of workers. The motive for becoming a more central participant in a community of practice can provide a powerful motivation for learning. Of course, what is learned in apprenticeship may not generalize easily to other contexts. Collins et al. (1989) attempted to characterize how the modeling, coaching, and fading paradigm of apprenticeship might be applied to learning the cognitive subjects of school, in an approach they called 'cognitive apprenticeship.'

A major goal of educational reform is to have students participate more actively in learning communities, including participation in formulating and evaluating questions and problems, and constructing and evaluating hypotheses, evidence, arguments, and conclusions (Brown and Campione 1996). Abilities for participating in these activities have to be learned, and the research literature on that kind of learning is sparse. Several projects have focused on creating classroom practices of discussion and inquiry, and the investigators in those projects have discussed some aspects of the process of establishing norms and expectations by the students that support productive collaborative learning (Cohen 1986, Lampert 1990, Slavin 1983).

In the view of learning as coming to participate in a community of practice, *transfer* becomes a problematic issue. The question is whether transfer applies to new practices within the community (e.g., for school

communities this might mean working new problems or accomplishing new kinds of tasks) or to practices outside the community (e.g., for school these might be work environments). Many of the resources and supports that occur within a community of practice do not carry over to a different community, and so the problem of transfer becomes one of marshalling the resources needed to be successful in a new environment. This requires sophisticated social and information-processing skills: the kinds of skills that businesses think they will need in the future.

For transfer to be possible, there must be some constraints and/or affordances that are invariant under the transformations that change the learning situation into the transfer situation. For transfer to occur, learners must become attuned to those invariants in their initial learning. One of the ways to be attuned is to have an abstract representation that can apply in the new situation, but this is only one possible way for attunement to occur, and may not be the typical way for many learned activities to generalize (Greeno et al. 1993).

Educational Media

Since Thorndike (1912) recommended pictures as a labor saving device for teachers, educational media have been the focus of research in many disciplines. Media such as computers and television are perceived widely as important because they provide essential communication links allowing the exchange of educational and other information between diverse and geographically separated groups and individuals.

Depending on the discipline conducting investigations, media have been defined from points of view that include journalistic, communication, philosophical, historical, economic, sociological, and psychological perspectives. The result is a mountain of studies exploring the influence of media on outcomes such as knowledge acquisition, political opinion, social learning, access to information, values, attitudes, business development, perceptions of reality, economic development, socialization processes, and learning in settings such as communities, schools, homes, and work. Most of this research has progressed without the unifying aid of theory development. The central focus of most studies is a concern with the impact of media on the learning and motivation of individuals,

groups, and societies. The emphasis in this review will be on educational uses of media from the perspective of social-psychological research.

1. Three Social-psychological Definitions of Educational Media

European, North American, and Asian social-psychological researchers tend to define media in one of three ways. First is the 'media as vehicles' definition where two or more information storage and delivery devices are examined for their capacity to provide different learning benefits and efficient access by learners to knowledge and instruction. The goal in many of these studies is to find the media or mix of media that provide the greatest learning benefit for different learners and curricula. Examples of media that fit this definition are books, cinema, television, radio, newspapers, and computers when used for teaching and learning. Two types of studies are often conducted. Comparison studies examine the relative learning and cost benefits of two or more alternative media (see for example, summaries and meta-analyses of these studies by the Kuliks and their co-workers (Kulik and Kulik 1991) to determine which medium or mix of media contributed more learning benefit. In most instances, the results of meta-analytic studies indicated that computer-based instruction resulted in learning benefits of approximately one-half a standard deviation over traditional media with a variety of curricula and learners. Other studies in this area question the relative efficiencies of different educational uses of media (for example, Levin 1983) and their contribution to instructional design (efficiency is often defined as the cost of different media for learner access to instruction in time, money, mental, or physical effort), time required to reach a preset learning criterion, and ease of use. The results of Levin's studies suggest that media can be very cost-efficient for educational purposes when the numbers of students to be served are quite large and geographically separated.

1.1 Media as Vehicles Plus Teaching Methods

A second approach can be found in the integrated 'media as vehicles plus teaching method' studies. Here media are defined not only as vehicles but also by the instructional methods or strategies they permit to teach specific curriculum content to specific learners. Most North American and European researchers with this view believe that it is not possible or beneficial to separate the delivery and instructional content functions of media (see Kozma 1994). A familiar 'media plus method' example is the use of the 'interactivity' between media and learner possible in computer-based instructional programs. This definition encompasses the capacity of some media to permit many real-time, interactive instructional 'transactions' (for example, a learner might respond to computer provided questions followed by corrective or elaborative feedback from the computer about the learner's responses). Typical research in the 'media and method' approach examines the learning benefits of developed instructional media programs such as Sesame Street or the Jasper Woodbury science program (Kozma 1994). An offshoot of this approach is exemplified by 'media attributes' studies. Researchers in this area study the capabilities of different media to provide a model for some of the mental processes required for learning. For example, Salomon (1979/1994) described studies that examined the capacity of cinema and television to 'zoom' from a wide field into a more narrow or specific view of a complex picture. After a zooming treatment where learners who had initial difficulty noticing parts of paintings significantly increased not only the number of details they reported but also increased the number of alternative views about the purpose of the artist. Salomon reasoned that his subjects had learned not only to notice more aspects and interpretations of paintings, but also had learned the perceptual and mental process of 'zooming' from this attribute or symbolic mode of real-time visual media.

1.2 Media as Learning Environments

A number of European, Asian, and some North American researchers have tended to take a 'media as learning context' approach to educational media inquiry. In this definition, media are viewed as contexts where education occurs, much like research on schools or homes as settings for educational experiences. Examples of this approach were described in an edited series by De Corte et al. (1992). The learning context focus investigates the ways that 'learning with media' in an educational context (as contrasted with 'learning from media' in the media as vehicles and methods approach) results in transformed learning environments and more durable learning-to-learn strategies for students. In these studies, the units of analysis are both the learner and the educational system. When new electronic media are added to educational settings '*Most everything has changed—curriculum*, *activity*, *engagement in learning*, *instruction*, *social interaction*, *teacher's roles*, (and) *modes of student evaluation* …that far transcended the mere introduction of computers' (Salomon 1992, p. 259, emphasis in original). The primary concern of learning context studies is to determine ways that educational media can modify and improve instructional settings. A more recent example of this work can be found in various studies reported by Kiesler and Kraut (see a summary of alternative views in Kiesler and Kraut 1999) on the

negative social and psychological consequences of increased Internet use in distance, media-based education, and communication.

2. Disputes about Methodological Issues

Educational media research has suffered from methodological disputes at least since the 1960s when Lumsdaine (1963) cautioned researchers about problems in the design of educational media studies. He claimed that the design of studies up to that date had confounded the effects of medium with the separate learning effects of the content and instructional strategies contained in media presentations. Salomon and Clark (1977) summarized the methodological concerns of Lumsdaine and others by distinguishing between research with media and research on media. Research with media employed newer media to study the effects of new (vs. old) teaching methods and curriculum reforms. An example would be the use of television to study the learning benefits of altering the length of educational presentations. Learning benefits found in these studies were sometimes mistakenly attributed to the medium. Research on media examined the unique contributions of various media to learning of different curriculum elements by different groups of learners.

2.1 Recent Methodological Disputes

Clark (1994) has argued that all studies that find learning or motivational benefits from media are flawed methodologically. He suggested that all learning benefits attributed to media are actually due to the uncontrolled and confounded effects of different instructional methods and information content in different treatments. He also claimed that all learning benefits attributed to any one medium or media attribute would also be found to be available from other media or attributes of media and therefore the benefits of media are economic (some media cost less than others to deliver the same instruction with similar learning benefits). He summarized his argument by suggesting that media do not influence learning any more than the truck that delivers food to a market influences the nutrition of its customers. Kozma (1994) and others have disagreed with Clark and other methodological critics of media studies. He argues for the medium plus method approach and suggests that Clark's 'separation of media from method creates an unnecessary and undesirable schism between the two…(because)…a medium's capabilities enable methods and the methods that take advantage of these capabilities of media are going to influence learning—methods must be confounded with media' (Kozma 1994, p. 16). A number of other media plus method and media as context researchers have agreed with Kozma (see a number of papers on this topic in Clark 1994).

3. Future Directions for Educational Media Research

A variety of new directions seem to develop constantly in educational media research. Most of these directions are focused on new electronic media or novel computer software that is adapted to educational uses. Saettler's (1968) history of educational media inquiry suggested that this has been a pattern for the past century. Each new medium attracts a group of new researchers to tend to ignore the lessons of past media studies and ask redundant questions. However, productive new areas are developing.

At least three novel or rediscovered research areas are developing as this article is being written. Vigorous research is being carried out in cognitive load theory, in economic studies of media, and in national surveys of educational media use in schools and universities.

3.1 Cognitive Load Theory and Educational Media Design

One group of theory-oriented researchers, stimulated by studies in Australia on cognitive load by Sweller et al. (1998), are examining ways to design educational media presentations so that cognitive overload is avoided. Sweller and his co-workers have developed a method of measuring the amount of cognitive load imposed and mental effort required by an instructional presentation. They have also identified a number of learning problems caused by common educational media design strategies and ways to overcome these problems. One example is the split attention effect. When learner attention is split between different sensory modes or media, Sweller hypothesizes that working memory is often overloaded. Studies by Mousavi et al. (1995) and Mayer (1997) have claimed that presenting novel and difficult concepts to learners in integrated auditory and visual symbolic modes overcomes the split attention effect and results in more learning than information presented in either mode alone for high visual ability and low prior knowledge learners. The theoretical explanation advanced for these findings is that integrated visual and auditory information is more efficiently processed in working memory. The added benefit of integrated auditory explanation and visual depiction of concepts and processes is presumably caused by auditory and visual sensory memory 'buffers' that specialize in storing information that exceeds the limits of working mem-

ory. This activity is hypothesized to extend the representational duration of information to be learned so that elaboration processes have more time to operate and transfer information to long term memory. It is likely that this area will receive much more attention from media researchers since it fits nicely with the current interest in 'multi-media instruction' (see a review and summary by Hedberg et al. 1993). This approach is also one of the features of a new theory of instructional design for teaching complex knowledge.

3.2 New Research on the Economics and Efficiencies of Educational Media

Recently, some of the media-as-vehicle researchers have attempted to encourage studies that examine the 'cognitive efficiency' of instructional presentations that use newer electronic media (see Cobb 1997) at a variety of levels (national, regional, small group, individual) and outcomes (for example, cost per unit of achievement or speed of learning a set of concepts). Cobb suggests that some media and symbolic modes lead to quicker and/or less demanding learning and performance outcomes than other media or symbolic modes for some people. So we have a question with at least two interactive independent variables: the media or representational mode used for presenting an instructional method (for instance, an example presented in either pictorial or verbal modes) and the individual or group differences that would predispose learners to process the method easier and/or faster during learning (for instance, high visual but low verbal ability learners will likely learn faster from pictures than from narrative descriptions of examples). The cost of learning is, after all, one of the most important issues for those concerned with the application of research to solving practical problems.

Cobb illustrates research in cognitive efficiencies by inventing a situation where we want to teach someone to recognize the song of a specific species of bird. He describes different media/modes of presenting bird songs to learners including audio recordings and musical notation. He asks 'How many hours are needed to learn a bird song with a recording vs. with sheet music?'(Cobb 1997, p. 26). He suggests that we show learners the musical notation for the song or play an audio recording of the song. If enough time is allowed for learners and if their motivation is adequate to support their persistence in difficult treatments such as the musical notation of the bird song, then all treatments should eventually produce learning. Yet few media specialists would consider teaching bird songs with musical notation to a majority of learners with adequate hearing and auditory discrimination ability. Is it possible however, that the two modes have different efficiency characteristics for different learners? While the example requires a stretch of the imagination, consider learners who have musical training and auditory discrimination problems. It seems plausible to assume that this small subset of learners might be able to recognize bird songs more efficiently with musical notation than with audio recordings. The work of Levin and co-workers (for example, Levin et al. 1987) has been useful for conceptualizing the various analysis protocols for cost-benefit and cost-effectiveness assessment of media for learning and performance. Levin's (1983) 'replacement method' of determining costs is a very conservative estimate of the economic gains from using media in a school or home setting. Additional work needs to be done in this area to facilitate the measurement of efficiency benefits during learning (for example, speed of learning, lowering the mental effort required to learn).

3.3 National Surveys of Educational Media Use in Schools

A number of governments currently are interested in surveying educational media use in schools and universities. The reason for this interest is, in part, a belief that preparing students for future work and social responsibilities requires skill and knowledge about media. In addition, there is considerable national and international interest in using the World Wide Web and computer-based teaching. Examples of educational surveys in the US have been described by Becker (1999) who has reported statistics on computer use in American schools since 1993 to support national policy decisions on educational media use and research. Among the findings of these surveys is that Internet connections in North American schools have increased from 35 percent in 1993 to over 90 percent in 1999. Becker and his co-workers are curious about the relationship between Internet use and educational philosophy. They have suggested that teachers who have a more constructivist approach (for example, a belief that students construct their own knowledge) use the Internet more in the their teaching than teachers with a traditional instructivist philosophy (for example, that students must be 'taught' knowledge). These studies reflect the educational media as context approach to research.

Educational Philosophy: Contemporary Views

The issues that are discussed nowadays in the philosophy of education, and the particular ways in which they are dealt with, must be understood as part of the history of the subject. Contrary to the post-Second World War English-speaking scene, where philosophy of education concerned itself primarily, though not exclusively, with analysis and accounts of schooling, the European counterpart occupied itself mainly with problems situated within the broader field of child-rearing including discussions of the concept formation (*Bildung*). Furthermore it is important to realize that continental philosophy of education placed itself firmly within the legacy of the Enlightenment tradition. From this philosophical stance, education was the means to becoming human, i.e., rational: becoming free from one's inclinations and passions, putting oneself under the guidance of reason.

Construing education as a means to realizing one's true nature was not interpreted in a narrow means/end fashion, however, in spite of some claims to that effect. Nor should it be seen as highly individualistic and alienating, for being rational was a state of affairs which was universal and which, being the same for everyone, precluded false consciousness and alienation. The educational implications of this Enlightenment tradition were spelled out mainly by German philosophers of education starting from Kant and Herbart during the eighteenth and nineteenth centuries. Through their work the project of Enlightenment became the project of education. However, a radical pluralism has swept the world and this has been the cause of a crisis in education. But it should be noted that the crisis of education, and the parallel crisis of philosophy of education, are part of a wider crisis of rationality itself. The questions whether reason, and reason alone, can decide what should be done, and if, moreover, rational thinking is even possible at all, are at the heart of the matter. For example, phenomenology, existentialism, neo-Marxism, the Frankfurter Schule (that critiqued the use of a rationality which subsumes the particular under the general because of a will to dominate) and others, have criticized the overambitious Enlightenment project of rationality. Though the critique of reason by reason belongs itself to the tradition of the Enlightenment, the assumption that our enlightened rationality is adequate is, however, called in question—particularly from Nietzsche onwards (cf. Peters et al. 2000, Blake et al. 2000).

Not surprisingly the traditional approach or framework of education has been criticized by twentieth-century philosopher educators. Their starting point in education is from the child-centered movement, or reform-pedagogy. For them child-rearing could no longer be characterized by activities pursued by adults in order to bring children to adulthood. From this position the educator (the parent and/or the teacher) is, first of all, the adviser to the child, and the facilitator of what she or he really wants. It is the child, it is argued, who is from the very beginning responsible for the learning process. Parents should respect their children's values. All of this is of course not unproblematic. It was doubted whether it is possible that

an individual can discover within him or herself what he or she really wants. The closed *cogito* rightly criticized is, so it seems, introduced again here uncritically. Values do not arise privately and individually but have to be thought of—from the beginning—as bestowed upon people by significant others. Furthermore, how could parents and teachers behave as if the values they embrace have the same significance for them as the values their children accept? Finally, it is not clear how parents could avoid initiating their children in the values they live by—must not parents inevitably influence their children in very important ways. In the Anglo-Saxon context, traditionally philosophy had assumed a foundational role for education. The works of the great educators and their employment in educational institutions reflects this belief. Yet the discourse and practices related to this belief were haphazard, discontinuous, and unsystematic. The field was therefore ripe after the Second World War for a coherent and systematic rationalization of its beliefs and practices.

The earlier works by Hardie (1942) and O'Connor (1957), written from a positivistic philosophical position, were not to serve as paradigms for the emerging professionalism of philosophy of education. It was instead Israel Scheffler (1960) and Richard Stanley Peters (1966) who would become the leading authors of the analytic philosophy of education. Their work had its roots in the early work of Moore, Russell, Wittgenstein, Tractatus, Austin, Ryle, and Ayer—clearly not an exhaustive list. Scheffler's *The Language of Education* (1960) was to stimulate considerable discussion on the concept of teaching, Peters' analysis of the concept of education (*Ethics and Education* 1966) was to provide an example of conceptual analysis which was to serve as a paradigm. In practice analytic philosophers of education claimed that they were attempting to clarify the criteria used in the use or application of concepts, by clarifying the rules or conditions under which concepts were used or applied. Borrowing the notion of language as rule governed activity from the work of the later Wittgenstein, though adapted improperly because ultimately they were searching for foundations, and for necessary and sufficient conditions, they adopted the research program of analysis and clarification. First under attack from sociologists of education and then from the general vocational thrust of education in Thatcher's Britain, philosophy of education lost much of its power and influence.

Within North America, while not abandoning the gains made by the analytic approach, not only methodologically but also professionally, attempts were made to broaden the field of philosophy of education, but whereas the *Proceedings of the Philosophy of Education Society* (USA) and *Educational Theory* have a decidedly different feel about them compared to the *British Journal of Philosophy of Education*, there is no one clear paradigm which has emerged in either to replace the analytic approach (see *Educational Theory* 1991, **41**(3) for a summary of the state of the art in North America). If philosophy of education was at its height in 1981 with the publication of the Yearbooks' special issue on philosophy of education, and if the division of chapters in the yearbook—into ethics, epistemology, metaphysics, etc.—revealed that philosophy of education had gone 'professional' by becoming, as editor Jonas Soltis seemed to see it, a collection of subfields of subfields philosophy, then it had also lost touch with educators. By seeking legitimacy in the ideas of philosophy—for example in Rawls, Marx, the phenomenologists and the Frankfurt school—they were no longer communicating with educators. On the contrary it was writers like Illich, Freire, and Bowles and Gintis, who were being discussed in education and not Scheffler, or Soltis, or... More recently it is Apple, Giroux, and McLaren whose works are being widely published and discussed. However not all of this contested 'ground' has been relinquished. For example, philosophers like Harvey Siegel writing on critical thinking, Denis Phillips on objectivity, especially in relation to educational research, and Robin Barrow on curriculum matters (among other things), do have a voice in this conversation on education. But it is clear that the general interest nowadays has shifted to thinkers such as Rorty, Derrida, Lyotard, and Foucault. A strong and sustained critique of foundationalism has emerged in recent years in philosophy, and thus philosophy of education is slowly catching up with some of these developments.

At the different centers in Europe in which philosophy of education is practiced, a varied landscape emerges. Some philosophers of education continue to follow the traditional paths as if nothing has really changed. Within the traditional approach, representatives of several paradigms can be found: phenomenology; existentialism; transcendental (Kantian) pedagogy; critical rationality; *geisteswissenschaftlich*-hermeneutic; and critical-emancipatory. However, in general, the scene is dominated mainly by those who have put these positions in question (see for instance *Zeitschrift für Pädagogik*, 1990, **36**(1)). A theme present in a large number of discussions is the relationship between theory and praxis (see, e.g., Hermann 1987 who reconciles both by the use of common sense). Another approach is to be found in the system-theory of Luhmann and Schorr (1982). Here the basic assumption is that theory cannot formulate any rules which make clear how a practitioner ought to act. Instead educational praxis has to be characterized by the self-sufficiency of the system. There is also the insistence on *Allgemeinbildung* (see Pleines 1987), which could be translated as general formation. The theme of the general is also approached in a different way in Kohlberg's developmental psychology (cf. Oser 1986). The task of the educator comes down to establishing the right conditions in

which the structures can articulate themselves and can change. An important stance which dates back to Horkheimer and Adorno is the critical-emancipatory. There reason signifies the ability to free oneself from a prereflective bond with nature and to be differentiated from it. The capacity of distancing contains the possibility of transforming nature into an object to be dominated. Authors such as Habermas, who is critical of the early starting point of the conscious subject, start from language. There the focus is on the emancipation of the individual in an intersubjectivity of unconstrained agreement with others. The interest in the latter, i.e., in critical theory, is of course not only present in the European context but is there worldwide. So is the interest for Wittgensteinian and postmodern philosophy of education generally. But before turning to these general strands it is important to point out that there are not only schools of thought which can be identified within philosophy of education, but there are also a number of topics which are given particular attention to in the debate nowadays. Among these are: liberalism and communitarianism, citizenship and nationalism, education and the market, multiculturalism, information technology and it goes without saying that pragmatism and feminism (including the ethics of care and its relation to virtue ethics) generate a considerable interest as well (cf. Blake et al. 2001).

From a Wittgensteinian position education can be conceived as a dynamic initiation into a form of life (cf. Smeyers and Marshall 1995). From this position parents are seen as the first educators and from this responsibility, the responsibility of the state concerning schooling can be derived. Parents offer the child the truths by which they live: what moves them, what appeals to them, what supports the idea of human being hoping that she or he will participate. This is an initiation into what is self-evident, or the initiation into the form of life, as Wittgenstein puts it. Insofar as meaning is involved, it will be clear that attention will be given to the particular aspect of a situation. This cannot be separated from the quest for justification. What falls outside one's actions and one's language is not intelligible and thus cannot be justified. Only through educational practice will it become clear what is there for us and what is valuable for us. For Wittgensteinian epistemology and ethics, there is no either/or. It is always language-and-the-world, always the individual-and-the-others. Wittgensteinian philosophy of education will try to make explicit the grammar of the educational language and its presuppositions. It will not offer new facts, nor hypotheses that can be tested. There would be no attempt to offer general justifications through ordinary language, nor to lay out necessary and/or sufficient conditions for the use of certain concepts. What it would offer is a discussion of the nature of an educational question. Here it is fully accepted that there is not one interpretation, but only an interpretation. Besides its task in indicating the incorrectness of certain arguments and the impossibility of accepting certain presuppositions, there is then the explication of reasons that carry one's engagement. Evidently, here philosophy of education cannot remain indifferent to developments within the educational context, but must take a stance (cf. Smeyers and Marshall 1995).

Postmodern philosophy of education on the other hand focuses on another aspect of the present *Zeitgeist*. A profound objection to modernity has always been that the modern technical genius for finding effective means to ends has too much diverted attention from serious consideration of our chosen or implicit ends themselves, whether ethical, economic or, educational. Modernity is instrumentalist. Can objection be heard no less from traditionalists than from the Left or any other quarter. Under the postmodern condition, as Lyotard has described it, the obsession with efficiency and effectiveness that he criticized, and memorably labeled as performativity, has finally parted company altogether from controversial, political questions of what we should be trying to achieve. All kinds of business and activity are measured and ranked against each other, with ever less concern for the rationale for doing so. Thus performativity obscures differences, requiring everything to be commensurable with everything else, so that things can be ranked on the same scale and everyone can be accountable against the same standards. This in turn entails the disvaluing, and perhaps the eradication, of what cannot be ranked. Schools in the United Kingdom, to give one example, are now ranked in gigantic league tables on the basis of the tested achievements of their pupils. Yet while their examination scores are neurotically compared, their social and moral ethos goes by the wayside. Schools and pupils are now required to speak their truth on pain of punishment. This they are to do in the methodical and routine terms of examinations and tests and moreover in the format acceptable to management.

Despite this drive to optimize the system's performance under centralized control, there has also been a countervailing tendency toward dispersal and differentiation. Such variety would, supposedly, empower consumers by giving them a wider range of choice in the marketplace. In itself this apparent contradiction is easily related to historic trends in modernity: to secularization and bureaucratization in the sphere of culture, and rationalization and liberalization in the sphere of society. What is new are the terms in which these processes have come to be understood and celebrated. Power has moved elsewhere, to consumers rather than producers, or at any rate to those (advertising agencies, marketing consultants and facilitators of all kinds) who have the expertise to manipulate consumer choice and sell the educational product just like any other. It is to the consumers that educators must now make confession. Thus confession supplants profession, method replaces thoughtfulness, and pres-

entation skills and image management come before scholarly authority. The family, too, suffers bewilderment in its attempts to educate the young. Like teachers, parents find themselves the objects of suspicion and distrust. An ethos of care sits uneasily with an emphasis on children's rights and, above all, on the individual child's right to choose. The family is scrutinized for its outcomes: how are your chances of good examination results, or your earning potential, affected by being brought up by a single parent? Children in this position may be compensated by being offered, in that most revealing phrase, quality time by the parent who has left, as if this improves the child's opportunity of turning into a quality product (by the standards of quality control). The courses of relevant experts in parenting skills will help obscure the fact that bringing up children is not really regarded as valuable in a society dominated by economic rationality. But the demands of performativity cause more than bewilderment: as Lyotard tells us, they cause terror. We have to be operational or disappear: to fit in with bureaucratic systems, to do the things that can be entered on computer databases, or pay the penalty. In this context one turns to a number of writers and theorists who show a way out of the intellectual paralysis of postmodernity. These writers—chiefly Jacques Derrida, Jacques Lacan, Jean-François Lyotard, and Michel Foucault—have mostly repudiated the title of postmodernists, yet they are clearly postmodernist thinkers in the sense that they help us think about the postmodern condition in which we find ourselves. They have set the stage for the contemporary debate at the time of the turning of the century. As well in the Wittgensteinian philosophy of education as in its postmodern counterpart, the link with education itself has thus been restored (cf. Blake et al. 1998).

Educational Philosophy: Historical Perspectives

Philosophical reflection on the nature of education and related issues is about as old as philosophy itself; Plato's *Meno* and *Republic* are not only foundational works of Western philosophy and political theory, but are also the first great classics in philosophy of education. And just as philosophy itself has been an extremely diverse field for the past two and a half millennia, and much of its terrain has been—and still is—bitterly contested, so it is with philosophy of education. To make the field even more complex to describe, during the twentieth century most of the significant intellectual and social trends, and not just the strictly philosophical ones, had an impact upon the work of philosophers of education. Analytical and ordinary language philosophy, and logical positivism, have had adherents in philosophy of education, but so have Marxism, critical theory, phenomenology, hermeneutics, postmodernism, feminist epistemology and social theory, and neoliberalism; furthermore, philosophers of education have often been embroiled in the disputes that rage over such controversial issues as multiculturalism, children's rights, national testing of students and the loss of standards, national curriculum, teacher training and accreditation, and the interface between school and work. There also have been important regional differences in the way in which the field has been conceptualized and institutionalized. This article sketches, necessarily in broad strokes, the development of this lively and diverse domain.

1. Classic Philosophers Writing on Education

Philosophy of education as a recognizable branch of philosophy, or area of specialization within it, is a product of the twentieth century; most commentators would agree that its institutionalized development was relatively insignificant until just before World War II. However, many of the writings of philosophers of the past dealt with educationally relevant issues, although these educational implications were most often left implicit rather than made the object of explicit discussion; direct discussion of education was only sporadic. The nature of knowledge, the nature of human cognition, the rational bases of belief and the causes of unbelief (or of false belief), the key aspects of critical thinking, the formal and informal logical fallacies that plague reasoning in everyday life, the nature of morality and the good life, the importance of personal autonomy, the nature of a just society, the obligations borne by those who aspire to full citizenship in a society, the education of the citizen, the logical features of inquiry in the human and social sciences, are examples of matters that have been grist to the philosophical mill, and which have great relevance to the field of education.

Indeed, it can be argued more strongly that philosophy always serves a vital educational purpose, for, as Amelie Oksenberg Rorty wrote in the introduction to a collection of essays she edited about philosophers of the past who did educationally relevant work: 'Even "pure" philosophy—metaphysics and logic—is implicitly pedagogical. It is meant to correct the myopia of the past and the immediate' (Rorty 1998, p. 1). On this account, then, almost any philosopher's work is also a work in philosophy of education, so it is no surprise that Rorty's volume has discussions of the educational philosophies of—or, more accurately, the educational relevance of the work of—a diverse group including Plato, Aristotle, Augustine, Aquinas, Maimonedes, Rene Descartes, Thomas Hobbes, Spinoza, John Locke, Rousseau and other early Romantics, Kant, Hegel, Mill, the Logical Positivists, and Dewey. Notable omissions are the nineteenth- and twentieth-century figures J. F. Herbart, Herbert Spencer, Bertrand Russell, Wittgenstein, and the two philosophers whose writings most explicitly addressed philosophical issues in education in the second half of the twentieth century—Richard S. Peters and Israel Scheffler. Chambliss, in an essay-length review of the history of philosophy of education, discusses a set of authors that overlaps with the group in the Rorty volume (Chambliss 1996); for a work that attempts to integrate historical and contemporary writing in the field, see Noddings (1995).

1.1 Philosophy vs. 'Cultured Reflection'

An important issue arises here, one that has not always been recognized by writers on the history of philosophy of education: When philosophers of the past—even noteworthy ones such as those listed above—have turned explicitly to address issues concerning education, it has not always been the case that their writings have been philosophical on even a charitable interpretation of this contested term. Some philosophers, to be sure, have developed educational positions that are closely related to, or which are fairly tightly derived from, their philosophical positions; but many others, when they have turned explicitly to education, have engaged in what has been called 'cultured reflection' upon education rather than in closely reasoned philosophical argumentation. The British analytical philosopher D. J. O'Connor noted as far back as 1957 that too often expressions like 'philosophy of education' or 'philosophical reflection on the bases of education' were 'no more than vague though high-sounding titles for miscellaneous talk about the aims and methods of teaching,' and he suggested that these usages 'could well be dropped in the interest of clarity' (cited in Phillips 1985, p. 3863). His suggestion was viewed, in some quarters, as imperious.

A book by John Locke can serve as one example of this nonphilosophical genre; his *Some Thoughts Concerning Education* (1693/1947), which has been reprinted many times and has been cited widely in histories of educational thought, deals with the education of the young gentleman who is likely to inherit a country estate, and it is filled with advice on such matters as hardening the youngster by having him wear leaky shoes in wet weather. There is little (if anything) here that derives from Locke's foundational work in empiricist epistemology or political philosophy; rather, his often interesting educational ideas seem to stem from his wide range of experience as a man of the world. On the other hand, his classic philosophical writings—which are not widely cited in histories of education, and which do not explicitly discuss the field at all—have been a major influence on educational thought; for example through their impact on associationist psychology, the child study movement of the late nineteenth century, and liberal social theory.

In the twentieth century there were many so-called 'philosophers of education' whose work was in this genre of 'cultured reflection' on education rather than being philosophical in any recognizable sense. As the twentieth century progressed there were growing numbers of nonphilosophical writers with strong educational or ideological commitments who self-identified as philosophers of education, and who thus helped to establish something of a gulf between philosophy of education and the parent discipline. (In this context it is interesting to note that Amelie Rorty had no contributor to her volume who is identifiable as a member of the philosophy of education community.) The works of these individuals are nonphilosophical in the sense that they do not contribute to the deeper

development or defense of any philosophical theses, and they would not be useful in courses on the traditional epistemological, metaphysical, logical, or axiological problems of philosophy offered in departments of philosophy.

1.2 Examples of Directly Relevant Philosophical Work

On the other hand, Plato's educational thought was a much more integral part of his philosophical and political thought. In his *Republic*, for example, after developing the metaphysical theory of the underlying realities, the 'forms,' he detailed the educational process that would lead the future philosopher–rulers to gain knowledge of them; their education would culminate in them beholding 'the form of the Good,' in the light of which they would be ably to govern wisely. Plato also discussed the education of the subordinate classes (the auxiliaries and the common citizens) that would allow them to take their allotted places in society—a society marked by complete justice, with everyone serving in the role for which nature had most fitted them. Plato's *Meno* is also regarded as a classic work in philosophy of education, and it has stimulated discussion down to the present; Plato depicts Socrates teaching a slave boy a variant of the Pythagorean theorem, not by direct instruction but by a process of 'Socratic questioning' in which the relevant information is drawn from him—illustrating Plato's theory (closely related to his epistemology) that learning is a process of remembering (for one cannot inquire about something that one does not already know).

Jean-Jacques Rousseau's novel *Emile* (1762/1955) is another work that has a niche in the history of philosophy, and an even more central place in the historical development of philosophy of education. A rather undisciplined thinker whose work is often marked by unresolved contradictions, Rousseau has nevertheless had a major impact on Western thought, in part through his influence on thinkers at the time of the French Revolution; his work on the 'social contract' is still discussed by political philosophers. His novel about the young man, Emile, which traces his life from birth until parenthood, created something of a furor upon its publication, and it was publicly burned in France. The novel—a founding work of modern progressive education—illustrates the philosophical view that all that is natural is good, and all that is 'man-made' (including the products of the civilization of Rousseau's time) is bad; Emile is taken to live in the country where a tutor arranges for him to have a 'natural' education. Emile acquires morality by suffering the natural consequences of his acts; his religious views are 'naturalistic' and are not scripturally based, and are acquired from the 'Savoyard Vicar' whom he meets while on a walk in the countryside. Emile is given very little by way of formal instruction in any topic that he has not developed a natural desire to pursue. (One of the major inconsistencies is apparent here, for—as many commentators have noted—the boy's tutor actually does not leave matters to natural happenstance but is extremely directive, albeit in a subtle way; furthermore it is notable that Rousseau does not provide a coherent account of the concept of 'natural,' which is so central to his line of argument (see Hardie 1962, Rorty 1998). The novel is notorious, too, for its treatment of Sophie, the young woman whom Emile eventually marries; in contrast to the rather progressive education of the latter, Sophie is raised to be 'pleasing' to her future mate. Late-twentieth century feminist writers and others have produced scathing analyses of this aspect of Rousseau's work (e.g., Rorty 1998).

There can be little doubt that, since the days of Plato, the major philosopher to see an intimate relationship between philosophy and education was the American pragmatist John Dewey (1859–1952). In the course of his long and productive philosophical life Dewey published more than 40 books and 800 journal articles; and yet for many years he regarded his *Democracy and Education* (1966; first printed in 1916) as the work that also best summarized his general philosophical position. Indeed, in this book—probably the most famous modern work in philosophy of education—Dewey claimed that philosophy *was* 'the general theory of education'; education, he said, 'is the laboratory in which philosophic distinctions become concrete and are tested' (Dewey 1966, pp. 328, 329). Dewey's views on the intimate relation between activity, and learning and thinking, stemmed from the evolutionary epistemology that he developed after reading the psychological writings of William James, and were directly translated into his recommendations for educational practice. Dewey's views on the classroom as a small community, and on the social functions of education, were part and parcel of his social philosophy that was an interesting amalgam of neoliberalism and communitarian ideas.

2. The Rise of Philosophy of Education as a Specialization

There are a number of widely recognized subdisciplines within the field of philosophy: epistemology, metaphysics, moral philosophy, social and political philosophy, philosophy of science, philosophy of language, logic, philosophy of mathematics, philosophy of law, history of philosophy, and so on. During the early decades of the twentieth century philosophy of education started to emerge as another subfield, although it never won the widespread acceptance accorded to these other specializations within the philosophical community. Indeed, the overwhelming majority of philosophers of education around the

world are members of schools or departments of education or pedagogy rather than being in departments of philosophy; a very small number hold joint appointments.

Despite their relative physical and intellectual isolation from their colleagues in academic philosophy, philosophers of education have interests that span the subdisciplines mentioned above. For example, there are some who pursue epistemological issues as they relate to education—such as the epistemic status of the bodies of subject matter taught in schools, or the epistemological issues that arise in educational research; some—taking a political theory, or neo-Marxist, or even a postmodernist, perspective—are concerned with issues such as what groups in society have the power to decide the structural features of the educational system, or what is taught (or not taught) in schools; others are interested in the philosophical issues surrounding citizenship, and the educational rights of individuals (including parents and children) versus sociocultural groups, in democratic societies—and the related issue of the nature of equality of opportunity; some are concerned with the philosophical issues involved in the field of moral education and moral development; others are concerned with issues that fall into the category of philosophy of psychology, such as the nature of human abilities, the relation between intelligence and creativity, and so forth.

The philosophers of education who pursue such issues are quite interdisciplinary, and follow the relevant literature in educational and psychological research, pedagogy, educational theory and policy, as well as philosophy; they tend to publish in a wide variety of journals, and not just in the philosophical ones. Other philosophers of education, reflecting the fact that the majority of those in the field are actively involved in the preparation of teachers, apply philosophical ideas drawn from a wide variety of sources (plus ideas drawn from other disciplines) to issues of classroom pedagogy and curriculum; there is no clear counterpart to their area of expertise to be found in traditional departments of philosophy. They tend to publish only in educational journals, and their work is unknown to the vast majority of their peers in such departments.

It is difficult to pinpoint the precise date of the emergence of philosophy of education as a field in its own right; the origins seem to lie in the second half of the nineteenth century when many 'normal schools' devoted to the training of teachers were established, and university departments of education or pedagogy were emerging around the world. Influential public intellectuals such as Herbert Spencer, T. H. Huxley, and Cardinal J. H. Newman in England were occasionally writing on education in a philosophical vein—again blurring the boundary between philosophy and philosophy of education, and illustrating the fact that one does not have to be a professional philosopher to sometimes write philosophically interesting material.

The expression 'philosophy of education' first seems to have been used in a systematic way in an encyclopedia produced in 1911–13; but the John Dewey Society was not established until 1935. The Philosophy of Education Society was founded in North America in 1941, and similar societies in the United Kingdom, and Australia and New Zealand, followed some 25 years later (Kaminsky 1996). Philosophical writing about education was not, of course, confined to the English-speaking world, but in Europe the intellectual landscape traditionally was carved up quite differently, leading to a different conception of philosophical reflection on education.

On the Continent there seems to have been a longstanding and stronger appreciation by those scholars working in the field of education that philosophical reflection was a vital part of the 'pedagogical sciences,' and that it was too important to be left to a small number of academic specialists. Thus there has been a lot of philosophical activity, but few have been labeled as doing 'philosophy of education' *per se*—rather, many have been engaged in discussing 'pedagogical theory' or 'pedagogical science.' As the German educationist Wolfgang Brezinka has put it, in the English-speaking world 'educology (or pedagogics) as an autonomous scientific discipline does not exist' (Brezinka 1992, p. 3). He goes on to show that in German-speaking countries, pedagogics as a mixed normative–descriptive discipline is understood to be a theory suitable for 'supplying guidelines for praxis.' Pedagogics should simultaneously 'attain a comprehension of reality and a determination of what should be.' It cannot 'limit itself to studying what is,' but is 'at least in part also a normative science which … develops guiding ideals and measures existing reality against its own claims.' It 'includes normative decisions' and should combine 'the establishment of facts' with the 'critical evaluation of these facts in the service of an obligatory norm' (Brezinka 1992, p. 5).

The Belgian scholar Paul Smeyers also sees marked differences between the way philosophy of education has been pursued in Europe and in the English-speaking world. Especially since World War II, Anglo-Saxon philosophy of education has been primarily—though not exclusively—a philosophy of schooling. Continental philosophy of education, however, concerned itself mainly with problems within the broad field of child-rearing. It is also important to realize that the Continental philosophy of education has to be situated within the legacy of the Enlightenment tradition. In this philosophical stance, education was regarded as the 'means' by which individuals became rational members of the human race (Smeyers 1994, p. 4456).

But it should not be assumed that all European writers adopt the same stance towards philosophy of education; the intranational differences are almost as great as the cross-national ones. For example, in Holland there are several philosophers of education

whose work strikes a resonant note with that of their colleagues in the English-speaking world, and who are recognizably within the analytic tradition that up until recently was dominant in the latter (and indeed they often publish in English, for example van Haaften et al. 1997); and in the USA there are some who work in a manner close to that of many of their colleagues on the Continent.

3. *Some Features of the Modern History of Philosophy of Education*

As indicated above, the field of philosophy of education is extremely diverse, with interesting cross-national differences, and with much variation even within the local scenes in North America, the UK, Australasia, The Netherlands and other nations on the Continent. This makes it impossible to generalize about the development of the field as a whole, but a few historical highlights from the twentieth century can be mentioned as significant.

3.1 *The 'isms' Approach*

For several decades around the middle of the twentieth century it was common to find philosophers of education suggesting that educators should first select a philosophical position that they found appealing, and then 'deduce' the implications for educational practice that followed from this. The 'isms' recommended as possibilities were such positions as idealism, realism, Thomism, existentialism, and pragmatism (see Broudy, in Lucas 1969). This approach was reflected in textbooks, journal articles, conference proceedings, and there was even a series of instructional films; the approach could be found in Europe as well as in the English-speaking world, and philosophers of all stripes seem to have accepted it as a valid approach.

It was some time before it was realized that this approach rested upon a serious philosophical mistake, and even late in the century an occasional textbook was released bearing its stamp. There is not a simple one-to-one correspondence between a person's deep philosophical commitments (such as to idealism or realism) and his or her everyday actions, or actions in the classroom. Idealists and realists, for example, are not offering different empirical theses about the world (e.g., that matter does, or does not, exist), but are giving different philosophical analyses of the concepts of 'matter' and 'existence.' Ludwig Wittgenstein captured the core issue well in his *Zettel* (Wittgenstein 1970, p. 413):

> One man is a convinced realist, another a convinced idealist and teaches his children accordingly … But the idealist will teach his children the word 'chair' after all, for of course he wants them to do this or that, e.g., to fetch a chair. Then where is the difference between what the idealist-educated children say and the realist ones? Won't the difference only be one of battle cry?

Those who advocated the 'isms' approach to philosophy of education were also making use of an over-simple notion of implication; a variety of premises are required to link an abstract position such as realism to the realm of schooling; clearly it is a non-sequitur to argue, as one adherent of the 'isms' approach did in 1957, that 'reality is independent of man's knowledge of it,' therefore 'man must learn impersonal science, and history; and the school plays the role of transmitter of knowledge' (see Phillips 1971, pp. 11–12).

3.2 *The Prominence of Analytic Philosophy of Education*

The 'isms' approach started to decline as the influence of analytic philosophy spread from 'pure' philosophy into philosophy of education during the late 1950s and 1960s. Philosophical analysis—considered broadly as involving careful attention to rooting out vagueness or ambiguity in concepts, to making the use of language more precise, and to scrutinizing trains of argument in order to expose hidden assumptions and logical imprecision—can be traced back at least to the work of Plato. The *Republic* is a book-length attempt to throw light on the notion of justice, and Plato depicts the main character in the book, Socrates, showing up the defects in the arguments and assumptions of those whom he engages in dialog. The tradition never died, but in the work of Plato and subsequent philosophers analysis was mixed together with metaphysical and speculative philosophical activity. During the twentieth century there were notable accomplishments that led to the rise of analytic philosophy as a separate movement in philosophy (for example, the work of Gottlob Frege, Russell, the early Wittgenstein, and the members of the Vienna Circle)—a movement that was for some time quite hostile towards metaphysics. For several decades analysis became the dominant type of philosophical activity in the English-speaking philosophical world, although there certainly were analytic centers in Europe (e.g., the logical positivists centered in Vienna).

Analytic philosophy of education (APE) was chiefly influenced by the so-called 'ordinary language philosophy' of the later Wittgenstein, and Gilbert Ryle's 'philosophical behaviorism' (which also drew from Wittgenstein) was another important influence—an extract from Ryle's *The Concept of Mind* (1949) was reprinted in one of the early compendiums in analytic philosophy of education edited by Israel Scheffler (Scheffler 1958).

As suggested by the titles of many books, the analytic philosophers of education focused much of their attention on the language of education; their work on the concept of 'education' itself can serve as a

typical example of their work. Hirst and Peters (1970), writing separately and together, developed an analysis according to which individuals have been educated insofar as they have acquired a broad cognitive perspective which changes them for the better; educating individuals is equivalent to initiating them into a new and valuable form of life about which they will come to care.

They wrote that if 'this analysis is correct, therefore, teachers who enter the profession because they are concerned about education, would be striving to initiate others into a form of life, which they regard as desirable, in which knowledge and understanding play an important part' (Hirst and Peters 1970, p. 20). Their analysis placed a great deal of emphasis on the normal usage of words; it would be extremely odd, they suggested, if a person claimed to be educated and yet virtually always preferred to play bingo than pursue good literature or study science and the like. Their work, as a result, was later attacked as reflecting a class-based set of attitudes, and it was argued that some classes in British society do not have the same linguistic intuitions as Peters and Hirst; one rebuttal was even titled 'In Defense of Bingo.' (Robin Barrow, in a reassessment of their work, defends Hirst and Peters against the general charge outlined above; see Barrow 1994. See also the debate between Peters, Woods and Dray in Peters 1973.)

Other topics that were widely discussed by analytic philosophers of education in the English-speaking world in the 1960s and 1970s were the (conceptual) differences between teaching and indoctrinating, the conceptual relationship between teaching and learning, the concept of autonomy, the concept of development, the logical structure of the disciplines taught in schools, and the conceptual bases of progressive education.

The criticism concerning reliance on ordinary usage, however, coupled with the related but philosophically more interesting attack on Wittgenstein's ordinary language philosophy by Gellner in his *Words and Things* (1959), and an increasing air of sterility associated with APE, all took their toll. The fall of analytic philosophy of education was also accelerated by the spread of neo-Marxism and critical theory, and then the rise of postmodernism and feminist philosophy, all of which found fertile soil in philosophy of education (Burbules 1994, Kohli 1995). In a relatively short period the center of interest in philosophy of education shifted from concepts and language usage, to the pressing social and political issues (and the associated social injustices) that play out in educational contexts. Many contemporary philosophers of education are socially more activist than the analytic philosophers of education, who are seen (rightly or wrongly) as having been educationally and socially rather conservative. Analytic philosophy of education, then, has only a shadow of its former influence; but, controversially, some would argue that on balance the analytic movement was a positive force and its example is sorely missed in the present climate where debates are marked by a certain lack of rigor (see Barrow 1994; and the debates in Kohli 1995).

3.3 What is 'Philosophy of Education'?

The debates over ordinary language philosophy, sketched above, inspired much discussion about the nature of philosophy of education itself, although philosophers and philosophers of education have long been debating the nature of their discipline. In 1969 Christopher Lucas edited a collection of essays with the revealing title *What is Philosophy of Education?* and debate has continued down to the present—as recently as 1998 the Newsletter of the Philosophy of Education Society of Great Britain published a number of letters from members on the topic 'where should philosophy of education go?'; one of the chief issues was how close the relationship should be between philosophy of education and the general field of philosophy itself.

A related development has been the growing number of encyclopedia articles devoted to philosophy of education. To cite just several of these: Phillips wrote a 16,000 word essay for an international encyclopedia in 1985; the second edition of this work in 1994 contained more than 30 entries covering the discipline and its history, and in 1996 Chambliss edited a one-volume encyclopedia covering the field with more than 200 entries (Chambliss 1996).

Educational Planning Worldwide

This article includes a tentative definition of what educational planning consists of, a brief history of the planning of education systems during the last decades of the twentieth century, an overview of the main evolutions in educational planning in those years, a presentation of the main features of educational planning today, the identification of new areas of concern for the planning community, and suggestions concerning some foreseeable future perspectives in the field of educational planning.

1. *Tentative Definition of Educational Planning*

Planning is the development and statement of clear goals, and the design of efficient and effective strategies to achieve these goals (Davis 1994). It is a process through which scarce resources should be allocated as efficiently as possible, in order to better respond to specific needs, in this case countries' educational needs. These are still huge in a number of countries, in particular developing ones.

Traditionally, educational planners are responsible for the building of new schools and institutions, the repair of existing ones, the forecasting of new enrollments, the allocation and (re)deployment of teachers, the projection of costs and budget estimates, and the planning of didactic materials. In each of these areas, they make thorough diagnoses, identify key problems, assess different policy options and strategies, present them to policy makers for decision, translate them into a number of programs and projects, and then monitor and assess the implementation of the latter. But these tasks have evolved considerably over the past years, and have become more and more complex, due to important evolutions in the general environment in which planners work. These will be dealt with below.

Among the various tasks of educational planners today one could mention (Caillods 1997): (a) participating in discussions about the political, economic, and cultural aspirations and goals of the concerned society that should be properly reflected in the objectives set for the education system; (b) developing, on this basis, an acceptable set of goals and objectives; (c) assessing the present state and past development of school systems, institutions, programs, and projects; (d) assisting, on this basis, in the design of policies, programs, organizational structures, and financial allocations for the next 10 to 20 years; (e) devising mechanisms for resource allocation according to specific criteria in line with policies; (f) identifying appropriate partners; (g) setting up the proper incentives and regulations so that the different actors identified take the most appropriate decisions; (h) monitoring the implementation of the designed policy; (i) ensuring a transparency of the educational markets; and (j) taking appropriate compensatory measures if needed (Ross and Levacic 1999).

As a consequence, for some people, educational planning is a technical exercise, based on the collection of a number of quantitative data, the creation of information systems, and the best use of research results. For others, it is a far more empirical process, involving policy making and implementation (Farrell 1994).

2. *Some Historical Facts*

The principles and methods of educational planning were first broadly developed in the former USSR and after World War II, in socialist states, mainly in Central Europe but also in other parts of the world. The ideological control that characterized those societies led to highly centralized, command-oriented education systems, with considerable attention paid to the control of the curriculum (Farrel 1994).

However, even if industrialized market-economy nations have always shown a strong desire not to be ideologically associated with the concept of planning, many have also participated to a considerable extent in the formulation of policies to regulate and control education. Plans, in that case, tended to be more indicative than directive, more decentralized, and

more incentive-oriented. Centralized educational planning has also played an important role among developing nations, as from the 1960s. The UNESCO International Institute for Educational Planning, created in 1963, has been specifically designated to help these countries develop their educational plans, essentially through the training of central planners. In the 1970s, major donor agencies insisted on educational planning as a precondition for external aid.

As a result of strong government commitment associated with strong social demand for education, in the 1960s and 1970s, developing countries made impressive efforts and progress in education. But in the mid-1970s, and especially in the 1980s, it became clear that, in most cases, planning had not produced the expected results. First, despite the extensive development of education systems, many children were still out of school, and many others had not acquired the basic competencies that they required. Moreover, declining quality, imbalances between supply and demand for educated manpower, and continuing or widening gaps between rural and urban areas could be observed; the absolute numbers of illiterate adults had increased; and a rise in costs and expenditures was noted. Second, it appeared that planners were often incapable of adapting rapidly to changing environments. Reforms and policy changes rarely complied with the calendar set by the plan. Moreover, centralized planning often failed to introduce a reform at local and grassroots levels successfully, largely because of the lack of involvement and empowerment of those directly affected by the process (teachers in particular). Finally, the progressive multiplication of levels of intervention and of actors involved tended to limit the value of any planning exercise conducted by a single actor, even one as predominant as the central government.

All these problems were exacerbated by the financial crisis that hit most nations in the mid-1970s, following the 'oil shock.' The collapse of the Central and Eastern European socialist states, interpreted by many as the failure of centralized and imperative planning, added to the questioning of the merit of central planning (Hallak 1990).

3. *Recent Evolutions*

The lack of confidence in all central planning that resulted from the economic recession—and above all from the questioning of the role of the central government—has nevertheless not led to the disappearance of national plans and programs. Quite the contrary, it is now widely recognized that:

(a) The traditional approaches used by educational planners (projection of a cohort, diagnosis, feasibility studies, etc.) are useful, as long as their range of implementation is limited to sectoral or subsectoral reforms, and to programs or projects affecting one particular level or category of education.

(b) Planning appears to be indispensable at a time when all countries have to face rapid changes, in a general context of globalization resulting from the worldwide integration of economic and financial sectors, and closely linked to the explosion of new information and communication technologies (Hallak 1998).

(c) The spreading of democracy in various regions of the world and the resulting decentralization process has called for more rather than for less planning at local, regional and institutional levels, and has highlighted the need for a new role for central authorities in promoting system-wide efficiency and equity (McGinn 1994).

(d) The challenges to be addressed by educational authorities are still of great importance: in 2000, more than 113 million children had no access to primary education; 875 million adults were illiterate; gender discrimination continued to permeate education systems; youths and adults were denied access to the skills and knowledge necessary for gainful employment and full participation in their societies, etc. (World Education Forum 2000).

A worldwide consensus thus seems to be emerging on the need for participatory planning that can take various forms according to the countries concerned and that should be applied not only at national, but also at regional, local, institutional, schools and program/project level (Govinda 1999).

4. *Main Features of Educational Planning Today*

Observing the worldwide trends in educational planning, one can note that there are still a number of countries where 'traditional planning' is still currently in use and that in a few countries, long-term plans—for 10 years' duration—are being formulated to guide policies and reforms.

However, as a result of the various evolutions described above, educational planning has undergone major changes over the past years, which can be summarized as follows.

4.1 *From Centralized to Decentralized and Participatory Planning*

The call for less central public, and, consequently, for more local public and private education supply, has led to the development of decentralized and participatory approaches in the field of educational planning. Hybrid systems of administration and management have been established, characterized by the devolution of responsibilities to those who are ultimately responsible for and affected by the results of planning, namely schools and various educational institutions (for routine management), local authorities (for experimentation and development), and the private sector (in the case, in particular, of

vocational training programs (Atchoarena and McArdle 1999) and of nonformal educational projects). As a counterbalance, the need to assume new responsibilities at the central level has emerged, in particular as regards the design of a globally coherent framework and the setting up of coordination mechanisms, thereby ensuring that the educational goals established are achieved (Hallak and Poisson 1997).

4.2 From Quantitative to Qualitative Planning

A major issue for educational planners lies in systems' inefficiency, and as a result increased attention has been paid to quality control and regulation. There is now a general feeling that matters of curriculum, pedagogy, educational materials, teacher training, assessment of educational outcomes, and accreditation of standards require much more attention than they are receiving, in particular on the part of planners and experts (IBE 2000). Particular attention should be paid to the four pillars defined by the Delors Commission; namely, 'learning to know,' 'learning to do,' 'learning to live together,' and 'learning to be' (Delors et al. 1996, pp. 85–97). At the same time, there is a call for greater teacher accountability, increased emphasis on outcome rather than input, and more efficient control/regulation systems.

4.3 From Rigid Systems to School-based and Learner-centered Approaches

It is now widely recognized that planning processes should be tailored to the specific characteristics of individual schools, classrooms, and even pupils in order to accommodate the diversity of environments in which learning takes place in a single country. In addition, greater emphasis is needed on the effective implementation of measures taken at the central level. In that respect, school-based and learner-centered approaches are being developed that have important implications for the management of education systems at various levels. The new roles to be played by teachers (more as tutors than as speakers) must be carefully taken into consideration and encouraged, possibly through incentives.

4.4 From Standardized Planning Supply-driven to Planning Though Incentives More Demand-driven

The involvement of new actors in the field of educational management, together with the greater focus on outcomes rather than inputs have led to reflection on ways of stimulating the involvement of all the concerned stakeholders. Incentives have appeared, in this framework, as useful tools to influence the attitudes and involvement of teachers, of communities resistant to education, of pupils, of private actors, of employers, etc. ('incentives' means here 'any reward or sanction, which has, as its effect, the modification of behavior'). These incentives can be simple financial rewards to a particular target group; legal arrangements encouraging or discouraging some initiatives and activities inside or outside the public sector; or any other nonfinancial rewards (such as awards, investitures, medals, affiliation with prestigious associations, etc.). The use of incentives is seen as particularly important in the case of teachers, as a means of stimulating their involvement in their work and their participation in teams, in the adaptation of new contents, and the implementation of new pedagogical methods, as well as in individual experimentation.

Among all the evolutions described, undoubtedly the use of incentives appears to be one of the most important, as it constitutes a way of promoting the desired behavior of key actors of the educational process, and, even more importantly, a means of reconciling regulation by the market with educational development monitoring and planning by the central government.

5. Areas of Concern for the Planning Community

As a consequence of the various evolutions detailed above, several areas of particular concern for educational planners can be distinguished.

5.1 The Need for 'Informed Environments'

Incentive-based planning requires very comprehensive, up-to-date, and operational information systems. Education Management Information Systems (EMIS), more and more associated with Geographical Information Systems (GIS)—which combine statistical and spatial analysis—should be modified in this sense. They should thus go on providing data used to secure or to allocate resources, as well as information about the rewards and penalties available to decision makers to encourage local authorities, institutions, and individuals to perform their tasks. They should also provide information about forms of alternative education and their costs and probable effects. The decentralization of data use, linked with the decentralization of authority and of incentives, constitutes a key issue to be addressed (Kemmerer and Windham 1997).

5.2 The Shift from Planning Toward Management

The design of adequate information models, the establishment of flexible budgets, the handling of qualitative aspects of education, the development of individual decision making through the use of incentives, the creation of proper certification and assessment mechanisms, etc. all imply a shift from a planning approach toward a management approach. This trend calls for a diversification within the plan-

ning profession and the involvement of new categories of experts (Caillods 1991). Additional disciplines, such as law, geography, etc., should be taken into account in strategic planning in order to enrich the planning methods. Training in planning should also target new categories, such as local administrators (in particular at city level), members of nongovernmental organizations, entrepreneurs, journalists, etc.

5.3 Renewed Tools for Educational Financing

The decentralization of the management of education systems necessitates cost-sharing schemes between both central and local authorities (which may mean drastic savings in salary costs for central administration), and public and private authorities. Fiscal reforms, cost-recovery mechanisms, etc. may also be required. In addition, grants-in-aid may be needed, in particular to support disadvantaged youth (among them, the disabled). Finally, learner-centered approaches could lead to an educational voucher scheme, consisting of allocating a capital of time, in other words, 'a study-time entitlement,' that each individual should be allowed to manage freely.

5.4 New Opportunities and Mechanisms for Policy Dialog

There is a crucial need for proper mechanisms of consultation and policy dialog in order to make possible the active participation of the main partners in the educational development; namely, the education profession, teachers' unions, families, communities, the private sector, the mass media, and various segments of the public sector (authorities responsible for health, for instance). This dialog should be organized in such a way that it is independent of party politics and the government of the day. Otherwise, if there is a frequent change of government policy, nothing long-term and solid will be able to take place. This may require certain social and political conditions in the country concerned.

5.5 The Fundamental Roles Played by Research and Experimentation

The provided adaptation of educational planning to today's needs should be based on the results provided by appropriate research (forecasting and scenario models, microeconomic studies, determinants of school achievement, methods of public-sector management, mechanisms of assessment and certification, etc.).

6. Future Perspectives

The World Education Forum, organized in Dakar in April 2000, provided the opportunity to assess the achievements, lessons, and failures of education systems since 1990. It made use of the results of the Education For All 2000 Assessment, which included national assessments of the progress achieved since Jomtien in 183 countries. Its *Framework for Action* (World Education Forum 2000) provided broad orientations for future activities of all actors in the field of education for the ensuing years, in particular planners.

Among the main goals laid down in the *Framework* are: (a) expanding and improving comprehensive early childhood care and education, especially for the most vulnerable and disadvantaged children; (b) ensuring that by 2015 all children, particularly girls, children in difficult circumstances, and those belonging to ethnic minorities, have access to and complete free and compulsory primary education of good quality; (c) ensuring that the learning needs of all young people and adults are met through equitable access to appropriate learning and life-skills programs; (d) achieving a 50 percent improvement in levels of adult literacy by 2015, especially for women, and equitable access to basic and continuing education for all adults; (e) eliminating gender disparities in primary and secondary education by 2005, and achieving gender equality in education by 2015, with a focus on ensuring girls' full and equal access to and achievement in basic education of good quality; and (f) improving all aspects of the quality of education and ensuring the excellence of all, so that recognized and measurable learning outcomes are achieved by all, especially in literacy, numeracy, and essential life skills.

To reach all of the above-mentioned goals, participating stakeholders suggested that national plans for action in education be set up or developed. Their preparation should imply a highly participatory process taking place at country level, within a well-integrated sector framework clearly linked to poverty elimination and development strategies. The national action plans of Education for All may well constitute a new starting point for planning worldwide.

Educational Policy: Comparative Perspective

Who and what are the key actors and institutions in education policy and how do they vary among countries? A difficult question is made more complicated by the fact that many languages lack a distinct equivalent to the English term 'policy,' whereas French and German have several terms to cover the concept of 'education.' But although politically developed countries vary in the degree to which parents, teachers, and private agencies share in influencing education policies, there are two sets of institution that are ubiquitous in this arena. These are the tiers in governmental authority and the levels of educational provision, ranging from preschool to university level education.

1. Centralized and Decentralized Systems

Whether the relationships between governmental tiers and the hierarchies of educational institutions were in the foreground of academic attention varied among the earlier generation of scholars of comparative education. But one can discern some conceptual continuity between the classification of education along a centralized–decentralized continuum systems by writers like Isaac Leon Kandel, and the analytic schemas utilized by influential comparative education analysts of the 1970s.

For Margaret Archer, political centralization was the most important variable determining paths of educational system development, which she defined as 'a nation-wide and differentiated collection of institutions devoted to formal education, whose overall control and supervision is at least partly governmental and whose component parts and processes are related to one another' (Archer 1979, p.54).

In her historical analysis, Archer compared two centralized unitary European systems, those of France and Russia, with the decentralized unitary systems of the UK and Denmark. The process through which education became anchored in the public sphere in centralized political systems like those of France reflected different policy priorities from those in decentralized areas. As monarchs and their bureaucracies developed earlier controls over national and local administrations they sought to use these to lay down uniform rules regarding school establishment. Where states were able to go beyond regulation to direct operation of schools they aimed initially for unification, and subsequently for systematization of school systems.

In terms of the tiers of governmental organization, some less centralized political systems were classified as federal ones, especially where strong state autonomy is grounded in greater longevity than the federation, as in the case of Germany and especially Switzerland. During the Napoleonic period, the French and their Swiss sympathizers attempted to impose a centralized republican regime, but widespread resistance forced a return to a confederal system. Reactions against this led, after 1848, to the founding of some higher education institutions by the Swiss federal government, a development which states rights advocates kept from occurring in the USA. For pre-1933 Germany, the relationship between governmental tiers and education was influenced strongly by the varying role of Prussia, which came to set standards for the other states of the 'German Reich.'

An opportunity for augmenting the traditional centralization–decentralization schema is provided by the fact that most technical and lay descriptions distinguish between three tiers of government—local, regional, and national, as well as three levels of education—primary, secondary, and tertiary. Much can be gleaned by seeking to distinguish among

interactions and control patterns of different intensity within the matrix constituted by the two sets of institutions.

Other than the 'top-down' and 'bottom-up' of classifications, the analytical schema based on morphological symmetry distinguishes differing degrees of structural affinity mainly by assessing the strength of horizontal linkages. The more symmetrical the financial and administrative interaction between analogous levels, such as between secondary education and regional government, the higher the degree of *isomorphism*. The less symmetrical the correspondence of financial and administrative interaction between the analogous structures, as when local governments are shut out from running or financing primary schools, the greater the tendency to be *anisomorphic* (or unisomorphic). Relational sets that are neither very symmetrical or asymmetrical can be conceptualized as being *heteromorphic*.

2. Isomorphic Relations and Policy Emphasis

At first glance we would expect greater similarity between the German and Swiss systems, since in these federal systems the role of Swiss 'cantons' and German states generate more autonomous policy-making power than we can expect to find in the unitary and centralized Japan. However, this expectation is not borne out upon closer analysis. For, 'it is overly ambitious to attempt universalistic expectations, across time and place, about how latent political motives drive decentralization policies' (Lauglo 1996, p. 22).

The Swiss pattern differs most significantly from the German one with regard to the maintenance of the communities' responsibility for operating the primary schools. Germany is one of numerous European systems that operate without local school boards or significant community influence on education policy. By contrast the Swiss communities have successfully defended these powers and retained the dominant role in financing primary schools, as Table 1 indicates. They have sustained their own identities by resisting the trend toward merger of small local governments, which in the course of the 1970s led to the disappearance through amalgamation of some two-thirds of German communities.

The role of the local Japanese school boards is not nearly as strong since their members are appointed and not elected, and since their power to affect hiring and retention decisions regarding teachers and principals is much more limited than in the Swiss case. Isomorphism is strengthened through enhanced regional responsibility for most secondary schools. This is lodged with cantons in Switzerland and mainly with the prefectures in Japan, but the autonomy of the latter with regard to areas like curriculum and personnel is much more limited, hence the heteromorphic classification.

Morphic affinities are less strongly manifested with regard to higher education, since in both these countries the national government agencies operate only one sector of the higher education institutions. Nevertheless, the fact that the Japanese Education Ministry, *Monbusho*, is in charge of the 96 national universities, provides some parallel to the Swiss case of national responsibility for the two technical institutes. The proportion of all higher education students in these institutions, 21 percent and 18 percent respectively, is very similar, whereas the German federal government operates no civilian higher education institutions.

2.1 The Anisomorphic German Case

The German case is distinguished from the other two insofar as the bulk of both operating and financing responsibility for all three levels of education is predominantly centered in one level of government, that of the state. Thus teacher appointments for both primary and secondary schools are centered in the state ministries to a degree not paralleled, especially for primary schools, in Japan or Switzerland. Since the appointment and financing responsibility for higher education are also lodged at this level, Germany constitutes a case that departs most strongly from the isomorphic pattern, since the inequality among the governmental tiers in education policy is so accentuated by the concentration of power in the states. The following attempts to explain how derivatives of party and bureaucratic influence and power positions can help to make the rationale for this placement more apparent.

One cross-national case of contrasting structural relationships can be found in the continued existence of small schools in which teachers have to instruct pupils from several grades in the same classroom. Such schools were gradually phased out in Germany in the course of communal amalgamation in the 1970s, whereas in typical Swiss mountain communities, quite a number of them were still operating in the 1990s.

In the anisomorphic German setting, the dominant state governments can impose strong uniform standards within their boundaries. But they can also pursue policies that differ somewhat from those pursued by the federal government, as well as by other states. Party majorities contrasting with the one in power nationally pursue different upper secondary school policies in both Japanese prefectures and German states. But the contrasting pattern was sustained more strongly in Germany, partly because the financing and credentialing powers of the national tier were lower than in the Japanese case (Heidenheimer 1997).

With regard to financing sources for public education, Switzerland is more like the USA and less like Germany. In the first two countries the states and

Table 1
Isomorphism and public educational funding, 1993

		Sources of Public Funds %		
		Local	Regional	National
Germany	Primary & Secondary	19	80	1
(Anisomorphic)	Tertiary	1	83	16
Japan	Primary & Secondary	0	75	25
(Heteromorphic)	Tertiary	0	14	86
Sweden	Primary & Secondary			
(In transition)	Tertiary	1	3	96
USA	Primary & Secondary	44	48	8
(Quasi-isomorphic)	Tertiary	6	58	36
Switzerland	Primary & Secondary	44	52	4
(Isomorphic)	Tertiary	1	55	44

Figure 1
Public education expenditures by level of government, 1988: Swiss isomorphism in contrast

cantons bear around half of the costs, the communities about a third, and the federal government only between 10 and 15 percent. Both are thus examples of bottom-heavy financing backing up relatively bottom-heavy decision making. But the Swiss pattern approaches the isomorphic model; as Fig. 1 shows, communities bear the majority of costs for primary schools, the cantons bear most of the financing of secondary and vocational education, and the federal government bears half the cost of higher education and almost all the burden of research financing. The US distribution is very similar, but there the national government does not operate any tertiary institutions. Hence we classify it as quasi-isomorphic.

What is implied by regarding Germany, a federal country, as exemplifying an anisomorphic model, whereas the highly centralized Japanese unitary system is classified in the intermediate, or heteromorphic, category. Does this essentially lead to the hypothesis that Mombusho, the powerful national ministry, is on balance, faced by a greater series of constraints, than are the collective powers of the state education ministers, and their conference of German school ministers?

Whereas the weaker German and Swiss national education agencies have to share jurisdiction for the vocational dual sector with economic ministries and business interests, the Japanese ministry has not had to interact as directly with a bureaucratic rival. In contrast to other policy sectors that are of concern to several ministries and perhaps also foreign governments, the Japanese education sector was long unique for remaining predominantly subject to the influence of only one ministry and one party. Whereas a greater range of bureaucratic and political interests were at play in Japanese policy areas like agriculture and environment, education policy was uniquely 'locked into the status quo' because issues in this sector were 'purely domestic concerns under the jurisdiction of a single ministry' (Schoppa 1993, p. 260).

On the other hand some expert observers assert that the dominant stereotype of Japanese education conveys a false picture about the uniformity of the postwar education experience. It focuses attention on one level—that of academic secondary education—of a multitiered institution whose other levels can be understood to be organized along often different principles (Kelly 1993, p. 207).

In the longer run Mombusho proved to be more successful in overcoming opposition from the teachers' union, and its allies on the level of secondary schooling, than in implementing its objectives for the tertiary level. This can be attributed to the greater strength of top-down bureaucratic influence, from the ministry to the prefectures, than the potential of bottom-up opposition party influence. The attempts of Socialist prefectural party leaders to oppose policies like those leading to prestige stratification of high schools were undercut by the way that prefectural bureaucrats followed the Mombusho line. Even though the Japanese prefectures have considerable potential education policy autonomy, they have seldom made significant use of it. It is telling that the Japanese Prefectural Superintendents Association has been characterized as an example of an 'incorporated interest' (Schoppa 1991, p. 146).

The reason why Germany and Switzerland constitute (an)isomorphic countermodels becomes clearer when one considers how decision-making powers reflect the way educational finances are shared by the three levels of government. Take the influence of Swiss communities over primary schools: They are much more powerful because of the way the selection of school personnel and other key powers are connected to a strong communal financing role, which is twice as large as in Germany. Also Swiss direct democracy has served to guarantee communal viability by providing veto protection against unwelcomed amalgamation from above.

While the similarity of the US and Swiss profiles in Table 1 is striking, there are two reasons for classifying the USA as only a quasi-isomorphic system. One is that like Germany, but unlike Switzerland, the US federal government does not administer any significant set of civilian higher education institutions in the way that the Swiss operate the Swiss technical institutes. The second is that the USA has a much larger set of private higher and secondary institutions, which has an indirect effect on the intensity of relations between government tiers and educational levels. Thus it contributes to promoting greater competition among US than Swiss universities. This would also hold for the contract between German and more mixed public/private Japanese universities.

By applying an 'aquatic' lens, one can discern the configurations through which swarms of adolescents are directed through gradually shifting channels in river beds whose capacity for carrying traffic loads undergo subsurface. Focusing this aquatic lens on the Swiss flow, one can see how size and political topography cause many streams there to be both smaller and slower. Mainly because the injunctions of referenda democracy safeguarded the powers of small and medium-sized communities and cantons, sandbars and dams kept the streams from changing or intermingling as much. Referenda democracy caused Swiss national interest groups to be superior to political parties for coordinating localized channel maintenance efforts (Heidenheimer 1997, p. 133).

3. *Tiers of Decision Making*

Further insights become apparent when examining how countries compare in the allocation of decision-making powers for lower secondary education as between four levels of governance, those of the school, local school boards, and regional and national governments. Given its propensity toward 'bottom-up' and direct democracy, we might expect Swiss schools to enjoy more autonomy than those elsewhere. But in fact it was found in a 1993 OECD level of decision-making study that the Swiss came in last among 14 countries, four places behind Germany, in the degree to which lower secondary teachers and parents at the school level could share in decision making (OECD 1993, p.136). This finding makes the surprising lack of Swiss school principals somewhat more plausible, since it bears out that local and cantonal school boards preempt schools' decision-making powers even more than in other countries with occasionally intrusive local school boards, like the USA.

The essential element that has kept the Swiss system bottom-heavy, and maintained the decision-making powers of the communes, is the ability of citizens to challenge both legislative and executive decisions through referendums. The decision-making powers of the parliaments and parties are limited because parliaments can only produce proposals for decisions which must expect to be submitted to plebiscitary finalization, creating an additional decision level,

which increases greatly decision-making costs. The fact that referenda proposals from all three levels of government are simultaneously submitted to voters about four times a year contributes crucially to keeping the Swiss education system close to the isomorphic model. Otherwise the municipalities' autonomy and influence might have declined somewhat in the way they did in both Germany and Japan.

Another indicator of the great state and cantonal level predominance of German and Swiss education can be deduced from the way in which the terms of office of top political and bureaucratic officeholders do or do not parallel each other. The average tenure of German state education ministers, five years, is about equal to the period of office of their top administrators, the state secretaries. When a Zürich education minister left office in 1995 he shared a platform with six rectors of Zürich University who had succeeded each other during his 24 years in office. Several Swiss cantonal education directors served terms during which as many as a dozen Japanese education ministers came and went. In Japan the average tenure of national education ministers is only about one or two years, or much shorter than the terms of office of their senior civil servants, or of many university presidents.

4. *Isomorphism and Equality Goals: Switzerland and Sweden*

An advantage of centralized educational systems has often been held to be that the greater uniformity of resources and curriculums which they can offer tend to be associated with reducing inequalities of achievement, especially those based on social class. Indeed comparative studies have shown centralized systems like those of Japan and Sweden as demonstrating decreasing dependence of educational achievement on social origins different from most other countries. (Shavit and Blossfeld 1993, p.112) Comparative research has shown that 'real and fairly substantial' equalization of education opportunity took place in Sweden in recent decades. The lower level of education inequality compared with Germany is attributed partly to the greater school continuation encouraged by comprehensive schools which were uniformly adopted in Sweden from the 1960s. These were only partially implemented in some West German states so that school continuation continued to be ' heavily dependent on grades and teachers assigned evaluations' (Eriksson and Jonsson 1996, pp. 91, 199–204).

After having imposed numerous education reforms under a strong national board of education, Sweden in the 1970s started to move gradually toward the Swiss modal structure. Both national and regional education boards were abolished, and much of their power was transferred to local government, which in turn empowered their schools. Teachers who had been employees of the state and counties came to be hired by municipalities. These reforms were pushed through by the Social Democrats, who had previously been so committed to supporting equality goals through centralism, over the opposition of the bourgeois parties and the teacher's union. One of the new goals was to allow individual schools to profile themselves as to content and ways of working. This led to uncertainty, complexity, and often changing divisions of labor.

What effect this tendency had on equality goals in education has come to be strongly contested. Some have continued to argue that 'proposals for decentralization of education acts against democracy' since 'transferring authority to local communities or individuals acts to reduce the achievements of educational outcomes that favor the whole society.' But some Swedes argue that they are observing a redefinition of policy norms, with 'a new type of egalitarianism' emerging as part of a more 'rational' long-term agenda. In education this trend moves away from the standardized system which had sought to facilitate the 'less privileged' to enter the more prestigious school tracks. Now an upgrading of vocational programs is held to exemplify a greater recognition of diversity so as to stress 'equally valued' service rather than 'equal provision' (Gustafsson and Lidström 1996, p. 156).

The Swedish move toward isomorphism illustrates how curricular contents and decision making at the level of the school can be linked dynamically to changes in the relationship between governmental tiers and educational levels. Gustafsson and Lindström claim that these changes have brought about 'a new balance' between the tiers of government, as well as different educational and other ingredients in the 'emerging Swedish welfare definitions,' which takes Sweden's new position in the European context into account.

5. *Educational Polices and National Choices: Some Illustrative Extrapolations*

5.1 *Japanese Uniqueness*

What makes Japan appear so unique as an 'educational society par excellence' may not be due to a uniform tendency expressed in how steep all Japanese educational ladders seem to those who climb them. Rather it may be concluded that the Japanese heteromorphic configuration had helped produce somewhat contrasting sets of ladders at the various levels of education. At the lower secondary school level the prevalent type seems to be that of the boarding ladder, designed for facilitating entry into new realms of knowledge and cooperative learning. At the upper secondary level the students are trained to perform

more on hook ladders, that become attached to the entrance ports of various groups of universities. Finally at the university or tertiary level it is the companion ladder, ensconced within a secure and protected setting, that constitutes the predominant model.

The synecdochal streak in the heteromorphic Japanese case is also anchored to the economics of the tertiary sector. Relatively low public expenditures there had been made feasible by leaving the bulk of tertiary expansion to be handled by the private sector. Thus private universities came to enroll the majority of students, in contrast to the minority enrolled in private US institutions.

5.2 American Test Rankings

The question as to whether, at the start of the new millennium, the USA's strategic position as the 'sole remaining superpower' was matched by rankings in education would probably elicit very divergent responses. Typical ones from those focused on the university sector would probably be 'yes' or 'maybe', but there would be little chance of getting such a reply from those focused on the secondary school sector. The story behind this situation, as in Germany, involves crossed wires between the federal government and the largest member state.

Until the 1970s public education in California had stood out on both quality and quantity. But this changed drastically, largely as a result of a 1978 referendum capping tax revenues for education. From this followed a decline of quality thresholds of the primary and secondary levels, which in turn fed into the poor performance of US high school students on the international achievement tests which gained visibility in the 1980s. To meet demands for leadership on this front, President George Bush and the state governors led by Arkansas governor Bill Clinton met at a highly publicized conference in 1989 and adopted the goal of getting US rankings in these subjects to the international peak by the end of the century. A decade later 49 states had indeed adopted some sort of standards which schools and school districts were to be evaluated on, but the goal of moving US achievements significantly upwards in international rankings had made scarcely any progress.

5.3 Small Country Choices

The advantages and disadvantages of strong isomorphic attachments are strikingly illustrated by the way in which education changes have occurred in relation to the potential entry into the European Union of two rich small countries like Sweden and Switzerland. For the Swedes an adaptation of their dominant equality goals became accepted as part of the cost of entry into Europe. For the Swiss an unwillingness to tamper with the sacrosanct powers of referenda democracy and local self-government have gone hand-in-hand with the failure of campaigns to make European Union membership attractive for the Swiss voters in the way that they had in Sweden and Austria (Kobach 1997).

5.4 German Cultural Status

In the European context Germany's anisomorphic inheritance has engendered what might be called a costly case of synecdoche, i.e., where the part is bigger than the whole. Germany's largest state, Northrhine Westphalia, not only spends more on education than does the federal government. But due to the Social Democrats remaining in continuous control, its ministers also have a dominant voice in German education, especially higher education, with its great dependence on federal funding. This has permitted them to veto proposals to introduce student fees as a significant source of funding, in the way that this had been pushed through under Tony Blair in the UK. The continued financial plight of German universities contributed to a decline in their attraction for foreign students. In turn this and similar factors contributed to a declining cultural weight of the enlarged post-unification Germany—as manifested, for instance, in the failure of attempts to upgrade German as an official language within the European Union.

6. Conclusion

The fruits of this analysis can perhaps serve as a basis toward efforts to seek to identify how governmental hierarchies affect the character of the ladders that link the various educational levels. The article has tried to show how isomorphic or nonisomorphic system configurations help to determine whether and to what extent the presumed 'imperatives' of centralization or decentralization are actually borne out, and sustained over time. Given a certain configuration, institutional outcomes may come out differently from what a path deterministic model would anticipate. In this manner it can be understood why a more decentralized Swiss political system has led to a larger national government role in operating higher education than in Germany; or why the more centralized Japanese higher education system encompasses a larger private sector than is found in these and other European countries.

Educational Policy, Mechanisms for the Development of

Discussions of education policy mechanisms have typically focused on the broad array of institutions that influence and enact policy aimed at changing or regulating patterns of practice and governance in schools, classrooms, and supporting organizations. However, as education policy has gained greater prominence on national agendas and the institutions that produce it have grown more diverse, the notion of 'policy mechanism' has expanded to include the governmental and nongovernmental institutions that formulate policy, as well as the ideas, interests, and strategies that shape the options policy makers have at their disposal. This article examines both the institutions that develop education policy, and the sources that give content to those policies.

1. Institutions as Arenas for Policy Development and Enactment

Since policy analysis emerged as a field of inquiry within educational studies more than 30 years ago, the emphasis has been on explaining why particular policies are adopted, what policy makers expect them to accomplish, and the extent to which they are

implemented and actually change teaching and learning. These studies are primarily intended to improve policy by suggesting how their conclusions might inform future initiatives and strengthen the connections between policy and educational practice. Within this paradigm, institutional characteristics are assumed to be critical factors in explaining the enactment and implementation of specific policies.

The overarching conclusions from such studies are twofold: (a) political institutions define the framework in which policy making occurs and thus shape its outcomes; and (b) different institutional arrangements advantage some societal interests and policy alternatives at the expense of others (Kelman 1987). These effects occur through the structure of rules and norms that determines who may participate in the policy making process, who is granted formal authority to choose among proposals, and what procedures must be followed before those with formal authority can make a decision. In education policy, institutional arrangements are particularly critical to explaining policy outcomes, because even in the most centralized systems, political power is exercised and policy decisions are made in multiple venues or arenas. As Mazzoni (1991) notes, these arenas are never neutral in their allocation of access and power: 'They legitimate a set of participants, establish the institutional and social context—including the governing "rules of the game"—mediate the potency of resources and strategies, and encourage some means (and discourage other means) of reaching agreements (Mazzoni 1991, p. 116).

1.1 Interactions Among Governmental Institutions

Much policy research in education, while not always explicit about this focus, examines the interaction in arenas that share authority but operate under different rules and norms. These analyses take a number of forms, but one approach has been to use case studies that compare variation in policy outcomes across national or subnational jurisdictions, and to explain observed differences by focusing on the rules that define the respective roles of different policy-making institutions. To some extent, generalizations can be made about the relationship between the institutions that produce particular policies and the nature of those policies. For example, a common basis of comparison is the difference between policy making in parliamentary and presidential systems. Another relates to the respective domains of civil servants, judges, and elected officials. Because of their professional expertise, education bureaucrats are best equipped to deal with policies requiring high levels of technical knowledge, while judges specialize in interpreting existing law in case-by-case applications, but both groups will typically be less effective in addressing highly politicized or controversial policy issues whose resolution requires the legitimacy of the mandate held by elected politicians. Nevertheless, such generalizations have to be qualified, depending on how a country's or a region's historical development and political culture have shaped its political and educational systems.

A study of judicial policy development is illustrative of this interaction between history and institutional function. In their comparative analysis of education policy making by courts in Germany, the UK, Israel, and the USA, Jung and Kirp (1984) conclude that the judiciary has assumed a more central position in the USA because of constitutional provisions that make judges interpreters of the constitution and enforcers of its guarantees. In contrast, in the other three countries, the courts occupy a less central policy-making position because their role has been circumscribed constitutionally, and because of a greater emphasis on accountability through legislative representation of majoritarian interests and through professional norms guiding decision making by education bureaucrats. These historical institutional differences help to explain why policies involving questions of individual and group rights that are decided in political or administrative arenas in many countries are often transformed into judicial issues in the USA.

Institutional effects on policy outcomes can also be observed in comparing policy-making institutions within a single country. For example, in his study of the politics of school finance in the USA, Wong (1999) finds that the national government's focus on social redistribution to address inequities based on race and social class is not reinforced by state and local allocative practices. Not only are governmental levels often operating at cross-purposes in their fiscal decisions, but the institutional rules at each level favor different constituencies and policy goals. Even in France, where education governance is highly centralized, officials recognize that there are multiple arenas in which policies can be decided, and that different arenas have different balances of power and provide incentives for different types of coalitions. Therefore, a policy outcome may depend in large measure on the arena in which the issue is decided. Across the 30 French cases that Baumgartner (1989) examined, participants ranged from small groups of experts to shared decision making by political appointees and civil servants to massive public debates and street demonstrations, with the intensity of conflict surrounding an issue a significant predictor of whether it was decided by a broad range of political participants or a narrow group of experts.

1.2 The Decentralization Debate

Probably the most common distinction among models of education policy making is the extent to which decisions governing finance, personnel, and curricu-

lum are made centrally or by decentralized institutions such as local boards of education or even councils at individual schools. The optimal balance between centralized and decentralized decision making has been debated on both normative and empirical grounds in industrialized and developing countries alike (Lauglo 1995, Weiler 1990). Over the last 20 years of the twentieth century, there was a move toward greater decentralization of education governance. The arguments in favor of such a strategy have been economic (enhancing cost effectiveness through more efficient deployment of resources), political (ensuring wider representation of legitimate interests), and educational (customizing the learning process to local conditions). Counterarguments focus on the need for the central government to enhance equity in the face of regional resource disparities; represent the interests of the broader polity in socializing youth; and ensure some level of curricular standardization, especially where population mobility is considerable. Despite the liveliness of the debate, research has generated few firm conclusions about the relationship between the degree of decentralization in institutional arrangements governing policy decisions and educational outcomes such as student achievement (Cummings and Riddell 1994, Elmore 1993). However, it is reasonable to conclude that decentralization of some decisions will continue to have political utility as a way to diffuse conflicts over educational goals, even as central states continue to assert greater control over their educational systems (Weiler 1990).

1.3 The Role of Nongovernmental Institutions

The design of policy-making institutions and research on those institutions have long taken into account nongovernmental entities, such as political parties and interest groups, in the formation of public policy. Both pluralist and corporatist models of decision making emphasize the role of voluntary interest groups, with the former focusing on their competition for power and influence, and the latter structuring that pluralism by allowing major interest groups to act in partnership with the state in policy formation. These two models have been particularly effective in explaining the role of large, well-established interests, such as teacher unions, in a variety of countries.

However, even in the context of corporatist states and especially in pluralist systems such as that of the USA, less formal institutions also function as key actors in the policy process. As researchers have gained a more nuanced understanding of the policy process, they have focused on the informal institutions that shape policy. The terms used to describe these informal groupings include 'policy networks,' 'issue networks,' and 'policy communities.' They refer to groups of actors who share an interest in a policy domain such as education, and who are linked by direct and indirect contacts with each other. Members of a policy network may come from within government (e.g., ministry officials, legislative staff) or from outside government, including interest group representatives, academics, and analysts in universities and policy research institutes, as well as journalists. A pivotal player in an issue network and in explaining the emergence of particular problems and proposals on the policy agenda is the 'policy entrepreneur'—someone either inside or outside government who is willing to invest their time, energy, and reputation promoting a particular policy concept in the hope of a future return (Kingdon 1995).

The actions of policy networks and policy entrepreneurs are particularly significant in explaining 'policy borrowing,' or the diffusion of innovations from one jurisdiction to another and across national borders—for example, the move to decentralize education governance and give parents greater choice in their children's schooling. Over the last two decades of the twentieth century, the volume and rate of policy diffusion within education significantly increased through a variety of mechanisms, including international organizations such as the World Bank and the Organization for Economic Cooperation and Development (OECD), associations of elected officials, international networks of politicians sharing similar political ideologies, and policy research institutes or 'think tanks' with national and international audiences. Most research on this phenomenon has been based on comparative case studies, although attempts have been made to calculate diffusion rates and identify major explanatory variables through quantitative analyses (for examples of each type of study, see Mintrom and Vergari 1998, Halpin and Troyna 1995). Although much remains to be learned in this area, research has found that policy makers are likely to 'borrow' policy innovations from other jurisdictions based on both the reliability and trustworthiness of the innovators, and the degree of similarity between the ideology and characteristics of the innovators's education system and those of the 'borrowers.'

2. The Sources of Policy

The focus on informal mechanisms acknowledges that policy development does not begin with the enactment process, but also includes the more diffuse agenda-setting process during which adverse educational conditions are identified as policy problems; new or preexisting proposals are framed as solutions to those problems; and political officials are convinced (often by policy entrepreneurs) that they have sufficient incentive to act on the issue (Kingdon 1995). During agenda setting and enactment, participants in the

policy-making process shape the content of a policy by defining its objectives and selecting the instruments or strategies used to achieve those objectives. The goals and strategies chosen depend to a large extent on how a policy problem is defined, with the entire process of problem definition and policy choice dependent on the competing motivations of participants.

2.1 Interests and Ideas as Policy Sources

Understanding the motivations of those who advance and enact policy proposals can shed additional light on the process by which policy is developed, the sources that give policies their substantive content, and, more generally, on the dynamics of the larger political system. However, over the last two decades of the twentieth century, the nature of those motivations has been the subject of a major normative and empirical debate within economics, political science, and policy analysis.

On the one side is the rational choice model, borrowed from microeconomics. It assumes that political actors know what their self-interest is, and pursue it in the political arena through bargaining with other actors who are also pursuing their self-interest and whose support is needed to build a coalition representing enough votes to enact a given policy. In this model, policy is the result of a series of negotiations or exchanges among self-interested parties.

On the other side are those who argue that accounts of policy making based solely on self-interest are incomplete, and that other goals or motivations are needed to explain policy sources and outcomes. This category of motivations is typically referred to as 'ideas,' and includes both the notion of a public interest that transcends self-interest and, in the case of education, theories about how children ought to be educated and who ought to be responsible for that education. Those who see ideas as a source of policy typically view policy making as more than just the result of whatever bargains can be struck. Rather, it is also characterized by deliberation among participants whose preferences are not fixed. During the deliberative process, participants consider various policy options on their merits. As a result, participants come to understand better their own interests and those of others, and policy decisions are more than just the result of 'splitting the difference' among competing interests (for a discussion of these two models applied to education policy, see the chapters in McDonnell et al. 2000).

Much of the debate over the validity of interests versus ideas in explaining policy outcomes has been waged deductively and on normative grounds, rather than on the basis of empirical research. However, over the past decade, researchers have realized that neither model provides a full explanation. Much of public policy is motivated by self- or group interest, whether it be politicians' desire to be reelected or interest groups's efforts to enhance their members's material advantages. Nevertheless, as Kingdon (1993) argues, self-interest provides an incomplete explanation for policy outcomes. Not only are ideas necessary to persuade others to accept even the most self-interested policy options, but comprehensive and farreaching policies are more likely than narrow, specialized ones to be motivated by ideology and by concepts that transcend self-interest (Kelman 1987). In fact, ideas and interests are so intertwined that it is often difficult to measure their independent effects (Kingdon 1993). One can acknowledge, for example, that teacher unions seek to improve their members's salaries and working conditions, but also that they represent professional values that may lead them to espouse policy options that may benefit the educational enterprise generally, but not necessarily the self-interest of all their members (e.g., consider peer evaluations leading to the dismissal of unqualified teachers).

2.2 Policy Instruments

Whether goals, such as access to advanced courses or higher student achievement, are the result of self-interest or ideas, the policies that embody them must also incorporate strategies for translating those goals into actions that lead to changes in school and classroom practices. To make systematic comparisons across individual policies and to understand how policy design influences implementation and ultimate effects, analysts have focused on the concept of policy instruments or tools. These are generic mechanisms that translate substantive policy goals into the actions needed to effect change, and they can be thought of as the basic building blocks of any policy. Although researchers differ in how they conceptualize categories of policy instruments, and in the total number of distinct instruments they identify, they agree that different types of instrument embody different assumptions about how a policy problem is defined, the causal process through which government action can change the behavior of policy targets, and what the expected effects of that action will be (McDonnell and Elmore 1987).

Two classes of policy instruments are included in all categorizations and are used frequently in education policy: mandates impose rules on targets and are intended to produce compliance (e.g., school-leaving policies, nondiscrimination requirements), and inducements provide money and other tangible payoffs on the condition that targets perform specified actions (e.g., grant-in-aid programs). However, a variety of other instruments are used in education policy, including: capacity-building strategies to promote

longer-term investments in enhancing human capital; hortatory policies that motivate action by providing information or appealing to policy targets's values (e.g., published reports on school quality); and system-changing instruments that transfer authority from one institutional sector to another (e.g., privatization schemes).

3. Future Research

Despite a growing recognition that much can be learned from examining policy mechanisms comparatively, such research is still limited. However, the current worldwide emphasis on implementing policies aimed at comprehensive school reform has given a new impetus to comparative education policy research (Fowler 1995). The most productive direction for that research is likely to be studies based on models that conceptualize policy making as the interplay of interests and ideas, constrained by the institutional rules and norms of the different arenas that share authority over education.

Educational Productivity

Educational productivity is the extent to which learning is increased while minimizing costs. Costs may be considered broadly as including not only total monetary costs but also the difficulty of implementing new programs and procedures, possible staff retraining, educational incentives, student time required, and similar considerations, which may lack explicitly estimated monetary costs. Learning can also be considered broadly as including such things as knowledge, understanding, critical thinking, creativity, skills, attitudes, and career success and other long-term adult outcomes. Despite such broad concerns, most empirical research on educational productivity has focused on achievement on standardized tests of knowledge and cognitive abilities related to specific skills and subjects such as reading, mathematics, and science in primary and secondary education. Although the monetary benefits, costs, and their relations are difficult to estimate, much psychological research identifies on educational practices and conditions that increase learning without necessarily increasing costs.

1. Economic Perspectives

Interest in educational productivity accelerated in the last few decades as policymakers, scholars, and educators realized more fully, the contribution of human, social, and cultural capital to economic growth and individual and national wellbeing—an insight that may be traced to Adam Smith's 1776 Wealth of Nations and to Aristotle and other thinkers in Western

and non-Western civilizations. Indeed, parents and educators have long sought the best means of raising and educating children. Today, moreover, civic leaders and citizens more clearly recognize that in addition to physical assets such as farms, industrial plants, machinery, and inventions, the abilities of individuals and their capacity to work together partly determine their wellbeing and future prospects. In addition, it is in the interests of nations and individuals to have productive or efficient education that conserves public funds, tuition, and students' time, which can be used for other purposes, including attaining more advanced education, starting careers and pursuing the other aspects of their lives.

The late sociologist James S. Coleman precipitated much interest in educational productivity by suggesting, on the basis of one of the largest student surveys ever undertaken, that learning does not depend on the amount of money spent on schools. This article sets forth the factors on which learning does depend, as revealed by psychological research of the last few decades of the twentieth century.

Productivity research in most industries lies in the province of economists who identify and measure activities that maximize benefits and minimize costs. Yet, it has proven difficult to estimate the monetary benefits and costs of education. Economists can estimate wealth and income, but the values of other qualities of life, such as citizenship, creativity, and capacity for teamwork, are difficult to evaluate. Policymakers and educators often have little grasp of the total and component costs of schooling and their bearing on the production of learning. They seldom estimate, for example, the monetary value of parent and student time contributed to the leaning process. Even the often-observed relation of the number of years of education and adult income cannot be unequivocally attributed to schooling, since both may partly be attributable to children's abilities and their parents' socioeconomic status and child-rearing practices.

Leading economists, moreover, have compiled a great deal of research on the effects of total and component expenditures on education (see Hanushek 1994). Their analyses show that beyond minimal levels, higher expenditures on teachers' years of experiences and advanced university degrees, physical facilities, smaller class sizes, and other items for which costs can be estimated have little or no influence on how much students learn.

For several reasons, educational productivity research and concerns have been concentrated in the USA. International achievement surveys in mathematics, science, reading, and other subjects show that the longer US students are in school, the more they fall behind those in other countries. Near the end of secondary school, they score last among the economically advanced Asian and European countries. Because they fall behind while in primary and secondary schools, the problem appears to be more attributable to schooling than to families and society. Even so, the per-student costs (adjusted for purchasing power) of schooling are higher in the USA than most other economically advanced countries. Finally, unlike most industries in the past few decades, the productivity of US schooling has declined: Inflation-adjusted costs have risen sharply, while students have made similar or smaller gains in achievement. Such analyses of productivity indicators across time and among nations have provoked much discussion among scholars, legislators, and citizens.

2. *Research on Psychological Productivity Factors*

Since economists have shown little relation between costs and quality, it would seem useful to focus on educational technology, that is, instructional programs, methods, and conditions. Here progress is apparent. Psychologists and educational researchers have measured the chief psychological variables in the education process and discovered their causal relations. Given such information, policymakers and educators can better analyze schooling to make it more productive.

The nine factors, shown in Table 1, have strong, consistent influences on how much students learn within and outside school. Potent, consistent, and widely applicable to many education settings, these nine psychological factors fall into the three groups—student aptitude, instruction, and environment. From two research traditions, considerable research corroborates the influence of these nine factors on learning. 'Meta-analyses' (statistical syntheses of multiple studies) shows that some methods of instruction produce far greater learning than others. From meta-analyses, Walberg and Lai (1999) compiled sizes of effects of 275 educational methods and conditions on the amount students learn. These effects are based on thousands of comparisons of experimental and control groups. Along with cost, feasibility, philosophy, and other considerations, educators can use the 'effects' sizes as criteria in designing and evaluating teacher education and school programs.

A second basis for the factors draws upon the social science tradition of 'secondary analysis,' in which large local, national, or international surveys are statistically analyzed to detect the size of simultaneous effects of multiple causes on outcomes. Analyses of several dozen surveys allowed productivity analysts to estimate the relative effects of the factors in Table 1, including those that are difficult to manipulate merely for the sake of research.

These two research traditions strengthen confidence in the productive efficacy of the factors and complement one another. More often employed by psy-

Table 1
Nine educational productivity factors

Student aptitude
1 Ability or preferably prior achievement as measured by the usual achievement tests
2 Development as indexed by chronological age or stage of maturation
3 Motivation or self-concept as indicated by personality tests or the student's willingness to persevere intensively on learning tasks
Instruction
4 The amount of time students engage in learning
5 The quality of the instructional experience including method (psychological) and curricular (content) aspects
Psychological environments
6 The 'curriculum of the home'
7 The morale or student perception of classroom social group
8 The peer group outside school
9 Minimal leisure-time television viewing (unless educational)

chologists, experiments employing random assignment to treatment and control groups allow strong inferences about causality but, because of costs and other constraints, they are often conducted with small groups of students in homogeneous conditions. Meta-analysis allows inferences from a broad base of many studies and can yield estimates of possible differential efficacy for educational conditions and types of students. Secondary analysts employ statistical rather than experimental control, which may be less telling of causality but often allows wider generality because samples are drawn randomly from nations or even groups of nations. The most confident conclusions come from methods and conditions that yield similar results for many kinds of students in widely varying settings, employing both research methods.

An additional basis for the productivity factors is the biographical study of the highest achievers, secondary school students qualified to compete in the international Mathematical Olympiad from China, Japan, Taiwan, and the USA, and eminent men and women from a variety of fields. Since research showed that the nine factors each promote achievement, it was hypothesized that the very highest levels of accomplishment require concentrating and optimizing all nine factors to attain peak performance in mathematical problem-solving ability and in preparation for outstanding careers. For top mathematics performance, data collected on biographical questionnaires supported this hypothesis.

To test the hypothesis with respect to adult eminence, a sample of pre-twentieth-century eminent men was drawn, based on the length of their biographies in American and European encyclopedias. A sample of twentieth-century eminent women was also identified by their outstanding contributions to such fields as art, music, science, writing, politics, and religion. Ratings made by biographers and ratings made by content analysts from biographies confirmed the hypothesis. Many eminent people, while not necessarily highly successful in school, persevered through difficulties and concentrated on their chosen fields, even in the first 13 years of life. Parents, teachers, and others identified their special talents, encouraged them, and provided opportunities for them to develop to their fullest. The general corroboration of the determining effects of the productivity factors was particularly important in these samples, because nearly all other research focused on academic achievement in school, rather than adult accomplishments.

3. *Specific Effects of Productivity Factors*

The economic idea of scarcity can promote understanding of how the factors affect learning. The first two sets of five factors in Table 1 may be termed essential, since without minimal levels of each, students are unlikely to learn. For example, if they are completely unmotivated, or given no time to learn, or taught in a language completely foreign to them, they learn little. These essential factors, moreover, appear to substitute, compensate, or trade-off one another, possibly at diminishing rates of return. Immense quantities of time, for example, may be required for a moderate amount of learning, if motivation, ability, or instructional quality is minimal. Thus, no single essential factor overwhelms the others; all appear important. In addition, concentration in one field makes high accomplishment in another more difficult; the best chess player is unlikely to be best at physics or drawing.

Although the environment factors in Table 1 are consistent statistically- or experimentally-controlled influences on learning, they may directly supplement as well as indirectly influence the essential classroom factors. In either case, the powerful influences of out-of-school factors, especially the home environment must be considered. For example, if students spend 12 years of 180 6-hour days in elementary and secondary school, they will have only spent about 13 percent of the waking, potentially educative time during the first

18 years of life in school. If more of the 87 percent of the student's waking time nominally under the control of parents, that is spent outside school, were to be spent exposed to academically-stimulating media and conditions in the homes and peer groups, then students might learn much more.

The strong influences of ability, motivation, and age are largely reflected in achievement tests in the academic subjects. Achievement at any point in time also reflects the previous home environment, exposure to mass media, and amount and quality of instruction. Current achievement predicts subsequent achievement, and the older the student, the better the prediction. High achievers in secondary school science, for example, can be expected to achieve well in science, engineering, medicine, and other university courses and programs with a heavy science content. Although 'late bloomers' can be identified, they are rare, especially in the more cognitively demanding fields; hence, the importance of a good early start. Another consequence of the cumulative nature of achievement is the need to consider 'value added' indicators of school productivity. Schools, for example, with relatively poorly prepared students, who nonetheless make good gains, should be given credit even though their end results may only be average.

Quantity of instruction or engaged learning time, along with the other factors, can be viewed as a scarce ingredient in learning. Quality of instruction can be abstractly understood as providing encouragement, information, questioning, and other stimuli to ensure the fruitfulness of engaged time. Diagnosis and tutoring can help ensure that instruction is suitable to the individual student. Inspired teaching can enhance motivation to keep students persevering. Quality of instruction, then, may be considered as an efficient enhancer of learning time. Some methods are more effective than others, though not necessarily widely employed. Expensive reductions in class sizes, for example, have led to highly inconsistent and debatable achievement results. Some methods of teaching, however, such as direct instruction, have excellent research records and do not necessarily cost extra money, since many teachers can learn these individually, and others during routine staff development. Still other methods are traditional and should always be included in teachers' repertoires.

The four psychological environments defined in Table 1 can enlarge and enhance learning time. Good classroom morale may reflect match of the lesson to student aptitude, the stimulating properties of the academic group, or, in general, the degree to which students concentrate on learning, rather than diverting their energies, because of unconstructive social climates. Peer groups outside school and stimulating home environments provided by parents can help by enlarging learning time and enhancing its efficiency; students can both learn in these environments and become more adaptable to formal schooling.

Because students spend so much time outside school, their parents play decisive roles in how well they do inside school. In addition to encouraging and supervising homework, parents can improve academic conditions at home. What might be called 'the alterable curriculum of the home' is much more predictive of academic learning than is family socioeconomic status. This curriculum refers to informed parent–child conversations about school and everyday events; encouragement and discussion of leisure reading; monitoring, discussion, and guidance of television viewing and peer activities; deferral of immediate gratification to accomplish long-term goals; expressions of affection and interest in the child's academic and other progress as a person; and perhaps, among such careful efforts, caprice.

Turning to the last and only negative factor, leisure-time media exposure including television (although many television programs can be educational) and radio, can displace homework, reading, and other educationally stimulating activities. They may also dull the student's keenness for academic work. Some of the average of 28 hours a week spent viewing television by US secondary school students might usefully be added to the mere four or five weekly hours of reported homework (Walberg 1984). Ten of those hours a week for several years could be sufficient to learn tennis, a foreign language or a specialized science.

Many experimental studies and analyses of survey data show the pervasive and fairly uniform effect of the productivity factors in the usual school subjects and on students of different ages, countries, and cultural groups. One recent study, for example, concerned the possible differential effect of the factors on mathematics achievement for African-American and other, mostly white students. The question was asked if some factors have greater or lesser effects on the African-American than on the other students. The longitudinal analysis of mathematics scores of a national sample of more than 10,000 students showed equal effects of the factors on African-American and other students. Thus, for example, more study time, better instruction, and a more stimulating home environment had equal effects on how much African-American and other students learned, and how favorably their attitudes toward subject matter changed.

4. *Current and Future Initiatives*

Even though educational productivity research is extensive, policymakers and practitioners seem to have made only partial use of it. Part of the problem could be an information gap. For this reason, the International Academy of Education, an honorary scholarly group headquartered in Brussels, Belgium, began a series of pamphlets on 'best practices.' In Geneva, Switzerland, the International Bureau of Education, a

part of UNESCO, distributes about 4,000 copies of the series to education officials throughout the world, who are free to reproduce the booklets. The booklets are also available on the Internet pages of the two organizations, and educators may download them for reproduction.

The barriers to implementing well established achievement-raising practices, however, may not be completely attributable to a lack of information but to failures in (a) setting achievement as schools' top priority, (b) choosing the most appropriate procedures to attain specified achievement goals, (c) specifying system-wide procedural plans and milestones, and (d) monitoring progress, particularly with respect to procedural and achievement goals. Because school systems have been slow to accomplish these things, policymakers are making radical changes to provide incentives for putting effective methods in place. These include closing failing schools, financially supporting public school students whose families want to send them to private schools, and giving authority for school governance to mayors and parents, rather than educators. At the same time, public and private education providers are experimenting with curriculum and instruction that can be provided through the Internet, and evaluating other technologies that may provide more convenient and productive education. Although it is difficult to say where all this will lead, it does appear certain that attention to and research on the problem of educational productivity, will continue to expand.

Educational Research and School Reform

Educational research is a growing industry. Its aim is to make a contribution to knowledge. How this knowledge can be used, and in some cases if it can be used, to reform education forms the focus of this article.

In 1899, William James in his *Talks to Teachers on Psychology* emphasized that education was 'an art' and not a science and could therefore not deduce schemes and methods of teaching for direct application from psychology: 'An intermediary inventive mind must make the application by using its originality' (p. 8). Nearly 100 years, later De Landsheere (1994 p. 1871) 'Like medicine, education is an art. That is why advances in research do not directly produce a science of education, in the positivistic meaning of the term, but yield increasingly powerful foundations for practice and decision-making.' Masters (1999), on the other hand, while making comparisons with medical research, suggests that in education research syntheses, sharper-focused research questions, and better communications between researchers and research utilizers, would do much to improve the link between research and school reform.

Husén (1994) suggested that the relationship between research and practice in policy-making had, for a long time, been conceived in a rather simplistic way. 'Policy makers wanted research that primarily addressed their pressing problems within the framework of their perceptions of the world of education.' They also wanted 'recipes' for their immediate problems (Husén 1989).

In 1960, there seemed to be general agreement that it would take at least one generation, about 15 years, between the results being produced by any of the then current research projects and their implementation at the school or classroom level. Since the 1960s, educational research has become a large enterprise with governments supporting it financially. Increasingly it is hoped that research can give pointers to the elements of reform that can either help to raise cognitive achievement, affective development and skills or cut the costs of education without damage to the desired outcomes.

This article deals with some of the different aspects of educational research, the contexts in which policy-making and research take place, the disjunction between researchers and policy-makers, and models of

research utilization, and also presents some examples of the establishment of links between research results and action or reform.

1. Different Aspects of Educational Research

Before proceeding with the link between research and reform, it would be desirable to deal with the various aspects of research.

Most policy-makers want, as mentioned above, clear results from research for the problems they have. These results should preferably be accompanied by a set of suggestions for reform or action. The research from which the results emanate should be 'sound.'

Given that it is often extremely difficult, if not impossible, to conduct good experiments in education from which 'cause and effect' can be safely identified, researchers often have to depend on natural variation using survey samples. However, this depends on natural variation being there for the phenomenon under investigation. Class size is an example of where there is some variation in school systems but it is often within fairly narrow limits. Within a country, the average class size may be 25 children per class at a certain grade level. But the range is only 20–30. Yet, in other countries, the average class size may well be over 40 or even over 60. And in these other countries the range will be small. As another example, a country may wish to examine the differences between private and public schools, but if there are no private schools, then there is no natural variation. Furthermore, there is always the criticism that cross-sectional and longitudinal studies are 'correlational' and assumptions must be made about 'cause and effect.'

The research must be 'sound.' Yet it can be argued that there are many studies that have technical deficiencies such that the results cannot be trusted. These deficiencies can include poor conceptualization, poor measurement, poor sampling and incorrect estimates of sampling error, inappropriate analyses, and false interpretations and conclusions. Some could argue that more unsound than sound research is produced in the field of education. The International Academy of Education produced a summary of 'The requirements of a good study' for sample surveys in international educational achievement studies (International Academy of Education 1999, Appendix 2). This attempts to describe in lay terms the kinds of points in research publications that policy-makers should look for when trying to decide whether or not the research was well conducted and trustworthy. It would be useful if summaries such as this one were to be produced for different types of research.

It is important that readers of research reports can identify if the research conducted was unsound and cannot be trusted. Many senior policy-makers do not have this ability and must rely on those skilled in these matters in their own ministries of education. Unfortunately, not all ministries have such people. The dangers of implementing policy based on poor research are obvious.

It is also the case that policy-makers need results that have, if possible, been replicated and that are generalizable to a grade level or general level (e.g., junior high school or elementary levels of education) in an educational system, and where the effects are large. Research that is only applicable to a few specific schools (case-study approach) is not of interest to them. Furthermore, the research should ideally be applicable to several key subjects in school and not just to one subject. Ministries allocate resources to schools and they want the resources to have wide application in each school and not just to one subject. Unfortunately, having results on the effect of variables on several subjects at the same time is costly and time consuming.

Keeves (1994) has distinguished between research studies associated with the generation of change and those that serve to maintain and consolidate existing conditions. It is the second type of research that he calls 'legitimatory research.' Thus the motivation for commissioning research must also be taken into account when viewing the links between research and change.

2. Contexts for Policy-making and Research

2.1 For Policy-making

As already stated, policy-makers are interested in their problems within their current frame of reference and understanding of education. They perceive of what researchers know as 'fundamental' research to be of no, or only peripheral, interest to them. What the policy-makers perceive to be of interest can change with a change of government. For example, the matters of bussing, educational vouchers, and private schools had different priorities under the Carter and Reagan administrations in the USA. Equality of educational opportunity, on the other hand, has had a high priority under various administrations in various countries. In the second project of the Southern Africa Consortium for Monitoring Educational Quality (SACMEQ), chief policy-makers in 14 southern African countries were asked to rate issues that were of interest to them in primary schooling. One of the issues was that of private tuition outside school. This was given very low priority despite the fact that the first study of SACMEQ had shown the practice to be very widespread, for the most part to affect achievement even after home background had been accounted for. It was later given a higher priority after the researchers had interacted more with the policy-makers.

Policy-makers have allegiances that influence both what they regard as relevant, innocuous or even 'dangerous' research and also their willingness to take account of research findings. Stories abound of ministries or government departments either ignoring research results or delaying the publication of government-sponsored research because the results did not accord with the current political interests. Ways of delaying the publication of research results that governments do not like have been hilariously resumed in 'Yes Minister' (Lynn and Jay 1982). Not only can research be delayed or ignored but also only partial results can be selected to help them argue a case. Keeves (1994) has dealt with many of the problems that arise with those in authority when conducting legitimatory research.

Governments, as a rule, last only a few years. The research they sponsor should be completed within that time period and preferably in less than two years. There are few research projects that can be completed in this time period when it is considered that the instruments have to be developed and tried out before the major data collection can begin. The findings should be made available in time for the decisions that have to be taken and which will go ahead with or without the necessary knowledge base. Operational decision-making cannot wait for the results of specifically sponsored research results.

It has sometimes occurred that governments have initiated a reform, often without much evidence of its worthwhileness, and then asked for research to be undertaken to assess its effect. Where the reform has been total, it is too late to compare the effects of the reform with any other form of education. Even if the reform has been in some and not all schools, the problem has arisen that the government wants quick results and yet it takes some time for an innovation to 'settle down.' It is not good, or even dangerous, to judge its effects in the first year of operation.

2.2 For Researchers

The researchers often tend to have different backgrounds and value systems from those of the policy-makers. Researchers have usually undertaken their work in research institutes or university settings. Researchers have been trained to think widely and to question all things. Their allegiance tends to be more to fundamental or conclusion-oriented research. They pay much more attention to how the quality of their research is received by their research peers than by government agencies.

In most cases, researchers are not involved in the planning and implementation of reform. They rarely have any interest in how to plan the costs involved in any reform. They can rarely phrase their results in the language of planning and implementing reform. Indeed, once they have published their research report they tend to lose interest in what happens after that.

Status in the research system depends on the reputation the individual researcher gains from his or her research work. Status in the administrative world tends to be based on seniority and length of service and not on the quality of research work.

3. Disjunction Between Researchers and Policy Makers

From the above, it can be seen that the 'ethos' pervading in the contexts in which researchers and policy-makers live is very different. In nearly all cases, the researcher has to write a proposal for the research project that he or she must submit for funding. Very often the researcher views the proposal from the point of view of its likely contribution to knowledge whereas the policy-maker examined it from the point of view of the relevance to the ministry's agenda. Education is value based and has certain underlying ideologies. It is a short step, therefore, to the political arena. It can often happen the governments view social science research with suspicion because when they want the status quo to be preserved social science research that wants to go to the root of the matter in the sense of critical inquiry can be seen as subversive radicalism. On the other hand, some social scientists—because of the relationship between education and certain political and social philosophies—have begun to act as evangelists and this has damaged their credibility.

In the 1960s, governments began to support social and behavioral sciences research on a hitherto unprecedented scale. This was particularly true in countries such as the USA, UK, and Sweden (Aaron 1978). It was not long before there were discrepancies between expectations on the part of the policy-makers and the actual research performance. There was a decreasing credibility of research work on the part of the policy-makers that began in the early 1970s.

4. Models of Research Utilization

Weiss (1979) distinguished among seven different models of research utilization in the social sciences (see also Husén 1994):

(a) *The R&D model*. This is a 'linear' process from basic research to applied research and development to application. Weiss pointed out that the applicability of this model was limited in the social sciences because knowledge in the field does not lend itself easily to 'conversion into replicable technologies, either material or social' (Weiss 1979, p. 427).

(b) *The problem-solving model*. Here the results from a specific project are expected to be used directly in a decision-making situation. The process consists of: identification of missing knowledge → acquisition of research information either by conducting a new study or by reviewing the existing body of knowledge → interpretation of the results given the policy

options available → decision about which policy to pursue. This model has sometimes been known as the 'philosopher-king' approach where researchers are supposed to provide the information from which policy-makers derive guidelines for action. The problem-solving model often tacitly assumes about goals but social scientists do not agree among themselves about the goals of certain actions. Nor is there necessarily agreement among all policy-makers about the goals.

(c) *The interactive model.* This model assumes an ongoing dialogue between researchers and policy-makes. This is usually a disorderly set of interconnections and back-and-forthness.

(d) *The political model.* Research findings are used as ammunition to defend a particular point of view. It is often the case that policy-makers have already made up their mind about taking a particular course of action and should there be research results that legitimize this, then they will use it.

(e) *The tactical model.* This is a negative approach in that it is a way of deferring any decision. Thus, a controversial issue can be buried or postponed by policy-makers calling for more research or further analyses.

(f) *The enlightenment model.* According to Weiss (1979, p. 428), this is the model where social science research most frequently enters the policy arena. Research can 'enlighten' policy-makers because as research results become available they sensitize informed public opinion about ways of thinking of educational problems and come to shape the way in which people think about social issues. This is sometimes known as the percolation effect. People are helped to redefine problems through research so that they begin to think of the problems in a different way.

(g) *The research-oriented model.* Weiss (1979) refers to this as the 'research-as-part-of-the-intellectual-enterprise-of-society' model. Social science research together with other intellectual inputs, such as philosophy, history, journalism, and so on, contribute to widening the horizon for the debate ion certain issues and to reformulating the problems. This is somewhat akin to the enlightenment model outlined above.

Shavelson (1988, pp. 4–5), when dealing with the utility of social science research, sought to reframe the issue of 'utility' by suggesting 'that the contributions lie not so much in immediate and specific applications but rather in constructing, challenging, or changing the way policy-makers and practitioners think about problems.' He suggested that one cannot expect educational research to lead to practices that make society happy, wise, and well-educated in the same way that the natural sciences lead to a technology that makes society wealthy. The assumption that 'educational research should have direct and immediate application to policy or practice rests on many unrealistic assumptions'. Among these are relevance to a particular issue, provision of clear and unambiguous results, research being known and understood by policy-makers, and findings implying other choices than those contemplated by policy-makers.

5. *Some Examples*

It is relatively easy to identify some research that has had an enlightenment effect. The work of Piaget in identifying 'stages of development' began to have an effect on work in curriculum development by the end of the 1950s. Bloom's 'Taxonomy of Educational Objectives' and 'Model of School Learning' had a marked effect on many later research projects, the results of which entered the market place and influenced educational thinking. Coleman's 'Equality of Educational Opportunity' produced the concepts of 'school climate' and later 'social capital,' both of which entered educational thinking. The 'Plowden Report' in England produced the concepts of parental attitudes and 'educational priority zones,' both of which entered the general educational thinking. Carroll's 'model of school learning' and later his 'human cognitive abilities' research both influenced how educators thought of school learning. However, in all of these cases, the process took a long time. In some special cases in Sweden in the late 1950s and early 1960s research studies led directly to some action especially in the revision of the curriculum. However, the direct effect examples are rare.

In the first two decades or even more of the work of the International Association for the Evaluation of Educational Achievement (IEA) (Postlethwaite 1994), a massive amount of effort went into attempting to identify the major determinants of educational achievement in each of the participating countries. It was to the chagrin of the research workers that very little attention was given to the results. It was rather the 'horse race' national mean achievement levels that gained the attention of the press and the policy-makers. In the 1970s the then Minister of Education talked of the results being like an electric shock because they showed that the gap between north and south Italy was much larger than had been expected. The Third International Mathematics and Science Study (TIMSS) of IEA (see, for example, Beaton et al. 1996) in the 1990s only presented aggregate estimates for the test scores and selected questionnaire variables in their first set of publications and did not present analyses identifying the major determinants of either between country differences, or between-school or between-student differences within countries. Nevertheless, it was these aggregated estimates that attracted enormous media publicity and comment. In some cases the comment was appropriate such as about the high achievement scores in Japan but the low attitudinal scores towards the learning of the subject. In other cases, several of the journalists' comments and even those of some ministry officials proffering policy

Table 1
Selected policy actions for the Mauritius report

Policy suggestion	Relevant department(s)	Time	Cost
Consultations with staff, community, and experts			
1. The Ministry should ask the Staffing Branch to meet with Teacher Union representatives to discuss the potential 'conflict of interest' that arises from the current practice of allowing the teachers of around 80 percent of Grade 6 pupils to receive high financial rewards for teaching their own pupils as private clients outside of school hours	Staffing Branch and Teacher Union	Short	Low
Reviews of existing planning and policy procedures			
2. The Inspectorate should be asked to review and, if necessary, establish benchmark standards for the educational environment that are deemed to be 'reasonable for the proper functioning of primary schools'	Inspectorate	Short	Low
Data collection for planning purposes			
3. The Supply Branch of the Ministry should investigate the reasons for the relatively high percentage of Grade 6 pupils in Rodrigues who reported that they lacked basic learning materials	Supply Branch	Medium	Low
Education policy research projects			
4. The Planning Unit should undertake an investigation into the practice of grade-repeating in Mauritius in order to determine whether the extra year of schooling being received by the 'average Grade 6 pupil' can be justified on either educational or economic grounds	Planning Unit	Medium	Low
5. The Ministry should plan to undertake a follow-up survey of the same target population employed during SACMEQ's initial project in order to examine changes in important educational indicators over time	Planning Unit	Medium	Moderate

suggestions assumed that the relationships between certain variables between countries would be the same as those within countries (Ross 1997). The question must be asked as to why the press and the ministries seem to be more interested in the mean score differences rather than in the determinants of such differences. Is it possible that an interface of persons skilled in translating research findings into policy suggestions is needed?

Several of these kinds of projects did attempt to communicate to schools that participated in the research and would send each school a school report. This typically consisted of giving the test scores for each child in the sample in the school, the school's mean scores on the test as a whole and on subscores, the mean scores of similar schools and the mean scores of the nation. It was assumed that these kinds of results would enable school principals to identify the weak parts of achievement in his/her school and then be able to take remedial action. It would seem that some school principals did take the feedback seriously, but many did not do so.

By the beginning of the 1990s, some progress was being made in the attempt to have educational planners and administrators work more closely with educational researchers in order to have more direct links between research and policy-making. One international study in the 1990s had the strategy of working out in conjunction with ministries of education the research questions and then working out the actions to be taken as a result of the findings. This latter step was undertaken *before* the research reports were finalized for publication. This study was that of the Southern Africa Consortium for Monitoring Educational Quality (SACMEQ). The last chapter of each national publication listed the suggested policy actions categorized by cost and time needed for implementation. An example is given in Table 1 of

selected suggested policy actions for the Mauritius report (Kulpoo 1998, pp. 86–92). There were 38 policy suggestions in all.

It should be noted that the units undertaking the research study were units within the Ministry of Education and not special research units either within the ministry or in higher education institutes. The actual suggestions were checked, and in one or two cases modified, by the senior ministry personnel before the book was published. To what extent the suggestions were implemented is not yet known. On the other hand, there was a similar study in Zimbabwe with similar policy suggestions in 1991 and a report documenting the implementations of the suggestions has been published (Ross 1995). Despite the fact that some of the suggestions were implemented, there was no improvement in Grade 6 reading achievement by 1997 (Shumba 1998). It is unclear whether the implementation was not well conducted or whether only some of the easier but not crucial suggestions were implemented. This will also apply to the other SACMEQ reports.

In the USA, the United States Department of Education (1986) published a booklet under the title *What Works: Research About Teaching and Learning*. This booklet reported the results of research syntheses. It was aimed at all involved in education and presented in one or two pages the results of research and the practical implications of those results. This was followed by a series of similar booklets on different aspects of education. These booklets were made available to all schools in the USA. This was an attempt to communicate directly with school principals and teachers and was said to be very popular.

From the mid-1980s onwards there has been a movement initiated by Ministries of Education known as the 'Indicators Movement.' The Organization for Economic Co-operation and Development (OECD) has coordinated this work and produced a series of annual reports called 'Education at a Glance' (see the most recent one at the time of writing, OECD 1998). Data are collected and aggregated and reported at the national level. In some cases these results are of interest. There is the danger that the correlation of two variables/indicators at the national level is not the same as at the within country between school or between student levels (cf., Ross 1997). Where policy is made on the basis of the national level correlations and the within-country correlations are different, this can lead to misleading policy. It is important to examine the relationships at different levels before arriving at suggested action for policy-making. The OECD has begun to overcome this problem by having initiated a 'Program for International Student Assessment' (PISA), where every four years students aged 15 years (i.e., just before the end of compulsory schooling in most countries) will be tested in mathematics, science, and reading as key subjects and variation in achievement will be analyzed at student, school, and country levels. Data were also collected on student and school background variables (indicators) and will be related to variation in student outcomes.

There has been a host of research studies on such topics as learning, programmed instruction, leadership (authoritarian, democratic, and laissez-faire), grouping of students and achievement outcomes, learning methods, motivation (expectations of success and failure), grading practices, creativity and teaching methods, language (and foreign language) learning, the regularity and sequencing of in-service teacher training programs, teaching styles, and so on. Many suggestions have emanated from such research but in some cases there were contradictory results from different studies or the suggestions, even from sound research, were ignored. In some countries, there has been a tendency to initiate 'bottom-up' reform from examples from single schools. These have been case-study type research and have suffered from two defects: they could not be generalized in the sense of knowing how the innovation would work in many schools, and in many cases they were successful because of the charisma of a particular individual. When attempts have been made to replicate the innovation on a larger scale, there have been problems.

6. *Conclusions*

A great deal of money goes into educational research and yet the results are rarely used directly. Indirectly and over time research results 'percolate' down (one of the Weiss models of research utilization) to the district and school levels and then demands are made on the policy-makers to 'do something.' Even when policy-makers take the results seriously, there remains doubt about how well the implementation of policy suggestions was carried out.

If research is in some cases to have a more direct link to school reform it would seem as though several steps should be taken:

(a) Researchers should talk to the policy-makers before the research begins and ensure that the design and proposed analyses will answer the policy-makers' concerns.

(b) Projects should be conducted in a sound technical way. This requires that the funders have a cadre of persons that can advise them about the technical soundness of the proposed research. This is a big step because there are not many ministries even in highly developed countries that possess such persons.

(c) Projects should, wherever possible, be replicated.

(d) Researchers should, after consultation with the policy-makers, make a list of suggested actions for reform.

(e) Ministries of education should train and employ a cadre of policy researchers who are able to translate the research results into suggested actions that constitute the crucial actions and not only those easy to

conduct. These persons may not necessarily be within the ministry but could be in university departments.

(f) Policy suggestions should be acted upon and well implemented.

(g) Studies should be conducted to assess the effect of the implementations.

Until these kinds of steps are taken, research will continue to have its indirect enlightenment effect.

Finally, it should be remembered that there are certain reforms that do not depend on research. When the great debate raged in the 1960s in Europe about comprehensive schooling versus selective schooling it was the then Minister of Education in England and Wales who wrote, when asked why England has not preceded 'going comprehensive' with research such as that conducted in Sweden, 'It implied that research can tell you what your objectives should be. But it can't. Our belief in comprehensive reorganization was a product of fundamental value judgements about equity and equal opportunity and social division as well as about education. Research can help you to achieve your objectives, and I did in fact set going a large research project, against strong opposition from all kinds of people, to assess and monitor the process of going comprehensive. But research cannot tell you whether you should go comprehensive or not—that's a basic value judgement' (Husén and Kogan 1984).

Educational Research for Educational Practice

After 100 years of systematic research in the fields of education and educational psychology, there is still no agreement about whether, how, or under what conditions research can improve educational practice. Although research and educational practice each have changed substantially since the beginning of the

twentieth century, the question of how science can actually contribute to the solution of real educational problems continues to be controversial.

Because there are no general rules or strategies for translating research into practice, the first part of the present article focuses briefly on some of the basic problems concerning the relation between theory and practice in education. Next, six different approaches that attempt in various ways to make research findings relevant to education, particularly in schools, are discussed. These approaches concern: (a) using theoretical knowledge to improve technology for teaching and learning; (b) facilitating teacher expertise as a practical application of research on teaching; (c) using studies on classroom learning to provide the scientific basis for ability grouping, mastery learning, and adaptive teaching; (d) using research on cognitive development and learning as a source of scientific information about how to train student's learning competencies and self-instructional skills; (e) using educational research to design, implement, and evaluate new models of schooling and instruction; and (f) using research findings as a source of background knowledge for practitioners. Suggestions for how research can be made more relevant to educators and for ways in which educational practice can be more research-based are proposed on the basis of these different approaches.

1. The Gap between Research and Educational Practice

Most research in education and educational psychology is conducted with the explicit or implicit goal of directly or indirectly improving educational practice. As Anderson and Burns (1985) stated, 'the primary purpose of classroom research is to help educators to improve the conditions of learning and the quality of learning of increasingly large numbers of students' (p. ix). The kinds of necessary research, the required theoretical insights, and the ways that scientific findings should be translated into practice to attain this goal are issues that have not as yet been resolved.

When empirical and experimental research on educational phenomena began, there was a widespread vision, conviction, and expectation that it would generate a scientifically informed basis for educational practice. For example, Rein (1893) stated that 'there is only one way in teaching that corresponds to nature; to follow carefully the laws of the human mind and to arrange everything according to these laws. The attainment of adequate instructional procedures follows from knowledge of and insight into these laws' (p. 107).

When these ambitious hopes did not seem to be realized, there was substantial disappointment among both scientists and practitioners. It was not clear how teachers could use such very general and vague recommendations as those, for example, based on a synopsis of classical learning theories by Thorpe and Schmuller (1954). They concluded that instruction was especially effective when learners were motivated, when task demands matched learners' aptitudes, when learners received sufficient opportunities to relate elements of the learning task to the learning goal, when learners could use external criteria to judge their progress, and when the learning process occurred under conditions that facilitated adaptation to the total situation. Although these conclusions are probably valid, it is not surprising that such nonspecific psychological statements and such obvious educational recommendations led the educational community to the cynical conclusion that learning theorists were perhaps the only ones who could derive personal benefit from learning theory.

Dissatisfaction was not limited to problems in finding practical applications for learning theory. The results from research on teaching also seemed unproductive in providing educators with practical guidance. This can be seen, for example, in Bloom's (1966) resigned summary of the state of research: 'large class, small class, TV instruction, audiovisual methods, lecture, discussion, demonstration, team teaching, programmed instruction, authoritarian and non-authoritarian instructional procedures, etc. all appear to be equally effective methods in helping the student learn more information or simple skills' (p. 217).

The limited applicability of educational science for educational practice has resulted in several metatheoretical debates that have contributed only a little to improving the research situation or to solving practical problems. Some examples of the debated issues are:

(a) Is the gap between scientific and practical work the result of a production deficit in research, a reception deficit in the practitioners, or deficits in translating theoretical knowledge into practical suggestions? This debate has led at least to the insight that scientists and practitioners have different ways of perceiving the world, prefer to define their problems in different ways, and thus speak different 'languages.'

(b) How relevant is basic research, as opposed to applied research, for education? This debate is especially unproductive, both theoretically and practically. On the one hand, it is difficult to differentiate pure or basic research from applied research; on the other hand, it has become clear that findings from both research prototypes have specific advantages and disadvantages with respect to their practical applications.

(c) Is it more appropriate to use quantitative or qualitative methods in educational research? This debate has almost become a religious war for many, even though the theory of science convincingly teaches that both approaches are necessary and complementary components of any system of research in the social sciences.

2. Theory and Research

These metatheoretical debates and the many concrete attempts to derive practical applications from research findings have led to a variety of different proposals for solving the research–practice problem. Two positions are especially characteristic of these proposals: The first is that theory should take precedence; the second is that empirical work should take precedence.

The first characteristic position, that theory should be preeminent, can be captured by a quotation from Mook (1983), who, in agreement with many other scientists, recalled the truth of the classical adage that nothing is more useful than a good theory:

> Ultimately, what makes research findings of interest is that they help us in understanding everyday life. That understanding, however, comes from theory or analysis of the mechanisms; it is not a matter of generalizing the findings themselves … The validity of those generalizations is tested by their success and predictions and has nothing to do with the naturalness, representativeness or even non-creativity of the investigations on which they rest. (p. 386)

Examples of the ways in which theoretical models have aided in the solution of practical problems include the use of attribution theory to provide a better understanding of students' intuitive explanations for their success and failure; the use of findings from the expert–novice research paradigm to estimate the relative importance of general abilities and domain-specific knowledge in the solution of demanding tasks; and the use of theories of prejudice in the analysis of social conflicts.

The second characteristic position, focused on empirical research, is invoked in instances where there are competing theories, where context conditions determine psychological processes, or where descriptive or causal models must be transposed into prescriptive statements. Sequential research strategies are proposed to solve such problems. One example is the description of 'six steps on the road from pure learning research to technological research and development in the classroom' suggested by Hilgard (1964, pp. 405–11): step 1—research on learning with no regard for its educational relevance; step 2—pure research on learning with content that is similar to school subject matter; step 3—research on learning that is relevant to education because the subjects are students, the material learned is school subject matter, and/or the learning conditions are similar to classroom situations; step 4—research on learning and instruction in special laboratory classrooms; step 5—use of experimentally tested learning and teaching strategies in normal classrooms; step 6—developmental work related to advocacy and adoption, for a wider use of the research-based educational strategies.

These and similar sequential research strategies are followed in many research and development centers around the world. The differences among the programs are, however, too large to allow conclusions about the success of such a strategy. In principle, the possibilities and limits of this approach also depend on the basic relation between educational research and educational practice. Good educational practice is not simply applied science, nor does it consist in the correct use of findings from applied research. Science can at best only provide an important and useful, but always limited, theoretical basis for the planning, analysis, control, support, reflection, and better understanding of educational practice.

The limits of scientific prediction and explanation of educational outcomes are expressed in the conclusions reached by Haertel et al. (1983) based on a comparison of different psychological models of educational performance. They concluded that:

> Classroom learning is the multiplicative, diminishing-returns function of four essential factors—student ability and motivation and quality and quantity of instruction—and possibly four supplementary or supportive factors—the social–psychological environment of the classroom, education-stimulating conditions in the home and peer group, and exposure to mass media. Each of the essential factors appears to be necessary but insufficient by itself for classroom learning; that is, all four of these factors appear required at least at minimum levels for classroom learning to take place. It also appears that the essential factors may substitute, compensate, or trade-off for one another in diminishing rates of return. (p. 75f)

3. Models for Bridging the Gap between Research and Educational Practice

There is no general rule that specifies correct, expedient, or appropriate ways to use scientific findings to solve the practical tasks of education. More importantly, there can in principle be no such rule. There are, however, various approaches available that show how research can be used in different ways and what strategies can be used to translate research into practice.

3.1 From Learning Theories to Teaching Technologies

Educational technology consists of systems of rules, tools, and activities designed to bring students to the point where they can achieve specific learning goals systematically, effectively, and economically. Even more, Glaser and Cooley (1973) perceive technology 'as a vehicle for making available to schools what psychologists have learned about learning' (p. 855). Such standardized technologies should, of course, be derived from explicit and tested scientific theory. Although not a necessary component of educational technology, technical devices are frequently used with the purpose of minimizing the negative consequences of fluctuation in attention to errors or mistakes, whether by students or teachers.

The first researcher who, from theoretical grounds, wanted to replace normal instruction in the classroom with almost revolutionary mechanical teaching techniques was Skinner (1954). In the early 1950s Skinner argued that the behaviorist models of learning and conditioning, and the psychological laws specifying how to shape behavior through contingent reinforcement of desired reactions, were the scientific prerequisites for successful and effective instruction. It was his belief that these principles could not be used in classroom teaching because teachers were not able to present the material to be learned in sufficiently elementary components and were not able to provide the requisite number of reinforcements in the necessary contiguity to learners' behavior, verbal or nonverbal. Thus, he recommended programmed instruction and the use of teaching machines.

Beyond Skinner's initial attempts, the development of educational technologies made dramatic progress in the 1970s, 1980s, and 1990s. Computer-assisted instruction, integrated learning systems, intelligent tutoring systems, instructional media, and intelligent learning environments are some of the key concepts referring to the development, study, and use of modern technical aids for improving educational practice.

In particular, modern computer technology offers a variety of possibilities for the technical design of controlled, but flexible, adaptive, and intelligently guided instructional systems and learning processes. The prerequisites for these systems are general learning theories and domain-specific models of knowledge acquisition that allow the following:

(a) analysis of the learning goal in terms of competent performance (specification of the learning task);

(b) description of the initial state of the learner (specification of individual differences in relevant skills and knowledge);

(c) determination of the methods that effectively lead to knowledge acquisition (specification of instructional methods);

(d) assessment of the effects of these instructional methods (specification and measurement of learning progress).

Although there is no disagreement that educational technologies provide an up-to-date tool for education as well as an excellent opportunity for employing research results in a practical way, the relative failure of educational computing in general, and in mathematics in particular, must be acknowledged. The high expectations supported by research that rose in the early 1980s, with respect to the potential of the computer as a lever for the innovation and improvement of schooling, have not been redeemed. Elsewhere De Corte (1994) has argued that a major reason for this relative failure of computers in education is that the machine has been mainly introduced as an add-on to an existing, largely unchanged classroom setting. In addition, due to a lack of good communication, teachers usually had only low expectations about computer support for their teaching. Also, there was in most cases no question at all of an orientation toward modifying teachers' conceptions about educational goals and their beliefs about learning.

3.2 Research on Teaching and the Acquisition of Teacher Expertise

A large part of educational research is directed toward investigating educational productivity, teacher effectiveness, and the relation between instructional quality and learning outcomes. Although the empirical findings are very impressive, they are also quite diverse and are not stable across different studies. In a synthesis of the effects of instructional variables on learning, the following rank ordering of noncontent-related factors was found (with decreasing effect strength): reinforcement, accelerated learning programs, cues and feedback, cooperation programs, personalized instruction, adaptive instruction, tutoring, higher-order questions.

If one considers that the effects of single instructional variables can be masked or mediated by combined, compensatory, and interactive effects from other teaching, student and context variables, it becomes apparent that training single teaching skills cannot be a practical implication of these research results.

It seems considerably more effective to provide a combined training program for teachers that uses the results from research on teaching. The paradigm of the expert teacher provides an interesting theoretical perspective for the practical application of such research findings. Prompted by work in cognitive psychology, this paradigm investigates how experienced and successful teachers differ from inexperienced and/or unsuccessful teachers in their knowledge about education and in their teaching activities. The research results from this paradigm have already been applied in the design of teacher training.

This paradigm allows the integration of two research traditions that have been portrayed as alternative approaches (Stolurow 1965): 'Model the master teacher or master the teaching model?'. In the expert teacher paradigm, it is possible to directly and systematically relate research on teaching and learning in the classroom to teacher training. Such training should not be directed toward producing a uniform type of 'expert teacher', but should explicitly assume that there are interindividual differences in the teacher competencies to be trained.

3.3 Studies of Classroom Learning

In contrast to the subject pools used in experimental investigations of learning, the classroom is best described as a group of students with very different

learning prerequisites who are to be instructed at the same time in the same place. Massive interindividual differences in cognitive abilities, knowledge, skills, motivation, interests, attitudes, and study habits affect both students' learning behavior and their learning achievements. The relevant research concerning these factors is very extensive. It has led to a large number of psychological theories about how personality states and traits are relevant to learning, and has contributed to the development of measurement models and measurement instruments for diagnosing individual differences in learning prerequisites and learning outcomes.

Carroll (1963) provided an important contribution to the practical application of this psychological research with his 'model of school learning.' Described simply, Carroll proceeded from the assumption that, given equivalent learning time, students with different aptitudes would diverge in their learning performance; that is, some students would not attain the required performance goal. To avoid this outcome, each learner must be allowed the learning time he or she needs to attain a specific learning goal.

This model has had a strong influence on subsequent research; in many respects it has been further specified, broadened, and extended, and it has also been used for a variety of different practical applications. For example, the following concepts and procedures can be traced to Carroll's original model: time on task (the time during which a student is actually involved in a learning task); the personalized system of instruction; individually prescribed instruction; mastery learning; and, largely independent of Carroll's model of school learning, the aptitude–treatment interaction (ATI) research program. All these approaches have been concerned with the question of whether and to what extent undesired effects of individual student aptitude differences on learning outcomes can be reduced by variations in instruction.

Research on the dependence of school achievement on aptitude differences and instructional conditions has led to important practical applications. Three of these are grouping students for learning, mastery learning, and adaptive teaching.

The educational benefits of grouping students for learning are controversial and seem to depend on the effects of a variety of factors. Furthermore, these benefits are both student-specific and criterion-specific. A successful practical application of ATI research has not been made.

Mastery learning is the attempt to ensure that as many students in a class as possible (90–95 percent) meet a required learning criterion (90–95 percent correct items in a criterion test). This goal is achieved by a limited increase in learning time (about 20 percent) and optimal instructional use of the learning time. Although what one can actually expect from mastery learning in normal school instruction is somewhat controversial, there is no doubt that this is a fruitful model that allows productive research and practical applications.

Adaptive teaching is based on many ideas from Carroll's model of school learning and ATI research. Adaptive teaching involves both learner adaptation to the environmental conditions presented and teacher adaptation of the environmental conditions to the learners' present state, to effect changes in that state. The teacher's goal, in other words, is to make environmental variations 'nurtured' rather than merely 'natural' for each learner concerned (Corno and Snow 1986, p. 607). 'Adaptive teaching' is thus an omnibus term covering a large number of different standardized and informal procedures for adapting teaching in variable, flexible, and dynamic ways to students' individual differences, so that optimal learning conditions can be provided for each student.

3.4 Fostering Students' Learning Competencies and Self-instructional Skills

In the above characterization of adaptive teaching it was noted that the optimization of individual learning requires not only that instruction be compatible with the cognitive and motivational demands of the student, but also that students' learning competencies and learning motivation be explicitly fostered. There is considerable research in cognitive psychology, developmental psychology, and educational psychology that addresses how to promote competencies and motivation. At the forefront are investigations on transfer of training, learning to think, the promotion of metacognitive skills, and the development of self-instructional skills.

Much of the theoretically oriented research also includes suggestions for applying the findings. Relevant support programs have been tried for elementary, secondary, and university students. Although these programs have demonstrated that intellectual skills and thinking performance cannot be arbitrarily trained, they have also convincingly shown that the training of metacognitive competencies and self-instructional skills can result in lasting improvements. When such programs have realistic goals, are provided over an extensive time frame, and if possible are directed toward the acquisition of domain specific knowledge, all students can profit.

3.5 The Use of Research Findings for New Models of Schooling

Research can be used not only to improve existing educational institutions, school organizations and instructional conditions, but also to plan new models for schooling. Such an approach to change is needed when it is unclear whether an educational goal can be reached by gradual and piecemeal changes in current

activities or whether fundamental reform is more necessary. Both theoretical discussion and practical experiences are available for using research findings in this way. Such change requires considerations of the factors that must be considered in planning a new educational system, the strategies that should be employed, the problems that must be addressed, and the implementation tasks that must be performed.

3.6 Research as a Source of Background Knowledge for Practitioners

The practical application of research consists in more than the instrumental use of research findings. In addition, science and research have an educational function; that is, they provide individuals with knowledge about themselves and the world, and allow them to act rationally.

Because people think, decide, and act primarily on the basis of their available knowledge (whether it is correct or incorrect, complete or incomplete, objective or biased), it is important and necessary for those involved in the educational process (politicians, administrators, principals, teachers, parents, students, and researchers) to be able to change or replace their personal beliefs, intuitive knowledge, prejudices, and suppositions with reliable and valid information. Such a replacement is not only a prerequisite for reflective, responsible, and effective individual action, but also a condition for rational communication and discourse among educational practitioners. Although it is not possible to measure the effectiveness of this function of research, it nonetheless seems plausible and important to translate as many research results as possible into the language of the practitioner.

A potentially very promising strategy to bridging the theory–practice gap is a combination of the last two strategies, namely using research for the design, implementation, and evaluation of new models of education and schooling, on the one hand, and research as a source of background knowledge for teachers on the other. This strategy consists in the creation and evaluation in real classrooms of complex instructional interventions that embody our present (hypothetical) understanding of effective learning processes and powerful learning environments. In order to have a reasonable chance of success, such attempts at totally changing the classroom environment and culture should be undertaken in partnership between researchers and knowledgeable practitioners.

Such partnership is essential not only to promote good two-way communication, but also in view of modifying and reshaping teachers' beliefs about education, learning, and teaching (see De Corte 2000). The positive effects of this partnership idea have, for instance, been shown by Huberman (1990). In a qualitative study of the linkages between researchers and practitioners, he has shown that contacts between both parties during a research project can result not only in better applications of the outcomes of a single study, but also in the establishment of more enduring forms of collaboration.

A specific approach which is in line with this holistic strategy is represented by scholars who advocate the use of so-called design experiments, and who aim at the development of a design science of education. According to Collins (1992, p. 15) 'a design science of education must determine how different designs of learning environments contribute to learning, cooperation, motivation, etc.' As a result a design theory would emerge that can guide the implementation of educational innovations by identifying the variables influencing their success or failure. This intervention approach has a twofold goal: it intends to advance theory building, while at the same time contributing to the optimization of classroom practices.

In this respect, Brown (1994) argued that theory building is crucial for conceptual understanding as well as for practical dissemination. In fact, Brown's project 'Fostering communities of learners' is one of the most representative examples of the design experiment approach. In this project the classroom is fundamentally redesigned using innovative components such as reciprocal teaching, the 'jigsaw method' of cooperative learning, and the creation of a new classroom culture. Reciprocal teaching establishes a learning environment in which a small group of students is provided with guided practice in acquiring four cognitive strategies with a view to improving their skill in reading comprehension. These strategies are: asking questions, summarizing, clarifying comprehension difficulties, and making predictions about the future content of a text.

A major feature of reciprocal teaching is that it takes the form of a dialog, in which the teacher and the pupils take turns in leading the discussion; gradually the pupils' share and responsibility in the dialogs increases. The 'jigsaw method' implies that small research groups of pupils each study a subtopic of a broader theme. Afterwards they regroup into learning groups in which each pupil is the expert in one subtopic, so that by combining their knowledge they all learn about the whole topic. A new classroom culture and climate is created based on four qualities, namely individual responsibility, mutual respect, establishment of a community of discourse, and a restricted number of participant structures (such as reciprocal teaching).

In the perspective of the further dissemination of this new kind of learning environments it is necessary to keep in mind that they should be realizable in existing classrooms. In this respect the notion of a partnership between researchers and practitioners is also crucial in the light of the necessity of the research–practice reciprocity. Whereas practitioners can help in translating theory into practice, and thus in making classroom teaching more research-based, their

partner role can also contribute to make research more practice-driven.

Finally, the orientation of this intervention approach to theory building raises a major challenge for the researchers, namely the development of an appropriate methodology for designing experiments in complex classroom settings in such a way that sound and theoretically valid conclusions can be drawn from a wide range of quantitative and qualitative empirical data.

4. Conclusions

While the effectiveness of these six different approaches to the problem of bridging the theory–practice gap has not been systematically studied, it is plausible that each of them has not only some merits but also some weaknesses. Moreover, much will depend on how each approach is used in translating research results into practice. In this respect, it can be argued that to be successful in making psychological theory and research applicable to education, one should develop a strategy that combines the following basic characteristics:

(a) good communication with practitioners, which means that the relevant outcomes are translated in such a way that they are palatable, accessible, and usable for the teachers;

(b) an orientation toward a fundamental change of teachers' belief systems about the goals of education and about good teaching and effective learning (in line with the view described above);

(c) a holistic (as opposed to a partial) approach to the teaching–learning environment, i.e., all relevant aspects of the learning environment should be addressed.

The relation between research and practice is complex and difficult. As a consequence, there is no simple, uniform solution to the problem of translating scientific results into practical suggestions. Nonetheless, some general conclusions can be drawn.

First, many different types of research are applicable to educational practice. The value of a scientific study for educational practice is not in any way directly related to the extent to which it mirrors typical features of an applied educational setting.

Second, research results can be used in educational practice in different ways. Six typical examples have been noted: the development of educational technologies, teacher training, the optimization of instruction, fostering students' learning competencies, the design of new models of schooling, and the use of scientific information as background knowledge for practitioners.

Third, these different strategies for applying research results are not mutually exclusive. Rather, it is desirable to combine several variants to improve the practical situation.

Finally, exploring the processes by which theoretical knowledge can be transformed into practical action must itself be an important domain of educational research.

Educational (School) Counseling: United States

At the outset it is important to note that this article is focused on counseling in elementary, middle, and high schools. The obvious omissions from this list include postsecondary institutions such as junior colleges, community colleges, vocational–technical schools, four-year colleges, and universities. These institutions were not included in this discussion because their historical antecedents and current status are quite different from those of counseling in other educational institutions and the space allocated to this piece does not allow for a discussion of counseling services in both groups of institutions.

1. *Historical Perspectives*

It seems likely that the delivery of guidance and counseling services in educational settings began in the USA near the end of the nineteenth century in San Francisco in the California School of Mechanical Arts. In 1895 George Merrill began offering services that included occupational exploration, career counseling, job placement, and follow-up services. Jesse B. Davis also pioneered in offering guidance services in high schools in Detroit and Grand Rapids, Michigan. Although his program also included vocational guidance, it also focused on character development and developing appropriate behavior (Miller 1968).

During the first two decades of the twentieth century, other programs were established in Cincinnati, New York City, and Seattle. However, one of the most important developments that emerged from this period actually arose from the work of Frank Parsons in the Vocational Guidance Bureau and his posthumous publication *Choosing A Vocation* (Parsons 1909). Parsons was a social reformer who was concerned about a number of groups including immigrants and school dropouts. He recognized the importance of making wise career choices and set several programs in motion to improve their decision-making processes. In his book he outlined a three-step model for this process: (a) develop a clear understanding of one's self, (b) acquire a comprehensive knowledge of occupations, and (c) using what Parsons called 'true logic,' choose an occupation that is suited to one's abilities, aptitudes, and interests. Parsons' simple model of occupational choice making, underpinned by the development of numerous psychometric instruments in the 1920s and 1930s was to underpin the vocational counseling and guidance process in the USA and elsewhere until the 1950s. In the 1950s, Super (1951), Holland (1997), and others published more sophisticated models of occupational choice and career development that would change the way counselors think about the process. In reality, much of what passes for career counseling in schools today still follows Parsons' model.

Most of the early developments described thus far have been centered in high schools. Although many people advocated the need for guidance services for children, activity in this area was limited to a few school districts such as the Baltimore city schools. In 1964, funds for elementary school guidance programs and the training of elementary school counselors became available because of amendments to the National Defense Education Act and since that time elementary school counseling programs have increased rapidly in the USA.

1.1 *Directive Approach*

To this point the general term guidance has been used more often than counseling to describe the services provided to students in educational institutions. Today, many school counselors in the USA are still called guidance counselors because of the early emphasis on guidance services. Guidance services include testing and appraisal; providing educational, vocational, and personal information; classroom guidance; consultation with teachers and parents; educational and occupational placement; and individual and group counseling.

Although the term counseling appears in connection with many of the descriptions of services provided in the late nineteenth and early twentieth-century services, the process of counseling received little attention in the professional literature until 1939 when E. G. Williamson published *How to Counsel Students*. Williamson (1939) set forth a counseling model that could to some degree be linked to Parsons' (1909) tripartite model, although it had six steps. These steps were (a) collect data about the student and his or her environment using tests, inventories, observations, and other data collection devices; (b) collate and synthesize the data that has been collected; (c) diagnose the student's problem; (d) predict what will occur to the student based on the various choices available to the student; (e) provide counseling; and (f) follow up to determine how the student has fared given the course of action taken, and recounsel as necessary. Williamson's approach, which relies heavily

on appraisal, became known as the directive approach to counseling because of some of the counseling strategies recommended. For example, Williamson suggested that counselors identify the most appropriate course of action for students, and if the student rejected the suggestion, send them out to consider their options before proceeding.

1.2 Nondirective Approach

In the 1940s and 1950s Carl Rogers (1942, 1951) provided counselors with a very different approach to counseling students that soon became known as the nondirective approach. Rogers' philosophy and his counseling techniques were simple. He believed that people have within them an innate ability to come to terms with and solve their own problems. The counselor's role, according to Rogers, is to create a climate in which individuals feel free to explore their innermost self-perceptions and feelings. In Rogers' counseling framework, appraisal of the individual was largely eliminated, as was diagnosis. Not surprisingly, Rogers' optimistic view of human beings and their ability to cope with their problems was widely embraced.

Historical hindsight suggests that the enthusiastic acceptance of Rogers' ideas was not the wisest course of action that could be taken by counselors working in educational settings. Most school counselors are faced with serving large numbers of students and therefore must provide counseling sessions that are relatively short in duration and few in number. The client-centered model, although it was touted as a briefer model of counseling than the psychoanalytic approaches that held sway in the 1940s and 1950s, turned out to be an approach that required several sessions of fairly long duration. Moreover, counselors found that children needed more structure than the client-centered model provided and as a result did not respond well in counseling. Although many elementary school counselors incorporate aspects of the client-centered model into their work, other briefer, more action-oriented approaches to counseling appear to be more popular (Gibson et al. 1993), a fact that reflects the status of client-centered counseling with other school counselors working at other levels as well.

2. Current Status and the Future of School Counseling

The National Defense Act of 1958 and the increased emphasis on counseling that began with the acceptance of Carl Rogers' ideas in the late 1950s and early 1960s marked the beginning of a rapid movement toward professionalization by school and other types of counselors. The result was the development of accreditation standards by the Council for the Accreditation of Counseling and Related Educational Programs (CACREP), higher standards for licensure to practice in school settings by every state, and the publication of a variety of position papers regarding the role and function of school counselors by the American School Counselors Association. Today school counselors utilize dozens of models of counseling to assist students with the wide range of problems they bring to them. School counseling, which began in the USA, has been adopted to varying degrees by all English-speaking countries, most Western European countries regardless of language spoken, and some African and Asian nations. Interestingly, the career development needs of students in all countries, including the USA, will continue to shape the services offered to students both in the USA and in countries such as Japan, the People's Republic of China, and Taiwan. However, a number of other forces continue to influence school counseling including concerns about the family, efforts aimed at substance use and violence prevention, and concerted efforts aimed at educational reform.

2.1 Counseling

Baker (2000) indicated that the need for counseling in contemporary services is substantial, and presented a list of concerns that are addressed routinely in individual and group counseling sessions. The problems on Baker's list were aggressive behavior, underachievement, grief, suicidal ideation, eating disorders, substance abuse, stress, problem pregnancy, career planning, and coping with dysfunctional families. Earlier Conyne (1994) provided data that support to some degree Baker's observations. He reported that 25 percent of high school students in the USA drop out of school, suicide is the second leading cause of death among the 11–24 age group, and that AIDS has become one of the leading causes of death among 15–24 year olds. Other data, such as the report that one in five students report at least one bout of depression before age 18 (Lewinsohn et al. 1993), also lend credibility to Baker's list of problems.

It should be noted at this point that most school counselors assume a very limited role when counseling students who have severe mental health problems because they lack the time required and may not be trained to deal with severe mental health problems. However, there is support from both quantitative and qualitative research for both individual and group counseling that school counselors perform according to the conclusions of Whiston and Sexton (1998). They reviewed the research literature regarding school counseling interventions and concluded that students appear to benefit from social skills training, activities related to coping with families, and career planning activities.

Whiston and Sexton (1998) also reviewed the research literature focusing on what they called guidance curriculum activities and drew different conclusions. Generally speaking, research has not been supportive of the efficacy of classroom guidance activities, although there were some positive results. Classroom guidance activities devoted to the development of self-esteem were generally not effective according to Whiston and Sexton. However, they concluded that research regarding the use of classroom guidance to improve academic achievement was somewhat effective. At the conclusion of their review, Whiston and Sexton made two types of recommendations. One recommendation was that more and better research regarding school counseling interventions is needed. The second recommendation was that school counselors should strive to improve the quality of their interventions.

2.2 Classroom Guidance

Given the rather limited support for classroom guidance, should school counselors abandon it as a strategy and use their time to provide additional counseling activities? The idea of eliminating large group interventions seems untenable since school counselors are faced with providing services to 350 to 1,000 students and the use of a large group delivery mechanism is an efficient means of reaching large numbers of students. Whiston and Sexton's (1998) recommendation was on target. There is a need for the improvement of the delivery of classroom guidance activities.

Another line of research, that dealing with resiliency, provides an even more compelling rationale for the improvement of classroom guidance, counseling interventions, and other strategies used by school counselors. Resiliency is the innate ability of children and adolescents to cope with numerous environmental difficulties and emerge with positive mental health (Lewis 2000). Although resiliency is innate, it seems to be fostered by a number of protective factors that school counselors can impact. Lewis (2000) reports that resilient individuals have a positive attitude toward school and develop good reading skills by age 10, have good reasoning and communication skills, believe that they can influence their own lives, set career success as a high priority, have special interests and hobbies, and have coping strategies when facing adversity. Factors that seem to promote resiliency include friendship-making skills, positive mentoring at school, positive affectional ties with alternative care givers, a caring environment, high expectations, and opportunities for participation. Clearly, the fostering of resiliency cannot be developed through a single intervention. However, social skills such as friendship-making skills, decision-making skills, coping with factors such as stress, study skills, and many other variables that positively affect resiliency, can be influenced if a variety of strategies are employed.

To this point only counseling and classroom guidance have been discussed. School counselors use a number of other strategies such as consultation to impact some of the other factors discussed.

2.3 Consultation

Consultation is a triadic process engaged in by a school counselor (consultant) and a caregiver (consultee) for the benefit of a student (client). The objectives of consultation are twofold. The most obvious of these is to improve the educational or psychological functioning of the student. The second goal of consultation is to improve the functioning of the consultee, who is typically a teacher or a parent. Although there is limited research on consultation with parents, the research that is available is generally supportive of this activity as is the rather extensive number of studies focusing on teacher consultation (Brown et al. 1998). Using consultation and parent education (Muro and Kottman 1995), school counselors help parents develop more positive parenting strategies and establish more positive, supportive family environments. Consultation with teachers typically focuses on academic achievement, disruptive classroom behavior, or a combination of the two. Depending upon the theoretical orientation of the counselor, interventions may range from individual behavioral contracts to entire classroom interventions employing democratic decision-making strategies.

2.4 Peer Intervention

Peer interventions have also been used successfully by school counselors, both as a means of preventing the development of problems as well as interventions to help students who have developed academic and psychological problems. For example, peer counseling programs have been employed successfully to improve communication skills, enhance decision making, teach relaxation strategies, and increase assertiveness (Baker 2000). Peer mediation programs have also been used successfully to reduce physical and verbal aggression in a large number of schools and peer tutoring programs have been instrumental in improving educational achievement among students at various grade levels (Brown 1999). Students have also acted as cocounselors in successful smoking cessation programs for children and adolescents as well as in other roles involving the prevention and elimination of addictions. The roles that school counselors play in peer counseling and tutoring programs include recruit-

ing peer counselors, mediators, and tutors; training them for their roles; supervising their activities; and evaluating the outcomes of their work.

2.5 Other Counseling Activities

Counselors at all levels utilize the interventions discussed to this point. However, educational planning and placement, career planning and placement, and scheduling students' classes are activities that are very much a part of high school counselors' roles, engaged in to a limited degree by middle and junior school counselors, and almost totally absent from the roles of elementary school counselors. Assessment for educational and career planning, including the interpretation of tests and inventories to students and parents, follows this same pattern, with elementary school counselors being only marginally involved in these types of activities and counselors at higher levels becoming progressively more involved. In the USA, school counselors have been caught up in the assessment of educational progress that characterizes the educational reform movement in many schools. The result is that elementary school counselors often coordinate the end-of-grade tests, while middle and high school counselors coordinate the end-of-course tests that are used to assess achievement in individual subject areas. High school counselors may also be involved in administering college admissions tests as well as general academic competency tests required for graduation by some schools.

3. Conclusions

If there is one role that is routinely ignored by large numbers of school counselors it is the evaluation of their work. Baker (2000) indicated that the increasing demand for accountability requires that the outcomes of school counseling programs be evaluated, but few counselors seem to be heeding his warning. The result is that a few schools are requiring that counselors conduct follow-up studies to determine opinions about the effectiveness of their programs. Even fewer schools require that specific interventions such as group counseling be evaluated periodically. If Baker is correct about the need to demonstrate the effectiveness of school counseling programs, conducting evaluation studies will become a more important part of the counselor's role in the future.

Finally, it is difficult to predict whether conducting evaluation studies will be an important activity within school counseling programs in the future because of the demands placed on their time by ever-changing educational institutions. It is even more difficult to predict the overall future of school counseling. The number of school counselors has increased dramatically since the 1960s and there is increasing interest in providing counseling services in schools throughout the world. However, counseling services come at a cost. As school officials set priorities designed to improve the educational experiences of students, school counselors will, as Baker has suggested, have to demonstrate that they are worthy of funding. If this is to occur attention must be paid to improving the quality of some of the interventions used, such as classroom guidance and presenting evaluative data that support the services provided.

Educational Sociology

Educational sociology is a field of sociology that directs attention to the social forces that affect all aspects of education in a given society, or across many societies. As such, it complements the study of education from other scientific perspectives.

The term 'educational sociology' is thought to have been first used by the philosopher John Dewey at the end of the nineteenth century, and university courses began to appear with that title in the United States already in the early twentieth century.

However, in the late nineteenth and early twentieth centuries, the precursors of modern sociology had recognized the importance of the social context of education. This was especially true of Emile Durkheim, and to a lesser extent Max Weber, Karl Marx, and others who in one way or another included education in their analyses of society. Thus, the sociological study of education can trace its origins to the writings of the early European founders of sociology itself. Since its early beginning, educational sociology has been the site of major theoretical and methodological developments. It has also produced a very large body of research knowledge about education in different societies and cultures. Noblit and Pink conclude in their discussion of the field that it '…is even more varied and vibrant than other subfields of the (sociology) discipline' (Noblit and Pink 1995, p. 8).

The purpose of this article is to provide a brief description of the origins, the characteristics of, and the major issues current in educational sociology.

1. *The Sociological Perspective in the Study of Education*

From its early beginnings, the sociological study of education was viewed with optimism. In one of the first widely used textbooks in the United States, *The Sociology of Teaching*, Waller commented 'I am convinced that Educational Sociology is a fruitful and challenging idea, and I have tried to put the evidence for this belief into my book' (Waller 1932, p. viii). A sociological approach to the study of education is one that focuses on social factors rather than psychological, biological, or physical factors in the study of education. The social factors of interest to educational sociologists include those that are related to social structures as well as social processes. Thus, for example, the study of schools as social organizations and bureaucracies is a well-established field in educational sociology. This organizational context also provides the framework for studies of processes at the individual level, such as the acquisition of attitudes, values, identity, and academic achievement.

Among the many other topics included in educational sociology are the family and its relationship to the socialization of the young, and its relationship to schooling. Teachers and students also receive attention, and interests range from the study of the recruitment and training of teachers to the study of the teaching profession and of teachers in schools.

Educational sociology also includes macrolevel studies of educational systems, for example, of educational expansion, of education in different ideological systems, and of the relationship between class structures and what takes place within educational systems. The study of education and social change includes the link between education and social and economic development, the relationship between technology and education, and the factors related to the formation of educational policy and planning.

2. *Educational Sociology or Sociology of Education?*

One of the most uncomfortable divisions within the sociological study of education has been the extent to which the field is seen as a 'science,' represented by the dispassionate investigation of educational phenomena, or as the development of normative policies and plans to build particular kinds of educational systems.

In the 1960s this basic division was characterized as a tension between the empirical and normative 'modes' in the study of education. Even today there are many who see the sociological study of education primarily as a change agent in education, either through the formulation of policy, or through the effects of research itself. In this respect, the discipline is seen as a normative agent which is concerned with specifying what education or schools 'ought' to be or to do in carrying out the educative function. This point of view dominated the early development of the field, at least in the United States. This approach was sometimes specifically labeled as 'educational sociology.'

However, there were those who viewed the sociological study of education as a science. The label 'sociology of education' has often been used to designate this perspective, and this term has its roots in the sociological tradition that attempted to emulate the natural sciences and create a 'science of society.'

The significance of the names educational sociology and sociology of education became an issue in the United States with the decision to change the name of the *Journal of Educational Sociology*, which was founded in 1927. When the journal came under the sponsorship of the American Sociological Association in 1963, it was decided that its name be changed to *Sociology of Education*.

Today sociologists and educational researchers tend to use the two terms interchangeably. The designation of the field to some extent depends on disciplinary location, such as in departments of sociology, where it

is largely known as sociology of education or in departments of education where it is often called educational sociology. Furthermore, textbooks and courses sometimes are given other labels such as 'social foundations of education,' 'social context of education,' and 'education and society.'

Language and culture also may affect the way that the field is labeled. For example, in German the sociological study of education is related to the three words *Soziologie* (sociology), *Bildung* (education), and *Erziehung* ('to bring up'), and the field is frequently referred to as *Bildungsoziologie* or *Erziehungsoziologie* (Chisholm 1996).

In this article, the terms educational sociology and the sociology of education will be used interchangeably without implying that there are subtle meanings that differentiate between the two terms.

3. *Some Classical Theoretical Contributions to Educational Sociology*

Virtually all social thinkers, since the time of Plato and Aristotle, have considered the education of the young as part of their theories of society. From a social point of view, the process of education has always been linked with other social processes, either as a source of social stability or a source of social conflict. However, the discipline of sociology itself did not emerge until the early nineteenth century with the writings of August Comte (1798–1857). Many of these early sociologists included education in their studies of society.

The formal sociological study of education did not emerge until Emile Durkheim (1858–1917) began to teach, and write about, education and educational institutions to students at the Sorbonne where he was made Professor of Pedagogy and Sociology in 1913. Durkheim quite rightly can be called the father of educational sociology. As a teacher of teachers at the Sorbonne in Paris, Durkheim considered education to be '...an eminently social matter' and therefore highly suitable for sociological analysis. In his introductory lecture upon taking up the Chair of Pedagogy in 1902, Durkheim began with the following words: 'As a sociologist, it is above all as a sociologist that I shall speak to you of education (1956, p. 114). Later in the lecture he added: '…if there was ever a time and a country in which the sociological point of view was indicated, in a particularly urgent fashion, for pedagogues, it is certainly our country and our time' (1956, p. 133).

Durkheim's contribution to the sociological study of education lay primarily in his focus on the relationship between education and society. He believed that in every society there is a notion of the 'ideal person' and that every society had some form of education system to produce the ideal. This notion of the ideal person varies from society to society, and even in the same society over time. But, according to Durkheim, the education system adjusts to meet this need. Because of the importance of education for the survival of society, Durkheim regarded all education as moral education. For him, morality was the set of duties and obligations that influence the behaviors of individuals. He saw modern morality as resting on reason rather than religion, and he constructed a theory of educational practice that included what he considered the three basic elements of morality, namely discipline, attachment to social groups, and individual autonomy. Unlike his major works in sociology, Durkheim's works in education are collections of his course lectures and include letters and book reviews.

The importance of the social aspects of education did not escape other early sociologists. For example, Max Weber (1864–1920) included education in his analysis of social stratification, and educational credentials formed an important part of his understanding of social class, social status, and the formation and maintenance of elites in society. Although Karl Marx (1818–83) never engaged in a systematic study of education, it was nevertheless an important social institution in his grand theory about class exploitation and class conflict. Unlike many other fields in sociology, the sociological study of education can trace its origins to the writings of the early European founders of the discipline itself.

4. *Some Modern Theoretical Contributions to Educational Sociology*

In the 1970s educational sociology began to move into the mainstream of sociological debate in both theory and research methodology. At that time the sociological study of education was criticized as being too conservative and constrained by the priorities and preoccupations of educators rather than those of sociologists. At the same time, sociologists were criticized as being too preoccupied with analyses of classroom interaction on the one hand and the relationship between education and status attainment on the other.

In the late 1960s and early 1970s the microlevel study of educational processes was developing in the United Kingdom. During this period Bernstein (1971) conducted research on language codes and learning, and pointed to the hitherto ignored symbols and meanings in the classroom situation as a possible locus of inequality in educational processes. Bernstein's research gradually led him to focus on the ways knowledge is valued, classified, and controlled in various kinds of pedagogic processes.

In the minds of some, this 'new' sociology of education, which included antipositivist sociological

movements such as symbolic interactionism, phenomenology, ethnomethodology, Marxist sociology, and the sociology of knowledge, constituted a paradigm shift in the sociology of education comparable to a scientific revolution in the Kuhnian sense. Perhaps the most important aspect of the 'new sociology of education' is that it directed attention to the study of classroom interaction, classroom language and the curriculum. Knowledge itself became the main focus of study, namely how knowledge was defined, controlled, and transmitted to students. During the 1970s and 1980s the 'new sociology of education' stood in opposition to the 'old' and was manifested particularly in resistance theory and social and cultural reproduction theories. Although it is clear that developments in educational sociology have moved into other 'newer' directions (Noblit and Pink 1995), the influence of the 'new sociology of education' continues in much of current theoretical debate and research.

A third new direction in educational sociology emerged in the United States. Sociologists began to use causal models to investigate the multiple determinants of educational outcomes, and subsequently, the effect of educational attainments on occupational and career attainments. Although the use of highly quantifiable data and statistical techniques was not new in the sociological study of education on either side of the Atlantic, the development of status attainment models added social-psychological variables to the educational and occupational attainment process. The use of causal (path) models has dominated aspects of educational research from the 1970s to the present day in many countries.

A fourth and more recent development in educational sociology is that of critical theory, particularly with respect to the study of education as a form of oppression by dominant groups, or education as means of liberation from oppression. Critical theory emerged out of the Frankfurt School in Germany in 1923. During the ensuing years, including a period of dispersion during the Second World War, members of the Frankfurt School developed a range of theoretical approaches which were a reaction to the scientism of positivist sociology, and an attempt to develop a general theoretical approach which combined theory and practice. These writers included Horkheimer, Adorno, Fromm, Marcuse, and Habermas. Although the focal points and precise details of the writers vary, the general perspective and its implications for education are coherent and relevant. Critical theory is based on the assumption that the power of capitalism has come to dominate all aspects of social life. Concepts such as 'the totally administered society,' 'one dimensional man,' and 'communicative competence' typify the portrayal of social life in modern capitalism. The purpose of critical theory is not simply to explain and analyze, but also to emancipate and transform society in the process (the unity of theory and practice).

By the late 1970s educational sociology had moved into the mainstream of sociological debate generally. These debates became so important that some writers suggested that educational sociology had become a battleground for theories and policies about inequality and social reform. By the mid-1980s educational sociology had become very much a mainstream area in the discipline of sociology generally.

5. *Educational Sociology in Various Countries*

Early surveys of research in educational sociology, for example in the Federal Republic of Germany, France, and Britain, suggest that the functionalist perspective was dominant during the 1950s and 1960s. However, during this period it was in France that Marxist approaches were developed.

There is now growing documentation about the current development of educational sociology in Western countries. Surveys of research in educational sociology, for example, in the United States (Dreeben 1994), the former Federal Republic of Germany (Chisholm 1996), the Netherlands (Wesselingh 1996), and South Africa (Muller 1996), to name a few, present a picture of a rapidly growing discipline with shifting and multiple paradigms.

In many countries educational sociology was late in becoming established. In India, for example, the earliest identifiable studies in educational sociology were conducted in 1953 and 1967 (Chitnis 1982). In 1974 there were only 89 educational studies that could be classified and reviewed as sociological, but by 1980 the number had more than doubled.

Also in Spain, like many other countries outside the United States and Britain, educational sociology was slow in getting established. Early studies occurred in the 1960s and were typified by an emphasis on human capital theory, particularly in relation to economic development in Spain (Subirats 1990). Spain is an example of a country where sociology was not favored politically. However, after 1970 educational sociology began to develop in more radical ways. Much influenced by French sociology, educational sociology since the mid-1970s has been dominated by the neo-Marxist perspective, with research being conducted on schooling and social reproduction, into the effectiveness (or noneffectiveness) of schools, the link between school and work, and particularly on the role of universities in social reform.

6. *Themes and Developments in Educational Sociology*

Although educational sociology has branched into a number of identifiable subfields such as the sociology of the curriculum and the sociology of teaching, there

are a number of themes that have dominated both theory and research across all specialties. In this section a number of these themes are described in terms of their relevance for educational knowledge and research.

6.1 Macro/Micro Perspectives and Structure and Agency

Since the 1970s, one of the major issues in sociology generally has been the dualism between macro and micro approaches to the study of human behavior. Macro approaches typically focus upon aspects of social structures as explanatory variables, and thus tend to adopt deterministic and constraining theories about human behavior, with little or no acknowledgment of individual autonomy or freedom. Typical variables for the macro-oriented sociologists are those of social class, gender, ethnicity, capitalism, and organizational hierarchies. Conversely, micro-oriented sociologists tend to focus upon individual actors, regarding them as autonomous actors with few or no constraints by the outside social and structural environment. Typical variables for the microsociologists are the subjective meanings of human interaction, resistance, action, and voluntarism.

In the study of education this has meant an almost irreconcilable gulf. Those adopting a macroperspective have tended to study the statistical relationships between variables, largely measuring structural characteristics such as socioeconomic status, social class, gender, ethnicity, and the like. Those taking a microapproach have focused on interaction patterns, individual attitudes, values, or beliefs, or the subjective meanings that individuals construct about educational realities. The impasse between the 'two sociologies' has prompted some sociologists to observe that the only solution is to continue to develop both macro- and microsociology.

Related to the macro/micro controversy, and perhaps an obstacle to solving it, has been the question of structure and agency. The conceptualization of these two dimensions of social action also represents a dualism in the sociological study of education. This dualism focuses around explanations of social action: large-scale structural (and therefore deterministic) forces or individual voluntarist forces. Thus, social action is seen as existing on two distinct levels. Examples of the former in the sociology of education are structuralist neo-Marxists, who explain social reproduction in schools in terms of the contradictions of the capitalist economic system. Regarding the agency frame of reference, those who adopt an interpretive perspective tend to see the source of action at the individual or the microlevel, but with a reference to the structural context.

6.2 Critical Theory, Critical Pedagogy, and Postmodernism

The sociological study of education has been influenced by the intellectual movements of the late twentieth century, such as postmodernism, deconstructionism, and critical pedagogy. These intellectual movements approach the study of education from a critical, oppositional, and sometimes neo-Marxist perspective.

Critical Pedagogy, derived from the critical theory perspective, advocates that the classroom should become the arena for '…intellectual resistance towards the ways in which our roles, our lives, and our subjectivities are defined and constituted' (Shapiro 1995, p. 191). Ultimately those who espouse critical pedagogy in classrooms seek to establish a truly democratic culture through a form of education that is empowering and liberating in terms of the dominant ideology.

Modernism refers to the industrial revolution, the artistic and literary movements of the twentieth century, and the beliefs and values of the Enlightenment, such as the idea of progress, and belief in reason and principles such as equality, liberty, and justice. In contrast, postmodernism rejects linear views of progress, relies more on a dialectical analysis of the opposing forces in society, and stresses a democratic, emancipatory and antitotalitarian theory and practice, particularly with respect to education.

Postmodernism, as a social theory and intellectual movement, differs from critical pedagogy and critical theory in that the notion of an underlying reality is denied. The notion of a postmodernist break or rupture with modernity has occurred through the penetration of the media, advertising and television. The surface signs (language) take on their own meaning. It has been argued that postmodernist social theory makes the notion of intellectual resistance and liberation meaningless (Shapiro 1995), and thus with little educational relevance.

As theoretical movements, it remains to be seen as to how these two will influence the social understanding of educational processes and educational policy and practice in the twenty-first century.

6.3 Equality and Excellence

In most Western societies, the concept of equality has been central to much of the planning for and expectations from educational systems. Generally speaking, structured social inequality is defined as a social problem, and education is usually seen as a way of resolving it. Furthermore most modern democracies espouse the principles of meritocracy in educational opportunity and social rewards. In this context, education plays a double role, for not only is it

expected to provide a major mechanism for bringing about greater equality, but it also serves as a mechanism for self-betterment, and therefore for social mobility.

Clearly then, since education is linked with equality and inequality, it is essential to clarify what is meant by the term. Two seemingly contradictory dimensions underlie notions of equality with respect to education. The first of these includes the notions of fairness and equity, and generally means that 'random inequalities of nature' should be acknowledged and taken into account in the educative process. Thus, naturally bright children should be treated in ways which will allow that brightness to be developed to its fullest. Not to do so would be unequal and inefficient.

However, there is a second dimension, and that is that education should help to rectify (mitigate) the 'random inequities of nature.' In other words, insofar as is possible, every person should have an equal opportunity to excel in ways that are not constrained by natural differences. Sociological research in education has addressed the origins of inequality in education, the consequences of inequality, and policies that may make educational access and outcomes more equitable. Much of the research into the importance of family background and schooling in educational and occupational attainments has the question of inequality underlying it. Ultimately, the extent to which education either creates or reinforces these inequalities means that it operates in an inequitable manner. Thus, the subfields of adult education, the curriculum, learning, special education, and teaching are all concerned, in one form or another, with equality and efficiency in the educational system.

6.4 *Gender and Education*

The process of differentiation by sex in education occurs early in schooling and continues throughout the education process. In most countries, the attainments and achievement of males and females at different education levels, and in different subject areas, differs considerably. In a study of science achievement in ten countries (Australia, England, Finland, Hungary, Italy, The Netherlands, Sweden, Thailand, and the United States), between 1970 and 1984, Keeves and Kotte (1992) found that the social roles of women changed in all countries with respect to participation in the labor force and declining fertility rates. They also found that the participation of women in secondary and tertiary levels had increased, and in some countries, the participation rates for women were higher than that for males.

The results of their study showed that in all 10 countries boys outperformed girls in science, even when other variables were taken into account, such as home background, aptitude of student, values and motivation to do science, and attitudes toward science. The authors concluded, however, that their model left much unanswered in explaining why it is that boys do better in science than girls: '…it is not firmly established exactly how the effects of being male or female operate to influence achievement outcomes in science' (Keeves and Kotte 1992, p. 163). Although it can be argued that sex differentiation has its origins in the family socialization processes during infancy and childhood, the school remains a key institution that accounts for some unequal educational outcomes. The school both constructs and reconstructs gender relations such that the subordinate status of females is continually confirmed. The fact that females are staying in school longer in many countries does not mean that gender differences are being eradicated. Questions of gender in education apply to teachers as well as students. Sex inequalities in student academic and career outcomes have often been related to the influence, subtle or otherwise, of the sex of teachers. More importantly the sex inequalities among teachers regarding their work experience and career opportunities have become a topic of importance for understanding the influence of gender in education generally.

Continued research into the processes of maintaining sex divisions in schooling will remain high on the agenda of educational sociology. Furthermore, social policies to eradicate gender inequalities in schooling can only become effective when they are based on sound research evidence, which until now remains inadequate.

6.5 *Cultural Diversity and Multicultural Education*

The movement of peoples across and between national boundaries continues to pose important research issues for educational sociology. The schooling of minority groups within countries has been a long-standing item on the sociology research agenda, particularly in countries such as the United States, Britain, Canada, and Australia. In these and similar countries the emergence of heterogeneous populations through voluntary and nonvoluntary migration has called into question again whether education serves as an assimilationist mechanism or a protector of unique cultural systems and identities. In reality the debate over the notion of a core curriculum and a multicultural curriculum has yet to be resolved, particularly with respect to learning among members of race and ethnic minorities (Ogbu 1992).

Considerable research has been conducted on the factors that contribute to the academic achievement of minority groups in various countries. However, these studies have often assumed homogeneity within minority groups themselves, and have also assumed that members of minority groups share similar values

toward education and its outcomes. However, research findings make it clear that this is not the case, and that for indigenous groups and other racial and ethnic minorities, 'differentness' and 'otherness,' both between and within groups, are major factors in explaining educational processes and outcomes.

Ogbu (1992) has argued that both countries which advocate a strong core curriculum (as in Germany, Japan, South Korea, and Taiwan), and those which support a more pluralistic multicultural curriculum, overlook the wider societal and dominant cultural impact on the learning processes of minority students.

Educational sociologists will focus more on the processes related to the education of refugees, to the consequences of new international economic and social alliances, such as the European Community, and improved knowledge about the determinants of academic achievement across and within minority groups of all types.

6.6 *Dropouts and Burnouts: Alienation in Schools*

School retention rates have steadily increased since the 1960s in almost all countries. Nevertheless, there will remain considerable concern over those students in the twenty-first century who do not complete secondary school. There are numerous reasons for this concern. Rumberger (1987) gives five: (a) the short-term increase in dropouts since 1968, at least in the United States, (b) the numbers of minority group students with high dropout rates are increasing, (c) as academic standards increase, dropout rates will also increase, (d) the standard of educational credentials for virtually all jobs can be expected to increase, and (e) completion rates will increasingly be used as an indicator of performance for secondary schools.

Most of the research on school dropouts has regarded the phenomenon as pathological, and as representing a loss to the individual as well as to society. Lee and Burkham (1992) group the causes of dropping out into three categories: (a) the personal and psychological characteristics of dropouts, (b) the academic and psychological behaviors of dropouts, and (c) schools as contributors to dropping out. Thus, they argue that dropouts (or 'at risk' students) tend to come from low status, minority backgrounds, from single parent or step-parent households, are alienated, make lower grades, have higher rates of truancy, and do not attend schools (such as Catholic schools) which have lower dropout rates (1992, pp. 422–3).

LeCompte and Dworkin (1991) draw similar conclusions, but direct attention to the equivalent phenomenon among teachers, namely burnout. They argue that teachers also experience alienation and often leave the teaching profession because of burnout. However they observe that many teachers who experience burnout and lose their commitment do not leave the profession, a process they call teacher entrapment. This phenomenon poses two problems for the quality of teaching in schools: (a) new programs are difficult to implement with unenthusiastic teachers, and (b) staffing becomes a problem when teachers who should leave, do not. The authors suggest that school reforms fail because of inappropriate measures of school success or failure, of mismatched reforms, of quick-fix reforms, or reforms that leave the alienating structure unchanged. In short, the problem of alienation in schools, both from individual and structural causes, results in problems that are only beginning to be researched. Educational sociologists in most countries will continue to research these processes as long as there are school dropouts and burned-out teachers.

7. *Educational Sociology and Educational Policy and Planning*

Educational planning generally is understood to be the identification, development, and implementation of strategies designed to attain, efficiently and effectively, the educational needs and goals of students and society. The practice of educational planning is not a new phenomenon and, according to some, can be traced to the writings of Plato, to Renaissance scholars, and more recently to post-Second World War experts.

What characterizes current activities is that planners have tended to rely upon nonsociological assumptions in formulating their planning models. Demographic projections, manpower models, rate-of-return approaches, and school mapping all approach the task of educational planning as though the social aspects of educational behavior were irrelevant. Each of these techniques has at its base an implicit theory that assumes that the needs of society can be clearly specified and measured in economic terms, and that the social behavior of individuals in response to these needs is unproblematic. It is for this reason that writers argue that educational planning needs a social theory of society that includes structure and process, and both macro- and microdimensions.

We have learned from research and from all theoretical perspectives that the actors in the planning process, the politicians, bureaucrats, and planners are part of the very system they want to change. The functionalists can explain how it is that these persons act largely to preserve the status quo, even though the planning programs may appear very radical. The Marxists can explain in whose interests planning decisions are made, while the interactionists can explain at the microlevel how and why the actors in the planning process come to define planning objectives in particular ways, and how competing views are 'defined away.'

Finally, sociological research has helped us understand the importance of consultation with all interested parties in the educational planning process. It has been argued that the compensatory education and desegregation programs in the United States were flawed by lack of adequate information about objectives and methods. Resistance to any social reform can indicate conflicting interests which could have been avoided had adequate information been obtained beforehand. It is only by understanding these social forces that means can be taken to ensure that the objectives and strategies of educational planning are appropriately, efficiently and effectively formulated and implemented.

8. *Educational Sociology in the Twenty-first Century*

The rapid development of educational sociology during the late nineteenth and twentieth centuries has resulted in considerable accumulated knowledge about educational systems and how they work in different cultural and organizational settings. The discipline has become increasingly relevant for policy making, as well as for theoretical development and methodological application. It is also a discipline which is increasingly comparative, as knowledge about educational systems across national and cultural boundaries adds to both our knowledge of consistencies in educational processes, as well as the idiosyncratic properties of education in different structural and cultural settings.

Because it is problem-driven, the future of educational sociology will continue to reflect the preoccupations of countries in the performance of schools and the needs of society. In this respect, Durkheim was correct in arguing that education was imminently social. It will continue to be so, and will continue to attract the vigorous attention of sociologists and educational researchers who take a sociological perspective.

Educational Systems: Asia

Asia is a vast continent with a large population. It accommodates a vast number of countries with diverse cultures and religions, at different states of economic development and with different political systems. Education, being a human activity, therefore also demonstrates a spectrum of varieties in Asia. Nonetheless, there are certain detectable trends in education

Table 1
Countries in Asia

East Asia	China, Hong Kong (China), Taiwan (China), Macau (China), Japan, Korea (Republic of 'South Korea'), Korea (People's Republic of 'North Korea'), Mongolia
South East Asia	Brunei Darussalam, Cambodia, Indonesia, Laos, Malaysia, Myanmar, Philippines, Singapore, Thailand, Vietnam
South Asia	Bangladesh, India, Maldives, Nepal, Pakistan, Sri Lanka

This table follows largely UNESCO classification, with the exception of Iran

development in the region, given strong trends of globalization and increased interactions between nations and cultures.

This article refers to subregions which are often known as East Asia, South East Asia and South Asia (see Table 1). It does not include three other major groups of nations: systems that belong to the former Soviet Union, systems in the Middle East, and the Pacific Islands.

In most of these nations/regions, there have been dramatic developments in basic education in the last two decades of the twentieth century, approaching universal basic education (which is defined differently in different systems) with varied degrees of accomplishment amidst various difficulties. There were also deliberate developments of vocational education in the past two decades, but it faces varied degrees of challenges given the change in the economy and the labor market. Higher education is relatively underdeveloped except in some of the most developed economies.

1. *The Structures*

The education systems in Asia are very much influenced by the West. The earlier systems of education, even in noncolonial China, and Japan, were modeled after the old German system and later the US system. The $6+3+3$ system of primary, junior secondary and senior secondary schools has become the common pattern in Mainland China, Japan, Taiwan, and South Korea in East Asia.

With the exception of Japan and Thailand, most of the nations and regions in Asia experienced colonial rule, and that has significance in the structure of the education systems. Quite a few systems in Asia adopt a traditional British model that took shape during colonial times. Hong Kong, Britain's last colony in Asia until 1997, preserves a $6+3+2+2$ system, with a three-stage secondary schooling: two years junior secondary, two-year senior secondary, leading to O-Level (Ordinary Level) examinations, and an additional 2 years of pre-university A-level (Advanced Level) study. Singapore maintains a similar system, except that there are staggered years of secondary schooling according to students' abilities. The British model is still the norm in past British colonies such as Pakistan, Sri Lanka, Malaysia, Bangladesh, Maldives, and Nepal. India, which was the largest British colony, maintains the same pattern, except that it has an integrated eight years' basic education instead of nine.

Meanwhile, there are still traces of French influence in Vietnamese, Lao, and Cambodian education; these regions belonged to French Indochina. Likewise, Indonesia used to be a Dutch colony, and maintains a system that is more or less in line with the Dutch system. The Philippines were earlier colonized by Spain, and later mandated by the USA. They follow a very American system. Macao, a former Portuguese colony, has a blend of schools following the Portuguese and Chinese systems, respectively. In Mongolia and North Korea, the former Soviet model was followed.

2. *The Cultures*

Asia hosts a number of strong cultures. The strongest among them are the East Asian culture, the Indian culture, and the Moslem culture.

The East Asian culture, often also called the Confucian culture, prevails in communities that use chopsticks: the Chinese communities (the Chinese Mainland, Hong Kong, Taiwan, and Macao), Japan, the two Koreas, Vietnam, and a large part of Singapore. Although there are significant variations between, and even within, these societies, they are often seen as societies of collectivism and conformity. They are cultures in which education inherits the strong examination orientation in ancient China, where formal education was the only path for upward social mobility. Societies in East Asia still place high values on formal education. These societies therefore often enjoy a high attendance rate, and are champions in international comparisons of educational achievements, particularly in the realms of science and mathematics. However, the examination orientation has also rendered the systems rather weak in the relevance of the curriculum and flexibility in learning. Among others, the East Asian education systems also place serious emphasis on the social or moral aspects of students' development.

The Indian culture is an oversimplified umbrella term that covers different traditions derived from Hinduism. Against common beliefs, the South Asian

subcontinent societies encompass a large variety of religions, including Buddhism, Christianity, and Islam. However, it is safe to say that Hinduism underpins a large part of the education philosophy in South Asia. The education systems in South Asia often carry a strong religious orientation, and emphasize the relations between humans and nature. Because of the British colonial past, many of the South Asian systems of education also bear a strong framework borrowed from the traditional British system.

There is a strong tradition of Islamic culture in some of the South East Asian nations: Malaysia, Indonesia, and Brunei Darussalam. There are also sizeable Islamic communities in China, India, and Singapore. The Moslems in Asia seem to have developed a particular paradigm about education, which is able to integrate the emphasis on human–God relations in traditional Islamic education, with the learning of science and modern technology within the education system.

The cultural factor plays an important part in the shaping of education systems in Asian nations. Overall, there is an emphasis on the social (human–human) and religious (human–God) dimensions in the educational philosophy, and separation of such from knowledge and skills. Hence, in most of the education systems in Asia, there have been comprehensive and deep-rooted traditions of education about morality, attitudes, and values.

The strong cultural traditions in Asia have influenced not only education within the respective nations/regions, but have also affected the education of the Diaspora communities. The Chinese and Indian immigrants in other countries, for example, regardless of their countries of origin, are known for the outstanding academic performance of their children.

3. *The Economy and Education*

The continent also comprises nations in rather polar economic conditions. On the one extreme, there is Japan, which is among the strongest economies in the world. On the other extreme, there are the South Asian countries such as Nepal, Bangladesh, and Pakistan who are among the least-developed economies. In between, there are the newly emerged economic powers, the so-called little dragons: Singapore, Hong Kong, Taiwan, South Korea. There are the two giant economies: China and India; both are still in the 'developing' category, but are growing rapidly. Then there are the other South East Asian nations, once called 'advanced developing economies,' Malaysia, Thailand, the Philippines, and to some extent, Indonesia. Other nations have just recovered from the inefficiency of planned economies: Vietnam, Laos, Cambodia, Mongolia, and more recently, North Korea.

The economic strength of these nations affects their education systems in at least two dimensions. The economy constrains the resources available, and hence affects the supply of education. The economy also carries with it manpower structure and manpower requirements that affect the demand for education among the population. However, a special feature of education systems in Asia is that strong cultural elements often override economic conditions and enable many Asian nations to develop their education systems beyond that which the economy could seemingly warrant. Again, typified by China and India, followed by Sri Lanka and Mongolia, many Asian systems demonstrate a very strong literacy rate and enrolment ratio, when compared with systems in other parts of the world.

Most of the economies in Asia have seen positive growth in the last two decades of the twentieth century, despite intermittent interruptions by political instability or financial crises. One distinct move among such economic growth, common to the Asian economies with almost no exception, is the opening of the local market to foreign investments. This has sped up the process of globalization among Asian societies. Such a trend has tremendous implications for education, both in terms of human resources demand and of the philosophies in the development of education.

4. *Enrollment in Basic Education*

It was not a surprise that critical international endeavor on *Education for All* was launched in Asia (in Jiomtian, Thailand, 1990). Asia hosts the largest student population in the world. Among others, China and India alone host a total of 250 million primary school students, which is more than one-third of the world's students in primary education.

Population is always an issue in Asia. Population poses two types of problems for the education system: scale and growth. The sheer scale of the population in some of the Asian countries has made access to education an almost formidable problem. In addition, the problem is amplified by the rapid growth of the population in some nations.

There are very small systems of education in Asia, such as that in Brunei with around 40,000 students, and the Maldives, which has around 50,000, but they are not typical of Asian systems.

China and India host the two largest systems of education in the world, with primary school populations of around 140 million and 110 million, respectively. In both countries, the policy emphasis in the last two decades of the twentieth century has been on expansion of access to basic education. Both countries have launched major expansions of basic education since the mid-1980s (1985 in China, and 1986 in India). Both have demonstrated spectacular

improvements in access and school attendance; however, both countries are still struggling with access problems because of the size and growth of the population.

In China, there have been rigorous measures of birth control, which have effectively slowed down the growth in the population. There has also been rather successful mobilization of community resources in the building of schools. Hence universal attendance is achieved in most parts of the country. The national enrolment ratio for primary education, age 6–12, has been over 97 percent. However, there are pockets of population where either the economy is underdeveloped or the minority culture does not accept formal schooling as it is. There are both supply and demand problems of even basic education within these pockets. It has to be borne in mind that with the vast population in China, even a small percentage would mean millions of children out of school.

In India, there has been an unprecedented increase in the scale of basic education. There has also been great success in mobilizing nongovernmental organization of education, particularly in the nonformal sector. However, the increase in access is often offset by the rapid growth in the population. In the past two decades, India has demonstrated spectacular expansion in the number of children in schools, yet there is a decrease in the enrollment ratio because of the even faster growth in the population.

Both China and India face challenges of school drop-out. There are broadly two causes of school drop-out: (a) inability of the families to bear the private costs of schooling, and (b) income-earning economic activities that distract children in their teens from schools. In China, this is more serious in rural areas of the newly prospering economies, where there is usually a drastic increase in the private costs for formal schooling, and where there are plenty of other opportunities in economic activities for the young. This is particularly serious in the final years of the nine-year compulsory schooling. In India, school drop-out is also more serious in the final years of the eight-year basic education, and occurs mainly in rural villages where schooling does not promise foreseeable employment opportunities in the modern sector.

The problems facing China and India are not limited to those two giant countries. Indonesia, for example, hosts a student population of more than 26 million. Although Indonesia does not have a vast area compared with China and India, its over 600,000 islands have made universalization of basic education an even more formidable task. Other countries such as Pakistan and Bangladesh share the problem of rapid population growth.

Population and access are less of a problem in the more developed economies. Japan, South Korea, Taiwan, Hong Kong, and Singapore have seen universal or near-universal basic education since the 1970s. The demographic situations in these societies are fairly stable; the economy poses demand for more education, and both the public and private costs are largely met with little difficulty.

Low female enrollment is a serious issue in many South Asian systems of education. It is also an issue in Japan and Korea at tertiary education level, very much because of the social expectations for women. In most other societies in Asia, there is a general increase in the percentage of female students in higher education. In some systems, such as Hong Kong and Taiwan, there are more female university students than male.

5. *Schools and the Curriculum*

Schools are a relatively new concept in many Asian countries. Before the school model was borrowed from the West, education took place as private tutoring, or within the temples. Still, in many Asian countries, particularly those where the population is strongly Islamic or Buddhist, education or learning is a concept that goes far beyond schools, and schools are seen only as training geared for the modern sector.

Unlike in the West, where the early schools were largely associated with the church, schools in Asia were started deliberately separate from the traditional religions. In most of the Asian systems, strong government intervention in the school system was only a post-World War II phenomenon. In the Asian context, there was the Karachi Declaration of 1962, which urged all countries in the region to achieve universal basic education within 20 years. In the decades that followed, universal education was the policy goal in most Asian countries, although the target goal of universal basic education still remains a remote vision in many countries.

The concept of a school varies from society to society. Physically, schools in Asia may vary from modern concrete buildings, which are not very different from any urban school in other parts of the world, to makeshift bare shelters, with the blackboard as the only symbol of a classroom. In the mid-1980s, there was a movement in China to supply each student with a desk and a chair. At exactly the same time, India launched the 'Operation Blackboard' in order to equip each class with a good blackboard.

There have been success stories of mobilization of local communities in building and running schools. This is now common practice in China, India, Pakistan, and Bangladesh, and is well regarded among the developing world.

Asian classes are relatively large by world standards. It is not unusual to see classes of over 50 or 60 students, at both primary and secondary levels. Such classes may be seen in relatively underdeveloped rural areas in South Asia, but are also common in developed urban cities in Korea, Japan, and the Chinese com-

munities. In many cases, the large class is seen as a necessary community for collective learning, rather than a matter of economy.

Most of the Asian systems of education maintain a traditional curriculum. Few systems in the region have seen fundamental changes in the curriculum, and the modes of teaching or learning. Typically, schools teach the national language and mathematics as the core subjects, plus a foreign language, which since the 1980s has been predominantly English in almost all countries.

Among others, most of the systems in South Asia place a high value on the English language, and the societies use English as their language for wider communication among different language groups within the countries.

The Asian schools, East Asia and South Asia in particular, have a strong tradition in mathematics. This has made the East Asian systems of education envied by many outside the region, who regard mathematics as the most reliable evidence for student performance. The high level in mathematics learning is sometimes regarded as contributing to the success of the East Asians and South Asians in the American Silicon Valley, or the recent championship of India in software industries.

However, the Asian systems of education are also known for the frequency and intensity of examinations, both inside and external to schools, and the pressure therefore brought upon students. Private tutorials are common in many Asian countries. In East Asian societies, private tutorials are formalized in after-school tutorial schools. Typified by the *juku* in Japan, a large percentage of students attend tutorial schools as a normal part of their lives. In Korea, the tutorial classes start even earlier than schools in the morning. The examinations are often seen by educators as distorting the aims and relevance of learning. The reduction of adverse examination pressures has been the major theme in recent educational reforms in China, Singapore, Taiwan, and Hong Kong.

Nonetheless, the examinations play a crucial role as quality controller, and have contributed to the extraordinarily small variance among students' achievements. This has often lent itself to supporting movements for national assessments in some Western countries.

In most of the strong cultures in Asia, there was also a strong oral tradition in imparting knowledge. This has been translated into reading, reciting, memorizing, and copying, which are a large part of school activities. Such a tradition is a common point of reform in China, Singapore, Hong Kong, and Taiwan. Meanwhile, there are also recent discoveries, e.g., 'rote-learning' could be a particular way of learning, and practicing is seen as an alternative path to understanding.

There are also strong elements of 'moral' education in Asian schools. They are implemented either through religious or ethics education, in schools that are sponsored by religious bodies. Even in secular schools, it is regarded as essential to have elements of education in moral values, attitudes, and conscience, and these are often more important than the cognitive development of students. Such moral education is fulfilled through formal lessons (such as in China, Singapore, and Taiwan), internal publicity and communications (such as campaigns, assemblies, or media within the schools), and extracurricular activities. In many Asian systems of education, the schools pay particular attention to a large variety of extracurricular activities as a way of training of student leadership or social awareness.

6. *Challenges of the Knowledge Society*

The coming of the knowledge society has posed new challenges to the Asian systems of education. Most of the Asian economies have seen a rapid growth in the service sector that demands educated human resources. In many major cities in Asia, the 'white-collars' have exceeded the 'blue-collars' and there is little room for uneducated 'cheap labor.'

In these circumstances, the traditional high respect for education in Asian cultures has become a blessing, and that has been witnessed through the strong community support for basic education in many Asian countries in the last few decades of the twentieth century. Most Asian societies have no phobias about modern technology, and that attitude assists the development of learning technologies and lifelong learning.

The systems have inherited strong cultural traditions that place high importance on the development of the person. That is another strength, given the emerging emphasis of 'social competency' or 'character education,' which is increasingly seen as essential to a society where acquisition of knowledge is no longer seen as the major function of education.

However, the strong tendency to conformity in the systems, which has led to rigidity in the curriculum and uniformity in expectations, might pose a challenge to the Asian systems. There is a perceived need to facilitate and enhance diversity and creativity among the younger generation, and this is on the agenda of educational reform in many systems of long tradition in Asia.

Educational Systems: Australia

As the individual governments of the six Australian states and the two territories have the major responsibility for education there is no one national system. Despite this, the provisions in each jurisdiction are similar. Collaboration on matters of policy take place in a council of ministers of education and the roles of the federal government have increased in recent years. Education is provided as part of preschool education, school education, and tertiary education (consisting of vocational education and training as well as higher education). Major elements of the education systems in Australia are represented in Fig. 1.

1. *National Context*

In 1997, Australia had a population of 18.5 million in an area of 7.7 million km^2. Although the overall population density is low, it is a highly urbanized society; the two largest cities contain 40 percent of the population. Outside the cities, the country is sparsely populated; 30 percent of primary schools have fewer than 100 students and 30 percent of secondary schools have fewer than 500 students. Commentators have noted that centralized administrative structures emerged to promote uniformity of educational provision for a dispersed population. Although the Australian population is mainly of European background, recent immigration has produced greater ethnic and cultural diversity. One-fifth of the population was born overseas. English remains the language of most activities in education. About 2.5 percent of Australian school students are of Aboriginal descent, some of whom still live in isolated communities.

The Government is a parliamentary democracy. After the federation of former colonies in 1901, states retained responsibility for education. Two territories have education powers similar to the states. Political responsibility, federally and in each state, resides with a minister who is accountable to the relevant parliament. State governments provide about 60 percent of all public expenditure on education (90 percent of the expenditure on school education). The federal government provides 40 percent (including most of the expenditure on universities). For the financial year 1996 to 1997, total public and private expenditure on education was A$29,300 million, which represented 5.7 percent of GDP. Government outlays amounted to A$24,500 million. Over half of these outlays (A$13,900 million) were directed to primary and secondary schooling (ABS 1998a).

The World Bank classifies Australia as a high-income country. In 1996 to 1997, per capita GDP was just over A$24,000. Literacy among adults is nearly universal and 43 percent hold a post-school qualification. Just over 12 percent have university degrees and 11 percent have a vocational qualification. Amid general affluence, unemployment among young people has remained high in recent years. In November 1996, some 11 percent of 15–19-year-olds were unemployed and a number of programs are concerned with

Figure 1
Representation of the Australian Education System

transitions between education and work (OECD 2000, p. 128). Shifts in patterns of employment towards service industries have also resulted in changes to education and training programs.

2. Preschool Education

Although the states and territories provide preschool education there is no national policy on its provision. The age at which children attend preschool varies across jurisdictions and differences exist in the organization of preschools. A national survey reported in 1996, that 188,200 children younger than five years attend preschool. Children of three and four years old make up 92 percent of children at preschool. A majority of 4-year-olds attend preschool on a part-time basis (ABS 1996).

3. Primary and Secondary Schooling

Education is compulsory from six to 15 years (16 in Tasmania). Most children start primary school at five years of age and continue for either six or seven years (depending on the state), and students complete primary school at the age of 11 or 12 years. Students in Australian primary schools usually have one teacher for most subjects, and are promoted each year. During the 1990s, there emerged a national focus on the development of literacy especially in the early years. This focus is embodied in a *National Literacy and Numeracy Plan* agreed to by federal, state, and territory education ministers (DEETYA 1998).

Secondary education is provided for either five or six years depending upon the length of primary education in the state. The first one or two years of secondary school typically consist of a general program followed by all students. In subsequent years, a basic core of subjects is supplemented with optional subjects available to students. Students in secondary schools generally have a different teacher for each separate subject area. In the final two years of secondary schools students have more scope to specialize and a range of elective studies is provided from which students choose five or six. Almost all (95 percent) final-year students study English and 85 percent study a mathematics subject. Subjects from the sciences and studies of society and environment are taken by 70 percent of students. Just fewer than half the students include a technology subject, 30 percent take an arts subject, and 10 percent study a foreign language (Ainley et al. 1994).

One of the most marked changes during the 1980s was an increase in the percentage of students who remained to complete secondary school. The percentage of commencing secondary students remaining to the final year of school rose from 35 percent in 1980 to 77 percent in 1993. It has since declined a little to 72 percent in 1997. Since 1976, the school completion rate has been higher for girls than boys. In 1997, 78 percent of girls, compared to 66 percent of boys, remained to the final year of school (DETYA 1999).

For both primary and secondary schools the length of the school year is approximately 200 days; beginning at the end of January and ending in the third week of December and divided into four terms of nine to 11 weeks. The summer vacation is five or six weeks. Students attend school five days per week. In primary schools, there are five hours of tuition per day and in secondary schools there are 5.5 hours tuition per day.

3.1 Government Schools

State education departments recruit and appoint the teachers in government schools, supply buildings, equipment, and materials, and provide limited discretionary funding for use by schools. In most states some responsibility for administration, staffing, and curriculum has been devolved to regional education offices and schools (which has become more extensive in recent years).

In 1997, the average sizes of primary and secondary schools were approximately 230 and 780 respectively (MCEETYA 1997). During the 1990s there was a planned reduction in the number of government schools so as to increase the average school size. Most government secondary schools are comprehensive and coeducational. There are a small number of selective-entry secondary schools in some states. In Tasmania and the Australian Capital Territory, the final two years of government schooling is in separate senior secondary colleges.

In 1997, the ratio of students to teachers was 17.9 in primary schools and 12.7 in secondary schools. In the 1996 to 1997 financial year, per capita expenditure was A$4,686 in government primary schools and A$6,447 in government secondary schools (MCEETYA 1997). In the largest system, in 1993 the average class size in primary schools was 27.4 and the average size of English classes in secondary schools was 22.9 (MCEETYA 1994).

Taxation revenues provide almost all the financial resources for the operation of government schools. Although parents are not officially required to pay fees for students to attend government schools, many schools seek voluntary contributions from parents and raise funds from other local sources.

3.2 Non-government Schools

Non-government schools enrolled 30 percent of students (26 percent of primary and 34 percent of

secondary school students) in 1997, a proportion that has gradually risen since 1970. Most private schools have some religious affiliation, most commonly with the Catholic Church (66 percent of private school students are in Catholic schools). Other private schools vary from long-established prestigious schools to relatively new lower-cost schools. A range of funding sources including government grants supports private schools. In 1997, 44 percent of private school income was derived from fees or donations, 18 percent from state government grants and 38 percent from federal government grants. Government grants comprised 72 percent of the income of Catholic schools and 34 percent of the income of independent schools. In 1997, per capita expenditure was estimated as A$3,996 and A$6,510 in non-government primary and secondary schools respectively (MCEETYA 1997).

3.3 Special Education

Special education programs are provided for students with physical, intellectual, and emotional disabilities. A national study in 1992 estimated that about 2 percent of students in Australian schools had some form of disability. At that time, about 30 percent of students with disabilities were enrolled in special schools, 25 percent were enrolled in special classes or units attached to other schools, and 45 percent were enrolled in regular school classes. Over the past 20 years, policies have been directed towards supporting education for a greater proportion of students with disabilities in regular school classes (deLemos 1994).

3.4 Curriculum

Although there is no national curriculum, governments collaborated in the early 1990s to develop curriculum statements and profiles in eight key learning areas: English, mathematics, science, technology, studies of society and the environment, the arts, health and physical education, and languages other than English. The statements provide an account of the aims and content of each area of learning as a framework for curriculum in primary and secondary schooling. The profiles provide an outline of a sequence of students' development of knowledge, understanding and skills and a framework for assessing and reporting student progress and achievements. Although the national statements were not adopted, states and territories use statements and profiles in some form for curriculum development, incorporating variations that reflect local policies and priorities. In 1990, the state and federal education ministers established the Curriculum Corporation, a semi-autonomous body with a charter to develop curriculum materials on a commercial basis.

Within states, central authorities specify curriculum guidelines and schools have considerable autonomy in deciding curriculum detail, textbooks, and teaching methodology at primary and junior secondary level. At the senior secondary level, the curriculum is specified in detail by a state authority responsible for examining and certifying student achievement.

3.5 Assessment and Monitoring of Student Achievement

All states operate statewide assessment and monitoring programs for primary schools. There is population testing of students in government schools in English and mathematics at Grade 3 and Grade 5. The purposes are to report information about student achievement, based on a common test to parents, teachers, and schools and to monitor the overall performance of the education system. Most of the assessment instruments used in these programs of testing incorporate a range of items including multiple choice and open-ended response items, and make use of modern measurement techniques that have enabled forms of criteria-referenced reporting to be implemented. Formal statewide assessment programs are currently less common in the lower secondary grades than in primary school. Evidence from the *National School English Literacy Survey* (Masters and Forster 1997) conducted in 1996, indicates the extent of differences in early literacy achievement; the top one-fifth of students in Year 3 performed at a level close to the average for Year 5.

3.6 Teachers

A little over 207,000 (full-time equivalent) teachers were employed in schools in 1997: approximately 104,000 in primary and 103,000 in secondary schools. Overall 65 percent of teachers are female (77 percent in primary and 53 percent in secondary schools) (ABS 1998b). Teaching is an occupation with relatively high prestige, being the third top of 16 categories on the occupational prestige scale. Salaries are determined at state level and there are differences between states. The annual starting salary is approximately A$30,000 and for a teacher with 10 years' experience is about A$45,000. Teacher training occurs in universities, but states determine acceptable qualifications. A total of 4 years of higher education is the normal length of initial training for secondary teachers; typically, a 3-year degree in a major discipline and a 1-year diploma of education. Primary teachers normally complete a 3-year diploma of teaching, but many later improve their qualifications with specialist diplomas or a 4th year, resulting in a degree.

3.7 Information and Communication Technologies in Schools

From the mid-1990s, efforts have been made to incorporate information and communication tech-

nologies in school programs. The intention is for students to become proficient at using information technologies, graduate as skilled users of the technology, and use these tools to support learning across the curriculum. Schools vary in the extent to which students have access to these technologies and high costs are an impediment. A national survey in 1998, estimated that 64 percent of schools operated with a ratio of between 6 and 15 students per computer; the average figure being approximately 12 (Meredyth et al. 1999).

4. *Vocational Education and Training*

Vocational education and training (VET) is an important component of education in Australia. A variety of courses are provided through institutes of technical and further education (TAFE) and other organizations. Most (over 95 percent) vocational education and training is provided in colleges (or institutes) of technical and further education (TAFE). Courses include a range of vocational training from entry-level employment preparation to trades (e.g., through apprenticeships) through advanced vocational courses to para-professional and professional courses. In addition, many recreation and leisure programs are provided.

4.1 *Students*

In 1997, approximately 121,000 TAFE students graduated with a qualification from a vocational course of at least 200 hours, or one semester, duration (NCVER 1998). Some 20 percent of young people participate in a TAFE program by the age of 19 and a further 15 percent (mostly males) undertake apprenticeship training through TAFE (Long et al. 1999). Overall, there were 1.4 million enrolments in VET programs in 1997. Participation is characterized by part-time attendance and a wide age range (people aged 15–24 years comprise 38 percent of the clients). Entry to many courses is possible after Year 10, but in practice nearly half of the entrants to vocational courses have completed Year 12. In the early 1980s the corresponding figure was one-fifth. This change has arisen from a combination of labor market conditions and increased school retention rates.

4.2 *Apprenticeship*

Apprenticeship is an important component of VET. Over 4 years, an apprentice works for an employer (or group of employers) and attends a training institution (traditionally a TAFE institute) part-time (typically a total of 800 hours). Recent changes have been a response to perceived limitations (inflexibility, limited occupations, old technology, and lack of access for women) and declining numbers. In 1985, traineeships were introduced to provide a shorter and more flexible approach to entry-level training. Traineeships, typically involved a one-year program, with an employer incorporating on-the-job and off-the-job training, mostly in office-based and retail industries. More recently, apprenticeships and traineeships have been integrated as part of a more unified entry-level training system.

4.3 *Organization*

Responsibility for administration of VET lies with the state and territory governments. In 1997, recurrent and operating funding of the TAFE system was about $3,800 million, with the states and territories providing 56 percent and the federal government 25 percent, with the remaining 19 percent coming from fees and other sources. A national vocational education and training system was established in 1992. A ministerial council determines national policy and priorities, strategic directions, funding arrangements, and planning processes for vocational education and training, on the advice of the Australian National Training Authority. State training agencies manage the delivery of VET in a manner consistent with the national strategic plan.

5. *Higher Education*

Prior to 1990, higher education comprised universities and colleges of advanced education (which placed more emphasis on teaching and less on research). In 1990, formal distinctions between the two types of institution were removed and since then amalgamations stimulated by federal government policy have reduced the number of institutions from around 70 to 36. In addition to the 36 public institutions there are two private universities. Most universities operate under state legislation and are autonomous bodies responsible for their own governance, allocation of funds, staffing, and academic courses.

5.1 *Students*

Students commencing higher education courses are required to complete secondary school, or otherwise demonstrate a capacity to complete a course. There is keen demand for higher education places at most institutions. In 1997, there were nearly 660,000 students enrolled in universities with slightly fewer than 500,000 enrolled in undergraduate courses. The basic undergraduate course is a bachelor degree of three or

four years' duration, and these enroll 75 percent of all students. The fields of study with the largest numbers of students are: the arts, humanities, and social sciences (23 percent); business, administration, and economics (23 percent), and science (15 percent) (DEETYA 1997). Approximately half of the students who complete secondary school proceed to university by the age of 19, this being approximately 38 percent of each cohort. In 1997, a little more than half (54 percent) of university students were female, a figure that has risen steadily over the 1980s and 1990s. Despite the expansion of higher education during the 1980s, university students are still drawn disproportionately from those with managerial and professional home backgrounds (Long et al. 1999). In 1997, approximately 60 percent of students were enrolled in full-time study, 27 percent in part-time study and the remainder in external studies.

5.2 *Organization and Funding*

The federal government funds universities. In 1996, the operating revenue of universities amounted to just over A$8,000 million, 57 percent of which came from federal government grants. In addition to government funding, institutions receive payments from students who are required to contribute to the cost of their education through the *Higher Education Contribution Scheme* (a deferred, income-contingent repayment program that operates through the taxation system), and from full fee-paying students.

6. *Education at the Turn of the Millennium*

At the beginning of the new millennium (2001), there are a number of issues that will challenge the education systems of Australia. The balance, and funding, of public and private schooling, establishing a new mix of central authority and local responsibility in public school systems, and developing new forms of quality assurance seem likely to continue as important issues in the next few years. So also will questions of securing greater levels of engagement among students in the middle years. Providing resources for an appropriate mix in programs of education and training beyond school has emerged as an issue as the demand for education continues to rise. In senior secondary school and in higher education there will most likely be new initiatives to facilitate the pathways between education and work. In addition the ongoing issues of providing programs for a dispersed, and an increasingly diverse, population will continue.

Educational Systems: Europe

National coherence and the feeling of national identity depends mainly on a common frame of reference of language and values, and this depends upon a common

language and mainly common systems of formal schooling, at least at the basic level. The modern national state, represented by the industrialized countries in Europe, was shaped by the mandatory primary school which was legislated in many European countries and became an instrument of socializing children into the respective national cultures, the mother tongues, and the predominant values. It also contributed to establishing a national language over and above the various dialects or local languages. When, in 1870, the French parliament decided to make *école primaire* mandatory all over the country, French was spoken by only half the population within the geographical area today referred to as France. In peripheral areas German, Italian, Spanish, and Breton were spoken.

1. Similarities

The school systems in most European countries have a rather similar historical background. Primary school has a relatively short history. It was established along with mandatory school attendance over a few decades in the nineteenth century, in most cases by legislation in national parliaments. What is now referred to as secondary school has its roots in the Middle Ages with its monastery and cathedral school. These took care of an elite and were preparatory for university studies. The German *Gymnasium*, the British grammar school, and the French *lycée* were typical of this type of school. Well into the twentieth century, preparation for entry into the secondary schools was taken care of privately.

The parallel between the first grades of secondary school and the last ones in primary school were brought into serious question after 1945. Behind this was the demand for greater equality of opportunity, but also the social and economic changes in a society where formal education increasingly became crucial for individual career and social status.

In the late 1930s steps began to be taken in reforming British education. The Labour governments in the 1940s to 1960 were strongly in favor of a comprehensive school system which would replace the tripartite system of 1944. Part of the breaking up of the old structure in France was the presidential decree of 1959 which introduced a *cycle d'orientation* (middle school) of two years after five years in *école primaire*. In Germany a similar, two-year *Orientierungsstufe* comes after four years in *Grundschule*. The rationale behind such an arrangement has been to get ample opportunity and time to find out which students are able to proceed in the academic and vocational programs respectively.

Reform movements after 1945 in several countries aimed at making secondary school available and comprehensive for all young people. The 1959 French decree by President de Gaulle made the transfer from primary to secondary more flexible by the *cycle d'orientation*. The same occured in many places in the Federal Republic of Germany where the more radical reformers were demanding a *Gesamtschule* (comprehensive school) which would cover the entire period of mandatory schooling. The German system, however, was more institutionalized and rigid than the French, and parallel to the new system in Germany, transfer could occur from the fourth grade in the primary school to the first grade in the nine-year *Gymnasium*. In France an intermediary type of school at the lower secondary level was introduced, called *collège d'enseignement secondaire*, which broadened the opportunities for the majority of students. In Italy, for a long time after 1945, the *scuola media*, the lower secondary school, played an important role in the debate about school reform. The debate primarily referred to northern Italy; the southern part of the country was lagging behind in this respect.

It is not possible here to describe each national system of education in Europe. Therefore, the article is limited to the systems in France, Germany, the UK, and Russia, all of which have influenced the other countries by serving as models. Each of these systems is represented by an outline of their structure. Common to all of them is the division into three main stages: primary, secondary, and higher education. They also all have in common a mandatory primary stage, whereas for a long time the secondary institutions educated a social and intellectual elite in separate, adademically oriented schools, such as *Gymnasium* in Germany, *lycées* in France, and grammar schools in the UK, all preparing for higher education.

2. Differences

The various national systems differ in several respects (see OECD 1998, European Commission 1995, 1991, Husén et al. 1992, Eurydice European Unit 1991). Some countries have a 'comprehensive' school that caters for all children of primary school age and covers the first 8–10 years in primary school which then runs parallel to the secondary for the next few years. The Nordic countries today have a comprehensive system which gradually has been gaining ground in France, the UK, and some of the *Länder* (states) in Germany. In these countries there are also private schools more-or-less independent of the state. Most of the countries in Eastern Europe introduced postwar comprehensive systems modeled after the one in the USSR.

Transfer from primary to secondary school occurs, as mentioned above, in various countries and at different age levels. In Germany transfer has in most *Länder* taken place at the age of 10 after four years of primary school. In the UK it takes place at the age of

11. In the Netherlands, most children start school at the age of four but it becomes mandatory at five, and primary school lasts until the age of 12. In Italy, mandatory school is from 6 to 14; children have to take an examination called *licenza elemenare* after which they can proceed to the next stage, *scuola media*, which is also comprehensive.

Secondary school is thus organized very differently in the various countries. What in Sweden is referred to as *gymnasium* consists in Germany of grades 11–13 (in some *Länder* grades 11 and 12). It is an academically oriented school running parallel to schools with vocational programs.

3. School Structures in Four Countries

3.1 Germany

In the late 1940s Western Germany became a federation of states which had full sovereignty in matters of education. After four years in the *Grundschule*, transfer to a two-year *Förderstufe* can take place. This stage can be part of a *Gymnasium* (nine-year), *Realschule* (six-year) or a *Hauptschule*.

A striking feature of the German *Gymnasium* has traditionally been the multitude of subjects in the final grades. The purpose is to give a broad general education which can be a heavy task for the students. In this respect the German system differs radically from the British with its specialization on three or four subjects during the final two grades of secondary school.

The number of students reaching *Abitur* (examinations necessary for university entrance) was for a long time rather low, for instance less than 10 percent of the age group in the 1960s, but during the last few decades it has increased to 25–30 percent.

In the DDR (East Germany) before unification there was a 10-year polytechnically oriented school where during the last few grades students could work and learn in business enterprises. The *Gesamtschule*, the basic and/or comprehesive school was the model taken over from the USSR. It was also introduced in the Federal Republic (West Germany) in some states, such as Hesse, in the 1960s.

3.2 France

The school system in France had for a long time two kinds of parallelism. There were public schools running parallel with religious (Catholic) schools. Furthermore, there were municipal schools parallel with *lycées* run by the state. The structure at the beginning of the twenty-first century is as follows. After *école maternelle*, the preschool which traditionally covers a larger portion of the age groups than in most other European countries, comes the five-year *école primaire*. Then follows secondary school, *collège* or *lycée* of which the first two grades, along with the corresponding grades in the *école primaire*, make up a *cycle d'orientation* (middle or transition school), after which a decision is taken as to whether or not the student is capable of transferring to an academically oriented *lycée* or will have to finish schooling in a *collège d'enseignement géneral*, which is the final stage of madatory schooling. In 1959 the latter was increased to nine years but in 1975 a *classe terminal* was added. Thus the 10-year school covers the age range 6 to 16.

Grade repeating (*redoublement*) has traditionally been a dominant feature of the French system. As late as 1980 about one third of the students in *école primaire* consisted of grade repeaters. This means that in the upper grades students on the average are one year older than 'normal' for the grade.

3.3 The United Kingdom

During World War II, in 1944, the British parliament passed an Education Act which provided access to secondary school for all young people in the age range 11 to 16. After five years in primary school they could transfer to secondary school with mandatory attendance up to the age of 15. Since schooling began at five, transfer to secondary school took place at 11. Then students had to go through a selection procedure, the '11 plus' examination, which more or less decided the allocation of students to three types of secondary school: grammar schools, technical schools, or secondary modern schools, which all had five-year programs. About one fourth qualified for grammar school, the rest were roughly equally distributed among the other two types. Schools reformers, particularly in the Labour party, were proponents for a unitary school, a comprehensive school for all students. Comprehensivization occurred in the UK after the early 1960s and the 11 plus examination was abolished in most of the UK. But the students are as a rule differentiated according to ability within the schools.

At the end of the nineteenth century the great majority of schools in the UK were divided into two stages: primary from 5 to 11 years of age and secondary from 11 to 16 (or for those taking a preparatory program for university entrance, to 18). The distinction now in some parts of the UK is between three stages of schooling: first school from 5 to 7 or 8, middle school from 8 to 12 (or 9 to 13), and upper school from 12 or 13 to 16 or 18. Some 5 percent of children of primary school go to private schools. At the secondary stage the percentage is 8–10.

After five years in secondary school the student can take General Certificate of Secondary Education

(GCSE) external examinations. Those who intend to go on to higher education can, after two more years of specialization in three or four subjects, take the examinations for the General Certificate of Education advanced level (A-levels).

The school reform of 1988 means that for the first time a national curriculum has been introduced, along with national assessments of student competence at several stages.

3.4 Russia

The disintegration of the USSR meant that several of the republics in the Union tended to move away from the model which was dominant, namely the Russian one. The literacy of the population within an essentially agrarian economy had until the 1930s been a central task, which meant that adult education played a dominant role in the educational system. When universal schooling for children was legislated the big cities were given priority. Thus Moscow and Leningrad early provided 9–10 year schooling for the majority of children, whereas in rural areas for a long time five-year primary school was common. A comprehensive eight-year basic or primary school has traditionally been common in Russia, at least in the urban regions. A secondary two-to-four-year school with various vocational programs followed. Higher education has also had a clear-cut vocational bias which reflects the 'polytechnical' orientation that has characterized the communist educational philosophy, a kind of symbiosis between theory and practice. Whereas schooling in many districts was easily available for all, selection to higher education has been rather tough. For a long time adult education played a prominent role in Soviet education with evening courses, distance teaching, etc.

The system was, and still seems to be, strongly centralized. Curricula were conceived and issued from Moscow. The Academy of Pedagogical Sciences thereby played an important role in preparing a common curriculum. The reforms that followed upon the disintegration of the USSR implied in certain respects a decentralization.

4. Private School Systems

In most European countries there has traditionally been a private sector both at the primary and secondary level. This sector is in the UK referred to as 'independent' and is financed by fees and private funds, but in some instances students from less affluent backgrounds can be excused fees. In the 1990s between 6 and 9 percent of the age groups at primary school level went to independent ('preparatory') schools and 12–15 percent at the secondary level. Many of these schools in the UK are boarding schools; the secondary schools are referred to as 'public schools', the most famous of which are Eton, Rugby, and Harrow. Elite universities, such as Oxford and Cambridge, for a long time recruited roughly half of their students from the independent schools.

In France a 'cultural struggle' went on for more than a century between the state and the Catholic Church about what basically had to do with religious instruction. The Catholic schools, which in around 1900 recruited about 20 percent of the age group at the primary stage, had until then no public financial support, but gained one in 1905. Recurrent attempts have been made, as late as in the mid-1980s, to incorporate the Catholic schools into the state system, but the attempts have failed. In other Catholic countries, not least in Spain, the church has a firm hand on the school system and the curriculum, whereas in the Protestant countries the state usually rules the system. In the Netherlands there are, in practice, three systems; one Catholic, one Protestant, and one secular, each with its own central administration. The curriculum is, however, on the whole common. In Belgium there are one Flemish, one French-oriented, and one German-oriented system, each with its own Minister of Education.

Denmark has a long tradition of independent schools, which goes back to the reformer Grundtvig. The pedagogical cornerstones are student self-reliance and free approaches to learning.

In 1988 a school reform in Great Britain was passed which reduced the influence of the local education authorities (LEAs) and made the Ministry of Education more powerful. Thus, a majority of parents in a local school could decide to 'opt out' from the LEA and had the right to get financial support directly from the Department of Education in London.

There have in recent years been tendencies in several countries to make the boundaries between public and private schools more fluent with regard to the role of both central and local authorities.

5. Higher Education

Three national systems of higher education have been influential outside the boundaries of the respective countries: Germany, France, and the UK. The German system has influenced particularly the countries in northern and central Europe, the French has been a model in some East European countries, whereas the British has been emulated in former colonies.

The idea of the university, which Wilhelm von Humboldt launched at the beginning of the nineteenth century and implementend in Berlin, had a strong influence both on the European continent and in northern Europe. The basic idea was the unity of

teaching and research which, among other things, was realized by introducing departments at the undergraduate level and special institutes for research at the graduate level. For instance, the model established by Wilhelm Wundt in 1879 by setting up an institute at the university in Leipzig had an important impact on the development of experimental psychology on both sides of the Atlantic. Great distinction was made at the time between basic and applied research and between theory and practice. In German philosophy of education at higher level the word *Bildung* was of central importance. The study of classical languages and history was regarded as contributing a good deal to general education, although in Germany natural sciences were also appreciated. The faculties of natural sciences, as well as those of medicine, played a more important role at German universities than at UK ones. Teaching was provided mainly by professors, the 'chair holders,' one in each discipline.

French higher education on the whole got its present structure during the era of Napoleon, with the establishment of the *grandes écoles*, elite institutions for training various professions, such as civil engineers, senior civil servants in the ministries, and teachers in the upper grades in the *lycées*. The teaching put high intellectual demands on stringency and analysis. The professors were expected to be in contact with what happened in their respective disciplines but not to devote too much of their time to research, which was conducted mainly outside the universities in *Centres Nationeaux de Recherche Scientifique* which were placed directly under the Ministry of Education. As an outcome of the student revolution of 1968 the university system and its administration was thoroughly reformed by the *lois d'orientation*. For instance, the University of Paris, which until then had been entirely concentrated at the Sorbonne, was divided into a dozen new units. The new law created almost one thousand *unités d'enseignement et recherche*, something in between faculties and departments for various disciplines. More influence was given to the students with regard to instruction and the governance of the bigger units. The French system, not least the university system, is traditionally rather centralized and therefore rather rigid and difficult to reform.

The UK had, until 1992, 47 universities, which had the right to grant examination certificates including the doctoral degree. Parallel to the universities in this dual system were about 40 polytechnics with two-or three-year, vocationally oriented programs. The polytechnics have constantly struggled for university status, among other things by acquiring research resources. In 1992 they were incorporated into the university system, which meant that the UK now had 88 institutions which could call themselves universities. This also means that there are great differences in quality and status. Elite institutions like Oxford and Cambridge, which are very selective and account for only three percent of the total number of university students, are often regarded as 'typical' of the UK system.

In 1988 a reform of the system made regular evaluations a condition for funding. British universities have traditionally enjoyed a high degree of autonomy vis-à-vis the central government. Thus, until 1988, the University Grants Commission, which consisted entirely of representatives of the universities, received a lump sum from the Government which was then distributed by the Commission among the universities. From 1988 there have been Higher Education Funding Councils for England, Wales, and Scotland, one for the universities and one for what were then polytechnics and college. In these bodies the majority of the members still have experience from the academic world. But there are more bodies ordering services in terms of training and research than distributors of available funds. Formal purchasing contracts are negotiated which makes funding dependent on the number of students in the respective disciplines, and on the 'productivity' demonstrated.

For a long time the elite universities in Britain could take credit for bringing about 90 percent of those who entered studies to an academic degree. This is taken after three or four years of study, which is shorter than in most countries on the continent where the basic degree can take five to eight years of study. Since UK university students begin their study earlier than on the continent, the basic degree is usually taken at the age of 21 or 22. The specialization of university studies is facilitated by the fact that the two final years in secondary school studying for A levels is specialized to three or four subjects.

Educational Systems: North America

North America is home to two national systems of public, compulsory education that differ in size, degree of centralization and organizational structure, but have been shaped by similar historical and cultural forces. In this article, common cultural dynamics are discussed and an overview of other sub-systems of education, such as military schools and religious schools, is provided.

1. The Effect of Religion and Language on Early Forms of Schooling

Early in the seventeenth century, Father Superior Paul Le Jeune sat down with 'a small Indian boy on one side and a small Negro on the other' and attempted to instruct the children in the Catholic faith. While brief and ineffective, 'as neither of the three understood the language of the others,' Le Jeune's efforts epitomize the tenor and focus of schooling in North America during the seventeenth and eighteenth centuries (Parkman 1983, p. 413).

In both the French and English colonies, schools were used to maintain existing social hierarchies and assimilate non-European populations by disseminating religious views, inculcating moral virtues (European), and instilling literacy. Early colleges, (e.g., the Jesuit College in Quebec, or Harvard College) provided instruction in religious dogma and the Christian sacral languages. Literacy was tied to religious indoctrination, and the Bible was probably the most common school 'text' (see Kett 1977 or Sutton 1988). As Cremin noted: 'during the first phases of the Virginia settlement, for example, education was in the hands of the ministers, who used it both as an instrument for promoting discipline and order among the colonists, and as a device for winning the loyalty of the natives, (Cremin 1970, p. 9).

The impact of schooling was limited though, due to the fact that during the seventeenth, eighteenth, and early nineteenth centuries most of the population received little if any formal education. There were early attempts at vocational (or domestic) education—for example, the Ursuline nuns of Montreal received 'a thousand francs to buy wool, and a thousand more for teaching girls to knit.' (Parkman, 1983, 1357), but most 'education' consisted of skills learned in the family or apprenticeships. Even slaves participated in these forms to a wide extent: Equiano notes that he was trained as a ship's pilot as a slave (Equiano 1995, p. ix). Education in the colonies was unsystematic, polymorphous, and above all, practical.

2. Emerging Systems: Education to Transform Society

In the USA, networks of public schools developed rapidly in the early 1800s. Early architects of the public education system, such as Thomas Jefferson, believed that a secular, public system of schools would serve as the foundation of democracy in the new republic. Benjamin Rush, lobbied (albeit unsuccessfully) to create a state-funded system of education in the US State of Pennsylvania. Horace Mann worked tirelessly in the cause of the 'common school' in Massachusetts and worked to establish 'normal schools' to train teachers—a group whose educational accomplishments were often astonishingly meager in the 1800s.

Driving these movements for educational reform was a widespread belief in the transformative power of education and a desire to build a system of education that would change society—a cultural tendency that has been piquantly labeled as a propensity to 'tinker toward utopia' (Tyack and Cuban 1995). Rush was one of the first to articulate these ideas in a systematic way. He noted: 'Our schools of learning … will render the mass of people more homogenous, and thereby fit them more easily for uniform and peaceable government.' Enumerating 'a few advantages of learning upon mankind,' he wrote 'A free government can only exist in an equal diffusion of literature … and where learning is confined to a "few" people, we always find monarchy, aristocracy, and slavery' (Rush 1787, pp. 1–2, 14).

Yet, during this same period, many state legislatures began to systematically prohibit literacy and other forms of schooling to both slave and free African populations by denying them access to education. Nearly 150 years after thinkers like Thomas Jefferson proposed universal schooling as the foundation of a democratic society, racially segregated schools were common in the USA. At the same time that profound educational experiments, such as Lowell's incorporation of educational programs for his mill workers were occurring, African-Americans were denied the opportunity to learn to read.

It was not until the late 1800s when educational progressives like the philosopher John Dewey gained widespread political ascendancy and began to 'tinker' with public schools in order to transform the social order. From the late 1800s through to the end of the World War II, scholars and politicians from a

wide range of backgrounds worked to extend and systematize public schooling. Yet these reformers typically assumed, as did Rush, that schooling would homogenize new waves of immigrants and make them 'good citizens' of Canada or the USA.

3. *Conflict of Ideals: Maintaining Society or Transforming it through Schooling?*

The historical development of the North American school systems was affected by conflicting ideals about what schools should do for society. One end of the continuum is the view that school should be a vehicle for instilling morals, proper behavior, and transmitting a stable social order. At the other is the view that schools should allow students the widest range of self-determination and exploration and eliminate old prejudices thereby paving the way for a new, and better, social order.

3.1 *Colonization, Native Peoples and Schooling*

Early in the development of both the US and Canadian systems of education, special schools were created for the children of Native or First Peoples that stripped them of their culture and language and attempted to replace them with English, European moral sensibilities, and 'Christian' virtue. These sub-systems of education, including Bureau of Indian Affairs schools in the USA and church-run boarding schools in Canada, continued to function in this manner well into the twentieth century. At the start of the twenty-first century, some groups in Canada are still pursuing legal action against such schools for the abusive treatment of children. From the 1960s on, there has been considerable educational reform among Native communities including the development of a system of tribal colleges in the USA.

3.2 *From Segregation to 'A Nation at Risk': The Federal Role in US Public Schools*

In the former Confederate States of the USA, freed slaves made significant educational advances during Reconstruction until 1873, when the political imposition of Jim Crow laws and subsequent legalized segregation (flowing from the Supreme Court decision of Plessy vs. Ferguson, 1896) reversed the educational advancement of African-Americans and held it in abeyance until the 1950s. Beginning with the early Civil Rights movement in the USA, renewed political battles occurred over the role of the nation's schools. The US Supreme Court decision of Brown vs. the Board of Education (1954) overturned the legal support for school segregation, fomenting widespread social unrest and unprecedented school reform. In one of the few instances where federal troops have been used to countermand the orders of state leaders, national guardsmen opened a high school in Birmingham, Alabama and allowed a handful of black teenagers to enter. The US federal role in public elementary and secondary schools has continued to grow, and has increasingly become the focus of intense political conflict. Events such as the launch of the Russian satellite Sputnik and the publication of *A Nation at Risk* set off tremendous public debate about how schools were failing children and what could be done about it. While many have interpreted school reform since 1980 as an 'attack on the public schools,' attempts to create charter schools, provide vouchers for parents to send children to private schools, or pass laws making home schooling easier, are evidence of a continued belief that education is the best tool for creating a better society.

3.3 *Achieving Equity: Conflict over Language, Religion, and the Curriculum*

A concern with educational equity has dominated educational concerns since the 1960s but the focus has shifted from assuring equal access to ethnic or racial minorities to one of who ultimately controls what values the school will transmit. These battles—over language, the teaching of religion (e.g., offering Creation Science), and general course content—have been far more vociferous in the USA than in Canada. In the US constitution, there is no clear enumeration of educational rights comparable to that found in the Canadian Charter of Rights and Freedoms which specifically details the educational rights of language minority parents. This leaves open the possibility of political referendums, like the California act ending bilingual education, to substantially change the focus of schooling.

4. *The Systems Today*

Despite the progress made in establishing comprehensive, egalitarian systems of public education through the secondary level, the public school systems in the USA and Canada have not yet been able to fully rectify persistent problems of social inequality and conflicting cultural values. Yet the history of tension and educational experimentation has resulted in highly decentralized systems of free, public education, often emulated by other industrialized nations. In the Canadian system, under the British North America Act of 1867, provinces have wide discretion in setting educational policy, and there is no national ministry of

education. In the USA, individual states have broad powers to set educational standards but locally elected school boards exert considerable control on the day-to-day operation of the schools. Federal control over schools in the USA is indirect, typically using laws that require states to meet certain standards in schools in order to obtain federal funds for education to ensure compliance.

In both nations education is compulsory from about ages 6 or 7 to about age 16. In Canada, students make the transition from elementary to secondary schooling between sixth and eighth grade (with a slightly different system in Quebec). In the USA, despite the highly successful junior high school movement of the early twentieth century, there is no standard form of early secondary school organization. Completion rates for schooling are similar for the two nations: roughly 85 percent of 25- to 34-year-olds in 1996 had completed upper-secondary school (OECD 1998, p. 39). However, this statistic belies the fact that many US students do not complete high school but later complete general educational development (GED) tests. This statistic also fails to document the fact that minority students have statistically significant lower mean achievement scores, higher dropout rates, and lower rates of college enrollment than the majority students do. Detailed statistical reports on enrollment and other educational indicators are published yearly by the National Center for Education Statistics in the USA and by Statistics Canada.

The cultural emphasis on public school as the means of promoting social change or maintaining a peaceful and orderly society has often led scholars to ignore other nation-wide systems of education. In any catholic assessment of systems of education in North America, the role of tertiary education, military schools, and religious schools must be addressed.

4.1 The Tertiary Sector: Dominance in the World System

At the university level, in the USA, and to some extent in Canada, the cultural oppositions that affect elementary and secondary education have largely disappeared. If we compare two institutions that have had a profound impact on the development of college education in general—Harvard University and the University of Virginia—we find two distinct historical roles. For much of its history, Harvard educated the New England social elite and the Protestant clergy. UVA, while also transmitting social privilege, had a secular orientation that was replicated in the land-grant colleges set up around the US. Although land-grant colleges were sometimes modeled on elite private colleges (e.g. the University of Georgia and Yale University), these institutions focused on improving the conditions of the state populace and offered courses in pedestrian subjects such as agricultural or domestic science. Enrollment grew rapidly; most states now boast a network of high quality public colleges or universities accessible to a large segment of the populace.

Over time the differences between highly ranked private and public universities has declined, giving rise to the 'research university' that combines undergraduate training with advanced research in virtually every discipline currently studied. Many US and Canadian universities have eclipsed the European institutions on which they were originally modeled as international centers of knowledge production, and the USA is widely recognized as the world leader in the production of Ph.D. recipients.

4.2 Military Schools and Education

Over half of high school graduates go on to some form of college in the USA and Canada, but a large percentage of the population still uses the military as a means for educational advancement. For children of working-class families, military training and military service offer low-cost educational opportunities. Not only does the military provide basic instruction to its enlisted men and women, in both nations it also runs an independent system of elementary and secondary schools for the children of military personnel.

The US military also has a substantial tertiary presence. It operates highly regarded military colleges such as the Army Academy at West Point and funds students in public and private colleges through the officer training (i.e., the Reserve Officer Training Corps). Less visible, but not less important to tertiary education, the US Department of Defense funds extensive research projects, providing substantial external sources of revenues for many colleges.

4.3 Religious Schools and Churches

Churches and religious schools form another diverse system outside of public schooling. 'As in colonial times, the churches continued to serve as centers of formal and informal education.' (Cremin 1970, p. 383). The role of churches as centers for disseminating education and promoting social change was dramatically seen in the USA, when in the 1960s, Sunday sermons melded into political calls for ending segregation. At present, US and Canadian churches are host to a wide array of meetings that have an explicitly educational component. Large suburban churches typically offer a range of weekly classes and meetings ranging from independent piano lessons to church-sanctioned marriage classes. These activities are distinct from, and constitute a considerable educational impact over and beyond, the activities of private (US) or state-related (Canada) religious schools. Religious schools (primarily, but not exclusively Christian) are found throughout North America, ranging from local

kindergarten programs up to world-class universities like Notre Dame. Both nations experienced considerable political conflict over the role government should play in supporting these schools. In the USA political battles and court challenges (such as the conflict in the 1840s regarding Catholic schools) have generally been resolved to reinforce the separation of church and state, although groups like the Amish have mounted successful court challenges that have limited the state's ability to enforce compulsory schooling laws. In Canada many school boards were organized along denominational lines, and there is considerable variation in the relationship between provincial educational authorities and church-supported schools.

5. *Experimentation and Innovation: The North American Educational Dynamic*

Mr. Fredrick Douglas, a former slave, penned one of the most compelling statements of North American beliefs in the transformative power of education. Douglas wrote: 'Mr. Auld [his owner] … at once forbade Mrs. Auld to instruct me further, telling her, … that it was unlawful, as well as unsafe, to teach a slave to read. The very decided manner with which he spoke, … served to convince me that he was deeply sensible of the truths he was uttering … and the argument which he so warmly urged, against my learning to read, only served to inspire me with a desire and determination to learn' (Huggins 1980, pp. 42–3).

North Americans share a culture that places extreme emphasis on the power of education to transform both the individual and society and typically view schools as important institutions of social change or control. However, there is considerable cultural conflict over how schools are to be used: many citizens hold the view that a good government should mandate a system of free and comprehensive public education that is uniform for all, while others view any government intrusion into educational matters with extreme aversion.

North Americans also share a cultural tendency to engage each new educational innovation as a chance to move one step forward toward social utopia. This facet of North American culture may appear to others in the world as an obsession with educational reform, yet, this cultural dynamic has served to create a system of public education that is widely emulated. In the 1980s and 1990s, the performance of US and Canadian students on international tests of academic achievement caused many to declare the failure of North American schools and praise the educational culture of East Asia. Few saw the irony of the situation: educational reformers heavily influenced the Japanese school system. Educational policy makers in East Asia continue to look to North America as a center of educational reform and research.

Educational reform initiatives originating in North America will continue to influence educational systems around the globe. Looking toward the future, the most significant changes in systems of education will be wrought by the historical confluence of new electronic communication networks and a resurgence of political efforts to decentralize the control of schools. This can be seen in both the home schooling and charter school movements.

Widespread access to immense databases and electronic communication now allows parents to provide children with access to a world-class curriculum within the home, thereby weakening old claims that 'home learning' is greatly inferior to 'schooling.' While the majority of home-educated children belong to fundamentalist, Christian groups, a wide range of parents, anywhere from 300,000 to over half a million around 1995, now opt to school their children at home (US Department of Education 2000).

Charter schools, in the USA, have also increased in the wake of the educational restructuring movement of the 1980s and 1990s. These schools are publicly funded and are subject to governmental regulation but operate under fewer restrictions than ordinary public schools. There is great variation in state laws regarding the establishment of these schools, and only a small percentage of the US school-age population attend charter schools. But again, the ability of a small number of adults to access an immense amount of literature, music, and art via computer-based networks has made the establishment of such schools quite viable.

The demand for these, and other alternatives to public education, will continue to arise from the important cultural role that education has in North American society. The early part of the twentieth century saw the dramatic expansion of an organized public school system, then viewed as the best way to move society forward. The early part of the twenty-first century will no doubt see dramatic decentralization as families push for more autonomy over their child's education and individuals of all ages continue to resist any attempt to control what they can, or cannot, learn.

Eff

Efficacy: Political

Political efficacy refers to citizens' beliefs that they can affect a political system. People with a high sense of political efficacy believe that they can, through their own individual or collective efforts, influence a political system that is regularly responsive to the actions of ordinary citizens. It is primarily a cognitive concept, a set of beliefs about one's citizenship role in relationship to governmental institutions. It is related to, but distinct from, affective or behavioral measures of political engagement.

Efficacy represents a subjective assessment of the political system. It differs from objective measures of a citizen's ability to affect a political system, such as political knowledge, or subjective measures of political engagement, such as political interest or civic obligation. One may feel politically efficacious while neither feeling motivated to participate in politics, nor judged by others to be capable of doing so.

Although political efficacy is generally measured at the individual level by social scientists, in practice it may also represent a propensity to draw upon collective social resources to effect political change. Political efficacy is significant not only because efficacious citizens have a greater propensity to engage in political action, but also because the presence of high levels of political efficacy within a population is important in creating a reservoir of citizen support for the political system.

1. *Intellectual Context*

Rooted in a social psychological theory of 'ego strength' (Lane 1959), Campbell et al. (1954) introduced political efficacy as one of several independent components of political engagement that predicted voter turnout but not voter preference. This basic role as a predictor of political participation has not changed much, although significant elaborations have been made in our understanding of that role.

Several years after its introduction as a predictor of political participation, scholars began to look at political efficacy as an indicator of existing and aspiring democratic systems. Almond and Verba (1963), attempting to understand the process by which aspiring democracies might achieve stability, conducted a comparative investigation of how political culture sustains existing liberal democracies. In order to connect the 'civic culture' concept, with its focus on political efficacy, to non-Western democracies, the authors included Mexico as one of five countries studied. Additional research by Indian scholars, with an awareness of the relative youth of Indian democracy, focused on the egalitarian distribution of political efficacy. They compared levels of political efficacy between different castes and between Hindus and Muslims. In particular, this research assessed whether lower castes had developed any sense of political efficacy since their inclusion in the Indian political system (Vir 1989).

Two separate lines of research have also used the concept of political efficacy as a yardstick to assess the health of mature liberal democracies. One is the differing levels of political engagement and participation by women and minorities, caused in part by differing levels of political efficacy (Abramson 1983). The second line emerged with the availability of repeated measures of political efficacy in the American National Election Studies (ANES). Converse (1972) showed decreasing levels of political trust and external (see below) political efficacy in the US, trends which continue to the present day. Easton's (1965) concepts of diffuse and specific support for a political system were applied to research on declining levels of trust and efficacy. According to Easton, democracies could continue to function well in the face of public dissatisfaction with current 'outputs' as long as a sufficient reserve of diffuse support (support for the structure of the political system) existed. However, Easton predicted that persistent public dissatisfaction and lack of specific support could erode diffuse support over the long term. This added urgency to findings of declining trust and efficacy.

2. *Conceptual Distinctions*

The distinction between internal and external political efficacy represents one of the most significant conceptual changes in understandings of political efficacy since the 1970s. While both types of efficacy refer to beliefs about the relationship of citizen political participation to the political system, they identify different explanations for the presence or absence of political efficacy. Internal political efficacy represents beliefs about the impact a person may have on the political process as a result of their own skills and confidence (or people just like themself). External political efficacy represents the impact a person believes they may have on the political process as a

consequence of political institutions' responsiveness. This distinction was implicit in earlier definitions of political efficacy, which addressed both components with the understanding that the two were strongly related (Lane 1959): internal feelings of efficacy arose in part because the political system was responsive, and at the same time, people perceived a political system to be responsive because they believed their actions could influence it. Indeed, subsequent studies of internal and external efficacy always found a significant and positive relationship between the two. But it was the performance over time of specific items measuring political efficacy in the ANES that suggested that the two components could behave quite differently (Converse 1972).

Balch (1974) first demonstrated empirically that the four ANES political efficacy questions behaved in ways congruent with a distinction between internal and external efficacy. In particular, he found that internal, but not external, political efficacy items had significant positive correlations with political interest, knowledge, and activity. External, but not internal, political efficacy items correlated positively and significantly with political trust. In general, these patterns have held up in subsequent research, to the extent that correlations between political efficacy and political engagement, activity, and trust serve as checks on the external validity of proposed internal and external political efficacy measures (Craig et al. 1990). Although this distinction has gained widespread acceptance, scholars have too often treated political efficacy as a single construct.

The performance of both internal and external efficacy, both in the aggregate and on the individual level, over time points to similarities and differences in the nature of the two concepts. Internal political efficacy has largely remained stable since the late 1960s while external political efficacy has declined steadily. Both aspects of political efficacy are relatively stable at the individual level. Internal political efficacy is strongly related to changes in an individual's socioeconomic background and life stage (Abramson 1983). By contrast, external political efficacy appears to be sensitive to changes in the political environment, but is less responsive to changes in individuals' characteristics. While the presence or absence of specific elected officials may affect external political efficacy, individuals' reactions appear to be heavily related to their partisanship. External efficacy rises for those whose favored party is in power, with the presidency representing this incumbency effect for the US (Craig 1993, Miller and Listhaug 1990). Such effects may be quite specific, even distinguishing between party control and local and federal levels (Stewart et al. 1992).

Some scholars distinguish between political trust as a judgment about governmental performance regardless of citizen participation, while external political efficacy is a judgment of the responsiveness of government to citizens' expressed preferences. However, as Balch (1974) noted earlier, the correlation between political trust and external political efficacy is often higher than the association among political efficacy items. This persistent pattern has led some scholars to question the distinction between external political efficacy and political trust. As a result, external political efficacy and political trust have at times been treated as broad indicators of political system support. In part this is due to their similar pattern of decline over time among Western democracies (Craig 1993, Miller and Listhaug 1990).

3. *Nature of Political Efficacy*

Prewitt's (1968) assessment of the concept of 'political efficacy' focused on the personal antecedents as well as the consequences of political efficacy. Education, socioeconomic standing, and ethnic majority status were positively related to political efficacy. Higher levels of political efficacy in turn predicted higher levels of a range of political behaviors, voting being the central concern. Political efficacy was also thought to play a key role in general citizen support for a democratic system, although this hypothesis was largely untested. Subsequent research provides confirmation for some of these findings and broadens others. Education and socioeconomic standing continue to predict levels of political efficacy, while the disadvantage accrued to ethnic minority status appears to be dependent on local political context (Abramson 1983, Vir 1989).

Thus, the earliest studies of political efficacy examined personal antecedents and went on to argue that political efficacy affects the political system. One major trend in research on political efficacy has been to complete the circle of causation by examining the structural antecedents of political efficacy. Pateman's work (1970) occupies a central place in this tradition. She drew on the work of liberal democratic theorists as well as findings by Almond and Verba (1963) to argue that all forms of participation, broadly conceived to include nonpolitical settings, could educate citizens to take part in self-government. Political efficacy was one measure of such educative effects and although her work suggests a specific focus on internal political efficacy, much research following her thesis has focused on external political efficacy.

Of special concern to Pateman were the effects of workplace conditions. Workplaces that emphasized democratic decision making would teach necessary skills for political participation and be intrinsically valuable, contributing to citizens' self-development. But Pateman's general thesis—that nonpolitical and political participation has educative effects in a democracy—has been tested mainly in areas besides work. Soss (1999), for example, successfully argued that how public policy is implemented has significant conse-

quences for socializing political efficacy. Clients generalize from the responsiveness of administrators in public benefit programs, and from opportunities to shape the implementation of policy to responsiveness of government in general, producing an impact on external political efficacy that contributes to voting turnout.

Finkel (1985, 1987) tested Pateman's underlying assertion that political participation has an educative effect on citizens. Using panel studies in the US and West Germany, he found that although levels of internal political efficacy affect conventional participation, the reverse is not true. By contrast, external political efficacy is affected more directly in a reciprocal manner by political participation.

Related research examined the effects of the larger political system on political efficacy. Scholars have identified persistent gender and race differences in internal political efficacy. Blacks, Hispanics, and women consistently report weaker feelings of internal and external political efficacy than whites and men. Abramson's (1983) explanation of this difference with regard to schoolchildren has been mirrored in later studies of adults. Abramson's basic argument, based on previous studies including his own with children, is that black children are influenced indirectly by the presence or absence of blacks in positions of political power. Differences among minorities with respect to political efficacy reflect actual low levels of political influence.

While some scholars emphasized the structural antecedents of political efficacy, others examined the causes and consequences of declining external political efficacy and trust. Gamson (1968) proposed that unconventional behavior would result among citizens whose sense of personal political efficacy was strong but trust in the political system was low. Subsequent evidence for this interaction effect between trust and political efficacy has been rather weak, however (Craig 1993; Sigelman and Feldman 1983). Scholars seeking to test Gamson's thesis have disagreed on a number of issues concerning its operationalization. Greater support for Gamson's hypothesis appears to lie in considering the context of unconventional behavior, especially the presence or absence of viable challengers to a political regime.

Other scholars have investigated the causes of declining levels of political support, including external political efficacy and political trust. Such work has been influenced by Easton's (1965) analysis of the implications of specific and diffuse political support for a political system. There is disagreement over whether political trust measures specific support while external political efficacy measures diffuse support for a political system, or whether both are indicators of specific support. This research found multiple causes of the decline of political support but has assigned at least part of the blame to a general perception of governmental unresponsiveness. Craig (1993), who focuses on the importance of procedural values to the American public, argues that the gap between a growing sense of 'democratic entitlement' among the public and the failure of political elites to respond accordingly is the main cause of declining political support. Miller and Listhaug (1990), in a comparative study of Sweden, Norway, and the US, argue that a perceived lack of representation by the party system has led to an erosion of political support. Declining specific support for particular institutions and parties is translated into a lack of diffuse support for the party system in general.

4. *Measurement of Political Efficacy*

The American National Election Study (ANES) has provided the most frequently used measures of political efficacy. The main advantage of these measures is their continuity. Three of the five original items used in 1952 have been asked on each ANES study, including two items that are taken as measures of external efficacy, and one that is taken as a measure of internal efficacy. Aside from this, a single potential measure of external political efficacy, asked on the General Social Survey since 1973, is the only other measure available over time.

Although many scholars have adopted the ANES measures, a number of different measures of political efficacy exist, often combining political trust or social alienation with political efficacy. The differentiation of efficacy by level of government (local, state, federal), and even specific governmental institutions appears to be the most useful recent innovation (Reef and Knoke 1999).

If the continuity of the ANES measures is their main advantage, the imprecision of these measures constitutes their main drawback. Craig et al. (1990) analyzed new efficacy and trust items alongside regular ANES efficacy and trust items in the 1987 pilot survey. Their results cast doubt on the separation of external political efficacy and trust, at least when both address incumbents rather than political procedures. While they validated one ANES item used consistently to measure internal political efficacy, their suggestions for additional internal political efficacy measures were not consistently adopted. In addition, a potential hazard to the use of ANES measures over time is a change in the response set. Beginning in 1988, respondents were also offered a 'neither agree nor disagree' option. Scholars who study these items suggest that the change has not substantively affected the continuity of these measures.

Political efficacy has proven to be exceptionally amenable to combining multiple investigative techniques. Such techniques include more qualitative methods such as in-depth interviews, open-ended questions in structured interviews, and even observational research, as well as quasi-experimental work

(Almond and Verba 1963, Craig 1993, Soss 1999). This research generally involves using qualitative methods to generate hypotheses or illustrate trends in secondary data, and using quantitative analysis of secondary data to confirm hypotheses.

5. Future Directions

Recent trends in research on political efficacy focus on the relationship between specific political institutions and political efficacy as contrasted with political systems as a whole. Future research will likely rely on a reciprocal framework, examining the consequences of efficacy for support of specific institutions and the 'educative effects' of such institutions. This may include a focus on the implementation of public policy, along the lines of Soss's (1999) work or specific governmental institutions, particularly local and state. Earlier work along these lines consistently found effects for external, but not internal, political efficacy.

The effect of political culture on political efficacy has been under-examined. The few comparative studies of political efficacy have consistently supported the basic findings about political efficacy, such as the effects of education. But such studies have also consistently found that political history plays a significant role, either in mediating the impact of events or of individual characteristics on political efficacy, or as an independent contributor to existing levels of political efficacy (Almond and Verba 1963; Finkel 1987; Miller and Listhaug 1990).

Future research is likely to compound fragmentation of a concept that has undergone at least one significant modification since the 1970s. At the same time, research that points to specific effects by government institutions or political culture may provide insight into the more general nature of political efficacy. In addition, recent focus on trust as a fundamental element of social capital suggests that it would be wise to incorporate political efficacy into the analysis. The fact that both trust and efficacy have declined significantly indicates that attempts to rebuild reservoirs of social capital ought to attend to both trust and efficacy.

Egalitarianism: Political

Equality is one of the foundational principles of modern democratic states. Every citizen—man or woman, black or white, rich or poor—must be treated equally in certain respects. They must, for example, have equal rights and equal opportunities. Only racists and a few other such extremists would deny this. Yet it remains intensely controversial how far this equality

of treatment must go. Must citizens enjoy economic and social equality as well as political equality in the sense of equal civil and political rights, for instance? Here conservatives, liberals, socialists, and feminists part company. This article looks briefly at the origins of egalitarianism, and then at the different forms of egalitarianism advocated in contemporary democracies.

1. *The Origins of Egalitarianism*

As just noted, in modern democracies equality in one or other of its versions has gained widespread acceptance as a political principle. For most of human history, however, this was not so. The idea that all human beings are, at some level, one another's equals can be found in the major religions and in a variety of cultures. But this foundational equality did not translate into a demand that human beings should associate politically on an equal footing. On the contrary, although a society of equals was sometimes presented as a Golden Age, or a utopian vision of the future, the current human condition was thought to require hierarchical relations in which men exercised authority over women, masters over slaves, lords over vassals and so forth. Accordingly if we search through the texts of classical or medieval political thought, we do not find equality held up as a principle that should inform existing practice (see Lakoff 1964)

This began to change in the early modern period, with the emergence of the centralized state and the accompanying gradual transition to a market economy. The state was founded on the assumption that everyone living within its territorial boundaries was to be equally subject to its authority and its laws. This idea was expressed with particular clarity by contractarian thinkers such as Hobbes, Grotius, and Locke, who argued that the state emerged from a covenant between men whose natural condition was one of equality: each had equal rights by nature, and they would therefore consent only to a state whose laws afforded them equal protection. Meanwhile the gradual shift away from feudal economic relations, in which people were linked together in a vertical hierarchy, toward a market economy, in which contracts and exchanges took place between individuals who were at least formally equal to one another, fostered the notion that each person had an equal right to freedom, and an equal right to the fruits of his labor.

By the end of the eighteenth century these principles had become widely accepted in Western societies, and found expression in the two great political documents of that era—the American Declaration of Independence and the French Declaration of the Rights of Man and of the Citizen—both of which boldly inscribed the principle of equality at the heart of political life. In practice, however, equality was still very far from being realized: large sections of the population (most notably women and the working class) were still denied the vote, many Americans found it possible to reconcile the equal rights of mankind with the practice of slavery, and economic opportunities still depended very largely on inherited social position. The story of the last two centuries can be seen from one angle as the steady (though still far from complete) overcoming of these inequalities in the name of equality itself.

2. *Political Equality*

The fierce debates in the nineteenth and early twentieth centuries over the extension of full political rights first to the working class and then to women have long since ended, and yet the issue of political equality is still far from settled. One problem has to do with representation. Even though every citizen in contemporary democracies has an equal right to vote, those elected are still primarily male, middle class, and drawn from majority ethnic groups. Does this matter? The answer depends on whether political representation means the representation of interests, and if so whether the elected members are able adequately to represent the interests of those who belong to a different section of the population. Critics argue that political equality requires the direct presence, in elected bodies, of people drawn from different groups in society, who are then able to articulate the perspectives and interests of those groups in an undistorted way (see Phillips 1995).

A second problem has to do with majorities and minorities—a problem, it should be noted, that may arise even within fully representative political institutions. At first sight it might seem as though political equality entails the majority principle for making decisions, since this is the only method of deciding issues that gives each vote an equal weight. But consider a case in which a relatively apathetic majority defeats a minority whose members care intensely about the issue that is being decided; or consider a case in which a minority group finds itself repeatedly outvoted in a series of decisions that affect its interests. Reflection on these cases suggests that political equality entails more than just formally equal voting rights. It requires something like an equal chance to influence the outcome of the decision procedure. But it is hard to design institutions that can achieve political equality in this fuller sense (see Beitz 1989).

3. *Equality of Opportunity*

Alongside political equality, equality of opportunity—the principle that each person should have an equal chance to gain jobs, offices, and other positions of advantage—has become a staple of liberal-de-

mocratic thinking. Yet here, too, we find ongoing disagreement about how the principle should be understood. In its original formulation, it meant simply that there should be no legal barriers preventing those with certain characteristics (class or religious affiliation, for example) from attending schools and universities, entering careers or holding public office. But this left in place the practical obstacles, chiefly lack of resources, that effectively closed off such options to many citizens. Many people therefore now take equality of opportunity to mean what John Rawls has called fair equality of opportunity, the principle that 'those who are at the same level of talent and ability, and have the same willingness to use them, should have the same prospects of success regardless of their initial place in the social system' (Rawls 1971, p. 73). Taken literally, this calls for the elimination of all those disparate influences—family background, school choice, and so forth—that today help to determine a person's likely social destination. Most liberal thinking opts for the middle ground: the state should try to mitigate disadvantage by, for example, curtailing the right to inherit, and insuring that children from all backgrounds have access to good schools, but it should not interfere directly with the transmission of cultural and other advantages through the family (see Fishkin 1983 for an analysis).

4. *Equality of Outcome*

The most radical versions of egalitarianism hold that equality of opportunity is not enough, since even in its stronger Rawlsian guise it still permits a person's life prospects to be determined by their talent and ability. Instead it should be the goal of public policy to make every citizen as materially well off as every other, except insofar as people can be held personally responsible for having less (thus equality of outcome, as it is usually understood, does not require that people who gamble away their share of resources should subsequently be compensated).

Several questions may be asked about equality of outcome. The most basic has to do with the respect or respects in which people's condition is to be made equal—what is sometimes referred to as the currency of equality. The natural currency might seem to be that of welfare: how much happiness or well-being each person enjoys. This suggestion faces acute difficulties of measurement—how can we decide when one person is happier or has more welfare than another?—but beyond that it may be criticized on grounds of principle. Someone's level of welfare depends in part on how far they are able to realize their aims and ambitions, but should they not be held responsible for having these aims and ambitions in the first place? Should equality involve giving more material resources to people whose welfare is reduced because they cannot fulfil expensive ambitions such as consuming fine wines or collecting great works of art?

Some contemporary liberals, most notably Ronald Dworkin, have therefore advocated equality of resources as a better alternative to equality of welfare (Dworkin 2000). People are equal, on this view, when they have access to resources of equal value, which they can then choose to use in whatever way their preferences dictate. Dworkin proposes the device of an auction as a way of determining when external resources are equally distributed. He has greater difficulty when he comes to deal with internal resources, the talents and abilities that determine what people can do with the external resources they are given. How can equality be achieved here without forcing highly talented individuals to use their talents in ways that they may strongly dislike—the so-called 'slavery of the talented' (Roemer 1985)?

A further problem for equality of resources is that it appears not to accommodate people whose special needs mean that they derive less welfare than others from a given bundle of resources almost regardless of their preferences about how to live. In recognition of this problem, a third interpretation of equality of outcome has been proposed by Amartya Sen: basic capability equality, according to which people should as far as possible be made equally capable of achieving a set of functionings, such as being well nourished, moving about, etc. (Sen 1992). Sen claims that this conception focuses, properly, on what resources can do for people, as opposed to the bare fact of having resources, while it avoids the difficulties that arise when equality is defined in terms of happiness or preference satisfaction. It does, however, face the problem of comparing different capability sets. If I can do A, B and C and you can do D, E and F, how do we decide whether we are equal or unequal to each other, without surreptitiously referring to a criterion such as welfare?

5. *Social Equality*

Equality of outcome faces serious problems beyond that of finding a suitable currency in which to express it. The most rehearsed of these is perhaps the incentives problem: if everyone is to be made equally well off at the end of the day, what incentive is there for people to use their talents in productive ways? A different line of criticism challenges the view that equality of outcome is something we should care about ethically. Instead, it is argued, we should be concerned about sufficiency—about insuring that everyone reaches a standard of living sufficient to satisfy their essential needs and interests, or alternatively about giving priority to the worst off—about insuring that public policy attaches special weight to improving the material situation of those who have least. (See Raz 1986,

Chap. 9, Frankfurt 1987, Parfit 1998 for arguments of these kinds.)

Another view maintains that inequalities of outcome matter only when they create social inequalities. On this view, what matters is that each member of a given society should feel himself or herself to be the equal of every other, that there should be no inequalities of status such that A regards himself as socially inferior to B in an across-the-board sense. One way to achieve this is to prevent inequalities from accumulating in such a way that when B enjoys more goods of one kind than A, he also enjoys more goods of other kinds. Michael Walzer has applied the term 'complex equality' to a society where different people are ahead along different dimensions of advantage (some enjoy greater wealth, others more power, yet others are more highly educated, and so forth) and there are blocking mechanisms that prevent people from using their advantaged position on one dimension to gain unjust advantages on others (Walzer 1983). One merit of this way of understanding equality is that it allows justice and equality to be reconciled, even in cases where justice itself mandates inequality, such as cases in which some people deserve more than others. Such justified inequalities need not threaten social equality provided Walzer's conditions are met. (See Miller 1999, Chap. 11 for a fuller discussion.)

Egalitarianism, Sociology of

Egalitarianism is an ideal that motivates many normative political visions and many social movements. It is a relatively modern concern because it is only in relatively advanced nations that states have the capacity to redistribute systematically on a grand scale. Indeed, they have had the capacity to tax incomes effectively only since the early nineteenth century. Most contemporary discussions of equality are reformist and addressed to reducing inequalities, but many earlier movements were radical and addressed to remaking society. There are two classes of obstacles to achieving egalitarianism: causal problems and value-theory problems. The chief causal problems are that, in achieving equality, we typically must affect other things, such as productivity (Rawls 1971, Okun 1975, Bowles and Gintis 1998). We cannot achieve equality while holding all else equal. The chief value-theory problems are suggested by the questions: equality of what? and; how do we measure it?

The philosophical literature on egalitarianism is deeply equivocal on the questions of what we should equalize and how we could measure it. Social scientists most commonly suppose that the answers are simple; we should equalize incomes, measured in monetary terms only. The most conclusive arguments are about obstacles to achieving equality or even to reducing inequality very much. These causal arguments are about the tradeoffs that we must make if we are to have complete or even greater equality. I will first address these tradeoffs and then turn to measurement issues. Finally, I will briefly comment on international inequality.

1. Tradeoffs

The chief appeal of the market organization of an economy is that it enhances production—but it does so by introducing massive inequalities of benefit from social organization. Most of the concern with tradeoffs in achieving greater equality is with the effects on incentives for production. Having strict equality of incomes is equivalent to turning national production into one vast problem in which the collective national income is produced by collective action. That income would then be divided equally among all citizens (or all families or producers) independently of the scale of their personal contributions to the total product. Hence, individuals would have no incentive to contribute much to the collective good beyond altruism or public-spiritedness. Even if we merely wish to reduce inequality of income, we must tax away part of the higher incomes to transfer money to those with the lowest incomes. As we do that, the highest earners may increasingly prefer to substitute leisure for income, because their effective hourly wage is reduced so that leisure, which is untaxed, costs less than other things

International Encyclopedia of the Social & Behavioral Sciences ISBN: 0-08-043076-7

their income could buy for them. Consequently there will be lower overall production and there will be less to tax and transfer, so that greater equality will entail lower average income. If government transfer is inefficient, not least because it requires labor that is otherwise not productive, the reduction of average income will be exacerbated. There are other detrimental incentive effects. Personal investment in human capital to be productive will not be rewarded if incomes are equal, and it may therefore be substantially reduced. Also, the incentives to entrepreneurs to take large risks will be eliminated.

For many collective achievements, a hierarchical organization seems to be necessary. Although hierarchy without inequality of wealth or income is conceivable, high status in a sharp hierarchy is likely to be an unequal reward in its own right. Very generally, we require extensive division of labor if our society is to be prosperous, diverse and interesting, and such division is itself likely to be hierarchical and unequal in its rewards of status and other nonmonetary emoluments. Émile Durkheim (1933) argued that the equality that fits with relatively primitive conditions of mechanical solidarity gives way to the division of labor and the organic solidarity that it entails. The emoluments from hierarchy and many other things cannot be equalized (Hirsch 1976). Finally, inequality of wealth may actually be enormously beneficial to technological progress in many areas, because the relatively wealthy will buy new technologies while their prices are far too high for a mass market. Their early entry into the market often then drives down the costs of production so that the new technologies become much more widely available, as has been true for computers in the 1980s and 1990s. The green revolution of developing nations was made possible by the prior investment in wealthy nations in agricultural innovations that, as they became cheaper, became attractive to much poorer nations. For example, chemical fertilizers, highly productive seeds, and light tractors have all become cheap. Similarly, after wealthy nations had eliminated smallpox infection in their own populations, they worked successfully to eliminate it everywhere, in part for their own benefit. They now attempt to do the same for polio and there are promising prospects for malaria, cholera, and other pervasive diseases. F. A. Hayek (1960, p. 40) supposes that 'if all had to wait for better things until they could be provided for all, that day would in many instances never come.'

Finally, the evidence of twentieth-century experiments in national programs of reducing inequality suggest a grim tradeoff. Because incentives can be extraordinarily powerful in stimulating unequal efforts, any substantial degree of equality in a whole society is likely to require strong government control over distribution and wages and perhaps even over production. If government is empowered to intervene in such ways to make major redistribution, it is very likely also to be empowered to do other, generally harmful things. Stalin and Mao sat in capricious, brutal judgment of artists and their work. Many national leaders, including Nehru and many revolutionary idealists, have supposed that they should design and run the economy even though none of them has been a competent economist. Indeed, even the seemingly best economists historically had theories that, if put into policy, would have been destructive. As David Hume, Adam Smith, and James Madison insisted, weak government has many appeals.

2. *Measurement*

Conceptually, perhaps the first instinct is that we should equalize welfare or well-being as far as possible. In the days of cardinal utility theory, comparing welfares was a simple matter in principle, although impossible in practice. In the twentieth century, economists largely rejected cardinal welfare theory and adopted an ordinal theory in which it is not even possible to make interpersonal comparisons. If we can make at least ordinal comparisons, then we can compare whole states to each other, so that we might be able to say that India is worse off than China, or vice versa, or that one very general policy is more egalitarian than another. Such ordinal evaluation can have seemingly anomalous implications. For example, an inegalitarian Bangladesh can be compared to Iceland if its 250,000 best off citizens are better off than the citizens of Iceland, while a Bangladesh with the same resources overall, but more equally distributed, might not be comparable one way or the other to Iceland. Hence, the inegalitarian Bangladesh might be found to have greater welfare than Iceland, while the egalitarian Bangladesh might be found to be, on a Rawlsian or other assessment, more just than the inegalitarian Bangladesh. The egalitarian Bangladesh might, however, not be comparable to Iceland either on a Rawlsian or an ordinal utilitarian assessment. The first of these pairs permits a welfarist comparison, the second permits a Rawlsian justice comparison, and the third permits neither comparison. Although such implications may sound strange on first hearing, they are likely to be commonplace in an ordinal world. If such implications sound very strange, we may find it difficult to redirect our understanding to think in ordinal terms. But that is what we must do if we wish to make consequentialist sense of our real world.

Because welfare is hard to measure, many analysts focus on other things that might be equalized. Perhaps because they seem like a reasonable proxy for welfare, resources are the most common alternative focus. Among the earliest visions of an egalitarian society was that of the seventeenth-century Diggers in England, who wanted equal plots of land for each family to farm (Winstanley 1973). They thought that even the wealthy should be reduced to simple farming,

because such a life of hard work would make them better Christians. Hence, theirs was a program of equalization both up for the poor and down for the wealthy. (Many political movements and regimes from the Diggers to Pol Pot and the Taliban have sought to achieve equality by reducing the welfare of the best off rather than by raising the welfare of the worst off.) The central focus of much of the debate on equality has long been private ownership of property, especially of the means of production. For Karl Marx, such ownership meant that nonproductive owners gained much of the profits of production. The route to greater equality was public ownership of such property so that all income would be in the form of wages from labor.

3. *International Inequality*

In the twentieth century, several major societies attempted to achieve greater equality in the midst of other societies that were highly inegalitarian or to overcome their own poverty by closing themselves off from the world economy and centrally directing their own development. Such autarky can have substantial costs. The Soviet recourse to autarky was partially imposed from outside, but Nehru's relatively autarkic policies in India were plausibly motivated by desires to keep India out of the commercial mold of the West and to maintain control over the prospects for greater equality. Unfortunately, one nation cannot be as creative and innovative as the entire rest of the world, and impoverished Indians were made relatively worse off internationally during the 40 years of Nehru's legacy. When a nation blocks inequalities that other nations allow, many citizens have strong incentive to emigrate. Some states have blocked such emigration with harsh controls on movement, so that again egalitarianism forces a grim tradeoff.

In much of the contemporary public discussion of the poverty of developing nations, the focus is often on achieving greater equality through straight redistribution from the wealthy nations, as though the issue were the static problem of current distribution of what is already available. This is almost entirely wrong-headed. The crux of the problem of grievous inequality between very poor communities and prosperous communities is dynamic; it is to enable people in impoverished communities to become engaged in productive work that will raise their level of welfare. Transfers that are aimed at providing work opportunities make sense, as do transfers that are aimed at momentary emergencies such as drought and starvation in the Sahel. Transfers that merely equalize static distributions cannot be practically justified in a world in which the problem is inherently dynamic.

What impoverished nations need is investment in production facilities, such micro-lending institutions as the *Grameen Bank*, human capital, and good legal systems. The chief differences between the advanced and impoverished economies are not natural resources but human capital and the social capital of relevant institutions. The truth of this claim is now revealed to an extreme degree by the wealth-generating information industries whose inputs are almost exclusively human and social capital (and, of course, intellectual property). The actual contribution of natural resources to production in the advanced economies is very slight (apart from energy resources, which are not found in many of the most advanced economies). Any move to address inequality that ignores this issue of production is hardly of any interest. We must consider institutions for improving the prospects for internal economic production. Indeed, apart from emergency cases, this should be the first and primary focus for reducing international poverty and gross inequality.

Ego Development in Adulthood

Jane Loevinger's theory of ego development (Loevinger 1976, Hy and Loevinger 1996) has provided an approach to personality, emotion, and values that is distinct from approaches that are concerned with the assessment of stable dimensions or traits.

Table 1
Characteristics of levels of ego development

Level	Code[a]	Impulse control	Interpersonal mode	Conscious preoccupations	Example
Impulsive	E2 (I-2)	Impulsive	Egocentric, dependent	Bodily feelings	… shut up
Self-protective	E3 (Delta)	Opportunistic	Manipulative, wary	'Trouble,' control	… date as many guys as she likes
Conformist	E4 (I-3)	Respect for rules	Cooperative, loyal	Appearances, behavior	… ask her mother's and father's advice
Self-aware	E5 (I-3/4)	Exceptions allowable	Helpful, self-aware	Feelings, problems, adjustment	… make her own decisions about any job she wants to have
Conscientious	E6 (I-4)	Self-evaluated standards, self-critical	Intense, responsible	Motives, traits, achievements	… do what she wants as long as it is within reason and it does not hurt anyone including herself
Individualistic	E7 (I-4/5)	Tolerant	Mutual	Individuality, development, roles	… do anything men can do but still being a feminine person in the process
Autonomous	E8 (I-5)	Coping with conflict	Interdependent	Self-fulfillment, psychological causation	… realize her potential, regardless of …the role restrictions society may try to impose
Integrated	E9 (I-6)		Cherishing individuality	Identity	[very rare, probably less than 1% of responses; no example given]

[a]Notation in parentheses is original notation; 'E' notation is notation revised by Hy and Loevinger (1996).

Instead, ego level theory focuses on how individuals organize meaning and information relevant to the self or ego. Loevinger suggests that such organization of meaning changes as a function of the conceptual complexity of individuals. She distinguishes several ego levels, which are derived from developmental theory. However, these levels not only serve to assess time-related or age-related aspects of personality organization, but also are important in understanding individual differences.

1. *Definition of Ego Levels*

Loevinger's theory borrows from both cognitive-developmental theory and from psychodynamic approaches (Loevinger 1976). From cognitive-developmental theory, it borrows and develops the notion that more mature levels of ego functioning emphasize aspects of complex and abstract thinking—and thus are oriented towards objectivity and impersonality. From psychodynamic theory, it introduces the assumption that abstract thinking is not merely impersonal, but that others and reality in general are approached in terms of the relation or meanings they have for the individual—with his or her needs, anxieties, and goals, with the impulses and methods of controlling them, personal preoccupations and ambitions, interpersonal attitudes and social values (Blasi 1998). All of these aspects are described in terms of a series of less to more complex levels of ego development.

Ego levels are assessed through the sentence completion test (Hy and Loevinger 1996). This test consists of 36 sentence stems such as 'Raising a family … ,' 'Being with other people … ,' or 'A girl has a right to … .' Individuals are asked to complete these stems, and responses are coded along several dimensions such as (a) impulse control and character development; (b) interpersonal style, such as independence, manipulativeness, need to belong, autonomy; (c) conscious preoccupations; and (c) cognitive style, such as tolerance of ambiguity and tendency towards objectivity. Table 1 presents coding criteria and sample responses for the item, 'A girl has a right to … .' At lower levels, responses are dictated by impulsivity, egocentrism, and bodily feelings, while at the higher ends they are characterized by acceptance of conflict, the realization of interdependence and a cherishing of individuality, and a focus on self realization and psychological causes.

2. *Ego Levels and Age/Development*

Since ego levels are derived from developmental theory, an obvious question to ask is how they relate to age or development. Research indicates that from childhood to adulthood, age is positively related to ego level. However, throughout adulthood, the relation between age and ego level may vary; depending on the circumstances, ego level may even decline. This is to be expected if one accepts that age and development are not necessarily identical. Thus individuals may grow older but not necessarily more mature or complex. Hence, one would expect patterns of change to vary with the conditions in which individuals age.

In support of the notion that age and development can diverge in adulthood, Loevinger et al. (1985) suggest that the pressure towards conformity in adulthood can actually lead to a lowering of ego level. In general, one would expect that ego level is enhanced by experiences that challenge one's adaptive strategies. If individuals are in stable niches, no ego level growth may be observed. As Block (1982, p. 289) stated, 'The passage of time does not mean development.'

Helson's work (e.g., Helson and Roberts 1994) has paid particular attention to the contexts that may encourage or discourage growth in ego level in her long-time study of women's development. While in general ego level is strongly predicted by such variables as intelligence and education, women's life path (life stimulation and difficult experiences) additionally affected ego level. For example, with respect to life stimulation, women who had remained in traditional family roles or who had never made a commitment to family or career roles were the lowest in ego level, whereas women who had careers had the highest levels. Women high in ego level also were more likely to tell difficult stories about issues of abandonment or searching for an independent identity.

3. *Ego Levels, Values, and Beliefs*

Loevinger's theory maintains that ego levels assess a particular conceptual style by which individuals integrate self-relevant experience. Research has provided ample evidence that this notion is valid. Individuals of higher ego level have been found to be more open-minded than lower ego level individuals, and to hold less conventional beliefs and values (McCrae and Costa 1980). They are also more likely to question fundamental religious beliefs and values, and to be open to different religions. Overall, they are more tolerant, less authoritarian, and less compliant. They are also more likely to engage in complex thinking about new events and situations (Helson and Roberts 1994), and are less traditional in their endorsement of gender roles (McAdams 1985). They are more likely to display patterns of unusual creativity (Helson and Wink 1987).

Individuals of higher ego levels are also more differentiated from others than are those of lower ego levels. For example, high ego level women were found to have more appreciation of others as autonomous and independent beings (Helson and Wink 1987). In a related vein, research by Labouvie-Vief and coworkers (e.g., Labouvie-Vief et al. 1995) also reported

that at lower ego levels, individuals describe their parents primarily in terms of the immediate emotional bond and the global quality of the relationship (such as 'My mom is the greatest mom in the world, I love her!') or in terms of their parental roles (e.g., 'he is a good provider'). In contrast, individuals of higher levels of ego development are better able to view parents as persons separate from the immediate parent–child bond.

Ego levels also imply that individuals differ in the way they modulate their impulses. This is shown in research (Labouvie-Vief et al. 1989) in which individuals described different emotional states: happy, sad, anger, and fear. At lower ego levels, individuals described their emotions statically in terms of concrete actions, bodily symptoms and their concerns to modulate them along conventional and role-defined ideals. However, more mature individuals explored the tension between conventional standards of emotion regulation and what they feel is a deeper self which was defined in terms of contrasts and transformations over time and across contexts.

4. Ego Level and Adjustment

Loevinger claimed that ego level and adjustment are completely independent dimensions. Indeed, when adjustment is measured in terms of subjective well-being (Helson and Wink 1987, McCrae and Costa 1980, Vaillant and McCullough 1987), ego level appears to be independent of adjustment, at least where adult samples are concerned (Noam 1998). For a wide range of adults, ego level does not appear to predict such indices as life satisfaction, emotional adjustment, positive affect, or well being. Why should ego level not be predictive of adjustment? Helson and Wink (1987) suggested that two forms of maturity characterized adults. The first, 'ego level,' is primarily related to growth in cognitive complexity, tolerance of ambiguity, objectivity, and intrapsychic differentiation; this form is related to measures of individuality and creative expressiveness, including such variables as recognition for work, interest in self-understanding, and philosophical and religious interests. The second indicator, 'competence,' was defined as the ability to align with social norms and to regulate behavior by reducing friction and obtaining rewards in social life. This indicator was related to such variables as emotional security and lack of defensiveness and it was negatively correlated with use of drugs and medication and positively with confidence and lively engagement. Similarly, Vaillant and McCullough (1987) found that ego level appeared to be part of a cluster completely distinct from a psychosocial maturity cluster.

Labouvie-Vief (1999) explains such evidence in her theory of self and emotion. She proposes that ego level and adjustment result from two independent core emotion regulation strategies. One of those, affect optimization, is a strategy aimed at maximizing positive emotions and damping negative ones; the second is a strategy of affect amplification, or affect complexity, in which individuals are open to negative affect. This strategy is strongly related to ego level and conceptual complexity. Individuals adopting this strategy process and explore information with the general aim of achieving a more balanced, objective view of self and reality.

5. Conclusion

Ego level represents an important approach to understanding individual differences and development in adulthood. Ego levels are meaningfully related to how individuals organize their experience in terms of their life stories, their values, and their emotions. They emphasize the ability to be open, to engage in complex thinking, to be tolerant and oriented towards objectivity. Although ego levels mature with development in early life, in adulthood their further development appears to be dependent on the context; indeed, constraints of institutions may even hamper further ego development. In addition to adjustment criteria that primarily emphasize individual well-being and positive affect, ego levels provide a broader view of adjustment. They add to positive affect an emphasis on openness, tolerance, and objectivity as additional criteria for mature adaptation in the life course.

Despite the demonstrated importance of ego levels, many approaches to personality and adaptation have not yet made the dimension of complexity that underlies ego level an integral part of their assessment. To integrate ego level and other cognitively based approaches with general theories and assessment approaches to adaptation will constitute an important domain of future research.

Ego Psychology and Psychoanalysis

Ego psychology represents a significant historical as well as current perspective within psychoanalysis. Most broadly, ego psychology extends classical psychoanalytic drive theory, combining biological and psychological views of individual development with frameworks referring to complex sociocultural dimensions. In this way, ego psychology moves psychoanalytic theory and practice from study of unconscious events and psychopathology to explorations of adaptive processes and conscious experience within a matrix of interpersonal, familial, and broader sociocultural forces (see, for example, Erikson 1950, Hartmann 1936, Hauser and Safyer 1995). In contemporary theoretical and clinical discussions, the construct of the ego refers to cognitive processes (e.g., self-reflectiveness); perceptual processes (e.g., self-observing); defenses (e.g., suppression); and executive functions (e.g., planning). Moreover, these components can operate at several levels of consciousness—rather than conscious *or* unconscious—within the same individual (Vaillant 1998).

1. Early Formulations

Freud's definition of the ego evolved through three phases (Rappaport 1959). The ego was initially defined with the least precision, the term being used interchangeably with one's own person or self. Despite this ambiguity, one aspect of ego processes was already being highlighted—the defensive functions of the ego. In this first definition then, the ego was conceptualized as focused on preventing painful memories from entering awareness. In a second definition, Freud distinguished central aspects of ego functioning: secondary process (e.g., conscious ideas), reality principle, and repression. The third definition began with Freud's introduction of the structural model, constructing the ego as a coherent system, which—together with the id (drives, nonrational ideas) and superego (conscience) systems—is a component of the tripartite personality organization model. In this most comprehensive formulation, ego processes refer to many connections among perceptions, ideals, moral principles, and conflicts generated within and between id, superego, and ego structures. In this third model of the ego, the groundwork was laid for our current view of the ego representing the individual as an active agent with his or her own independent interests, rather than passively responding to other psychological forces (e.g., conflicts, moral precepts, responses to others) (Rappaport 1959).

Subsequent theoretical, clinical, and empirical contributions have led to clarification and extension of a number of constructs first suggested in these earlier models of ego functioning. Their additions to ego psychology have led to an increasingly refined appreciation of significant relations between ego psychology perspectives and other domains of knowledge, ranging from the social sciences to clinical theory and practice.

2. Contemporary Perspectives on Ego Psychology

Between the late 1930s and the early 1980s many important new additions to ego psychology appeared in psychoanalytic literature. Freud was among the contributors. For although he continued to focus on drives and unconscious mental processes, together with changes in clinical technique, he clearly remained invested in developing ego theory during his later years (Schafer 1995, p. 224, Freud 1933, 1939, 1940). Psychoanalyst critics of ego psychology inaccurately characterize the perspective as minimizing the significance of drives, the pleasure principle, unconscious fantasy, unconscious conflict, danger situations, or transference. 'Instead, one aims to develop further the context for each of these dynamic concepts. The [ego psychology] theory is designed to encompass the total mind and not just its damaged aspects and its primitive, id, or primary-process aspects' (Schafer

1995, p. 224). A major assumption within ego psychology is that through theorizing about mature, rational, and stable modes of function it becomes possible to more precisely conceptualize the 'non-primitive' and the so-called 'normal.'

The last decades of the twentieth century witnessed further extensions of the fine-grained formulations of ego functions begun by Hartmann and colleagues (Hartmann 1936, Hartmann et al. 1964). For example, understanding development and change in such processes as remembering, language learning, communicating, and experiencing insight have been discussed by a wide number of writers with respect to the phenomena themselves and their relation to problems of organization within aspects of the personality, particularly in terms of ego, id, and superego structures. However, in current psychoanalytic theory it has been difficult to trace ego psychology links to current major interests in such broad and important domains as object relations, intersubjectivity, and constructivism. Much of ego psychology deals with the individual as he or she is embedded in the broad biological and social field. But the theory has not consistently conceptualized reciprocal influences between individual development/functioning and the surrounding social fields. Schafer (1995) argues for the relevance of ego psychology for reconciling the theoretical tensions between constructionist and objectivist stances within psychoanalytic thinking; tensions manifest in discussions of psychic reality, communications, and social conditions. 'In psychoanalysis, it is specifically ego psychology that tries to give an account of the development of this complex mixture of constructivism, conventionality, and systematic thought, and what is required to maintain and extend it. Those who reject Freud's and Hartmann's ego psychology … are simply ignoring this area of complete conceptualization and explanation. They claim too much for intersubjectivity alone' (Schafer 1995, p. 230).

During the evolution of ego psychology and the pioneering work of Hartmann and his colleagues (Hartmann et al. 1964), it was already clear that there was not a monolithic theory of psychoanalysis. This pluralistic perspective is more obvious now than ever before. Yet with one exception, we find no new theoretical contributions to the ego psychology literature. The single exception is Erik Erikson.

3. *Extensions of Ego Psychology: Erik Erikson*

Erikson is best known for his writings on ego identity (e.g., Erikson 1959). However, Erikson's impact reaches even further through his creative work at the interface of psychoanalytic theory and the social sciences including history, economics, anthropology, sociology, and all of developmental psychology. Keenly focused on the intertwining of individual development with sociocultural forces, Erikson has been termed by some as the father of psychohistory (Smelser 1998). Consistent with the ego psychology perspective, Erikson considers individual development and functioning within family, community, and cultural contexts. Recognizing biological forces with respect to psychosexual development, Erikson goes further, conceptualizing historical, sociological, political, and economic influences through theoretical analyses and intensive analyses of major figures (for example, Ghandi (Erikson 1969) and Luther (Erikson 1958)). Central in Erikson's work are connections between ego development and society, the intertwining of generations with respect to ego identity development, the 'meshing of individual neurosis and social history' (Smelser 1998), and the necessity for interdisciplinary efforts in understanding human development: 'only psychoanalysis and social science together can eventually chart the life-cycle interwoven throughout with the history of the community' (Erikson 1959, p. 18i; Smelser 1998).

In light of the interdisciplinary nature of Erikson's work considering the individual within his or her social matrix—including intersections of specific life histories and historical eras—it is not surprising that his contributions are not readily incorporated into earlier ego psychology conceptualizations. And for the very same reasons his work has neither been drawn into more mainstream psychoanalytic theories nor into discussions of clinical practice (Wallerstein 1997). On the other hand, social scientists and other scholars applaud and utilize his creative insights in psychoanalysis and neighboring disciplines (Smelser 1998, Cavell 1998, Friedman 1999). Perhaps the most salient explanation for the marginalization of Erikson from the traditional ego psychology literature is the challenge of aligning his complex formulations (drawn from many conceptual frameworks) into the primarily 'individual mind' categories of ego psychology, with precise theoretical definitions.

One further strand of Erikson's work is his conceptualization of the human life-cycle along the lines of developing individual's capacities to master increasingly complex social relationships and maintain continuity with his or her own history and community. Vaillant (e.g., 1993), a major clinical scholar, has called attention to this core theme in Erikson, beginning with his early adolescent (identity) writings and continuing to later considerations of adult development (Erikson 1982).

4. *Ego Psychology in Contemporary Psychoanalytic Practice*

Translating the refined theoretical distinctions of ego psychology into the practice of psychoanalysis is a daunting challenge. Since the early 1980s a group of writers have risen to this important challenge, by

delineating an ego psychology approach to the psychoanalytic technique (Gray 1994, Busch 1997, Kris 1982). Examining implications of ego psychology concepts (e.g., defenses, executive ego functions) and clinical interactions, these contributions attend to the content and style of patient communications, encouraging 'close monitoring,' the clinician's listening to the patient's associations as 'constructions of the ego filtered through a lens measuring the degree of risk' (Busch 1997, p. 407). While not minimizing the importance of unconscious fantasies, drives, and motivations, this clinical approach informed by ego psychology represents 'an attempt to read the text as written by the patient, rather than a reading of the meaning hidden behind the text' (Busch 1997, p. 410).

The idea of risk leads to consideration of defenses, long considered a central construct within ego psychology, first most comprehensively conceptualized with respect to the many forms of ego defenses by Anna Freud (1936). Recent writing on defense processes—including diverse mechanisms as anticipation, suppression, displacement, and denial—draws attention to conscious and unconscious aspects of these functions and their vital importance in adaptation in contrast to psychopathology and dysfunction (Vaillant 1993). Gray's (1986) view of clinical interpretation focuses on the patient's current abilities to grasp new self knowledge, allowing novel constructions into their consciousness: 'The interpretive task is to estimate sensitively the patient's ability to comprehend in order to make a formulation that is not too superficial, yet does not stimulate more reactive defenses' (Gray 1986, p. 253). In other words, this attentiveness to the patient's defenses and other adaptive capacities must be maintained if the psychoanalyst is to involve 'those healthy aspects of the patient's ego that seek to fill out understanding and memory, while searching for pleasure in the form of more effective ego functioning' (Busch 1997, p. 421, Klein 1976). It is of interest that ego defenses, of all hypothesized ego processes, have been the focus of the most sustained empirical efforts at investigating ego psychology constructs.

5. *Empirical Research: Ego Processes and Ego Development*

In addition to the gap from ego psychology to clinical practice, a second important gap is from ego psychology to systematic empirical research. Operationalizing ego psychology constructs and propositions, and designing systematic studies, has posed daunting challenges for investigators. Nonetheless, several programs of research have focused on specific questions and hypotheses regarding ego functions and ego development. Arguably, the ego psychology domain is too vast to be included in any single program of empirical studies. Selected constructs relevant to ego psychology—in particular defenses and ego development—are targets of previous and continuing successful research efforts.

5.1 *Ego Defenses*

The study of ego defense mechanisms has been problematic to clinicians as well as to empirical researchers. 'Investigators who have attempted systematic research on defense mechanisms have often found themselves without a common language for describing them and without replicable methods for assessing them' (Vaillant 1998, p. 1147, Hauser 1986). The multifold problems of classification, conceptual definition, operationalization, and adequate assessment design have plagued dedicated clinical researchers for many years. Since 1971, Vaillant has persistently provided conceptualizations, assessment strategies, and enlightening narrative and quantitative findings regarding the diverse array of defense processes (see, for example, Vaillant 1994). Based on a theoretically-derived hierarchy of defense processes, Vaillant constructed operational definitions and scoring approaches for examining interview material gathered through clinical interviews. His approach has been applied in numerous studies of college men (Vaillant 1997), and inner city men (Vaillant 2000). In addition to dealing with questions about conceptualization and assessment of defenses, much of the interest in Vaillant and colleagues' work has to do with the 'transmutation of less adaptive defenses into more adaptive defenses' (Vaillant 2000, p. 98). Ego development, in particular as manifest through transformation of defenses, is a major theme throughout Vaillant's many contributions (Vaillant 1993, 2000).

5.2 *Ego Development*

Ego defense processes and ego development are intertwined in numerous ways, including the observation that maturation of defenses reflects one important aspect of ego development. The many complex facets of relations between defenses and ego development have not yet been fully articulated (Hauser 1986, 1993). One illustration of the interplay between defenses and ego development is illustrated through two extant models of ego development. One view considers the ego as representing the collection of ego mechanisms, while the other model emphasizes the centrality of a single ego process, comprising integrative activities (e.g., of thoughts and feelings, of present and past ideas) (Hauser 1979).

Bellak et al. (1973) assume the 'collection' model. From this perspective, ego development refers to an unfolding of multiple functions, including adaptive strengths, cognitive processes, defenses, and perceptions of others (Hauser and Daffner 1980). The

second model of ego development focuses on integrative or synthetic processes and the individual's overall frame of reference. Elaborated by Loevinger and colleagues, this view is linked with a widely-used sentence completion assessment technique (Loevinger 1976, Hy and Loevinger 1996). For over 25 years empirical studies have incorporated this theoretical approach and psychometrically rigorous assessment instrument to study ego development in children, adolescents, and adults. Moreover, since the late 1970s these studies have encompassed psychopathology variables together with cross-cultural dimensions (see, for example, Cohn 1991, Westenberg et al. 1998, Hauser 1976, 1993, Hauser et al. 1991, Loevinger 1979). Growing knowledge of connections among individual behavior, individual experience, and ego development has added invaluably to diagnostic and longitudinal studies of psychopathology and development arrests in varied contexts (Hauser 1999, Hauser and Safyer 1995, Hauser et al. 1991). An ongoing longitudinal investigation of adolescent and adult development over the past 20 years focuses on ego development, attachment, and family contexts (Hauser et al. 1991, 1998).

In Loevinger's model of ego development, it is assumed that each individual holds a customary orientation to the self and world, and that there is a continuum (ego development) along which these frames of reference can be arrayed. 'In general, ego development is marked by a more differentiated perception of one's self, of the social world, and the relations of one's feelings and thoughts to those of others' (Candee 1974, p. 621). Thus, in contrast to Bellak's model, this assessment of ego development does not distinguish specific ego processes (e.g., defense mechanisms) from one another, since they are considered aspects of one integrated structure of the developing ego (Loevinger 1979b). Interesting empirical questions then arise—for instance, how are defense mechanisms and other ego processes are linked with ego development (e.g., Hauser et al. 1998).

6. *Future Directions*

In terms of ego psychology theory, there are suggestions of new integrations of this theory with contemporary psychoanalytic studies of focuses on intersubjectivity, object relations development, and dialogue. Related to this is the theoretical challenge to find connections of the highly creative work of Erik Erikson to other psychoanalytic theory and practice. A second direction in the recent effort to apply ego psychology observations and theory to clinical practice with respect to the nature of clinical observations as well as techniques relevant to facilitating the expansion of insight and development. Arguably, these advances in moving from ego psychology at a theoretical level to ego psychology within clinical theory and practice are important ones that will likely continue in the next decades. Finally, several research programs are inspired by ego psychology constructs. Longitudinal studies of ego development now include psychopathology and normal development. Systematic studies of ego defenses and related processes are embedded within these longitudinal investigations. Additional operational definitions of ego processes will likely be developed in the future. It is vital and completely consistent with the work of such ego psychologists as Heinz Hartmann and Erik Erikson, that the perspectives and constructs of ego psychology become even more explicitly integrated with the insights, theories, and empirical approaches of neighboring disciplines (Holzman and Aronson 1992). These disciplines include those investigating aspects of stress, social context dimensions (e.g., family, school, neighborhood), coping, and individual development.

S. Hauser

Elaboration in Memory

1. Introduction

Elaboration is a conscious, intentional process that associates to-be-remembered information with other information in memory. Examples of elaborations include retrieving a semantic associate of a to-be-remembered item (e.g., 'cat' for 'dog'), retrieving the taxonomic category of a to-be-remembered item (e.g., 'fruit' for 'pear'), and identifying the relationship between two to-be-remembered items (e.g., recognizing that the to-be-remembered items 'sour' and 'grapes' may constitute an idiom). The construct of elaboration has been used in cognitive psychology to explain why a variety of instructional and materials manipulations produce superior memory performance. In addition, differences in the spontaneity or efficacy of using elaborations have been proposed as explanations of differences in memory performance across populations (e.g., young subjects vs. elderly subjects). At a general level, the construct of elaboration is consistent with cognitive psychology's tripartite emphasis on intentional processing, mental contents as mediating variables, and information transformation. The succeeding sections describe the intellectual antecedents of the construct of elaboration in modern cognitive psychology, the specific genesis of the contemporary use of elaboration in the levels-of-processing literature, the theoretical mechanisms that have been proposed to explain the beneficial effect of elaboration on memory performance, and three important empirical applications of the construct. These applications involve the explanation of population differences in memory performance, differences in the memorability of various types of materials, and differences in performance on various memory tests.

2. Historical Antecedents of the Construct of Elaboration

The modern concept of elaboration emerged from a series of information-processing models emphasizing the roles of filtering and rehearsal of information as critical determinants of memory performance (Broadbent 1958, Atkinson and Shiffrin 1968, Baddeley and Hitch 1974). Filter models of attention (Broadbent 1958) emphasize that attention plays an important role in sensory processing by giving priority to information arriving through certain sensory moda-

lities or channels while filtering information arriving through other modalities or channels. These models introduced the ideas that earlier stages of information processing were required for later processing and that only a limited subset of information received this initial processing. These notions of filtering were adopted in stage models of memory (Atkinson and Shiffrin 1968). Stage models assume three distinct types of memory stores (a sensory store, a short-term memory store, and a long-term memory store) and that information flows sequentially from one store to the next. Information entering the sensory store was assumed to be filtered by attentional processes so that only a limited set of this information entered the short-term memory store. Upon entrance to the short-term store, an intentional rehearsal process, generally referred to as maintenance rehearsal, was assumed to maintain information, mediating its transfer to the long-term store. Transfer to the long-term memory store was assumed to be a necessary condition for later memory performance. Thus, stage models emphasize that conscious, intentional processing is a critical influence on memory (see Baddeley and Hitch (1974) for more complex descriptions of intentional processes that might operate in short-term or working memory).

The emphasis of stage models on maintenance rehearsal led to a series of investigations of the properties of maintenance rehearsal. In the current context, the most critical studies were those which demonstrated that, contrary to the assumptions of the stage model, maintenance rehearsal did not necessarily enhance memory (Craik and Watkins 1973, Woodward et al. 1973). For example, Craik and Watkins (1973) demonstrated that increasing the duration of maintenance rehearsal by manipulating characteristics of a secondary task did not enhance memory. This counterintuitive finding led to a distinction between type 1 (maintenance) and type 2 (elaborative) rehearsal, with only the latter type of rehearsal assumed to affect retrieval from long-term memory. Thus, by the early 1970s, filter models of attention and stage models of memory had emphasized the role of conscious, intentional rehearsal processes in memory and ensuing empirical investigations had demonstrated that maintenance rehearsal did not necessarily enhance memory.

3. *Specific Genesis of the Modern Construct of Elaboration in the Levels-of-processing Literature*

Filter models of attention and stage models of memory focused attention on the process of memory storage. In the early 1970s, the levels-of-processing approach presented an alternative characterization of memory storage (Craik and Lockhart 1972). In contrast to stage models, the levels-of-processing approach assumed that to-be-remembered information was processed in three sequential stages of *perceptual analysis*. Presented materials were assumed to be subjected to an orthographic analysis, a phonological analysis, and then a semantic analysis. As in stage models, the character and nature of this processing were assumed to influence memory. Specifically, it was assumed that earlier stages of analysis (i.e., orthographic and perceptual analyses) led to transient memory traces, whereas semantic analyses led to longer-lasting memory traces. Thus, the levels-of-processing framework predicts that semantic processing should lead to better memory than phonological or orthographic processing. Consistent with this prediction, numerous empirical studies demonstrated that semantic orienting questions (e.g., 'is a pear a fruit?') during study lead to better memory than phonological or orthographic orienting questions (e.g., 'does pear rhyme with fair?') during study. Despite this support for the levels-of-processing approach, the congruity effect (Craik and Tulving 1975) presented a major challenge to this approach. The congruity effect is the finding that memory is better when responses to orienting questions are positive (i.e., 'yes') rather than negative (i.e., 'no'), independent of the level of processing of the orienting question. For example, the word 'pear' is better remembered if the orienting question is 'Is a pear a fruit?' than if the orienting question is 'Is a pear a weapon?' The congruity effect presents a problem for the levels-of-processing approach because it demonstrates substantial variability in memory performance with a fixed level of processing.

To explain the congruity effect, Craik and Tulving (1975) argued that elaboration—the association of to-be-remembered information with other information—was critical to memory performance. Thus, the congruity effect was assumed to occur because 'positive' orienting questions created episodic associations between the to-be-remembered item and information in the orienting questions (e.g., 'pear' and 'fruit') whereas 'negative' orienting questions did not form such associations (e.g., 'pear' and 'weapon'). Further, Craik and Tulving (1975) proposed that elaboration was a fundamental determinant of memory performance, hypothesizing that it was the basis of levels-of-processing effects. Specifically, they argued that the elaborations produced by semantic orienting questions were more likely to enhance memory than the elaborations produced by phonological or orthographic orienting questions.

4. *Theoretical Mechanisms of the Effect of Elaboration on Memory Retrieval*

Two classical approaches to memory retrieval provide explanations of elaboration's effects on memory. These mechanisms are compatible and one can conceptualize effects of elaboration as arising from their joint influence. The first mechanism arises from associationist models of memory (e.g., Raaijmakers

and Shiffrin 1981). In these models, to-be-remembered information is associated with episodic or list representations and to other information presented or retrieved during a study episode. During a memory test, episodic and other representations can be retrieved and used as cues for to-be-remembered information. In this perspective, elaboration enhances memory because it creates additional cues for to-be-remembered information. A simple example demonstrates the benefit of additional cues. The presentation of the word 'dog' in the study list creates an association between this item and the representation of the study list. If a subject then elaborates the presentation of the word 'dog' by recognizing that 'dog' is associated with 'cat,' this elaboration creates a second cue (i.e., 'cat') for 'dog.' In addition to providing an account of the effects of elaboration, a focus on multiple cues also provides an account of other memory effects such as those of encoding variability and imagery. Encoding variability effects occur when information studied from two perspectives is remembered better than information studied twice from a single perspective (Reder et al. 1974). For example, studying the word 'bank' in relation to its meanings as 'the side of a river' and 'a financial institution' produces better memory than studying 'bank' twice in the context of either of the individual meanings. Effects of imagery occur when words that have concrete referents (e.g., 'dog') are remembered better than words with abstract referents (e.g., 'justice') (Paivio 1971). The effects of encoding variability and imagery can be ascribed to the availability of additional retrieval cues. In the case of encoding variability, the second meaning of a word provides an additional cue, while in the case of concrete words, a visual/imaginal representation provides an additional cue.

The second mechanism focuses on the idea that elaboration creates distinctive associations (Craik and Jacoby 1979). This approach assumes that cues are more effective when they have unique associations to to-be-remembered information. Thus, elaboration can enhance retrieval by creating distinctive or unique cues. For example, if 'xylophone' is part of a to-be-remembered list, the elaboration 'a musical instrument beginning with x' should enhance performance more than the elaboration 'a word containing many vowels.'

This focus on distinctiveness has been used to explain the standard levels-of-processing effect (i.e., semantic > phonological > orthographic) by assuming that semantic cues are more distinctive than phonological or orthographic cues. Further, investigators working in this tradition have demonstrated that nonsemantic information can be well remembered if it is distinctive. For example, Hunt and Elliott (1980) have demonstrated that orthographic distinctiveness can enhance recall and recognition.

The preceding account of the effects of elaboration emphasizes the cue-dependent nature of memory. The availability and distinctiveness of cues are critical determinants of memory performance. This focus on cue dependence helps explain how powerful mnemonic devices such as hierarchical organization (Bower 1970) produce exceptional memory performance. In hierarchical organization, each cue is associated with a relatively small number of to-be-remembered items which, in turn, serve as cues for other items. Thus, the initial retrieval of a single cue at the top of a hierarchical organization can permit access to a large amount of information. Consistent with this view, hierarchical organization has been implicated in the exceptional performance of many mnemonists (e.g., Chase and Simon 1973).

5. *Applications of the Elaboration Construct*

5.1 *Interactions with Populations*

Difficulties in using elaborations have been proposed as explanations of differences in memory performance across populations. Most notably, difficulties in using elaborations have been proposed to explain why both young children and older adults have poor memories. Consistent with this account, studies of young children have demonstrated that young children are much less likely to create spontaneously elaborations than older children. For example, Barnes et al. (1996) demonstrated that six-year olds were less likely to construct elaborations about a text than 15-year olds, even when the two groups of subjects were equated on prior knowledge of the text. Similar arguments have been applied to explain the memory deficits of older adults. In addition, it has been proposed that the elaborations produced by older adults are more idiosyncratic than those produced by younger adults. These idiosyncratic elaborations are unlikely to be effective cues when they are retrieved during a later test. Consistent with this view, Zabrucky and Moore (1995) demonstrated that elaborations of text generated by older adults were less likely to be related to the text (i.e., more idiosyncratic) than the elaborations generated by younger adults. Further, the number of idiosyncratic elaborations generated was negatively correlated with recall and accounted for much of the variance in recall performance across older and younger subjects.

Additional evidence that deficits in elaboration produce the memory problems demonstrated by young children and older adults is found in studies manipulating elaborative processing. These studies demonstrate that manipulations designed to increase elaboration minimize the memory deficits demonstrated by younger children and older adults. For example, Cherry et al. (1993) demonstrated that asking older adults to create elaborations that focused on explaining a text minimized age differences in recall, even though such differences occurred in a control

condition in which participants were not directed to construct elaborations.

The elaboration construct has also been applied to the explanation of memory difficulties in a wide variety of patient populations (i.e., learning disabled, brain injured, and mentally retarded persons). As with younger children and older adults, it is assumed that these patients do not spontaneously or effectively use elaborations. In this context, numerous studies have demonstrated that teaching elaboration techniques to these patients enhances their learning and memory. For example, Scruggs et al. (1994) demonstrated that fourth and fifth graders with mild learning disabilities demonstrated a substantial benefit in text recall when encouraged to construct elaborations.

5.2 Interactions with Materials and Prior Knowledge

A large number of studies have investigated the interactions of elaborative processing with the nature of the to-be-learned materials and the participant's prior knowledge. These investigations help specify the conditions under which elaborations enhance memory. The semantic relatedness of to-be-learned materials is one of the most important determinants of memory with strongly related materials generally being remembered better than weakly related materials. Further, the effects of elaboration interact with those of semantic relatedness, so that elaborative processing produces a larger benefit for weakly related than strongly related materials, often equating overall memory performance on these materials. For example, Horiba (1996) examined recall of pairs of sentences that were either strongly or weakly related when participants were given elaboration or memorization instructions. Horiba found that strongly related sentences were remembered better than weakly related sentences under memorization instructions, but that elaboration produced a greater benefit for the weakly related sentences, equating performance on strongly and weakly related sentences. Explanations of such finding emphasize that elaborations occur spontaneously for strongly related materials, but not for weakly related materials. Consequently, elaborative instructions produce a greater benefit on weakly related materials.

This focus on the beneficial effects of elaborative processing for weakly related materials can be used to explain circumstances in which weakly related materials produce better memory than strongly related materials. For example, Erdfelder and Bredenkamp (1998) hypothesized that atypical events presented in text are better remembered than typical events because subjects must extensively elaborate the atypical events to produce a coherent mental representation of the text.

One assumption underlying the preceding account of the beneficial effects of elaboration on weakly related materials is that participants can retrieve the semantic information necessary to create the appropriate elaborations. This assumption suggests that participants' degree of prior knowledge should interact with the effects of elaborative processing. Consistent with this suggestion, numerous studies have demonstrated that elaborations produce greater memory benefits when participants have more extensive prior knowledge. Willoughby et al. (1993) demonstrated this finding by examining memory for facts learned about well-known and unfamiliar animals. They compared memory when subjects were asked to explain why a fact about an animal was true to memory in a repetition control condition. The elaboration condition produced greater memory relative to the control condition for familiar animals, but not for unfamiliar animals. The absence of an elaboration effect for unfamiliar animals is consistent with the view that prior knowledge is critical to the beneficial effects of elaborative processing.

These interactions of elaborative processing with the structure of materials and participants' prior knowledge play an important role in memory for, and comprehension of, text (Kintsch and Van Dijk 1978). While an extensive discussion of the text comprehension literature is beyond the scope of this article, there are two important parallels between the literature on text comprehension and memory that should be noted. First, consistent with the views derived from standard memory paradigms, elaborations of a text are assumed to have important effects on the memory representation of the text. Second, the issue of the materials and knowledge states that permit elaborations has been a topic of extensive study. One example that represents some of the issues arising in such investigations is Lea's research (Lea 1995) on inference generation. Lea demonstrated that subjects will use propositional logic (e.g., given p or q and not p, they will infer q) to generate elaborations about a text, even when such elaborations are not necessary to maintain a coherent text representation.

5.3 Interactions with Memory Tests

As discussed above, numerous studies have demonstrated that elaborating materials during study enhances performance in episodic memory tests. A large number of recent studies have examined the effects of elaboration on implicit memory tests. Implicit memory (Schacter 1987) demonstrates an influence of a prior episode that is independent of the participant's conscious awareness of that episode. Implicit memory tests generally attempt to show that performance on a task is enhanced by a prior episode even though participants are not necessarily consciously aware of the effect of the prior episode on their performance. Examples of such tests include perceptual identification and fragment completion. In perceptual identification, words are presented very briefly (e.g., for

33 ms) and participants are asked to identify them. Some of the items presented in the perceptual identification test are items that were presented in an earlier study episode and the test attempts to see if identification is better for these old items than for new items. Differences in perceptual identification between old and new items are generally referred to as 'priming.' The fragment completion test operates analogously to the perceptual identification test, except that, instead of rapid presentation, letters are deleted from the to-be-identified item.

Graf and Mandler (1984) hypothesized that elaborative processes affect explicit memory tests such as recognition and recall, but not implicit memory tests such as perceptual identification and fragment completion. Their rationale was that implicit memory tests are primarily sensitive to integrative processing of perceptual information. Assuming that elaborative processing occurs following item perception, one would not expect variations in elaborative processing to influence the integration of perceptual information.

The literature investigating these hypotheses has generated a complex pattern of results, with some manipulations of elaborative processing (e.g., levels-of-processing, Jacoby and Dallas 1981) producing no detectable effects on implicit memory and other manipulations of elaborative processing (e.g., generation, Masson and MacLeod 1992) demonstrating robust effects on implicit memory tests. Further, even in the cases where effects were not detectable in individual experiments, meta-analyses have demonstrated effects. For example, Jacoby and Dallas (1981) demonstrated that levels-of-processing produced no effect on perceptual identification. However, Brown and Mitchell (1994) demonstrated effects of levels-of-processing on perceptual identification in a meta-analysis. A final complication in this literature is that results demonstrating effects of elaborative processing on implicit memory tests may arise because explicit memory processes contaminate performance in the implicit memory test.

While the preceding summary demonstrates a literature in ferment, and one that has far from definitive conclusions, two hypotheses may help rationalize this complex pattern of results. First, it may be the case that the small effects demonstrated in meta-analyses arise from contamination by explicit memory processes. If this is the case, results such as those of Jacoby and Dallas (1981) support Graf and Mandler's original hypothesis that elaborative processing does not necessarily influence performance on implicit memory tests. Second, there may be some heterogeneity in the effects of different types of elaborative processing on implicit memory tests.

Thus, while the levels-of-processing manipulation used in the experiment of Jacoby and Dallas (1981) may not affect performance on implicit memory tests, the generation manipulation used by Masson and MacLeod (1992) may do so. Establishing such heterogeneity in types of elaborative processes would be consistent with cognitive psychology's tradition of differentiating types of encoding processes (see introductory sections).

6. *Conclusion*

The modern construct of elaboration arose from cognitive psychology's emphasis on intentional processing and information transformation—an emphasis reflected in filter models of attention and stage models of memory. Its specific genesis was in attempts to explain the congruity effect demonstrated in the levels-of-processing literature. Elaboration of the relation between an orienting question and to-be-recalled information was assumed to enhance performance, producing the congruity effect. Theoretical accounts of effects of elaboration have emphasized that the availability and distinctiveness of retrieval cues are critical to memory performance. The construct of elaboration has been widely applied with differences in the ability to create or use elaborations being proposed as explanations of differences in memory due to the effects of age, materials, participant's knowledge, and type of memory test.

E. Hirshman

Electoral Geography

Electoral geography provides a spatial perspective to the study of the organization, conduct, and outcome of elections, all of which are inherently geographical. It focuses on the nature of, and interactions among, four maps. There are two main input maps—the geography of votes for a party or candidate (itself in part a function of the geography of the social groups from which each draws its main support) is set within a geography of constituencies: their interactions produce the first output map—the geography of representation—that can be converted into a second output map, a geography of power.

This study of spatial aspects of elections is a small subfield within geography. No synthesizing text has appeared since 1979 (Taylor and Johnston 1979), although the subject matter studied has expanded substantially since (Johnston et al. 1998). Its main concerns are with: spatial variations in the support for parties and candidates, and in the campaigning for that support; the processes by which territorially-defined electoral constituencies are defined within different electoral systems; the geographies of representation which result from the pattern of votes across constituencies; and the geography of political power—of 'who gets what, where' because of politically- and electorally-influenced decisions on the location of public goods and services.

1. *The Geography of Votes*

The classic works on the geography of votes include several by André Siegfried, who pioneered *géographie électorale*. He drew cartographic correlations between patterns of party support and the physical, social, and economic landscapes, sophisticatedly linking environment to voting through agrarian systems, land ownership, and rural social stratification and tradition, demonstrating that social factors underpinning party support have environmental foundations. Support for parties in the Ardèche during the Third Republic (1871–1940) reflected variations not only in geology and relief, but also in agricultural activities and the distribution of industry: parties obtained their support in different sociospatial milieux (Siegfried 1949; see also Dogan 1967 and the volumes edited by Lacoste 1986, follow the Siegfried tradition).

Siegfried showed substantial continuity in the Ardèche's geography of votes throughout the Third Republic, as did another seminal work (Key 1955). Consistent geographies of support reflect stable electoral cleavages, with parties sustained within the same milieux over sequences of elections. Those cleavages are broken occasionally, either temporarily, producing a deviating election from the normal sequence, or permanently, whereby one or more elections is

critical in the realignment from one cleavage to another. Changed cleavage structures are reflected in changing geographies of support.

The concept of electoral cleavage was broadened in Lipset and Rokkan's (1967) identification of those characterizing most European countries. Two—between subject and dominant cultures (the core-periphery cleavage) and between churches and secular interest groups (the church vs. state cleavage)—followed the national revolution from the seventeenth century onwards, whereas those between the primary and the secondary economy (the urban–rural or town–country cleavage) and employers and workers (the class cleavage)—were products of the industrial revolution. The class cleavage occurs in nearly all European countries but the others' relative strength reflects local history and culture; understanding a country's geography of votes involves mapping its cleavage structures and exploring how parties mobilise support in different social milieux and places.

Key's theory underpinned studies of American electoral mosaics, notably Archer and Taylor's (1981) detailed analysis of the changing geography of support for American Presidential candidates, which they related to the geography of the country's political economy. Shelley et al. (1996) linked maps of support for presidential candidates and for parties at Congressional elections to the geographies of various interest groups and of policy outcomes (such as support for various policies in the House of Representatives from different parts of the country).

1.1 Local Variations Within Cleavage Structures

The cleavage model suggests that the geography of votes at an election can be 'read-off' from the geography of the cleavage structure(s): if the class cleavage dominates, for example, knowledge of each area's class structure should successfully predict spatial variations in each party's support. This was widely assumed in Great Britain: Butler and Stokes' (1969, 1974) classic study identified considerable uniformity across the country in both voting at individual elections (though with some variations, such as differences in working-class voting between resort towns and mining areas) and interelection shifts in support between parties—the so-called 'uniform swing.'

These assumptions were challenged by geographical work showing that the cleavage and uniform swing models could not account for changing geographies of support. People in the same class position voted differently in different parts of Great Britain (Johnston 1985) and interparty, interelection swings also varied spatially (Johnston 1983). Parties performed even better than the cleavage model suggested where their class base was strong; the geography of support was spatially more polarised than the geography of cleavages. (These findings were contested by some who believe that all spatial variations can be accounted for by the characteristics of individual voters: McAllister and Studlar 1992, Johnston and Pattie 1998).

One major reason for this polarization has been identified in geographical studies. As class dealignment advanced after 1960 and cleavages became less deep-seated in British culture, short-term economic factors increasingly influenced voting decisions. American work on 'economic voting' (Lewis-Beck 1988) shows people influenced by their perceptions of the economic situation: they reward governments which deliver prosperity, and punish those which do not. Such retrospective voting may be either egocentric (people who are prospering individually vote to re-elect governments) or sociotropic (people vote to reward governments that deliver national prosperity, but punish those blamed for economic difficulties). Alternatively, economic voting decisions may be prospective: voters support the party considered most likely to deliver future prosperity (national or personal).

Studies of the 1983 and 1987 British general elections suggested that economic voting accounted for the growing spatial polarization in support for the two main parties—the so-called north–south divide. Similar types of people in different areas perceived a different national economic situation and voted accordingly (Johnston et al. 1988)—the incumbent government performed better in the prospering 'south' than in the depressed 'north.' Pattie and Johnston (1995) introduced a third component to the retrospective voting model: as well as evaluating the government's record on the production of national and personal prosperity, voters also judged its economic performance against the state of their own region's economy.

1.2 Local Influences on Voting Decisions

Most voting decisions result from interactions, many indirect, between political parties and electors, which include local interactions that influence election outcomes. Key's (1949) book on elections where party cues were irrelevant provided a major stimulus; the Democratic party dominated politics in the southern US for nearly a century, and voters' main choices were among contenders for its nomination at primary contests. Many candidates performed best in their home areas, creating a 'friends and neighbors effect.' This was formalized by Reynolds (1969) and extended by Cox (1969): voting decisions are influenced by spatially-biased information flows—what Cox called the acquaintance-circle process—which generate not only support for local candidates but also more general 'neighborhood effects' whereby an area's majority opinion is accentuated if those initially favoring minority views are won over through a process of 'conversion by conversation.'

Results consistent with the neighborhood effect have been produced by studies using ecological data,

but their generating processes can only be inferred (Miller 1977, Eagles 1995a, 1995b)—hence Dunleavy's (1979) critique. The few process studies that have been undertaken (notably Huckfeldt and Sprague 1995) provide strong evidence that 'those who talk together vote together' (however, see Curtice 1995 and Pattie and Johnston 1999).

Study of neighborhood, or local contextual, effects has been extended by geographers interested in the specificity of particular places, especially their local cultures. Cox (1969) called this the forced-field process: a local political culture is established by parties and/or other interest groups (such as trades unions) and forms the basis for mobilizing the local electorate around either particular views on general issues or local issues. The resulting geography of votes may show some areas deviating significantly from wider trends, as in Cox's (1970) work on Wales. The approach was extended by Agnew's (1987) case studies from Scotland, Italy, and the US on mobilization within local milieux. He codified the processes involved through six claims (Agnew 1996):

(a) Class and community affiliations take on different meanings according to the nature of individual places within the spatial division of labor;

(b) Communication systems limit interaction across space in some situations, leading to separate networks within which politically relevant information flows and is interpreted;

(c) There are continuing tensions between local areas and their encompassing national states, which foster spatial variations in political mobilization;

(d) All cleavages—class, gender, race, age, etc.—have local as well as national histories within which the structuration of political movements occurs;

(e) Many political parties claim local roots and policy directions in their electoral manifestos, which can result in spatially-varying support; and

(f) The microgeography of everyday settings—home, work, leisure, etc.—can stimulate local distinctiveness that is reflected in voting patterns.

1.3 Local Campaigns and Election Outcomes

Mobilizing support in communities is particularly active during the campaign period preceding an election. Although national and regional media are used widely, local campaigns are crucial for disseminating information about candidates and canvassing support and turnout. This requires expenditure, and the more that candidates spend in their constituencies the better their performance (Jacobson 1980, Johnston 1987, Pattie et al. 1995); spending is a good surrogate for other aspects of local campaigning, demonstrating that the more intensive a party's campaign in a place, the better its relative performance (Denver and Hands 1997)—including campaigns for tactical votes to unseat an unpopular incumbent (Johnston et al. 1988).

2. The Geography of Constituency Definition

Almost all electoral systems allocate (at least some) legislative seats by territorially-defined constituencies. Definition of constituency boundaries is crucial: victory or defeat can depend upon a constituency's voters' characteristics.

Interest in constituency definition developed during the US 1960s 'redistricting (or reapportionment) revolution' (Baker 1966). Two 'abuses' were practiced widely where parties controlled redistricting: malapportionment, whereby constituencies with widely differing populations were created—parties maximized their returns (the ratio of seats to votes) by having small constituencies where they were strong but large ones in their opponents' heartlands; and gerrymandering, whereby parties delimited constituencies, whatever their size, so that their supporters were in a majority in as many as possible (Morrill 1973, 1981). Malapportionment was outlawed by the Supreme Court in the 1960s and strict equality criteria were set. Gerrymandering was considered much harder to tackle, because of difficulties proving intent to discriminate against those minorities protected under the Fourteenth Amendment, used in most of the relevant cases (Grofman 1990); the *Voting Rights Act 1965* and its successors provided a basis for challenging maps which apparently discriminated against black voters, although the Courts have been inconsistent in their rulings (Grofman 1998). Redistricting is largely nonpartisan in its conduct elsewhere, but parties in the UK influence the details to their own electoral benefit (Rossiter et al. 1999).

Defining constituencies, using smaller areas as building blocks, exemplifies the modifiable area unit problem well-known in spatial statistics. Gudgin and Taylor (1979) developed a sophisticated theory of the process which they linked to the production of electoral bias—both intentional, through explicit malapportionment and gerrymandering strategies, and unintentional, through nonpartisan procedures with outcomes consistent with those strategies: other geographical factors are important bias generators, such as district size effects (Taagepera and Shugart 1989). Bias identification has been extended using Brookes's (1960) index, subdivided into six components, all spatial (Johnston et al. 1999, Rossiter et al. 1999).

3. The Geography of Representation and the Geography of Power

Relatively little has been done on the second pair of maps: electoral geographers have concentrated on the inputs to electoral systems rather than their outputs.

Studies of the geography of representation focus on the translation of votes into seats, especially under the first-past-the-post electoral system. A party's representation is spatially more polarized than its support

among the electorate in many cases, as in the UK during the 1980s (Johnston et al. 1988): such 'geographical divisiveness' was presented as a major rationale for reforming the country's electoral system (Jenkins 1998).

Spatial polarization of representation may be reflected in the geography of public policy, with governing parties favoring areas they draw legislators from. Shelley et al. (1996) illustrated this for the US where the allocation of some public goods involves pork-barreling: individual Representatives and Senators use their positions on Congressional Committees to win benefits for their constituencies (Johnston 1980, Stein and Bickers 1995).

4. Conclusions

Elections are based on geographies. Electoral geographers stress the importance of the creation and interaction of the geography of votes and the geography of constituencies, for which they have developed novel analytical procedures (such as: Archer and Taylor's (1981) adaptation of factor analysis for identifying electoral continuity and critical elections; Rossiter and Johnston's (1981) computer simulation of the UK redistricting procedure; Johnston and Hay's (1982) adaptation of entropy-maximizing methods to estimate detailed voting patterns at various spatial scales; Jones et al's. (1992) multilevel modeling of voting patterns at scales from the individual upwards; and Johnston et al's. (1999) extension of Brooke's algebra for estimating biases in election outcomes). They have shown that the map of votes cannot be 'read off' from a map of cleavages but must take account of other influences on voting decisions, many of which (such as the friends and neighbors effect, the neighborhood effect, the pattern of local culture, and the geography of campaign mobilization) involve processes that are differentiated geographically. These interact with the geography of constituencies to produce electoral outcomes that frequently are biased towards one party, and which in turn produce geographies of representation within which geographies of policy implementation are inscribed.

Electoral Systems

An electoral system is a set of rules governing an election. The study of electoral systems has tended to be restricted in a number of respects. First, most research focuses on elections to legislative assemblies and to political executives, even though, of course, many nongovernmental agencies also hold elections as the means of filling various offices. Second, many issues of central concern in the study of electoral systems—such as paradoxes emanating from the application of particular voting rules—are usually studied within the 'theory of voting' branch of rational choice analysis; in some respects, therefore the study of electoral system can be understood as more of an 'applied' social science, while the 'theory of voting' is 'pure' theory.

1. *Elements of Electoral Systems*

Following Rae (1971), many scholars distinguish between three main elements of an electoral system: ballot structure, constituency structure, and the electoral formula.

1.1 *Ballot Structure*

There are several different ways in which this can vary, including:

(a) The number of votes each voter is permitted. In some systems the voter casts as many votes as there are positions to be filled (e.g., plurality systems with multimember constituencies—as employed in many state legislatures in the USA before the 1960s); in others, voters may cast only one vote irrespective of how many positions are being filled (e.g., the Single Non-Transferable Vote system used in Japan before 1994).

(b) The kind of information the voter can reveal in voting. Some systems permit two different kinds of vote to be cast; for example, in the German Additional Member System (AMS) the voter votes for a party candidate in a constituency, as well as for a party for

the party list component of the ballot. In many versions of party list systems the voter can reveal both which party they prefer, and which of that party's candidates they prefer. Again, by combining two separate elections, a system may make it possible for voters to reveal extra information about their preferences. For example, in Israel since 1996, voters reveal not merely which party they prefer, but also which party they wish to form the government: the Israeli voter can vote both for a party in the election for the legislature, and for a particular candidate to be prime Minister following that election. Furthermore, in some systems, voters can reveal only their first preference (whether for a party or a candidate), while in others they can provide a rank ordering of the different parties (or candidates); the plurality system used in British parliamentary elections is an example of the former, while the Single Transferable Vote (STV) employed in the Republic of Ireland is an example of the latter. Finally, some electoral systems limit the expression of voter preference to those candidates or parties listed on the ballot, while others allow the 'writing in' of names not on the ballot, or allow the voter to register opposition to all those listed on the ballot by voting for 'none of the listed candidates.'

(c) Whether the ballot is open or secret. In the twentieth century it has become the norm for national elections to be contested under a secret ballot, but until the late nineteenth century balloting was a public act. In the USA, parties in the nineteenth century printed their own ballot papers, and in several states the parties used different colors of paper for the ballot so they could tell who had voted for them. Whether the ballot should be secret or not was a major controversy in nineteenth-century political debates, and some of those who advocated an extensive franchise (e.g., John Stuart Mill) still favored an open ballot.

1.2 Constituency Structure

There are three main ways in which electoral systems vary in this regard.

(a) The election can be conducted on an 'at large' basis, or an election can be held in each of several constituencies. Generally, though with some exceptions, 'at large' elections are held only in smaller territories and when a proportional mechanism is used to allocate seats in an assembly (e.g., The Netherlands). Most national and subnational assembly elections are divided into constituencies.

(b) Whether the constituencies are organized on a territorial or some other basis. Although there have been debates about the desirability of a functional, rather than a territorial, basis for representation, most electoral systems use the latter. The odd exceptions include the 'university seats' of the British Parliament that were abolished before the 1950 election. Any territorial subdivision of a polity involves the drawing of boundaries for the constituencies, and how the boundaries are drawn may affect the overall election result. This issue becomes most significant in systems using nonproportional means for allocating seats, but it is still an issue in those using proportional mechanisms.

(c) Whether the constituencies are single-member or multimember. Systems that employ proportional means for allocating seats in an assembly have to use multimember systems, as does the SNTV; other systems do not. Generally, polities using the plurality system for allocating seats have moved towards the exclusive use of single-member constituencies during the twentieth century.

1.3 Electoral Formula

This is the way in which votes are connected to the office(s) being contested—in an assembly it is those rules governing how votes are translated into seats. There are three main kinds of formulae:

(a) *Majoritarian*. Under these systems, the winning candidate or party must obtain more than 50 percent of the vote. The two most commonly used means for achieving this are the Alternative Vote System (AV), and the double Ballot System (DB). The AV, which is used in Australia, involves voters showing their second, and subsequent, preferences on the ballot form; when no candidate obtains more than 50 percent of the vote, the lowest-placed candidate is eliminated and his/her voters have their second-choice votes counted. This process continues until one candidate attains more than 50 percent of the vote. The DB requires a second election to be held in all constituencies in which no candidate obtains more than 50 percent of the vote; this second contest includes only the two leading candidates from the first election.

(b) *Plurality*. Here the candidate(s) with the largest number of votes wins. In relation simply to its electoral formula, the SNTV system is merely a plurality system; however, its very different ballot structure—voters having only one vote each in multimember constituencies—mean that it is a radically different system in its operation.

(c) *Proportionality*. This formula attempts to provide a 'fit' between the share of the votes that the candidates or parties obtain, and the share of the seats the parties get in the assembly. There are two main devices for achieving this. One is to use a formula, of which there are a number of variants including d'Hondt and St. Lagüe, that distributes seats to parties on the basis of their share of the vote. The other method is to permit voters to rank-order all candidates, and to redistribute the 'wasted votes' of those candidates who have more votes than they need to get elected; that, broadly speaking, is the basis of STV. Disproportionalities in supposedly proportional systems can occur for three main reasons:

(i) the ways in which electoral boundaries are drawn, if the system is divided into constituencies, thereby giving an advantage to particular parties;

(ii) relatively small district magnitude—that is, a small number of seats being contested in each constituency; the fewer the seats in each constituency, the more likely it is that, in aggregate the allocation of seats between parties will diverge from the distribution of total votes. (STV has to be employed in conjunction with relatively small district magnitude; it becomes unwieldy with large district magnitude because of the complexities involved in expressing preferences between a large number of candidates.); and

(iii) in party-list systems, through the use of thresholds which require that parties failing to secure a minimum share of the vote will fail to win any seats at all. A threshold of between 2 and 3 percent of the total vote usually reduces the number of parties represented in a legislature quite dramatically, while a threshold of 5 percent (as used in Germany) restricts seriously the number of parties represented.

2. *Classification of Electoral Systems*

There are a very large number of possible electoral systems, including many hybrids of the most common types. (An example of such a hybrid is the system used for the French National Assembly, which is a variant of the DB; a second ballot is used, but it is not confined to the two leading candidates from the first ballot. Instead, any candidate with more than 12.5 percent of the vote is permitted, but not required, to take part in the second ballot.) Given this large variety, considerable attention has been given to classifying the main types of system. It is widely agreed that the main distinction is between 'proportional' systems and other types, but there is some disagreement on two matters.

The first is whether the principal division is a bifurcation between 'proportional' and 'non-proportional' systems, or whether a more complex main division is appropriate. The second disagreement concerns how to treat a variety of electoral systems that are sometimes grouped together under the heading 'semiproportional'; these include the SNTV and the Cumulative Vote (CV). (The latter is a system used in Illinois for many years that, in a three-member constituency would give three votes to each voter but would allow the voter to give all three votes to one candidates, give two votes to one candidate and one to another, or to give a single vote to each of three candidates.) Sartori (1994), for example, argues in favour of treating the SNTV as a form of proportional representation (PR), but most scholars do not do so.

The most common classification is to distinguish between those systems that have mechanisms for generating proportional results that are internal to the systems themselves, and which do not depend for their proportionality on the behavior or strategies of voters or candidates, from those that do not.

2.1 *Proportional Electoral Systems*

Within the class of proportional systems there are two main variants—the *party-list* and the *STV* systems, and within the party-list subclass there are four main sub-subclasses:

2.1.1 *Party-list*

(a) *Pure party-list*. In these systems the order of the party's candidates on the list, and hence their likelihood of being elected, is determined exclusively by the party. The voter can vote only for a party and not for a candidate. (Such systems are relatively uncommon, but this system is used in Israel and was used in France in 1945–6, and in a slightly less pure form during the rest of the fourth Republic.)

(b) *Voter-choice from party-list*. These systems allow the voter to express a choice between candidates on the party-list, though great variations in the procedures are evident. In some systems it is actually difficult for voters to propel a popular candidate from a low position on the list to a higher one; in other systems it is much easier to do so. These types of system are the most common form of the party-list, having been used in many European countries.

(c) *Mixed systems*. The AMS is the principal variant of this type. A proportion of the seats (sometimes one half) are contested in single-member constituencies under plurality voting. The remaining seats are contested using a party-list, and the allocation of seats from the party-list is used so as to correct for any disproportionalities resulting from the elections in the constituencies. This type of system, which is used in Germany and New Zealand, produces election results that are rather similar to those that would occur under other party list systems.

(d) *Panachage*. Used in Switzerland, this system permits voter choice between candidates of more than one party. Some experts argue that it is not really a form of party-list system because of this rule, although its operation more closely resembles such systems than any other types.

2.1.2 *STV*

Unlike party-list systems, STV achieves proportionality in the distribution of seats in a legislature through a mechanism that allocates seats to particular candidates. A party acquires seats through given candidates of theirs receiving sufficient votes to win seats, rather than the parties being allocated votes through a formula that distributes seats directly to the parties.

2.2 *Nonproportional Electoral Systems*

Among the nonproportional systems, there are three main subclasses:

(a) *Plurality*. The first-past-the-post system has been used in many Anglo-Saxon democracies, and it is still the system used in Canada, and most of the USA, as well as for elections to the UK Parliament.

(b) *Majoritarian*. The most common variants of systems requiring the winning candidate (or party) to win more than 50 percent of the vote are the AV and DB. Outside national elections, there are some majoritarian systems that require the winning candidate to receive more than 50 percent of the vote—one example being the Democratic National Convention which, until the 1930s, required that the nominee for the presidency receive two-thirds of the delegates' votes. Since such systems can produce many rounds of balloting and still fail to produce a result, they are wholly unsuitable for elections at which electors cannot interact personally with each other in an effort to achieve a definite result.

(c) *Semi-proportional*. This is a subclass containing several rather different kinds of system, including the CV, SNTV and the Limited Vote (LV). The last is rather similar to the SNTV in that there are multi-member constituencies, but, whereas in SNTV voters have only one vote, under LV they have more than one vote, but fewer votes than there are seats being contested. It is employed for some seats in the Spanish Senate, and was used in a few urban constituencies in Britain between 1867 and 1883. Semiproportional systems acquire their (rather misleading) name from the fact that they tend to generate greater representation for smaller parties than does the plurality system. However, the objection to classifying them as a form of proportional system is not that they tend to produce disproportional results—though in fact they do tend to do so—but rather that how proportional they are depends on the particular behaviour of voters and parties. In some situations they may not be proportional at all. By contrast, proportional systems are designed to generate a degree of proportionality.

3. *Consequences of Electoral Systems*

Public and academic interest in electoral systems tends to be much greater when the franchise is being extended (as in Britain in the 1860s), or new legislative assemblies are introduced (Britain in the 1990s) when democratic regimes have collapsed or are unstable (Europe from the 1920 to the 1950s), and when regimes are democratizing (Eastern Europe in the 1990s), or redemocratizing (Latin America in the 1980s and 1990s). One of the main focal points of attention is the likely consequences that one form of electoral system will have compared with others.

In the 1950s, and in light of the experience of collapsed democracies in the interwar years and with the potentially unstable regimes in postwar France and Italy, Duverger (1959) propounded an argument that has come to be known as Duverger's Law: 'the simple-majority single ballot system favours the two-party system'. He also argued that PR tended to be associated with multipartism. His argument was often linked to the widely held view in Britain and the USA at that time that PR was responsible for unstable governments with multiparty systems, of the kind found in the fourth Republic, whereas plurality systems were a recipe for stable two-party democratic government.

Since Duverger's Law was first propounded it has had its critics, and at the time of writing many political scientists would point to its limitations. It does not apply when there are strong regional cleavages, for example; they also reject the popular view that PR was causally responsible for unstable government. That view does not fit well with the evidence: most European countries since 1945 have used some form of PR, and most have had multiparty systems and coalition governments, yet most have not had unstable regimes. Although there are some exceptions, notably Sartori (1994), many political scientists now argue that the electoral system has only a limited effect on a regime's party system, and hence on its potential for instability. Increases in the number of parties in a system, for instance, tend not to follow the introduction of PR, but rather tend to precede it; moreover, the timing of the introduction of PR is significant in relation to whether party fragmentation will occur. An early switch to PR following democratization does tend to produce fragmentation—because the larger parties have had limited opportunities to develop loyal electorates. A switch much later does not lead to fragmentation, because the established parties now have loyal electorates who are not likely to defect to new or small parties.

Nevertheless, the precise form of electoral system used can have an impact on election results: changing the rules does change the political game. For example, the switch from plurality voting to AV in British Columbia in the early 1950s probably did prevent the socialist CCF party from gaining power in that decade. Similarly, the switch to PR from DB for the 1986 Assembly elections in France helped to minimize the Socialists' losses and to establish the National Front as a credible party that could win seats in the Assembly. Electoral systems cannot transform the social bases of electoral politics, but they can make it more likely that some parties will win office, or share power in government, and make it less likely that others will do so. For that reason, politicians are tempted sometimes to change them. For the most part, though, they are not changed frequently—partly because those in office are the people who usually benefit from the working of the existing system, and partly because the full consequences will be unknown, and hence might actually run counter to the interests of those seeking change.

Electrical Stimulation of the Brain

Direct electrical stimulation of brain tissue, in both animals and humans, has proven over more than a century of experimentation to be a truly powerful tool for revealing functional relations between brain and behavior as well as connections within the brain. Various sorts of current have been delivered through electrodes that are either applied acutely to localized brain regions or chronically implanted deep within the brain or on its surface. This article will describe experimental studies that have used animal models in laboratory settings, and clinical studies in which human patients have received electrical stimulation of the brain (ESB) in order to observe its effects, including especially possible therapeutic effects.

1. *Brain Stimulation and the Elicitation of Motor Responses*

In the late nineteenth century, pioneering experiments mapped motor functions of mammalian cerebral cortex using ESB (e.g., Fritsch and Hitzig 1870). These investigators, using dogs, were able to elicit discrete motor responses of specific muscles and muscle groups by applying brief electrical stimuli directly upon the exposed cortical surface. These studies laid the empirical foundation for our current understanding of topographic motor maps on the brain's surface; later work filled in the outline provided by these early investigations. Central concepts began to emerge that eventually shaped current thinking about brain function and guided much later research. These include the notion of functional localization within brain structures, an idea originally set forth in the pseudoscientific ideas of phrenology. With the contributions of Fritsch and Hitzig (and others), however, a valid basis was afforded for specific types of localization. Not only was the frontal region of mammalian cortex recognized as a major source of neural output controlling responses of the striate musculature, but this region was observed to contain a map which was topographic in nature; that is, adjacent muscle groups are represented in adjacent groups of neurons. Furthermore the principles of both proportional and contralateral representation became apparent. Muscle groups capable of relatively finely calibrated, skilled movements (e.g., digital and some facial muscles) are represented by very much larger populations of neurons than muscles capable only of grosser movements, so that there is a topological distortion within the topographical map (proportional representation); also, cortical motor neurons in each of the brain's hemispheres exert their influence over muscles on the opposite side of the body (contralateral representation).

2. *Brain Stimulation and Perceptual Prostheses*

Analogous concepts have been developed for the cortical representation of somatosensory responses originating at the skin: topographical maps exist on each cortical hemisphere representing the contralateral side of the body's surface, with topological distortions similar to those of motor cortex, but corresponding instead to differences in sensory acuity, with the digits and some facial areas over-represented in terms of quantity of neural tissue involved. The somatosensory maps have been localized to the central and posterior parts of the cortex (in humans, the parietal lobe). Auditory and visual maps have also been studied in detail; the two halves of the visual field (left and right), for instance, are mapped onto the contralateral cortical hemispheres in the most posterior part of the cortex (in humans, the occipital lobe). Although multiple maps exist, the principle of proportional representation is clearly evident in the primary map, where the areas of greatest acuity (at and near the fixation point) are greatly over-represented compared to peripheral parts of the visual field.

Since it is widely accepted that all sensory responses are due to some unique pattern of electrical activity in the corresponding sensory cortex, it has been evident for some time that, in theory at least, an appropriate pattern of ESB within any sensory region of cortex might be arranged to mimic any specific normal, exteroceptive pattern of sensory stimuli in the corresponding modality. The possibility thus exists of developing prostheses for artificial vision or hearing,

for example, using brain stimulation to evoke perceptual responses in persons lacking functional peripheral receptors or even sensory nerves.

Considerable exploratory work has been done on these problems, although practical prostheses based on ESB are not at the moment close to realization. A promising approach developed recently involves the implantation of relatively large (30–100) arrays of microelectrodes arranged to deliver ESB to the auditory or visual parts of cortex. For instance, cats trained to lever-press to an external auditory stimulus will respond similarly to very modest levels of ESB delivered over an array of microelectrodes implanted within auditory cortex (Rousche and Normann 1999); furthermore, patients with profound or total bilateral hearing loss may receive acoustic information through stimulation of electrodes implanted in the auditory regions of the brainstem (Laszig and Aschendorff 1999). By the same token, visual responses have been demonstrated in a blind patient receiving intracortical ESB over an array of electrodes implanted in the occipital lobe (Schmidt et al. 1996).

3. *Brain Stimulation and Associative Learning*

Since the 1980s a major neuronal network has been delineated, responsible for much of what memory theorists call 'procedural learning' (e.g., Thompson and Kim 1996). The elements of this network specifically responsible for plasticity and associative learning are located within the cerebellum, and include the mossy and climbing fiber systems afferent to (providing information for) intracerebellar structures; the cerebellar cortex, especially its Purkinje cells and their inputs and output; and the deep cerebellar nuclei, especially the anterior interpositus nucleus. A useful model that has frequently been used to study this network is the classical conditioning of eyeblink and other discrete motor responses in the rabbit: a neutral or conditioned stimulus, the CS, which does not initially elicit a response, is paired repeatedly with an eyeblink eliciting stimulus (the unconditioned stimulus or US), usually a brief airpuff delivered to the cornea. After 100–200 trials the CS acquires the property of eliciting the eyeblink (associative learning or acquisition). If the rabbit is subsequently exposed to repeated CS presentations in the absence of the US, the conditioned response weakens and eventually disappears, in a process referred to as extinction. An appealing feature of this preparation involves the similarities seen here between human and animal learning. The form of the response, the curves of both learning and extinction, and certain more detailed aspects such the timing of the response within each trial and the changes in timing that are seen as conditioning proceeds, are all quite similar when comparing rabbits and humans. It is generally accepted that this particular form of conditioning, which is simple and readily adapted for well-controlled laboratory studies, shares many features with human learning of motor skills, including both simple and complex motor learning and performance.

Validation of the role of these cerebellar network elements and circuits in associative learning has involved the application of numerous neurobiological approaches in both animals and humans. The use of ESB to selectively activate the specific cerebellar neuronal networks involved in procedural learning has been particularly fruitful (e.g., Thompson et al. 2000). The earliest use of brain stimulation to demonstrate the direct involvement of the cerebellum in learning was reported by Brogden and Gantt, who showed that a variety of motor responses, including eyelid closure, forelimb and hindlimb flexion, head turn, and pinna movement elicited by electrical stimulation of cerebellar white matter (chiefly in lobule HVI) were readily conditioned to auditory and visual CSs, using conventional stimulus pairing procedures of classical (Pavlovian) conditioning (Brogden and Gantt 1937, 1942). Recent experiments have been aimed at identifying and characterizing more closely the relevant pathways, using electrical microstimulation delivered over chronically implanted semi-microelectrodes in the awake, behaving rabbit during conditioning. For instance, ESB of the inferior olive, which elicits specific motor responses, substitutes effectively for the unconditioned stimulus when paired with a CS in classical conditioning, thereby lending support to the role of olivary efferent pathways (climbing fibers) in providing information about the unconditioned stimulus. By the same token, studies of the conditioned stimulus pathway have established that ESB delivered to either the pontine nuclei or the middle cerebellar peduncle, activating the mossy fiber projections to cerebellum, serves the same function as the tone that has long been used in conventional eyeblink classical conditioning. Steinmetz et al. (1989) combined these effects in a single preparation, and showed that conditioning is reliably obtained using pontine ESB as the CS and olivary ESB as the US, dispensing altogether with exteroceptive stimulation.

In subsequent experiments associative learning has been shown in a preparation in which both CS and US are delivered directly to, and confined within, the cerebellum. Four chronic stimulating electrodes are implanted in rabbit cerebellum, one bipolar pair in cerebellar cortex, providing an electrical CS activating cortical parallel fibers and thence Purkinje cells, and another bipolar pair in underlying white matter of lobule HVI, delivering an electrical US that elicits unconditioned responses. Paired CS–US presentations lead reliably to the development of conditioned responses; after conditioning is established, repeated presentations of the CS alone lead to extinction as in conventional conditioning. Also, increased local excitability is observed in cerebellar cortex following conditioning; that is, the threshold for eliciting

responses to ESB delivered over the CS electrode is significantly decreased after conditioned responding is well established. Pseudorandom unpaired presentation of CS and US does not produce any CRs, indicating that true associative learning, and not sensitization, is responsible for these results (Shinkman et al. 1996).

Furthermore, associative learning that is localized within the cerebellar cortex has been demonstrated in exploratory studies, discussed in Thompson et al. 2000). These investigators delivered ESB over a single bipolar electrode implanted in the Purkinje cell layer of cerebellar cortex and used this stimulation both as the CS (very low-level stimulation that does not elicit any response) and as the US (higher-level stimulation through the same electrode that reliably elicits a discrete unconditioned motor response). When paired CS–US trials are followed by CS-alone trials, in a paradigm formally identical to a standard classical conditioning protocol, both acquisition and extinction of conditioned responses is observed, and following conditioning there is increased local excitability in cerebellar cortex (the threshold for response elicitation decreases). The effects of highly localized blocking of neuronal activity have also been studied in this preparation, using intracerebellar injections of muscimol, a substance that reversibly inactivates the firing of neurons in the immediate vicinity of the injection. The expression of previously established conditioned responses is blocked by injection of muscimol into the region surrounding the electrodes, but occurs normally in the absence of muscimol. Because muscimol affects only neuronal cell bodies, and does not influence fibers of passage, it can safely be concluded that its presence has no remote effects other than those attributable to the lack of output from the region of inactivation. These results suggest that the observed plasticity involved in classical conditioning depends upon changes in the interaction between neuronal elements in cerebellar cortex, especially parallel fibers and Purkinje cells, and in the deep cerebellar nuclei.

4. *Brain Stimulation as Reward: 'Pleasure Centers' in the Brain*

In 1953 James Olds, a postdoctoral fellow at McGill University in Montreal, was studying behaviors elicited in rats by the application of ESB. He was using a relatively new technique in which stimulating electrodes are chronically implanted under surgical anesthesia so that stimuli can be delivered at specified locations in the brain while the subject is awake, relatively unencumbered, and engaging in ongoing behaviors. Although the focus of these experiments was on behaviors directly elicited by the stimulus, Olds had the remarkable insight, based upon some of his subjects' behaviors, that the stimulus was in some cases apparently rewarding (or, more technically, reinforcing) whatever behavior immediately preceded the application of the stimulus. That is, in B. F. Skinner's terminology, the stimulus was serving a 'reinforcing' rather than an 'eliciting' function. Olds quickly undertook a series of experiments to verify this intuition, and ascertained that in specific subcortical regions (e.g., lateral hypothalamus, septal area), ESB can exert powerful reinforcing effects (Olds and Milner 1954).

In terms of potency, the reinforcing effects of ESB delivered using appropriately placed electrodes far outweigh those of conventional (i.e., biological or adaptive) reinforcers. To establish that this was so, Olds unearthed a long-forgotten apparatus called the Columbia Obstruction Box, which had been used in the 1930s at Columbia University in an ill-conceived attempt to 'compare motives.' Rats were placed on a platform separated by an electrified grid from a goal. In the original experiments, the amount of footshock the subject would tolerate to reach the goal was compared for deprived rats responding for, e.g., water, food, or sex (the flaw here, of course, is that deprivation levels for different goals do not fall on the same metric). Nevertheless, levels of footshock absorbed by implanted rats to reach rewarding ESB far exceeded those for all other reinforcers, including the previously top-ranked one—access for a mother rat to her newborn pups.

An enormous literature on various aspects of this extraordinary finding emerged over subsequent decades. A particularly intriguing line of experimentation has linked rewarding ESB with the reinforcing properties of addictive substances such as cocaine and opiates. It has now been established that the rewarding effects of ESB may be augmented or potentiated in the presence of such substances. Indeed, it appears likely that addictive substances and rewarding ESB may both exert their reinforcing effects upon a variety of behaviors by activating the same neural circuits involved in the brain's response to conventional or natural reinforcers (e.g., Wise 1996).

5. *Brain Stimulation in Human Patients*

Electrical stimulation of the brain through chronically implanted electrodes, with the aim of alleviating various symptoms in human patients, has been used infrequently but to considerable effect since the 1950s. Early studies (e.g., Heath and Mickle 1960, Mark and Ervin 1970) focused on very severe affective disorders. In at least some patients, it was shown that symptoms including violent or inappropriately aggressive behavior could be triggered by stimulation of certain limbic structures, notably the amygdala, and abolished or prevented by ablation (removal) of these structures or by stimulation of regions (e.g., the septal area) whose activity is mutually antagonistic to amygdaloid excitation.

Recent studies have concerned a variety of other disorders, including conditions as diverse as Parkinson's disease, multiple sclerosis, intractable epilepsy, and chronic pain. It is now well established, for instance, that stimulation of certain parts of the human motor nervous system, collectively designated as the extrapyramidal system, can lead to dramatic improvement in the motor disorders experienced by patients suffering from Parkinson's disease. In this case the stimulation serves to functionally block the abnormal activity of these brain regions; although similar effects can be achieved by ablation, the use of ESB is clinically preferable (e.g., Montgomery 1999), because it is reversible, readily calibrated and adjusted, and may avoid such side effects as cognitive impairment.

While studies of the clinical efficacy of ESB in reducing or abolishing chronic pain have yielded conflicting results, the most common finding has been an impressive reduction of symptoms and a corresponding increase in patients' quality of life (e.g., Young et al. 1985). This particular application, like many others, has its origins in the animal experimental literature. It is interesting to note that some of the most effective electrode placements in human pain patients (e.g., brainstem periaqueductal and periventricular gray matter) correspond to regions where stimulation had been shown much earlier to be both rewarding and analgesia-producing in rats.

Newer stereotaxic techniques allow for guided, precise electrode placement; at the same time, advances in electrode technology permit the application of highly localized, parametrically controlled stimulation. It seems reasonable to expect that clinical applications for ESB will continue to expand, and that directions for such expansion will continue to be informed by basic experimentation on the effects of ESB in laboratory animals.

Electroencephalography: Basic Principles and Applications

1. Introduction

Electrodes placed upon the scalp record the integrated post-synaptic potentials generated by inhibitory as well as excitatory activity in the subjacent neuronal population. If this activity were distributed randomly in polarity and in time, the net surface potential would be zero. Correlative studies between the scalp and the pial surface have resulted in the estimate that about $6\,cm^2$ of cortex must be synchronously active in order for a net voltage deflection to be detected on the scalp. Thus, EEG potentials arise from highly nonrandom synchronized activity in very large neuronal assem-

blies. This coordination of discharge is mediated by cortical-cortical, cortico-thalamic and thalamo-cortical processes which, in view of the high degree of reciprocity in intra-cortical connections, may reflect some degree of reverberatory activity. Such synchronization of oscillatory discharges may involve electrotonic as well as trans-synaptic interactions.

Zero-phase synchronization of high frequency oscillations between anterior and posterior brain regions takes place shortly after presentation of sensory stimuli. Energetic contemporary research suggests that synchronization of high-frequency oscillatory activity among distant brain regions may play an important role in 'binding'—the integration of features of a complex stimuli, extracted by spatially separated 'feature detectors,' into a perceptual whole.

These aspects of brain organization and information processing are accessible from quantitative analyses of EEG recordings from the scalp. Usually, such recordings are obtained from an array of electrodes placed in accordance with the internationally standardized 10/20 Electrode Placement System and affixed to the scalp with paste. Data can be recorded from different numbers of electrode positions varying with the purpose of the study, but 19 channel recordings most commonly are used. Numerous economical and reliable EEG recording instruments are commercially available. While EEG machines initially recorded ink traces upon moving paper, present technology utilizes desktop computers for digital collection and storage of EEG data, so-called digital EEG or DEEG. Analysis usually is performed by computer after visual selection of artifact-free data.

These analyses usually utilize the Fast Fourier Transform (FFT) to quantify the amount of power at selected frequency intervals in the EEG from every recording channel to compute the power spectrum. Normative QEEG databases have been constructed for the power spectrum and the covariance matrix of spontaneous brain electrical activity. QEEG methods provide sensitive and precise measures for study of normal as well as abnormal brain functions.

2. *Neurophysiological Basis of the EEG*

An anatomically complex homeostatic system regulates the EEG power spectrum. Brainstem, thalamic, and cortical processes involving large neuronal populations mediate this regulation, utilizing all neurotransmitters. Some of the neuroanatomical interactions and neurochemical transmitters comprising this control system have been clarified by recent neurophysiological and neuropharmacological research (Llinas 1988, Lopes Da Silva 1996, McCormick 1992, Steriade et al. 1990). On the basis of such studies, it is believed that pacemaker neurons distributed throughout the thalamus normally oscillate synchronously. Efferent thalamo-cortical projections globally distributed across the cortex receiving cortico-thalamic feedback produce the rhythmic electrical activity known as the alpha rhythm (7.5–12.5 Hz), which dominates the EEG of an alert healthy person at rest and can be seen readily as the most prominent peak in the power spectrum. Nucleus reticularis can hyperpolarize the cell membranes of thalamic neurons by gamma-amino-butyric acid (GABA) release, slowing the dominant alpha rhythm into the lower theta range (3.5–7.5 Hz) and diminishing sensory throughput to the cortex. Slow delta activity (1.5–3.5 Hz) is believed to originate in oscillator neurons in deep cortical layers and in the thalamus, normally inhibited by input from the ascending reticular activating system in the midbrain. Activity in the beta band (12.5–20 Hz) is believed to reflect cortico-cortical and thalamo-cortical transactions related to specific information processing. Activity in the 20–60 Hz band is referred to as gamma, and recent studies have included so-called 'higher frequency' activity as high as 600 Hz. These very fast oscillations appear to arise from cortico-cortico transactions and geniculo-cortical projections.

Evidence is reviewed below to support the belief that a complex homeostatic system regulates the stability and predictability of the normal EEG and may be genetically specified. A circuit summarizing the hypothetical neuroanatomy and neurochemistry of the homeostatic system postulated to achieve regulation of the EEG power spectrum has been published (Hughes and John 1999), in accordance with the insights provided by the research cited above. Activation of the mesencephalic reticular formation (MRF) causes inhibition of nucleus reticularis by cholinergic and serotonergic mediation which releases the thalamic cells from inhibition by nucleus reticularis. The dominant activity of the EEG power spectrum becomes more rapid, with return of alpha activity and the higher frequency beta activity (12–20 Hz), and the flow of information through the thalamus to the cortex is facilitated. The cortex can activate n. reticularis directly by glutamatergic pathways to suppress the arrival of information to the cortical level and, by dopaminergic projections, the striatum can inhibit the MRF. Such inhibition of the MRF enables inhibition of thalamic neurons to occur and blocks the flow of sensory information through the thalamus to the cortex.

This model suggests that deficiencies or excesses of any of the neurotransmitters should produce marked departure from the homeostatically regulated normative EEG spectrum. Such neurotransmitter perturbations are widely believed to make decisive contributions to much psychiatric pathophysiology. Abundant documentation exists in the literature that demonstrates the sensitivity of QEEG to psychiatric disorders (for a review, see Hughes and John 1999).

Since this regulatory neurophysiological system is common to all humans, the EEG power spectrum can

reasonably be expected to be stable and characteristic for all healthy individuals, with high specificity reflecting their common genetic heritage. These measures can also be expected to be sensitive to many modulations of the resting brain state as well as to brain dysfunctions present in some developmental, neurological and psychiatric disorders. The data supports both of these expectations. A thorough review of the abundant such evidence is beyond the scope of this article; only illustrative examples will be cited.

3. Principles of QEEG

3.1 Normative Databases

The QEEG has been found to display remarkable stability and reproducibility among healthy, normally functioning individuals of any age, ethnic or cultural background (John and Prichep 1993). After proper editing to remove artifacts and transformations to achieve normal distributions and appropriate age-regression, the values of extracted QEEG measures referred to normative databases possess high predictability (Fein et al. 1983, Oken and Chiappa 1988). Test–retest replicability, both short- and long-term, has been shown to be extremely high (Kondacs and Szabo 1999).

3.2 Data Acquisition and Analysis

In QEEG, multichannel recordings (usually 19 electrodes at standardized positions) of eyes closed resting EEG are edited visually. An artifact-free sample, usually 1–2 min long, is analyzed using the FFT. The power at each frequency of the EEG is averaged across the entire sample, providing a Power Spectrum with very high test–retest replicability.

The bandwidth of interest has long been considered to extend from about 1–20 Hz. traditionally separated into four wide frequency bands, typically defined as Delta (1.5–3.5 Hz), Theta (3.5–7.5 Hz), Alpha (7.5–12.5 Hz), and Beta (12.5–20 Hz). More recently, the region of interest has been extended to include Gamma or 'high frequency activity,' with bands up to 100 Hz and beyond. Intracerebral as well as scalp recordings have related oscillatory activity at these high frequencies to cognition and information processing (Curio 2000).

4. Stability and Specificity of the EEG Power Spectrum—The Basis of QEEG

Confirmed reference databases provide reliable 'population norms,' thereby minimizing the need to collect control data. Comparison of individual QEEG results to such norms enables sensitive detection of developmental, neurological or psychiatric dysfunctions. Further, QEEG stability facilitates identification of transient brain activity related to temporary changes of brain state due to cognitive activity or other influences, by comparing sequential QEEG samples from the same person to each other or to a preceding 'self-norm.' QEEG studies using statistical evaluation of computer extracted features relative to population or self reference norms are often referred to as 'neurometric' studies (John et al. 1977, 1988). A major advantage of QEEG vs. all other contemporary brain imaging technologies is the unique availability of confirmed, ethnic fair, normative data that reduces or eliminates the need for separate control studies. The high specificity of QEEG is beyond the confidence level achieved by many routinely used clinical tests, such as mammograms, cervical screenings, or CT brain scans (Swets 1988). Further, the demonstrated high test–retest replicability provides potential simplification in repeated measure experimental designs.

Using analog methods, the eyes closed, resting EEG power spectra of large samples of healthy normally functioning individuals were found to show systematic changes, initially from ages 17–64 (Matousek et al. 1967), and then from ages 1–21 (Matousek and Petersen 1973). Using general purpose digital computers, not only were the systematic changes with age soon confirmed, but no significant differences were found between the age-regressed EEGs of normally-functioning Swedish children and white or black US children (John et al. 1980).

Normative data now exist from 1 to 95 years of age, for each electrode in the standardized International 10/20 System, for absolute power, relative power, mean frequency, coherence, and symmetry, as well as for covariance matrices which quantify inter-relationships among brain regions (John et al. 1988, John and Prichep 1993). These multivariate composite measures are unique to QEEG. Since cognitive processes as well as psychiatric disorders rarely engage focally localized brain activity, QEEG measures are, therefore, well suited to studies in these areas.

4.1 Independence from Cultural and Ethnic Influences

Soon after the initial demonstration of cross-cultural equivalence of normative data, normally functioning black children in Barbados were found to display the same values of the EEG power spectrum as the US and Swedish groups (Ahn et al. 1980). The independence of the normative QEEG descriptors from cultural and ethnic factors enables objective assessment of functional as well as anatomical brain integrity in persons of any age, origin, or background, repeatedly confirmed in studies from Barbados, China, Cuba, Germany, Holland, Japan, Korea, Mexico, Netherlands,

Sweden, US, and Venezuela (Ahn et al. 1980, Alvarez et al. 1987, Gasser et al. 1982, Harmony et al. 1987, Jonkman et al. 1985, Yingling et al. 1986, Diaz de Leon et al. 1988, Duffy et al. 1993, 1995, Matsuura et al. 1993, Oken and Chiappa 1988, Ritchlin et al. 1992, Valdes-Sosa et al. 1992, Veldhuizen et al. 1993).

5. *QEEG Sensitivity to Changes in Brain State*

The temporal resolution of state changes detectable by QEEG is far superior to that of any other modality except the magnetoencephalogram, or MEG. The very high short-term replicability provides excellent sensitivity to transient changes in brain state. Such changes can reflect allocation of brain resources to various cognitive, motor or perceptual tasks, or functional alterations imposed by some internal or external influences.

5.1 Detection of Brain Regions Engaged by Mental Activity

QEEG has been used extensively to detect brain regions engaged during performance of various activities. Studies performed shortly after discovery of the EEG (Berger 1937) found that during mental activity, dominant alpha waves were replaced by low voltage fast beta activity, termed 'desynchronization.' This phenomenon has been exploited in numerous studies of 'event-related desynchronization,' ERD, or event-related synchronization, ERS (Petsche 1990, Pfurtscheller 1992). Very narrow band QEEG analyses compare the power spectrum in a reference state to the power spectrum immediately after presentation of a sensory stimulus, imposition of a cognitive task, or onset of a change in the environment (e.g., hearing a musical composition). Differential ERD or ERS in various brain regions enables topographic maps to display the loci of significant state alterations correlated with the experimental procedures. The detected topography has, in some cases, been confirmed by other functional imaging techniques such as regional cerebral blood flow (rCBF). Other QEEG studies of cognitive processes have focused upon changes during cognitive tasks relative to the profile before initiating the task (Fernandez et al. 1995, Harmony et al. 1996).

One variation on this theme uses the strategy of labeling several attributes of a stimulus by presenting each aspect at a distinctive repetition or 'tracer' rate. By very narrow band analysis of the power spectrum of every recording derivation, the modulation of power at the tracer frequency in different brain regions provides a functional image of the particular brain regions engaged in the sequential steps required to process the stimulus dimensions labeled by each frequency (John et al. 1997). This technique recently has been adapted to MEG studies of binocular rivalry (Tononi and Edelman 1998).

Another productive variation has been to examine the changes in phase angles of oscillatory rhythms between brain regions, rather than changes in local power, as cognitive tasks are performed (Gevins et al. 1981). The logic of this approach is based upon the expectation that transmission from one cortical region to another will be reflected in the phase angle of some critical frequency between the interacting regions. Topographic maps based upon cortico-cortical delays among brain regions allow inferential construction of the sequence of steps in the information processing system used in a given task.

5.2 Adaptive Segmentation of Brain Fields

Evidence has been provided that the topographic fluctuation of brain voltage fields in real time is quantized into intervals during which the field is stable in one topography followed abruptly by a period of stability with a different topography, etc. These brief stable periods have been called microstates (Lehmann 1971). Computer classification methods have been applied to the field contours manifested during a prolonged observation and four prototypic field patterns have been identified (Pascual-Marqui et al. 1995). Evidence has been published that different modes of ideation characterize these different microstates (Strik and Lehmann 1993).

Normative data have been computed from large groups of healthy individuals from age 6 to 90 and show that the same four basic microstate modes exist across this representative age span, with average duration of about 80 milliseconds (Koenig et al. in press). This duration is approximately the same as that of a 'perceptual frame' (Efron 1967), which is the period during which sequential stimuli will be perceived as simultaneous. This similarity suggests that microstates may reflect the parsing of time into discontinuous brief samples which characterize subjective perception. Evidence has been provided that microstate duration is altered from this stable value in abnormal conditions such as ADHD, Alzheimer's disease, and schizophrenia (Lehmann 1994).

Using the mathematically very different approach of spatial principal component analysis (SPCA) based upon the covariance matrices across the 10/20 scalp array of electrodes, it has been found that over 90 percent of the variance of the spontaneous EEG and event related potentials can be accounted for by 4–5 SPCs in normally functioning individuals (Duffy et al. 1995, Easton and John in press). It is noteworthy that the topography of these SPCs closely corresponds to that of the prototypic microstates. These stable patterns of spatial covariance in the scalp EEG may reflect

the organization of the major functional neuroanatomical systems which represent global resources allocated as needed by the brain.

5.3 QEEG Assessment of the Depth of Anesthesia

Studying several hundred actual surgical procedures, a set of invariant reversible QEEG changes during loss and return of consciousness were found which were independent of the particular anesthetic agents used (John et al. 2001). These invariant changes were translated into multiple stepwise discriminant functions and embedded in a real-time monitor of the depth of anesthesia, called the Patient State Analyzer, or PSA (Physiometrix, Inc.). The PSA has received approval from the Food and Drug Administration (FDA) for routine use as an intraoperative monitor of the depth of anesthesia.

The successful development of a quantitative index for the level of consciousness gives evidence that QEEG is a technology with the potential of making powerful contributions to basic and applied psychological research into the relationships between brain and behavior.

6. Three-dimensional QEEG Source Localization Images

In the 1990s, mathematicians, physicists, and neurophysiologists devised numerous approaches to the problem of localizing the sources of scalp voltages within the depths of the brain. Some of these methods are now used to pinpoint neurosurgical targets in patients with intractable seizures. Perhaps the most promising approach to the inverse solution of distributed generator sources is low-resolution electromagnetic tomography (LORETA) (Pascual-Marqui et al. 1994). This method has been applied to the localization of intra-cranial epileptic foci and space-occupying lesions. Locations identified by LORETA correspond well to the actual location of the abnormalities as confirmed by subdural electrodes or during neurosurgery.
