Topographic mapping of QEEG data has been extended to QEEG tomography, or QEEG-T, using variable resolution electromagnetic tomography (VARETA) (Valdes-Sosa 1997). A standard probabilistic MRI atlas in Talairach space, constructed from more than 300 normal MRIs (Evans et al. 1993), was evaluated to constrain the hypothetical generators of the distributed inverse solution to voxels composed of gray matter. For 3500 voxels, age regressed voxel-normative data were calculated across the age range 5 to 97 years over spectra ranging from 0.39 to 19 Hz in 0.39 Hz intervals. Statistical probability tomographic images (SPTI) were then obtained by Z-transformation of each voxel of the raw VARETA image at each frequency, obtained from any individual subject, relative to the corresponding voxel-normative data. Spatial statistical methods evaluate deviations from the norms of anatomical regions of interest. Results are displayed on slices from the probabilistic MRI atlas with each voxel color-coded for statistical significance. A complete description of the VARETA method and the underlying mathematical basis has very recently been published (Bosch-Bayard et al. 2001).

The accuracy of this QEEG-T method has received excellent confirmation in MRI and neurosurgical studies of space-occupying lesions (Fernandez-Bouzas et al. 1999) and is routinely in use in our laboratories to study brain dysfunctions in psychiatric and neurological patients. It has been used recently to localize invariant QEEG correlates of the loss and return of consciousness during anesthesia (John et al. 2001) QEEG-T is an economical brain imaging technology which provides very high resolution of brain electrical activity in space and time, yielding statistically interpretable images. These features make the method an attractive competitor to functional brain imaging alternatives such as PET, fMRI and MEG, which are not only more expensive (all), lack normative data (all), require substantial time for image acquisition and therefore lack temporal resolution (PET, fMRI), or impose a radiation burden which limits repeated testing for safety reasons.

7. QEEG Sensitivity to Brain Dysfunctions in Psychopathology

A voluminous literature attests to the utility of the conventional EEG in neurological and psychiatric disorders, but test-retest reliability between as well as within clinical EEG practitioners is poor. QEEG supplements the EEGer's trained eye with literally many hundreds of reliable quantitative measures which can be computed automatically and can generate precise statistical comparisons of each of these numerous measures from an individual relative to databases of age-matched normal subjects or of patients having different diagnoses. A broad consensus exists across hundreds of EEG and QEEG studies on the high incidence and particular types of abnormalities found in different psychiatric disorders.

Replicated findings of QEEG abnormalities have been reported in cerebrovascular disease, degenerative dementias, major affective disorders, mood disorders, obsessive-compulsive disorder, schizophrenia, learning disabilities, attention deficit disorder with and without hyperactivity, and mild head injury. Discriminant functions have been developed and independently replicated which accurately classify patients into DSM categories, using QEEG profiles. Using cluster analysis based upon QEEG measures, in several DSM categories subtypes have been identified

within samples of patients homogeneous by diagnosis. Subtype membership correlated well with response to treatment or evolution of illness.

Space precludes detailed descriptions here of the abnormal QEEG features distinctive for each of these disorders (see *Recovery of Function, Neural Basis of*). More complete details have been published elsewhere (Hughes and John 1999). The evidence overwhelmingly shows that QEEG assessment provides a valuable adjunct to clinical diagnosis and treatment selection in behavioral, developmental, neurological, and psychiatric disorders.

E. R. John

Electroencephalography: Clinical Applications

1. Introduction

The electrical activity of the brain, as manifested in the power spectrum of the electroencephalogram (EEG), is precisely regulated by complex homeostatic systems in the brain. Numerous quantitative electroencephalographic (QEEG) descriptors of spontaneous brain electrical activity can be readily extracted by simple computing algorithms. Measurements made from any individual can be objectively evaluated using statistical parameters which can be obtained from standardized, age-regressed, normative databases, and are: (a) highly stable and replicable within the individual, with few false positive findings in healthy, normally functioning persons; (b) independent of ethnic influences or cultural background of the individual; and (c) highly sensitive to many forms of developmental dysfunction, neurological disorders, or psychopathology. An overview of current understanding of the neurophysiological basis of the EEG, fundamentals of QEEG analysis, and of three-dimensional tomographic as well as topographic QEEG imaging, and a brief summary of major areas of basic research in which such methods are applicable, has been provided in a companion article in this encyclopedia (see *Magnetoencephalography*).

Invaluable assessments of the structural and functional integrity of the brain are accessible from quantitative analyses of the scalp EEG. QEEG methods provide sensitive and precise measures for study of normal as well as abnormal brain functions. Contemporary research suggests that synchronization of oscillatory activity among distant brain regions, as well as localized coherent activity, may play an important role in the processing of afferent information, particularly in 'binding' the diverse features of a complex stimuli into a perceptual whole, and in the storage of memories. Such processes are reflected in quantitative measures of the EEG power spectrum, symmetry, and coherence (synchronization) within and between the cerebral hemispheres. In most studies to date, results have been visualized as topographic maps. Validated methods for three-dimensional

QEEG tomography have very recently become available and provide statistical parametric 'virtual functional magnetic resonance imaging (MRI)' images, upon which the statistical significance of deviations relative to reference data can be encoded by colors assigned to each voxel. The importance of assessing the possible contribution of such objective neurophysiological and neuroanatomical measures to better understanding of the abnormal behaviors exhibited in psychopathology cannot be overemphasized.

QEEG methods have been used in numerous studies of patients with psychiatric disorders. This article will be restricted to QEEG applications in psychiatric patients. Due to the limitation of space, only illustrative articles can be cited here. A more comprehensive survey has recently been published (Hughes and John 1999), to which this article is indebted.

2. *QEEG Sensitivity to Brain Dysfunctions in Psychopathology*

A voluminous literature, using subjective visual pattern recognition, attests to the utility of the conventional EEG in neurological and psychiatric disorders. While the astute electroencephalographer is capable of a high level of recognition of pathophysiological patterns, test–retest reliability between as well as within clinical EEG practitioners is poor. Algorithms for computer pattern recognition, the computer's unsurpassed capacity to measure and calculate, together with the availability of normative databases across the human life span, have added an important additional dimension to electroencephalography. QEEG objectively supplements the EEGer's trained eye with literally many hundreds of reliable quantitative measures which can be computed automatically from a brief recording (John and Prichep 1993). Precise statistical comparisons of each of these numerous measures from an individual can be generated relative to a 'self norm' reference state or to mean values from databases of age-matched normal subjects or of patients with different diagnoses. A broad consensus exists on the high proportion of abnormalities found in drug-free patients with different psychiatric disorders and their distinctive nature. A brief overview of these findings follows.

3. *Cerebrovascular Disease and Multi-infarct Dementia*

In cerebrovascular disease, several QEEG parameters are highly correlated with regional blood flow or metabolism. Sensitivity and specificity are high for detection of ischemia-related diffuse or focal impairment (Nuwer 1994). These studies show sensitivity generally greater than 80 percent, false positive rates below 5–10 percent, and correlations of $r > 0.7$ between EEG and regional cerebral blood flow (rCBF) as measured using $Xenon^{133}$ or SPECT. EEG slowing (especially increased theta activity) is highly correlated with decreased rCBF (Passero et al. 1992) or diminished regional cerebral glucose metabolism.

QEEG can be quite abnormal even when the CT is still normal, such as in the first 1–3 days after a stroke or when the degree of ischemia is mild enough to cause dysfunction without infarction.

Differentiation between multi-infarct dementia (MID) and Alzheimer's dementia (AD) has been reported in several studies evaluating asymmetries (Clark et al. 1991) and coherence (Leuchter et al. 1992). Focal asymmetries and hypocoherences are more prevalent in MID.

4. *Dementias*

QEEG studies in dementia patients report increased delta and/or theta power, decreased mean frequency, decreased beta power, and decreased occipital dominant frequency. Many of these studies regard increased slow activity prior to reduction of alpha power as the earliest electrophysiological indicator appearing in Alzheimer's disease (Prichep et al. 1994, 1995). The amount of theta activity shows the best correlation with cognitive deterioration and with clinical outcome in longitudinal follow-up (Prichep et al. 1995). Increased delta appears to be a correlate of severe advanced dementia, subsequent to an increase of theta.

Multiple studies report accurate discrimination of AD patients from elderly patients with late onset depression and from normals using EEG or QEEG measures of slow activity (Robinson et al. 1994). Many of the distinctive features of AD, such as diffuse increased delta and/or theta power, decreased beta power and mean frequency, are absent in depression and are focal in multi-infarct dementia, enabling these disorders to be differentiated from AD.

5. *Learning Disorders and Attention Deficit (ADD/ADHD)*

Specific developmental learning disorders (SDLD) affect 4–6 percent of all school age children. Attention deficit disorders with or without hyperactivity (ADHD or ADD) have a prevalence of 6–9 percent in school age children. While both ADD/ADHD (see below) and SDLD are believed to be distinct neuropsychiatric entities, there is considerable comorbidity between the two disorders. Precise and accurate determination of the presence of ADD/ADHD vs. SDLD can be of critical importance in avoiding the potentially devastating impact of these disorders on children and their families. QEEG can contribute usefully to this distinction as well as in separating children with social or motivational factors underlying school problems from those with organic dysfunction.

The conventional EEG has been reported to be abnormal in 30–60 percent of children with ADD or with specific developmental learning disorder. Abnormalities reported in that literature often included diffuse slowing and decreased alpha activity. In QEEG studies, a high incidence of excess theta or decreased alpha and/or beta activity has been reported in SDLD children (Ahn et al. 1980, Lubar 1991) with theta or alpha excess often seen in children with ADD or ADHD. The types of QEEG abnormality have been shown to be related to academic performance in SDLD children (Harmony et al. 1990) and to cognitive, emotional, and behavioral problems found in a cross-national study of children (Matsuura et al. 1993).

A large percentage of children with attention deficit problems (over 90 percent) show QEEG signs of cortical dysfunction, with the majority displaying frontal theta or alpha excess, hypercoherence, theta or alpha excess, and a high incidence of abnormal interhemispheric asymmetry. Using QEEG measures, it has been possible to discriminate replicably between ADD/ADHD vs. normal children, with a specificity of 88 percent and a sensitivity of 94 percent and between ADD/SDLD children with a sensitivity of 97 percent and a specificity of 84.2 percent (Chabot et al. 1996).

6. *Mood Disorders*

The incidence of abnormal conventional EEG findings in mood disorders appears to be substantial, ranging from 20 to 40 percent (Duffy et al. 1994). The incidence of EEG abnormalities appears to be higher in (a) manic than depressed patients, (b) female than male bipolar patients, and (c) nonfamilial cases with late-age onset. Whether an 'abnormal' EEG is a necessary correlate of a clinically effective series of ECT treatment is controversial. This suggestion, analogous to assertions about the prognosis of treatments with clozapine in schizophrenia, will require further study.

Numerous QEEG studies have found increased alpha and/or theta power in a high percentage of depressed patients (Alper 1995, John et al. 1988a, 1998b). It is noteworthy that antidepressants reduce alpha activity, in contrast to the increased alpha caused by neuroleptics, suggesting that appropriate medication achieves normalization of deviant QEEG features in successful pharmacotherapy of psychiatric patients (Galderisi et al. 1994, Saletu et al. 1994, Schellenberg et al. 1994).

Interhemispheric asymmetry, especially in anterior regions, has been reported repeatedly, as has decreased coherence. In bipolar illness, in contrast to unipolar depression, alpha activity is often reduced (Knott et al. 1999, Clementz et al. 1994) and beta activity increased. This difference may serve to separate unipolar from bipolar patients presenting in a state of depression, without prior history of mania (Prichep et al. 1990).

Current treatment of bipolar disorder often includes polypharmacy, with the use of the anticonvulsant medications, carbamazepine, and sodium valproate. The successful use of these agents suggests overlap between convulsive disorders and bipolar illness.

7. *Anxiety, Panic, Obsessive Compulsive, and Eating Disorders*

The available studies suggest a high incidence of QEEG abnormalities in patients with anxiety disorders, panic disorders, and obsessive compulsive disorder (OCD). Diminished alpha activity has been found in anxiety disorder and increased theta activity has been reported in OCD. Two subtypes of OCD patients have been described. One, with increased alpha relative power, responded positively (82 percent) to serotonergic antidepressants, while the second, with increased theta relative power, failed to improve (80 percent) (Prichep et al. 1993). Epileptiform activity can occasionally be found in patients with tics (or stuttering), in addition to nonspecific diffuse slow activity. In patients with panic disorder, paroxysmal activity was four times more common than in depressed patients. Temporal lobe abnormalities, in particular, have been emphasized in QEEG studies in this type of patient.

In anorexia nervosa, abnormal background activity in the EEG can be seen in nearly 60 percent of patients, possibly related to the effect of starvation on cerebral metabolism. Paroxysmal abnormalities are seen in about 12 percent of these patients. In intractable binge eating, 'soft' neurological and EEG signs can appear. Patients with eating disorders frequently have a history of physical or sexual abuse as children, so the increase in EEG abnormalities in this group may be related to their abuse history. Alternatively, dietary and nutritional deficiencies may contribute to altered brain function. Both anticonvulsant and antidepressant drugs have been helpful in some of these patients (Grebb et al. 1984).

8. *Mild Head Injury or Postconcussion Syndrome*

Patients with complaints of cognitive memory or attentional deficit after mild head injury without loss of consciousness frequently present for neuropsychological evaluation for worker's compensation and disability benefits. Objective evidence of brain dysfunction in such cases is critical in the endeavor to separate the truly dysfunctional patient from the malingerer. QEEG evidence can play a critical role in such cases. While the absence of abnormal brain electrical activity cannot definitively exclude the possibility of brain dysfunction, the presence of abnormalities, especially those most frequently associated with unequivocal traumatic brain insult, must be considered supportive of such claims.

There is a high incidence of diffuse axonal injury in about 50 percent of the 50,000 patients/year with head injury who recover, and who characteristically do not display structural lesions on CT scan or even in MRI scans early after injury. Among those who recover after moderate head injury, 90 percent have cognitive or neuropsychological deficits (Rimel et al. 1982). Among such patients, studies involving many hundreds of cases have reported normal neurologic examinations but abnormal QEEG (Jerrett and Corsak 1988).

Numerous EEG and QEEG studies of severe head injury (Glasgow Coma Scale 4–8) and moderate injury (GCS 9–12), using samples of 50–200 patients, have agreed that increased theta and decreased alpha power and/or decreased coherence and asymmetry often characterize such patients. Changes in these measures provide the best predictors of long-term outcome (Thatcher et al. 1989).

There is a consensus that the most characteristic QEEG abnormalities persisting after mild or moderate head injury are similar in type but lesser in degree to those found after severe head injury, namely increased focal or diffuse power in the theta band, decreased alpha, low coherence, and increased asymmetry. Similar abnormalities have been reported in boxers (Ross et al. 1983) correlated with the numbers of bouts or knockouts and in professional soccer players who were 'headers' (Tysvaer et al. 1989).

The consistency of these observations, across a wide range of different degrees and types of head trauma, lend additional credibility to the multiple reports of discriminant functions based on QEEG variables which successfully separated normal individuals from patients with a history of mild to moderate head injury, years after apparent clinical recovery (Thatcher et al. 1989).

9. *Schizophrenia*

Evaluation of EEG and QEEG literature on schizophrenia is complicated by the evident heterogeneity of the illness, and the diversity of medication histories and dosage levels at the time of examination. In spite of these potential sources of difference among findings, considerable agreement nonetheless appears. Numerous EEG and QEEG studies of background activity have been performed on carefully evaluated groups of schizophrenic patients. Reviews of numerous qualitative studies indicate an incidence of abnormal conventional EEG findings in 20–60 percent of schizophrenic patients (Small 1993). With few exceptions, a substantial amount of agreement emerges from this body of literature. Alpha power is consistently reported as deficient (John et al. 1988a, 1998b), as well as altered alpha mean frequency or diminished alpha responsiveness. Numerous studies have reported increased beta activity in schizophrenia (Morihisa et al. 1983, Karson et al. 1987). It was pointed out earlier that neuroleptics typically increase alpha power (Galderisi et al. 1994, Saletu et al. 1994, Schellenberg et al. 1994) and reduce beta power (Niedermeyer 1987, Herrmann and Schaerer 1986), suggesting possible normalization of deviant features by medication.

Increased delta and/or theta activity has also been reported in a large number of studies. Such increased slow activity can apparently result from neuroleptic treatment, although there are reports of increased delta in patients off medication for several weeks (Morihisa et al. 1983) and reduction of delta or theta when medication is resumed (Galderisi et al. 1992, Saletu et al. 1994).

Among the various QEEG parameters, one which serves to discriminate schizophrenic patients from controls is the presence of increased amounts of delta activity in the left anterior temporal area. A decrease in fast alpha (10–12/sec) on the frontal areas has been called 'hypofrontality' (Gattaz et al. 1992).

An interesting observation with therapeutic implications is that there is positive correlation between the degree of QEEG abnormality and the degree of clinical improvement (Omori et al. 1992). This observation has raised the question as to whether this 'degradation' of the EEG is a necessary condition for a clinical improvement with clozapine. Clinical relationships include correlations between (a) negative symptoms and delta waves in the temporal areas (Gattaz et al. 1992); (b) blink rates, alpha power, and smoking (Klein et al. 1993); and (c) a more favorable prognosis and any EEG abnormality (Omori et al. 1992).

10. *Heterogeneity Within the Schizophrenic Population*

Results from a small number of studies are inconsistent with the consensus of a QEEG profile with increased delta or theta, decreased alpha and increased beta in schizophrenia. For example, increased slow activity has not been found by some workers, and increased alpha and decreased beta have occasionally been reported. It should also be noted that not all of the studies reporting the increased slow activity, decreased alpha, increased beta profile found the indicated deviation in all of these frequency bands.

This inconsistency might arise from the coexistence of several subtypes with different QEEG profiles within the population of schizophrenic patients, so that observations might vary depending on the fortuitous mixture of subtypes within the samples collected for a particular study. This heterogeneity has been recently documented in a study of a large sample of medicated, nonmedicated, and never-medicated schizophrenics, using cluster analysis based on QEEG variables. Five subtypes were detected, with QEEG profiles characterized by delta plus theta excess, theta excess, theta plus alpha excess with beta deficit, theta

excess and alpha excess with beta excess (John et al. 1994a, 1994b). Never-medicated patients were found in three of these subtypes. Schizophrenics with QEEG profiles corresponding to some of the groups identified by this cluster analysis have been reported to display differential responses to treatment with haloperidol (Czobor and Volavka 1991) or risperidone (Czobor and Volavka 1993). Additional evidence of heterogeneity in the schizophrenic population has been provided in QEEG studies by other groups (Roemer et al. 1991).

Findings of asymmetry in schizophrenia have been inconsistent. However, when the electrode array covered both anterior and posterior regions, power was highest over the right hemisphere in anterior but over the left hemisphere in posterior regions (Guenther and Breitling 1985, Roemer et al. 1991). This conclusion was supported by the cluster analysis just cited, in which this asymmetry pattern was found in every frequency band for all five subtypes (John et al. 1994a, 1994b).

Increased interhemispheric coherence in anterior regions has been consistently found (John et al. 1994a, 1994b, Nagase et al. 1992). Taken in conjunction with the decreased frontal coherence in depressive illness cited below, useful QEEG separation of schizophrenics from bipolar depressed patients should be attainable using measures of coherence.

11. Substance Abuse

Replicated reports have appeared of an increased beta (relative power) in alcohol dependence (John et al. 1988a, 1998b, Bauer and Hesselbrock 1993), and in children of alcoholic fathers or men at risk for alcoholism (Volavka et al. 1985). Increased alpha power, especially in anterior regions, has been reported in withdrawal, as well as after acute exposure to cannabis (Struve et al. 1994). Increased alpha, as well as decreased delta and theta, have been reported in crack cocaine users in withdrawal (Prichep et al. 1996).

12. Conclusion

The citations above document the wide applicability of QEEG as an adjunct to diagnosis, prognosis, treatment selection, and outcome evaluation in behavioral problems, developmental disorders in children, mild head injury, mood disorders, primary degenerative dementia, and schizophrenia. Familiarity with these data and with QEEG methods should enable psychologists to make major contributions to improve the management of patients in all of these categories. The EEG and Clinical Neuroscience Society (ECNS) offers training programs and board certification examinations in QEEG for psychologists, as well as for neurologists and psychiatrists. Psychologists interested in acquiring this professional qualification should contact ECNS.

Electronic Democracy

Electronic democracy refers to the use of information technology (IT) to expedite or transform the idea and practice of democracy. The capacity of computers to store vast quantities of data, and the relative ease with which such data can be accessed, combined with many forms of communication based on computers, satellites, telephone lines, and fiber optic cables, which enable information to be transmitted almost instantaneously from place to place, has created an infrastructure which can be applied to the operation of democracy. The capacity to store and access data allows citizens to gain knowledge about what is done in their name, just as politicians can find out more about those they claim to represent. Equally, political parties and interest groups can make similar use of these data stores, as well as using the communication networks to solicit support and funds for their causes. Finally, forms of electronic communication make possible systems of political participation, whereby citizens can vote online or engage in interactive communication with those who represent them or act on their behalf.

These political uses of IT (and there are many others besides those outlined above) do not secure universal acclaim. Just as there are those who see in electronic democracy a panacea for many contemporary problems—political apathy, alienation, democratic deficits, and so on—there are others who view it as creating new problems, or exacerbating old ones, by increasing the potential for surveillance and manipulation, for increasing inequalities of power rather than diminishing them. The emergence of the Internet has greatly increased the urgency and intensity of this debate, but it did not create it. The debate about electronic democracy, and the possibilities for its realization, predate the information superhighway.

1. *The Origins of Electronic Democracy*

Electronic democracy is neither the direct product of technological advance nor of abstract thought, but rather of the engagement of the two. Although the discussion of electronic democracy came into focus in the 1980s, it can be argued that it was a feature of every change in the technology of communication, from the printing press to the World Wide Web. Each new system of communication raises questions about the distribution and content of knowledge, about who has the right to know and say what. Knowledge is a key resource in politics. Dictatorships tend to restrict and control it, just as democracies are supposed to make it freely available. So it is that with each new technology of communication new questions are raised about how these technologies should be organized and used. Should the press or broadcasting be privately owned? Who should have access to the newsprint and the airwaves? To this extent, the debate about electronic democracy is just another moment in the long history of the politics of communications.

Nonetheless, we can trace the particular concern with electronic democracy, the use of electronic means to enable citizens to participate in politics, to the late 1970s and early 1980s, when reports emerged of experiments such as 'televoting' in Hawaii (Becker and Staton 1981) and the QUBE system in Columbus, Ohio (Neustadt 1985). What both of these early initiatives represented was the use of television and telephone technology to encourage citizens to take a greater interest in politics, to reduce the costs of participation, and increase levels of knowledge. Both created the possibility of local referenda in which citizens were given information on a particular issue and then encouraged to register their views by electronic means. These initiatives were not confined to North America, and other experiments emerged in Europe, most notably the Netherlands (for a survey, see McLean 1989). Roughly parallel with these developments were changes in political campaigning, especially in the United States. Politicians began to use computer-based databases, themselves the product of interest group and consumer behavior, to organize systems of direct mailing so that particular constituencies could be targeted with customized political propaganda. By the late 1980s, it was possible to identify a large variety of examples of the use of IT in politics, and to talk of the emergence of 'teledemocracy' (Arterton 1987) and of 'the electronic commonwealth' (Abramson et al. 1988). These various uses of IT were often pragmatic and instrumental responses to particular political problems: to increase participation, to reach key voters, to raise money. What gave them a wider significance was the ways in which a number of political theorists incorporated these experiments into a case for a new notion of democracy—or perhaps more accurately to revive the fortunes of an old one. A key figure in this was Benjamin Barber whose book *Strong Democracy* (1984) used examples of electronic participation to advocate an alternative to the hegemonic dominance of liberal democracy.

There have always been positive arguments for a liberal democratic regime based on a respect for

individual preferences, limited popular participation, and the principle of representation. Just as there have been good reasons for not advocating the direct system of democracy employed in Ancient Greece (and reincarnated in the writings of Rousseau and Marx). But while there are principles which help decide between these alternatives, practical considerations have also been implicated. The utilitarian case against liberal democracy, for instance, drew attention to the impossibility of assembling large numbers of people for political discussion, while other, later theorists have drawn attention to the difficulty of collating and comprehending the information needed for decision-making in complex modern societies. To this extent, the arguments against direct democracy have been practical ones.

What Barber argued was that, with the advent of new technologies of communication, these practical objections no longer hold the force they once did. They can be overcome by enabling people to participate electronically, recreating the experience of mass participation without the practical requirement of gathering them together. For Barber, given the ability to overcome the practical problems, the case for direct participatory democracy can be made, and can be seen to trump the rival claims of liberal democracy. Such thoughts have received yet greater impetus with the emergence of the Internet.

2. *Cyberdemocracy*

Set against the speed, flexibility, and apparently ever-proliferating possibilities of the web, the early experiments in televoting seem extraordinarily crude. Now every party and almost all politicians boast their own website, from which they solicit funds and set out their stall. More importantly, there has been an explosion of websites dedicated to advocating or realizing systems of direct participation. These extend from policy discussion forums to systems of direct participation. The accompanying rhetoric is now one in which politicians talk of the 'electronic town meeting' or of the 'virtual parliament,' and where academics produce volumes on 'cyberdemocracy' (Tsagarousianou et al. 1998).

This notion of a 'cyberdemocracy' refers to a number of different developments in democratic practice. The most obvious is the opportunity that the web provides for citizens to inform themselves. They can call up websites that provide reports and data on central and local government; they can access the arguments on any number of debates and issues. It is a small step from here to the opportunity to register a vote, simply by clicking on an option just as one makes a purchase from Amazon.com, or by entering a chat room to voice an opinion. From the other side, parties now tailor their websites to elicit support and to persuade the casual surfer. Mainstream interest groups do the same, while their more activist, radical colleagues go further. Campaigns against genetically-modified foods and motorway building, together with such movements as Reclaim the Streets or those opposing the World Trade Organisation, have used the web to coordinate their activities. Meanwhile their opponents in government have increasingly used the web to re-establish their fraying legitimacy, by appearing to engage directly with their citizens and by bypassing the traditional means of communication offered by the mass media.

'Cyberdemocracy', in encompassing all these different practical forms, also displays a similar theoretical eclecticism. For some, the opportunities offered by the web allow for the emergence of new democratic forms, ones that, as with Barber's strong democracy, allow for the rediscovery of the direct tradition. The emphasis, though, is less upon participation as *control*, as taking hold of the levers of power in the name of the people, as *deliberation*: the use of the net to constitute a public sphere within which people deliberate upon the collective good. The web is seen to enable a new deliberative democracy, which sets itself against a liberal democracy concerned, according to such critics, only with realizing pre-established individual preferences. The web allows individual citizens to revise their preferences in the light of this knowledge and understanding of other people's preferences. But cyberdemocracy is not claimed just by those who oppose liberal democracy. Liberal democrats too see in the web the potential for enhancing the practices and principles that enhance their version of democracy. The opportunity of unmediated contact between citizens and parties or interest groups, the potential for online accountability, provide means for enhancing the efficiency and efficacy of liberal democracy.

To the extent that the web produces new forms of access and participation, it does represent an important moment in the constant transformation of politics. But to the extent that traditional political divides replicate themselves in the use of the Internet, electronic democracy also forms part of an established continuity. The debate about the implications of electronic democracy similarly straddles the familiar and the novel.

3. *The Debate about Electronic Democracy*

The argument about electronic democracy runs along several different dimensions. Three are singled out here. The first is that of access. Critics of electronic democracy argue that its credibility depends on some principle of universal access. Where traditional forms of political participation (visiting the polling station to vote) allow for near universal access, computer-mediated participation is exclusive rather than inclusive. The barriers to entry include limits on access

to computer technology—not everyone in the industrialized West has access to a telephone let alone a computer. Furthermore, the networks which form the web are not evenly distributed; as Manuel Castells (1996) has illustrated, the political economy of systems of communication marginalizes the less-developed world. Finally, even where technical access is possible, there are political, social, and cultural factors which intervene to thwart the capacity of some people—women, for instance—to make full use of the technology (Wajcman 1991).

Other critics of electronic democracy (Lyon 1994) focus on the technology's capacity to centralize power rather than devolve it. The network of computer databases can become the infrastructure for a system of surveillance which allows central state authorities to monitor the activities of its citizens. Such fears have become linked to discussion of the desire for, and capacity of, the state to regulate the web. Through such devices as ECHELON it has become possible for states to monitor citizens' use of email and the web. In such circumstances, the democratic capacities of the web are replaced by dictatorial ones. For skeptics of electronic democracy (e.g., Sussman 1997), the democratic prospect held out by the web is illusory.

The last dimension of the critique of electronic democracy focuses on the underlying theory, the ideas which animate the interpretation of IT as opening up a new or improved form of democracy. Insofar as electronic democracy appeals to any one version of democracy—whether direct or liberal—it relies upon the principles which sustain that particular version. Those unimpressed by such claims will be equally unimpressed by the claims made for electronic democracy. As Iain McLean (1989) points out, the division between competing notions of democracy does not derive from a lack of conceptual clarification or from technical inadequacies in existing forms of participation, but are fundamental to the very idea itself. The thought that the deliberative democracy promised by the application of electronic democracy is simply the 'best' fails to recognize the case to be made against the deliberative form (Weale 1999). In summary, there is an important debate to be had about electronic democracy, but it will not be resolved by the application of technology; it will be just another phase in the endless debate about democracy itself.

4. *The Future*

Whatever the future brings, and it will establish undreamt of forms of participation and transformative moments in the conduct of politics, it will not bring an end to the arguments around principle and ideology that fuel our notion of democracy.

Electronic Economy: Governance Issues

Stories about the digital economy, the E-conomy, have moved from specialty journals to the business pages and from there to the front pages of mainstream newspapers. The issues have evolved from the narrowly technical discussions of how best to configure a data network and the narrowly legal issues of patents and copyrights into significant policy battles over taxes, privacy, and intellectual property that have significance for the character of the marketplace and the polity. At the same time, the discussion has evolved from contrasting futurist presentations, a new Jeffersonian era of frontiersmen freed from government constraint set against a neo-Orwellian technology enabled 'big brother,' into a more sophisticated and pragmatic debate about issues such as surveillance and control, private and public (Bar et al. 2000). The policy issues raised in the Internet economy will not be easily fixed by simple technical tinkering, adding new digitally sensitive wording to old rules. Rather, they portend fundamental struggles about the nature of the polity and the economy. The resolutions will not be a matter of policy management, but of political choices about basic values.

International Encyclopedia of the Social & Behavioral Sciences ISBN: 0-08-043076-7

At a minimum the collection of networks, computers, and information tools that emerged in the last decade of the twentieth century represented a new leading economic sector. Since the first industrial revolution there has been a sequence of such leading sectors, each bringing its 'explosion of invention and innovation that revolutionizes productivity in a narrow slice of the economy' (Cohen et al. 2000). But is there more? A case can be made that the emergence of an E-conomy represents the creation of a new set of general tools that is fundamentally transforming *each sector of the economy*. *This perspective sees a shift in* the very terms and dynamics of market competition. Stephen Cohen, Brad DeLong, and John Zysman have suggested that the new technologies 'do not just amplify productivity in one sector but give all economic sectors new "tools." They are tools for thought that amplify brainpower in the way the technologies of the Industrial Revolution amplified muscle power' (Cohen et al. 2000).

Two processes drive this revolution. Certainly *one process* is technological advance. The conventional measure of this advance throughout the 1980s and the first half of the 1990s was advance in semiconductor technology with the successive iterations of the memory chip or microprocessor reflecting the amount of information that could be stored or processed (Moore 1965). Now, particularly since 1997–98, it is tracked by the expanding network bandwidth that measures the amount of information that can be transmitted. The two technological advances together create a vector of information capacity.

The *second process* is one of social innovations and reorganizations. Together those innovations have constructed the networked business system, which includes digitally enabled reductions in transaction costs, but more importantly involves quite fundamental innovations. The Silicon Valley system, which rests on repackaging and redirecting people and technology and backing them with risk capital, provided new answers to real problems of industrial innovation and production (Saxenian 1994, Cohen and Fields 1999).

No revolution happens without substantial dislocation and uncertainty over the meaning of measures and indicators. Critically, though, the structural transformation of the economy we are watching needs to be separated from any debates about the valuations of stock prices (Weber 1997). The debates around these points are maturing toward more substantive questions, such as how does the digitalization of the economy change, if at all, the major causal forces of the macroeconomy.

For now, the Internet economy, the intersection of the technological advances of processing and bandwidth with the business process innovations, rests principally on business applications and business reorganization. But as broadband networks capable of delivering streaming media and other new applications reach the home, consumer applications that are intimately entangled with social and community evolutions will become the drivers that induce the ongoing sequence of technical innovation. Will this be viewed as another mass media such as television and radio in the twentieth century, as another communications instrument such as telephone and telegraph in the nineteenth century, or as with the book in the fifteenth century which became the base of the Renaissance? (Eisenstein 1980).

The dynamic, all encompassing nature of this transformation creates pitfalls for any brief discussion or any research strategy. First, traditional analyses or research strategies focus on particular threads, themes, and issues. They do so with good reason. Understanding relationships, specifying causal links, is difficult enough when dealing with limited, specific and fairly conventional arguments and issues. Weaving a broad pattern of relationships all too often produces not great insight but superficiality. Yet the more profound the transformation, the more difficult such a traditional strategy becomes. As context itself changes, what were once parameters become variables. Research problems cannot be so easily isolated nor causal relationships cleanly specified.

The issues, policy and political, present themselves in four packages. Each package is required to grapple with the whole; each constitutes in itself a set of social science puzzles. The four packages are: (a) networks and tools; (b) e-business and e-society; (c) the productivity dilemma resolved; and (d) governance and politics.

1. Networks and Tools—the Infrastructure of the E-conomy

The paraphernalia of this new Internet economy rests on advanced data networks and is facilitated by new software tools. The transformation of network communications underpins and expresses the evolving e-commerce and e-society story. The new Internet-based economy grew extraordinarily quickly in comparison with earlier communications and transportation technologies. It took telephone technology 38 years to reach a penetration level of 30 percent of US households. Television was faster, reaching 30 percent of households after about 17 years. The Internet, however, surpasses any previous communications technology in diffusion speed by accomplishing the same penetration in less than seven years (United States Internet Council 1999).

One of the main reasons for this rapid diffusion is that the new technological system, the Internet/web system for linking and addressing computers, could be initially deployed over the older, existing infrastructure for voice communication, telephones. This technologically-driven transformation interacted with and

fueled a move away from the older voice infrastructure, plain old telephones (POTS) over a switched analog, then later switched digital network, in a public utility, or regulated monopoly, model, and toward competing public providers, private data networks, and 'networks of networks' linked by routing data.

The deployment of the new infrastructures to date has demonstrated three features that are critical to understanding this transformation. *First*, the American network revolution has been user driven, that is, the products and architectures have been defined by large sophisticated users rather than by network providers. American data networks were defined, configured, and often controlled, even owned, by the users (Bar and Borrus 1994). The dominant American provider, AT&T, did not simply define the network rules to which customers adapted. It was competitive experimentation among user-defined networks that unlocked an avalanche of innovation. A primary difference between the European networks such as Minitel and the Internet is just that—the Internet is user controlled and developed. The Internet system that permitted and facilitated the new e-business strategies is now in turn being shaped by the emergence of e-business—its latest user constituency.

Second, the infrastructure of the E-conomy, the innovations and the evolving networks themselves have been developed and deployed by private companies in competitive markets. There has been intense and growing competition both among network providers—AT&T, Sprint, Deutsche Telekom, France Telecom, and the like—as well as among the equipment suppliers to these networks, companies such as Lucent, Nortel Networks, Alcatel, and Ericcsson, and newly established firms from Silicon Valley, such as Cisco and Ascend, and newly important firms from other regions, such as Nokia of Finland. Because this competition rages both at the network levels, equipment level, and the software to operate the equipment, the battleground is very complicated.

That private competition was driven by two public policy initiatives: (a) the push to deregulate telecommunications infrastructure, including the divestiture of AT&T, and (b) a series of investments and policy decisions by DARPA, NSF, and other research agencies that nurtured packet-switching technology into an open infrastructure that could be freely exploited and commercialized in many different ways (Naughton 1999, Hafner and Lyon 1996, Rosenzweig 1998).

Third, the network revolution may have been launched in the United States. However, the next generation of advanced networking, particularly wireless, will include network configurations and technologies that are being developed outside the United States. Certainly, American companies such as Qualcomm and Motorola are major players in this wireless world, but advanced wireless networking, for example, is presently defined in European markets. The wireless revolution has been a story of Europe's conscious and effective use of standard setting as a development tool (Bach 2000).

In sum, the network revolution was generated by user-defined needs, private provision, and intense and increasingly international competition. In addition to accelerating innovation, the legacy of user-control has been enshrined in the culture and to a large extent in the technology, and is now becoming an issue of policy debate (Bar et al. 2000). Legislation and indeed the culture that surrounds the Internet reinforce each other and make the social structure around the Internet quite robust.

2. *E-business and E-society*

Our society may ultimately be transformed by digital tools for thought and the data networks that connect the now omnipresent computers. It is important to remember that we are still in the earliest days of technological innovation, with only the first glimmers of the commercial and social implications to come. Although there is much speculation on the subject, the question of how new communities will be shaped by the new technological possibilities is, inherently, unknowable—there are simply too many degrees of freedom (Smith and Kollock 1999, Turkle 1995). The telephone was proposed to be a means of listening to symphonies, before switched signals made it a tool for social and business communication. We are still in a phase of rapid innovation where unforeseen technological change may undermine even the most far-seeing predictions about the social implications of communication.

What is clear is that the transformation, at least for the moment, is being driven by business applications. Business to business (B2B) and business to consumer (B2C) projects have induced the development of a new data communications infrastructure. If significant changes in the broad dynamics of the E-conomy emerge in the first half of the decade, it appears that they will begin with the transformation of business. This transformation goes far beyond the introduction of computers into the workplace: as Erik Brynjolssen and Lauren Hitt point out, for every dollar spent on computers or other information technology equipment, businesses spend about 10 dollars to reorganize their information, production, and social systems in order to use the new technology most efficiently (Brynjolssen and Hitt 2001). The real story is thus not about technology as such, but in the way technology enables and induces reorganization.

3. *The Productivity Dilemma Resolved*

It is this complex reorganization that impacts levels of productivity. And it is productivity, not technology

per se, that ultimately determines what people are paid, the types of skills and training required, and hence who can work and what schools must be like. Firms are the unit that will adjust to the new productivity dynamics and terms of competition and it is consequently on the level of the firm that we will first see the transformative capacity of the new digital technologies. The story of business transformation is, like the story of the network infrastructure on which it rests, central to understanding the community, policy, and governance issues. The phenomenon of e-commerce, or more broadly e-business, is unfolding extraordinarily rapidly. The conventional wisdom about its course and consequences shifts with equal rapidity. Because agreed upon 'facts' and the terms of discussion change so quickly, it is essential, but difficult, to establish a stable framework for observing the emerging transformation of business strategy and practice.

How will e-commerce and digital networks change the organization of economic activity and market competition? We are, as noted, in an era of experimentation with the ultimate outcomes emerging both from a series of marketplace struggles that will change how sellers and buyers interact and policy struggles that will develop around questions of regulating and taxing those processes. A series of rapidly changing codewords point at these rival experiments, for example, disintermediation, the elimination of actors who control information or goods in a value chain (a *filiere*, if you will), has given way to the notion of reintermediation, the introduction of new kinds of players (Shapiro and Varian 1999).

The flux that one sees in the language represents not just fad and fashion but real, fundamental uncertainty. The rapid churn of venture capital funding is not a surprise—it represents a series of bets in a setting where efficiency and competitiveness are hard or impossible to predict because the marketplaces in which those characteristics will emerge are still in flux. Theories of industry organization and competition policy already are shifting their emphasis and focus from issues of scale to scope, from the economies of production to the economics of networks and standards (Shapiro and Varian 1999). But these categories can only take us so far. The marketplaces themselves are being altered fundamentally as decentralized auctions (such as eBay) and reverse auctions with buyers setting the terms (such as priceline.com), change the ways prices are set and goods are sold. Significant parts of the markets for information products (from finance to media) have moved entirely online—and the limits to that move have not yet been seen (Negroponte 1995).

The transition can be monitored by looking not at one but all four of the following processes: (a) competing business strategies, and the tools on which those strategies rest; (b) evolving market structures, boundaries of the firm that contribute to market structure, and the parameters that shape the types of firms that will win; (c) changes in how the marketplace works as e-tools change the ways that buyers and sellers interact; and (d) the creation of cyber-market places in sectors such as media and finance and perhaps others where the entire industry moves its goods and interchanges onto networks.

Studying this transformation of markets by the tools of E-commerce reopens a series of traditional social science problems. Let us consider two. Put simply, will there be one E-conomy or several? Will the new economics of communication and information finally sweep away national boundaries creating the long awaited but never quite arriving convergence of national systems under an electronic manifestation of globalization? This question recapitulates older debates over whether there is one capitalism or several (Hilferding 1923, Gerschenkron 1962, Shonfield 1965, Katzenstein 1978, Zysman 1983, Hall 1986, Soskice 1999). A single E-conomy view builds on the common understanding of the world as composed of technological leaders and followers. No matter which country or region leads the world market, the powerful communications instruments of the digital technology will produce a single global market and similar business models under the governance of convergent, presumably neo-liberal regulatory regimes. Other forms of regulation and protectionism will either be circumvented, swept aside, or else doom the offending jurisdiction to technological backwardness.

The 'techno-determinist' view is partially right in suggesting that new capabilities erode or at least alter inherited market and regulatory structures (Castells 1997). However, this initial story is much too simple. A second view is that globalization becomes a matter of playing out on a large stage nationally rooted innovations. Historical perspective is important here. The first chapter in the e-globalization story was Japanese production innovation (Womack et al. 1991). A second chapter consisted of American technological revival built around innovation in computing, networks, and contract manufacturing to neutralize the Japanese advantage in production (Borrus and Zysman 1997). A third chapter, the Internet story, was launched by and rooted in American technology and deregulation.

Leading-edge users of the Internet and e-commerce are beginning to emerge in Europe and Asia as well as the United States. As new e-commerce technologies, usage patterns, business models, and legal frameworks develop outside the US, they will challenge the early dominance of American policy and market leadership. Regionally- and nationally-based lead users, with regionally specific market needs and operating in distinct policy environments, will drive distinctive lines of technology development in which local firms may have competitive advantages.

The distinction between these two perspectives is ultimately an empirical one. Convergence can be

measured over time, if not precisely, and divergent paths of development will be visible in familiar forms: distinct technologies and applications, differentiated market structures and business models, different structures of comparative advantage, and ultimately distinct policy and legal frameworks.

The second problem is that the manner in which technology is embedded by law and practice into society shapes the trajectory of technical evolution. This is dramatically clear in the case of open source software. Instead of retaining private ownership of the source code (the list of instructions in a programming language that comprise the basic recipe for a piece of software), open source software projects such as Linux, Apache, and others distribute source code freely, permit modification by users, and allow redistribution of modified versions without royalties or licensing fees to the author. Open source inverts the standard logic of intellectual property rights. It is built collaboratively by a geographically dispersed community who work in a highly parallel, relatively unstructured way and without direct monetary compensation. Because open source software is nonrival, nonexcludable, and subject to collective creation, it looks like an 'impossible public good' from standard perspectives (Smith and Kollock 1999). But in fact it is successful both technically (producing software that is as good or better, technically, than proprietary software) and in a social sense (sustaining a community of developers whose commitment to the collective project is extraordinary). The political economy of open source is ultimately a story about both economics and culture—but an economic and cultural logic that have each been modified, in specific ways, by the Internet (Weber 2000). The question of how the model scales and whether it can be extended to other areas of knowledge production generates dramatic arguments about business models, which are ultimately arguments about the structure of economic production in a digitizing economy and society.

4. *Governing, or at Least Steering, the E-conomy*

All market economies rest on rules (Polanyi 1944). Just as there were never separate rules for a fax economy or a telephone economy, there will not be separate rules for an Internet economy—rather, the decisions we make about the E-conomy, rules both for the networks of information technologies that are defining new market relationships and for the new business system that has helped generate it, will be critically important for the 'traditional' economy. We are beyond the point where simple tinkering will suffice. We are also beyond the point where we can sustain the illusion that the Internet can exist apart from and independent of the rest of the economy and society. The cyber world is intertwined with, not independent of, the 'traditional' world. Libertarian fantasies about the Internet economy have been left behind. Regulation in this new era ultimately is a story about how political decisions interface with technical possibilities. Lawrence Lessig's recent work differentiates between 'West Coast Code,' the code that defines how the networks and the programs work in a technical sense, and 'East Coast Code,' the laws and regulations drawn up by policy-makers (Lessig 1999, Rheingold 1993, Reid 1995). The key debates will ultimately be about what regulation can and should do to modify the technical possibilities that shape what kind of network world we have, what kind of code-constructed realities and businesses we develop, and hence what kind of economy we build.

The process of translating values for a new era, or creating new rules that encompass new values, is intertwined with qualitative changes in business and social life that reopen established policy bargains. The choice of rules will often have major outcomes in terms of private gain. It is hard to imagine a higher set of stakes as a new governance 'system' is simultaneously being created at home, domestically, and as a bargain amongst several national systems. Framing the initial policy debates is difficult enough. Perhaps because it was carried out mainly among technologists, the early debate was punctuated by libertarian conceptions that government and perhaps even traditional forms of political contestation somehow could be excluded from something loosely called cyberspace (Barlow 1996). There is now broad recognition that technical choices about the marketplace touch the character of our communities and polities in fundamental ways (Lessig 1999). And that, conversely, the choices we seek to make about community in an epoch of data networks in turn shape the marketplaces (Post 1995). The resulting political debate is not simply one of advantage and interest, but rather it concerns fundamental values and basic choices about markets, community, and democracy. These kinds of debates recast political alliances and reshape the character of the polity as actors redefine their interests in the New Economy (Litan and Swire 1998).

There is a set of profound issues already on the agenda today: competition policy, taxation, intellectual property rights, and privacy. They open debates about what kind of E-conomy, about what rules for Internet facilitated business reorganization, about what sorts of virtual communities with what rights of speech and anonymity, about what types of network arrangements, about which architectures of code are called for. For example, basic issues of competition policy are now being fought out over the fate of Microsoft (US vs Microsoft Corporation: Conclusions of Law and Final Order 2000, Bork 2000). More broadly, how the network and other key elements of infrastructure (such as operating systems, as in the case of Microsoft) are regulated will shape who can participate in the new E-conomy, and on what terms. It will powerfully influence national patterns of e-

commerce, both the speed of the transformation and the models which are adopted, which is why decisions about Microsoft are ultimately much more important than simply deciding the future of that one company.

A second issue set touches on more traditional questions of governance and the state, such as taxation. Though the numbers are still small, there is little doubt that a few years hence quite significant portions of commerce will take place over electronic networks (Shop.org/Boston Consulting Group 1999). The question of whether and how to tax the Internet will become ever more a debate about how and where to tax overall, rather than a sideshow. The intensity and urgency of the new debate will depend directly on the influence that the shifting locus of transaction has on government revenue streams and their capacity to deliver services to their community.

But the most basic issues are about information—who owns it, and what to do with it. At a minimum, these are questions about intellectual property, privacy, and speech. Here, new technologies will stretch familiar debates out into new territories of political values and the political theories that lie behind those values. Privacy is one dramatic example. Extraordinary amounts can be known about us by monitoring our activity in a computer-based economy. The bank or credit card company knows what we buy and may monitor spending patterns for risks of default, such as possible divorce suggested by unexpected patterns of flower or jewelry purchase. The grocery store knows what you eat. An Intelligent Transportation System that manages traffic flows may know where you are, where you go, and when. How may the data be used? Can it be combined? Or sold to an insurance company? Or provided to the IRS?

A new relationship between privacy vis-à-vis the government, and privacy vis-à-vis commercial interests is emerging. Is the law in the United States—originally crafted to protect the citizen against the state and state actions such as wiretap—appropriate in an era in which privately controlled data may provide a precise picture of our life, far more detailed than anything the government can know? What rights should government have to access this privately collected data? One proposed policy approach would provide property rights in data about ourselves that we as individuals can sell or withhold. But that property right, it appears, may not include genetic data about us obtained by physicians or surgeons in medical practice. A second approach would propose that privacy is a function of the community's needs, that there must be limits on the personal data that can be gathered or dispensed for the sake of security of the community. The questions of privacy blur quickly into questions of security of communication and transaction, and in turn to a balance between privacy and community safety and protection. The complexity of the values involved in these kinds of decisions ensures that the debates will be tortuous.

What issues such as privacy, intellectual property, free speech, consumer protection, or taxation have in common is that the debate about the kind of communities we would prefer becomes entangled with the way we will run our new electronic marketplaces. Consider the question of security and encryption. Once again the balance between personal privacy and national security as well as police purposes has to be reset. Similarly the question of jurisdiction, which political entity is responsible, for matters such as taxation and consumer protection have to be rethought. Consider the balance between free speech and the protection of minors against inappropriate content. Should the solutions be technical—filtering devices that block access to what parents would reject? Or should we instead seek solutions that require public rules? Some issues simply will be forced onto the political agenda as network-based transactions multiply. Whatever your views on taxation on the net, simply speculate how the debate would work if a majority of commercial transactions were on the net, but untaxed. Public services from roads to schools would not end; but the structure of taxation would be forced to change in a profound manner.

Complicating each of these debates tremendously is that they cannot be settled definitively in one country. If privacy rules are different in Europe and the United States, how do companies from AOL to IBM operate? (Litan and Swire 1998). While particular issues are thought out and fought out, care must be taken to assure that diverse national solutions are sufficiently reconciled to assure the operations of the global information system. An era in which national monopoly telephone systems could be imagined as closed almost watertight systems provisioned by a national cartel of suppliers and connected at the borders or halfway across an ocean has given way to the era of interconnected data systems, global service providers, and global equipment companies. Connection at the borders of separate systems will be difficult; more likely rules may be harmonized, that is made identical, or made interoperable. But a solution will have to be found.

The evolution of the E-conomy is a remarkable opportunity for the further development of empirical and theoretical social science. This is not a separate research domain for a few observers interested in technological evolution and the politics of technological change. Information technology is penetrating every aspect of business, the economy and society as a whole. Just as expressions such as 'e-commerce' and 'Internet economy' will be meaningless in light of the large share of commercial transactions and economic activity carried out over digital networks, differentiating between research on 'Political Economy' and 'Political E-conomy' is likely to become pointless. Understanding the way technological, organizational, and political-legal changes interact in shaping a future characterized by ubiquitous digital networks connect-

ing countless nodes globally will be essential for our understanding of political economy, whether domestic, comparative, or international, and for our understanding of society as a whole.

Keeping track of these changes will be difficult, to say the very least. In the short run, bargains will most likely be struck by existing coalitions or new coalitions composed of familiar interest groups in an existing institutional environment. But in the long run, the political sociology of communities of all kinds will change dramatically. Individuals will come to define their interests differently, new interest groups will emerge, new coalitions will rise, and new bargains will be struck and embodied in entirely new or fundamentally altered institutions. Indeed, the changes underway have the potential to radically change the very configuration and orchestration of social and political life. And we are only starting to study the very beginning of this transformation.

Eliade, Mircea (1907–86)

Mircea Eliade was the best-known contemporary theorist of religion from the discipline of religious studies. He was one of a handful of scholars within the discipline who influenced scholars outside it. Unlike specialists in a single religion, he was influential as a theorist of religion as a whole. While he wrote specialized tracts on Australian religions, Indian religions, alchemy, yoga, shamanism, and the religion of his native Romania, he was most celebrated as one of the last comparativists and, even more, as the latest defender of the defining tradition of religious studies. Eliade sought to demonstrate the universality of religion by finding it in even seemingly secular domains. He also wrote fiction, and in Romania was a popular novelist and short story writer.

1. *Life*

Mircea Eliade was born in Bucharest on March 9, 1907. He began writing for Romanian weeklies as a teenager. In 1925, after completing the *lycée*, he entered the University of Bucharest and received an MA for his thesis on Italian philosophy from Ficino to Bruno. His mentor was the philosopher Nae Ionescu. While at university, he continued writing regularly—short stories, scholarly articles, reviews, and translations. He also founded a journal.

In 1928 Eliade went to India to study Sanskrit and Indian philosophy with Surendranath Dasgupta of the University of Calcutta. He aspired to become sufficiently trained linguistically to secure a professorship in comparative religion at the University of Bucharest—an especially ambitious goal since no chair in the field existed at the University at the time. Daring to hope that one would be created for him, he immediately immersed himself in Sanskrit grammar. He also discovered the world-affirming variety of yoga known as Tantrism. This outlook came to express Eliade's view of religion universally: that the sacred is to be found within the profane rather than outside it.

Impressed by Eliade's diligence and enthusiasm, Dasgupta soon took him into his household and treated him almost as an adopted son. When Dasgupta discovered that Eliade was having an affair with his 16-year-old daughter, Maitreyi, under his own roof, he threw Eliade out of his house, and the two parted ways forever. Undeterred, Eliade proceeded to spend six months in the ashram of Rishiskesh, learning the practice, not merely the philosophy, of yoga. Even during his time in India, which constituted his fieldwork, he recognized that his heart lay in comparative religion rather than in any single religion. While in India, he continued writing, turning out newspaper columns and magazine articles about his travels, scholarly articles on yoga, and several novels. After three years in India, he returned to Romania, pressured by his father to undertake his already deferred year of military service. He intended to return to India but never did.

Back home, Eliade worked on his doctoral thesis on yoga, which he had begun in India, and simultaneously published articles, wrote novels, worked for journals, gave radio talks, and organized public lectures—all on a host of topics. He came to be considered the leading cultural figure of his generation of young Romanians. In 1932 he did his year of military service, largely doing translations. In 1933 he received his doctorate. In the same year he published the novel *Maitreyi*, about his love affair with Dasgupta's daughter. The book won a prize and became a best seller. It was the Romanian literary sensation of 1933, and Eliade became famous.

At the end of 1933 Eliade began teaching at the University of Bucharest. He had hoped to be offered a lectureship but had to settle for serving as an assistant to Ionescu. He held the post for five years, lecturing on various topics in both religion and philosophy. Ionescu, whom he continued to idolize, was the intellectual mentor of the Iron Guard, the Romanian counterpart to the Nazis, and wrote diatribes against Jews. Proclaiming that Jews deserved to suffer because they had rejected Jesus as their savior, he demanded that Romania rid itself of all Jews by any possible means. In his autobiography Eliade self-servingly emphasizes his own break with Ionescu over the status of Jews, but recent research has uncovered scores of viciously anti-Semitic newspaper articles written by Eliade himself (see Berger 1989; see, in reply, Rennie 1996, Chap. 13). Eliade associated Jews with everything foreign to true Romanian culture. In stock anti-Semitic fashion, Jews were blamed for communism, materialism, democracy, and modernity. Eliade's official biographer, M L Ricketts, uncritically accepts Eliade's own presentation of his position (see Ricketts 1988, II pp. 903–12). According to both, the fervently Romanian nationalism that Eliade espoused was spiritual rather than political. The Government nevertheless arrested and detained Eliade in 1938 because of his zealous support for the Iron Guard. Eliade was subsequently transferred to a sanitarium.

In 1940 Eliade was allowed to leave the country to serve in the Roman Legation in London, and in 1941 he was transferred to the Legation in Lisbon, where he remained until the end of World War II. He returned only once to Romania. Had he returned after the war, he would have faced arrest as a collaborator. He left for Paris in 1945, where he spent 10 years writing the scholarly tomes that made him internationally famous. In 1946 he served as a visiting professor at the *Ecole des Hautes Etudes* of the Sorbonne. In 1956 he was a guest lecturer at the Divinity School of the University of Chicago, and the next year he became a permanent Professor of the History of Religions. In 1962 he was named the Sewell S. Avery Distinguished

Service Professor. He co-founded the journal *History of Religions*. He became the best-known scholar of religious studies in the world and the leading advocate of the field. He retired in 1983, at the age of 76, and was honored with the establishment of an endowed chair in his name. He died in Chicago on 22 April 1986. Shortly afterwards, there appeared the culminating opus of his career: the 16-volume *Encyclopedia of Religion*, edited by him.

2. *Theory of Religion*

The tradition perpetuated by Eliade goes back at least to the nineteenth-century comparativists Friedrich Max Müller (1823–1900) and C. P. Tiele (1830–1902) and was continued by such figures as P. D. Chantepie de las Saussaye, Nathan Söderblom, Gerardus van der Leeuw, W. Brede Kristensen, and Raffaele Pettazzoni. This tradition, alternatively called comparative religion, phenomenology of religion, the history of religions, and, most simply, religious studies, maintains that religion is religion and little, if anything, else. Accordingly, religion is not the subject of anthropology, sociology, psychology, or economics. It is the subject of religious studies alone. The focus of religious studies is less on the truth of religion than on its origin and function. Religion, according to this tradition, arises for the distinctly religious purpose of making contact with God.

The tradition is, however, ambiguous about its aims. Sometimes it claims to be merely *presenting* the adherent's point of view, which purportedly deems religion a route to God. Other times the tradition claims to be *endorsing* the adherent's point of view. Now religion really does serve to make contact with God. The tradition thereby ceases to offer a mere description of religion and now offers an explanation, or a theory, of religion. But then the issue of the truth of religion proves difficult to sidestep. For if religion succeeds in making contact with God, God must exist.

Eliade's own position is unclear. He himself wavers between presenting and endorsing the believer's point of view. Typically, he declares modestly that 'The ultimate aim of the historian of religions is to understand, and to make understandable to others, religious man's behavior and mental universe' (Eliade 1959a, p. 162). In contrast to the theologian, from whom he repeatedly distinguishes himself, the historian seeks only to explicate, not to advocate, the adherent's point of view: 'The procedure of the historian of religions is just as different from that of the theologian. All theology implies a systematic reflection on the content of religious experience, aiming at a deeper and clearer understanding of the relationships between God–Creator and man–creature. But the historian of religions uses an empirical method of approach. He is concerned with religio-historical facts which he seeks to understand and to make intelligible to others' (Eliade 1959a, p. 88).

Yet in actuality Eliade ventures far beyond the mere presentation of the believer's point of view. He does not hesitate to discuss dead religions, whose adherents are scarcely available for consultation. His chief source of information for even living religions is not informants but their texts and practices. Moreover, he is prepared to grant that the meaning of all religions is partly, even largely, unconscious. Of religious symbols, for example, he states that 'we do not have the right to conclude that the message of the symbols is confined to the meanings of which a certain number of individuals are fully conscious, even when we learn from a rigorous investigation of these individuals what they think of such-and-such a symbol belonging to their own tradition. Depth psychology has taught us that the symbol delivers its message and fulfills its function even when its meaning escapes awareness' (Eliade 1959b, pp. 106–7). Eliade goes as far as to assert that even most professedly non-religious moderns are in fact religious: 'The majority of the "irreligious" still behave religiously, even though they are not aware of the fact.... [T]he modern man who feels and claims that he is non-religious still retains a large stock of camouflaged myths and degenerated rituals' (Eliade 1959a, pp. 204–5). Eliade outright bars any exceptions: '[E]ven the most avowedly non-religious man still, in his deeper being, shares in a religiously oriented behavior' (Eliade 1959a, p. 211). In imputing to avowed atheists a religiosity of which they are wholly unconscious and which contradicts their own conscious one, he is doing more than describing the actor's point of view. His defense of his view of religion as irreducibly religious cannot therefore be that it is so for actors themselves. It must be that religion is itself irreducibly religious. He must be offering a theory, not just a description, of religion.

The aspects of religion on which Eliade focuses are myths, rituals, and symbols. All are means of encountering God. Religion for Eliade arises not from an encounter with God but from a *yearning* for an encounter. Religion provides both places and times for the encounter. It demarcates as 'sacred' those places, or spaces, where God has previously appeared. Adherents assume that God, who is elusive, will more likely appear where God has already been than in a new place. Even if adherents believe that God is everywhere, they still go to church to seek out God. Similarly, religion sets off as sacred those times, always long past, when God most often appeared. Because adherents believe that God was closest at hand during or just after creation, they use myths about creation not merely to tell them when God was nigh but, more, to carry them back to that time: 'It is easy to understand why the memory of that marvelous time haunted religious man, why he periodically sought to return to it. *In illo tempore* the gods had displayed their greatest powers. The cosmogony is the supreme divine manifestation, the paradigmatic act of strength, superabundance, and creativity. Religious man ... seeks to

reside at the very source of primordial reality, when the world was *in statu nascendi*' (Eliade 1959a, p. 80). Myth works like a magic carpet.

In the tradition of religious studies, Eliade maintains that the quest for God, or the sacred, is not a means to an end but the end itself. Adherents seek the sacred because they seek the sacred, not because they seek something else through it. Religion can have anthropological, sociological, psychological, and economic benefits, but those benefits are considered to be only the consequences of a quest for the sacred and not the purpose of the quest. Furthermore, Eliade tolerates no reciprocal causality, the way, for example, Max Weber does. Religion can have non-religious effects, but not vice versa. Other scholars in the field of religious studies do allow for multiple causes as well as for multiple effects of religion, but they still insist that the main cause is the religious one. For the uncompromising Eliade, the sole cause of religion is religious. Somehow religion cannot arise for both religious and non-religious reasons.

Because Eliade pits the religious cause against all other proposed ones, he pits the field of religious studies against the social sciences, which he continually faults for accounting for religion non-religiously, or 'reductively': '…a religious phenomenon will only be recognized as such if it is grasped at its own level, that is to say, if it is studied *as* something religious. To try to grasp the essence of such a phenomenon by means of physiology, psychology, sociology, economics, linguistics, or any other study is false; it misses the one unique and irreducible element in it—the element of the sacred' (Eliade 1958a, p. xiii). Eliade takes for granted that, as disciplines, the social sciences stand committed to a non-religious account of religion.

Only once, in all his writings, does Eliade qualify his condemnation of the social sciences as resolutely reductive in their approach to religion. In fact, the qualification comes in an otherwise unbending indictment of anthropologists for spurning the adherent's point of view, which he assumes to be religious: 'Indeed, as it is well known, the main interest of the western scholars has been the study of material cultures and the analysis of family structure, social organization, tribal law, and so forth. These are problems, one may say, important and even urgent for western scholarship, but of secondary importance for the understanding of the *meaning of a particular culture*, as it was understood and assumed *by its own members* (broader, sympathetic and intelligent studies like those of Marcel Griaulle, E. G. [sic] Evans-Pritchard or R. G. Lienhardt, and a few other cultural anthropologists are rather exceptional' (Eliade 1967, pp. 502–3 [italics in original]).

Eliade's characterization of anthropology was outdated even when he wrote the essay, and it has become ever more outdated ever since. At best, his characterization, which borders on caricature, applies to the British brand of social anthropology influenced by A. R. Radcliffe-Brown. But the interest of British social anthropologists in social structure has rarely been at the expense of an interest in religion, as the cases of Evans-Pritchard and Lienhardt, as well as that of Radcliffe-Brown himself, conspicuously attest.

More important than the accuracy of Eliade's depiction of anthropology and of other social sciences is his argument. For him, the social sciences wrongly disregard the believer's point of view. But in fact they do not. Far from ignoring, let us even suppose, the religious nature of religion for adherents, social scientists begin with it. The actor's point of view constitutes the data to be accounted for. If social scientists ignored 'the meaning of a particular culture, as it was understood and assumed by its own members', they would have nothing left to account for. Why religion has meaning for adherents is what social scientists want to know.

Yet if social scientists necessarily turn to adherents for the data to be accounted for, they do not necessarily turn to adherents for an account of the data. Believers are akin to patients; social scientists, akin to doctors. It is not that religion is a disease to be cured but that religion is better understood by doctors than by patients. Patients may provide their own diagnoses of their ailments, but the final diagnosis rests with the doctor. That a patient rather than the doctor has the disease does not make the patient an expert on it. A patient's own diagnosis may turn out to be correct, but not because it is the patient's.

Eliade's indictment of anthropologists for spurning the actor's point of view is even more tenuous because as noted, he himself spurns it. If he is entitled to find a religious function in the professedly non-religious activities of avowed non-believers, why are social scientists not entitled to find non-religious functions in the professedly religious activities of avowed believers? In truth, both are entitled to venture beyond the actor's point of view.

Eliade's additional argument for accounting for religion religiously is that an account of any phenomenon must match the phenomenon being accounted for. Just as an account of a work of literature must be literary, so an account of a religious belief or practice must be religious. Eliade is right to insist on symmetry between an account and the subject of the account. But he is wrong to assume that the phenomenon being accounted for can be characterized and thereby accounted for in only one way. A 'literary' work such as a novel can alternatively be characterized as a work of history, sociology, or autobiography, and can then be accounted for accordingly. A Freudian account of religion characterizes a believer's relationship to God as a child's relationship to the child's father, and then attempts to account for that relationship psychoanalytically.

For Eliade to reply that God is more than a human being would miss the point. Freud never claims to be

able to account for all aspects of God, only for father-like ones. He never claims that his characterization of the relationship between believer and God as filial is exhaustive. As a whole, social scientific accounts of religion claim at most to be offering necessary, not sufficient, accounts of religion. Freud recognizes the gap between a father and a God, and he is prepared to turn to religious studies to close it. He claims only to be demonstrating how father-like God is. Eliade, however, would bar Freud from offering an account, whether necessary or sufficient, of any aspects of God, and would do so on the question-begging grounds that religion is religion and not psychology.

Elias, Norbert (1897–1990)

Born on June 22, 1897 to Jewish parents in Breslau (now Wrocław, Poland), then part of Germany, Elias, after completing his secondary education, first set out to study medicine, but soon changed to philosophy. Only after having completed his dissertation in that discipline in 1925 did he turn to sociology, pursuing his studies at Heidelberg, then one of the leading universities in Germany. He was accepted by Alfred Weber, Max Weber's brother, as a candidate for the *Habilitation* (conferring qualification as a university lecturer or professor), but when his colleague and friend Karl Mannheim obtained a chair at the University of Frankfurt, Elias followed him in 1930 as his assistant. His thesis for the *Habilitation* was completed by the beginning of 1933, but with the Nazis having taken over power in Germany, Elias had to flee, leaving Germany first for France, and then, in 1935, for London, on a grant from a philanthropic organization. Between 1935 and 1938, he completed his now famous two-volume *Über den Prozeß der Zivilisation (The Civilizing Process)*, which, as a book in the

German language published on the eve of WW II, did not receive much attention before republication in 1969. Elias remained in England where he obtained a post as lecturer in sociology at the University of Leicester but not before 1954. After retirement in 1962, he spent 2 years as professor of sociology in Ghana. Later on, he moved first to Amsterdam and then to Bielefeld (Germany), and was also invited to a number of European universities as visiting professor during the 1970s. In the mid-1980s he moved back to Amsterdam where he died on August 1, 1990 (on his biography, see Elias 1990 and Mennell 1989). Only during the 1970s, after a few sporadic articles, he had begun to publish extensively, first in English and later on, during his Amsterdam and Bielefeld years, drawing much on older manuscripts, in German. Some of the manuscripts were published only after his death.

There are few sociologists for whom knowledge about their biography is as central in understanding both their fate as a sociologist and their influence on the discipline as in the case of Elias. His first major book, and by far the most influential one, was not recognized as a masterpiece before his retirement as a university teacher. During the 1950s and 1960s, Elias seemingly was cut off, and cut himself off from his former German contacts, such as Theodor W. Adorno. Neither he nor those very few sociologists who acknowledged the outstanding achievement of *Über den Prozeß der Zivilisation* (e.g., Johan Goudsblom or Dieter Claessens) were successful in campaigning for this book. It only became famous in the early 1970s, when copies of the 1969 edition began to circulate among students and when a best-selling German paperback edition appeared in 1976. Translations into about 15 languages testify to the wide interest the book still attracts. Elias later complained about the insufficient recognition of his other works he published, among other subjects, on the sociology of sciences (Elias 1974), on time (Elias 1988), on relationships between the established and the outsiders (Elias and Scotson 1965), on sports (Elias 1970a) and even on topics such as Mozart (Elias 1991a) or *The Loneliness of the Dying* (Elias 1987a). Yet, without any doubt *Über den Prozeß der Zivilisation* is by far his most important, and probably also his only truly original contribution to sociology.

This is not to say that this work, like his others, does not draw on many concepts and notions developed by fellow sociologists. The idea of conceiving of society in terms of processes, instead of states, the absence of which from contemporary sociology was a reiterating theme in Elias's writings from the 1960s onwards, was firmly rooted not only in those American and English sociologists, such as M. Ginsburg and W. Osgood, whom Elias began to study in London in 1935 (van Krieken 1998, pp. 26–28), but also in important strands of German sociology, not least two thinkers whose work he was surely well acquainted with, Karl Mannheim and Alfred Weber. From the latter, he probably borrowed the notion of the civilizing process (Weber 1920), but giving it an entirely different content, as Weber by that term referred to the continual accumulation of knowledge, conceived of as a transition from 'naivité' to reflection and to mastering of nature (a theme that is not entirely absent from Elias's late writings). Other important influences that are easily recognized were Sigmund Freud and the Dutch historian Johan Huizinga, whose *Herftij de middeleeuwe* (Huizinga 1924) was Elias's dominant source on the late Middle Ages. But the blend Elias formed from these, and other ideas (such as traces of Darwinism or even Malthusianism), together with his own research, was decidedly unique.

The main achievement lies in the rigor with which Elias portrays the development of certain forms of conduct or manners, and ties this development to large-scale processes of state-formation and modernization on the one hand, and the concomitant effects on the psychic level, above all the display of emotions, on the other. The first volume of *Über den Prozeß der Zivilisation*, drawing on a variety of etiquette manuals, lucidly describes how norms of conduct we now think as self-evident, such as our eating habits, or norms concerning bodily functions including nakedness and sexuality, gradually developed from the Middle Ages onwards (with the selection of this 'starting point' not meant to imply that the process had not begun before that time). The Middle Ages are described as a time when man could answer needs and desires more spontaneously, when emotions were displayed with much less restraint. The gradual replacement of fingers with forks and knives at the table, the diffusion of the idea that spitting or blowing one's nose onto the ground or into the fingers are to be considered embarrassments to others, or the refinement and suppression of violence—all these are examples of the changes of our outward, overt behavior in the direction of increasing 'civilization.' These changes are accompanied by a gradual shift of the psychic apparatus which is characterized by an increasing influence of the super-ego (especially feelings of shame and embarrassment), and also of the ego, over the human drives, or the id, and by a restriction of affects and impulses, a 'damping' of the amplitude of the swings of emotion.

These developments were, in the second volume of *Über den Prozeß der Zivilisation*, analyzed as embedded in large-scale historical processes. The rise of the European empires, especially French absolutism, and the concomitant development of monopolies of violence on the state level restrained aggressive behavior in everyday conduct. The French court was also the site where the nobility developed those manners that were continually refined in the courtiers' competition for the king's favor (a process described in more detail in Elias 1969). These manners also served as elements of distinction of the entire nobility in contrast to the *bourgeoisie*—but to no avail, as the

latter, and later on also other social strata, began to imitate and to take over the nobility's patterns of behavior. These interdependencies are part of the overall process of modernization, especially of social differentiation, which requires of modern man a degree of reflection, foresight, and calculation unknown to medieval man. The distinctive overall characteristic of this process is the increasing internalization of social constraints, or the gradual replacement of 'outer' constraints by self-constraint—a self-constraint we are only sometimes conscious of, as it is routinized and habitualized, or incorporated, in our everyday conduct.

The main thrust of the book thus resonates well with a theme that has become central to the social sciences and the humanities in the 1970s: the investigation of domination, or constraint, not (only) on the (macro) level of relationships between social groups, but rather as it makes itself felt on the (micro) level of emotions and of individual conduct. It is a topic that can be found in the writings of Herbert Marcuse, or of Michel Foucault of the mid-1970s, who both echoed, albeit with very different emphasis (and seemingly without relating to Elias), the 'discontents of civilization' Sigmund Freud had already articulated in the late 1920s. Elias's account was perhaps received with even more sympathy as it nonetheless retained an optimistic tone. On the one hand, it was sensitive to the 'costs of civilization' that were felt by many at that time. On the other, Elias regarded the process of civilization as possibly leading to a balance between individual needs and the requirements of social life and in the long run to a more peaceful world society.

The uniqueness of *Über den Prozeß der Zivilisation* has two (related) dimensions: In terms of content, it lies in its blend of sociology with historical and psychological insight. In terms of method, it lies in its linking of grand theory with careful scrutiny of detail. Many sociologists would readily acknowledge that sociology has to look at historical processes; however, few, if any, have actually delivered a picture that so vividly describes the changes in people's manners and habits that have occurred from the Middle Ages onwards. Elias indeed gave a detailed description of how 'medieval man' (women are indeed largely absent from his account) gradually became 'modern man'; that is, where others have rendered snapshots, Elias has produced a movie. We can indeed understand that medieval man, as depicted by Elias (i.e., more impulsive, aggressive, and yielding to emotions than modern man) is alive today, but in a more suppressed, constrained way.

This, together with its often lucid language, largely free of sociological jargon, has rendered *Über den Prozeß der Zivilisation* popular among a wider audience of non-specialists. It has also been received well by historians such as Robert Chartier or Robert Muchembled, and also in psychology and other humanities. This is not meant to imply that Elias has triggered new research agendas in these disciplines; rather, his work was considered as congenial and as providing an overarching framework for research that had been devoted to similar topics, but without his broad, all-encompassing approach. At the same time, it is often concluded that by assuming a long-term trend towards 'more civilized' behavior, Elias possibly has drawn too far-reaching conclusions. While accusations of eurocentrism in his work easily can be refuted, the observation that other cultures have developed comparable standards of civilization (in Elias's sense) remains a challenge to the theory. It is also questioned whether medieval man indeed was so different. Certainly some of what Elias says on the display of emotions is valid; but the Middle Ages also had highly developed cultural rules for constraining and guiding behavior. A related problem is that Elias in the final analysis was not able to account for the cruelties of the twentieth century, not least those of Nazism. Elias certainly was aware of the ambivalences of civilization, but they were recognized by him mostly on the individual level, to the neglect of the dangers inherent in such seemingly civilized (and civilizing) forces such as modern technics or the state monopoly of violence. It must be added that during his late life, he became more sensitive to these issues, but still arguing fervently in favour of the possibility (not the unavoidability) of worldwide peace.

Elias's account exhibits serious lacunae also on the more factual level (van Krieken 1989). Among the deficiencies of *Über den Prozeß der Zivilisation* is the absence of an account of the processes through which the manners of conduct, described by Elias only with reference to the etiquette manuals, were effectively brought about by (private, and later on public) educational practices. Even more importantly, some presumably decisive conditions of modern civilization (in Elias's understanding of that term) are entirely lacking. Among these, most conspicuous are, first, the disciplinary mechanisms that were invented or became more widespread during the eighteenth and nineteenth century, especially the school and the factory, an observation that also points to the almost complete absence of the working class from Elias's work. Second, going further back in history, we also find a neglect of religion, certainly one of the most important sources of (European) civilization in the form of monastic discipline and more generally the religious prescriptions (and proscriptions), not least of protestantism.

Elias's later theoretical work, claiming to develop a general 'theory of human beings' (*Menschenwissenschaft*), exerted little influence on sociology in general. The earlier focus on social processes in these later writings was complemented by more emphasis on the 'figurational' nature of society, a term coined by Elias to point out that man and society could and should be understood as relational entities (see especially Elias 1970b, 1987b). With that concept, he claimed to

overcome the alleged dichotomy of individual and society that he saw prevailing in most other sociologists' thought—an idea borne not so much from in-depth acquaintance with sociological theorizing but rather from his desire, obvious in most of his late works, to portray himself as a unique innovator of sociological theory. Figurations were analyzed mainly in terms of power—or more exactly of power differentials—of the dynamics resulting from these, and finally of the outcomes which, as he often argued, cannot be understood as a realization of the purposes of social agents but rather as unintended consequences. In other words, his sociology was mainly a structural-relational one, with emphasis on the dynamics of social relations (in contrast to much of the 1930s to 1960s structuralism). The price was a neglect of individual motivation as well as of broader cultural systems of meanings, such as values or norms. The absence of such aspects from Elias's sociology is perhaps a consequence of his reluctance, acquired very early in his grappling with philosophy, of conceding ideas an existence of their own. Only in his latest writings did he start to acknowledge the influence of systems of meaning and language (Elias 1988, 1991b). With respect to some sociologists' claim to apply or to extend Elias's figurational sociology, it must be borne in mind that he never developed anything approaching a systematic account. Therefore, references to this theory must be viewed as partly gratuitous, as the idea of a 'relational' sociology certainly is not Elias's original contribution.

In contrast, fruitful inspirations continue to come from his theory of the civilizing process. Research in this spirit is accomplished above all in those places where he spent the last two decades of his life, that is, The Netherlands, especially Amsterdam, and also Germany, whereas in the USA, in spite of a few admirers such as Lewis A. Coser, his work has not met with wide attention. There have been fine extensions of the theory to specific phenomena such as eating practices, the history of marriage, or the domestification of fire, demonstrating how Elias's ideas are especially applicable to aspects of everyday cultural practices. But there are also attempts at rendering his approach useful to macro-analyses, such as in de Swaan's (1988) work on the development of modern welfare states. There is still much debate concerning the idea of civilization as an irreversible process and its relationship to modernity. While some researchers have explored the possibilities, and the conditions, of decivilizing processes, others have investigated processes of informalization, that is, the development of less restricted, destandardized norms of behavior, a topic on which Elias (1992, pp. 33–60) commented himself in one of his last works. Overall, it seems to be difficult to use Elias's ideas on the civilizing process as a starting point for really new developments; rather, much research focuses on applications of his insights to as yet unexplored phenomena, or on refining the theory in order to make it capable to account for phenomena that seem to contradict it at first sight.

Elicitation of Probabilities and Probability Distributions

Bayesian statistical and decision analyses require several inputs aside from observed data. Among these inputs are *prior distributions* and *utility functions* (Barnett 1982), which typically reflect the opinion(s) of an individual or group. *Elicitation* is the process of encoding the subjectively held beliefs of an individual (called the *elicitee*) or group into prior distributions or utility functions. Elicitation is thus a complex (and imprecise) mapping from human knowledge processing to a quantitative metric. As such, the study of elicitation methods has two primary divisions—first, the psychological aspects of how humans are able to articulate knowledge, and second, the mathematical aspects of how such articulated knowledge is captured for use in a Bayesian analysis.

1. Subjective Opinion within a Bayesian Framework

Subjective opinion is actually employed in several parts of any statistical analysis, Bayesian or frequentist (Lad 1996) (see *Decision Theory: Bayesian* and *Decision Theory: Classical*). The Bayesian model of decision making and inference is that prior beliefs about a particular attribute or state of nature are updated through data, and then used together with utilities to decide on a course of action. Formally, θ represents a (possibly multiattributed) state of nature such that $\theta \in \Theta$; $\mathbf{x}$ represents observed data; and

$f_\Theta(\theta)$	Prior
$f_X(\mathbf{x} \mid \theta)$	Likelihood
$f_\Theta(\theta \mid \mathbf{x}) = \dfrac{f_X(\mathbf{x} \mid \theta) f_\Theta(\theta)}{\int_\Theta f_X(\mathbf{x} \mid \theta) f_\Theta(\theta)\, d\theta}$	Posterior
$L(\theta, \mathbf{a}) = -U(\theta, \mathbf{a})$	Loss Function ($= -$Utility)
$D(\mathbf{x}) = \min_a \int_\Theta L(\theta, \mathbf{a}) f_\Theta(\theta \mid \mathbf{x})\, d\theta$	Optimal decision minimizes posterior expected loss

Under a personal and subjective view of Bayesian inference sometimes called subjective expected utility (Savage 1954), a decision maker will choose the course of action, a, that, based on prior beliefs updated by collected data, will have the least adversarial consequences when compared with other possible decisions.

Elicitation is concerned with mapping subjectively held opinions into prior probabilities, $f(\theta)$, and (subjective) preferences and value judgments into utilities (or exchangeably, loss functions) $L(\theta \mid a)$. These prior distributions and utilities represent an amalgamation of information available in addition to the data collected for a particular problem. As such, the most valuable elicited opinions are those of experts in the area of the problem, who may (or may not) have any training in statistical methods. Meyer and Booker (2000) and Chaloner (1996) outline reasons why subjective expert opinions are valuable in Bayesian analysis. These include the *a priori* information that can be quantified in the investigation of new, rare, complex, or poorly understood phenomena; when collecting large amounts of data is not feasible; when collected data alone is insufficient evidence for decision making; in designing experiments (see *Experimental Design: Overview*); in forecasting future events; and incorporating historical data and experiences that may not be well documented.

Spetzler and Staël von Holstein (1975) identify three stages of an elicitation process: the *deterministic phase*, which corresponds to choosing a functional form for a statistical model, the *probabilistic phase* where the subjective assessments are made, and the *informational phase* where verification checks are carried out. The primary focus of elicitation methods is on the middle phase (probabilistic). It is assumed generally, at least in statistical practice, that the first phase is fixed by the likelihood chosen for the data; the third phase is addressed more in the research on cognitive aspects of elicitation than the statistical aspects of encoding subjective beliefs and preferences.

2. Cognitive Aspects of Elicitation

In reporting subjectively held beliefs and preferences, there are several psychological heuristics that can lead to misrepresentation (see *Cognitive Psychology: Overview*). For more detailed discussion on these, early work on the subject is found in Kahneman et al. (1982), Kyberg and Smokler (1980), Hogarth (1987); updated coverage is detailed in Poulton (1986) and in Wright and Ayton (1994). The most common problems in eliciting subjective opinions come from:

(a) *Overconfidence*. Probability assessors tend to underestimate variability and the tails of the distribution.

(b) *Hindsight bias*. Most assessors believe they would have predicted correctly the outcome of an event; thus only the outcomes that actually occurred are viewed as having nonzero probability of occurrence.

(c) *Representativeness*. Expert judgments can be based on the synthesis of previously observed data. If that data came from small samples, it may not be representative. Other terms often used in conjunction with this heuristic are *base-rate neglect*, *small-sample fallacy*, and *misperception of randomness*. Another well-known aspect of representativeness is the *conjunction fallacy*, where higher probability is given to a well-known event that is a subset of an event to which lower probability is assigned.

(d) *Availability*. The probability of an event is judged by the frequency with which an event can be recalled in memory. The classic example of this is in the elicitation of beliefs about likely causes of death; botulism, which typically gets a great deal of press attention, is usually overestimated as a cause of death, whereas diabetes, which does not generate a great deal of media attention, is underestimated as a cause of death.

(e) *Adjustment and anchoring*. When an initial assessment is made, elicitees often make subsequent assessments by adjusting from the initial anchor, rather than using their expert knowledge.

To overcome possible biases introduced in the elicitation of probabilities and utilities by these heuristics, Kadane and Wolfson (1998) summarize several principles for elicitation:

(a) Expert opinion is the most worthwhile to elicit.

(b) Experts should be asked to assess only observable quantities, conditioning only on covariates (which are also observable) or other observable quantities.

(c) Experts should not be asked to estimate moments of a distribution (except possibly the first moment); they should be asked to assess quantiles or probabilities of the predictive distribution.

(d) Frequent feedback should be given to the expert during the elicitation process.

(e) Experts should be asked to give assessments both unconditionally and conditionally on hypothetical observed data.

3. *Eliciting Prior Distributions*

Eliciting prior distributions entails quantifying the subjective beliefs of an individual into a statistical distribution (see *Distributions, Statistical: Approximations*). Kadane and Wolfson (1998) discuss the distinction between *structural* and *predictive* methods of doing this. In structural methods, an expert is asked to directly assess parameters or moments of the prior distribution; in predictive methods, elicitees are asked questions about aspects of the prior predictive distribution; the predictive distribution is

$$f_Y(\mathbf{y}\,|\,\mathbf{x}) = \int_\Theta f_Y(\mathbf{y}\,|\,\theta) f_\Theta(\theta\,|\,\mathbf{x})\,\mathrm{d}\theta$$

and when no data has been observed (i.e., $\mathbf{x} = \{\varnothing\}$), this is known as the prior predictive distribution. In most complex problems, the predictive method is preferable, since it is more suited to the prescription for good elicitation methods outlined in Sect. 2. The functional form of the prior distribution is usually selected to be conjugate to the likelihood chosen to model the data.

The elicitation is generally executed by asking assessors to identify quantile-probability pairs (q, p) in some sense, where $p = P_X(X < q)$. Questions can be asked by specifying either a point or interval value for p or q, and responses can be given directly, as values, probabilities, or odds, or indirectly where preferences are stated between two alternatives.

To illustrate, consider various ways in which a prior distribution for the probability parameter in a binomial model might be elicited. The beta distribution is the usual choice for modeling the prior distribution, and functionally, the model is

$f_P(p\,\|\,\alpha, \beta)$	$\sim Beta(a, \beta)$	Prior
$f_X(x\,\|\,p, n)$	$\sim Binomial(n, p)$	Likelihood
$f_P(p\,\|\,\alpha, \beta, x, n)$	$\sim Beta(\alpha + x, \beta + n - x)$	Posterior

In this instance, x is the number of successes observed in n trials; from the way in which the prior parameters are updated by the posterior distribution, $\alpha + \beta$ can be viewed as a 'prior sample size' or measure of prior strength, and $\alpha/(\alpha + \beta)$ as a point estimate of the mean prior probability of a success. So one way to structurally elicit a prior would be to ask an elicitee to specify a prior sample size and probability of success, and this would uniquely define the parameters of the prior distribution. This, however, does not provide any feedback to the elicitee, and will almost surely be overconfident because of the way in which the variability of the distribution is never elicited directly. It also does not address the issue of the skewness of the distribution. Chaloner and Duncan (1983) propose a predictive method for eliciting this same prior distribution, where the elicitee is asked to specify the modal number of successes for given prior samples sizes, and then is asked several questions about the relative probability of observing numbers of successes greater than or less than the specified mode. The elicitee is also shown (graphically) the implied predictive distributions for future observations specified by their current answers, and then walked through a bisection algorithm to adjust the spread of the distribution.

While the predictive method just described is more difficult to implement, it is also more appropriate in terms of having the elicitee answer questions that will effectively allow them to communicate both their knowledge and their uncertainty within the constraints of the model. To illustrate, suppose that in the structural method, an elicitee specified a prior sample size of 15 and a prior mean of 1/3. In the predictive method, the same elicitee specified, for a sample size of 15, a predictive mode of five successes; the odds of observing four rather than five successes was specified as 0.8, and the odds of observing six rather than five success was specified as 0.7. The two priors, in the structural case, a beta (5,10) distribution, and in the predictive case, a beta (9.67,18.74), are shown in Fig. 1. This illustrates that way in which the predictive

Figure 1
Structural and predictive elicited distributions for the beta-binomial model

method allows for better representation of the actual state of knowledge the elicitee has.

Existing protocols for eliciting prior distributions are described in some detail in Kadane and Wolfson (1998). Elicitation protocols are described as being either *general* or *application-specific*. General methods are those that are meant for specific classes of models, such as the beta-binomial, the normal linear regression model, the dirichlet-multinomial, and others. Application-specific methods are ones tailored to the problem under study; several examples of these are described both in Kadane and Wolfson (1998) and French and Smith (1997). Application-specific methods are used typically for complex situations, where there may be no conjugate or standard prior that is suitable, or where the elicitation process must be *decomposed* in order to provide sensible assessments.

4. *Eliciting Utilities*

The ultimate goal of eliciting utilities is to make decisions that minimize expected loss (see *Decision Theory: Bayesian*), under the constraints of uncertainty specified by the prior distribution and likelihood function. Determining expected loss means constructing loss functions that consist of outcomes based on a quantity of interest, $\mathscr{Q}$, and the loss associated with each outcome. The loss can be fixed or random. In general, there is a set $\mathscr{A}$ of possible actions that can be taken, and for each element of $\mathscr{A}$, there are losses that may or may not depend on $\mathscr{Q}$. The set $\mathscr{A}$ must be exhaustive; in other words, all possible actions must be enumerated, and each action must be exclusive of every other action.

The first stage of the elicitation process should be to choose the action set $\mathscr{A}$ and the quantity of interest $\mathscr{Q}$. The set of actions should be well defined and must contain at least two elements. These actions are usually dependent on some quantity of interest. For example, if the action set consists of choosing which family planning program to implement, the quantity of interest might be some quantification of the state of infant mortality. In choosing the quantity of interest, it is important to make sure that $\mathscr{Q}$ is a quantity that incorporates the uncertainty inherent in the problem under study. Generally, $\mathscr{Q}$ will be a random quantity defined by a statistical model, and as such, it can have several dimensions.

Once the action set $\mathscr{A}$ and the quantity of interest $\mathscr{Q}$ have been determined, the second stage of the elicitation is to construct loss functions based on them. This is the most difficult stage of the elicitation process. If several stakeholders are involved in the decision-making process, they may construct these separately or as a group; regardless, those assessing the loss functions must give careful thought to the consequences resulting from each action in $\mathscr{A}$ for any value of $\mathscr{Q}$. For useful overviews of loss function elicitation strategies, see works by Clemen (1996), Zeleny (1982), Edwards (1992), and Saaty (1980). In general, it is necessary to specify the form the loss functions should take; this is sometimes specified in advance, but it is advisable to consider this as part of the elicitation process.

There are several 'standard' loss functions (see *Decision Theory: Classical* for a discussion of them). One of the best-known examples of a loss function is the 0–1 loss function generally applied to statistical hypothesis testing. In this case, the set of actions is given by $\mathscr{A} = \{a_1$: reject the null hypothesis, a_2: do not reject the null hypothesis$\}$ (Berger 1985). An extension of this is the 0–k loss function, which is typically written (letting $\mathscr{Q} = \theta$)

$$L(\theta, a_i) = \begin{cases} 0 & \theta \in \Theta_i \\ k_i & \theta \notin \Theta_i \end{cases}, \quad i = 1, 2$$

There are many possible variants on this loss function that could be considered, and identifying the 'form' of the loss function is the more controversial of the tasks that must be performed in eliciting utilities. Given the conceptual framework of a 0–k loss function, consider the next elicitation task—identifying the values of k_1, k_2. Because k_1, k_2 can represent rather intangible quantities, it is often advantageous to specify their relative rather than absolute values. Consider that the 'optimal' decision in this example is to choose a_1 when

$$\frac{k_1}{k_2} > \frac{P(\theta \in \Theta_2 \mid \mathbf{x})}{P(\theta \in \Theta_1 \mid \mathbf{x})} = \frac{P(\theta \in \Theta_2 \mid \mathbf{x})}{1 - P(\theta \in \Theta_2 \mid \mathbf{x})}$$

Then the remaining elicitation task needed for decision-making is to elicit the ratio k_1/k_2, which

Figure 2
A decision maker should choose a_1 or a_2 based on the values of $P(\theta \in \Theta_1)$ and k_1/k_2

simplifies the elicitation task from eliciting k_1, k_2 directly or independently. The ratio on the right-hand side above can be viewed as the ratio of the posterior probabilities that the parameter lies outside the 'rejection region' ($\theta \in \Theta_2$) to the posterior probability that the parameter lies within the region (or $\theta \in \Theta_1$). From this, a general relationship can be drawn between the functional form of the model and the two quantities for which preferences need to be elicited; this is illustrated in Fig. 2.

Exploiting the relationships between the functional form of the model and loss function and the quantities about which preferences and value judgments must be elicited is a useful strategy. Many examples of the application of evaluating utilities and preferences are found in journals in the fields of risk analysis, accounting, and economics.

5. *Other Issues*

It is sometimes advisable or necessary to elicit the opinion of more than one individual. Genest and Zidek (1986) review methods for combining the opinions of several experts; Cooke (1991), Meyer and Booker (2000), and Morgan and Henrion (1990) provide guidelines for structuring elicitation tasks with groups of experts. French and Smith (1997) have several examples of analyses where elicitation of more than one expert is used. In general, there are two approaches used in group elicitation—the collective opinion of the experts is elicited in the whole or the opinions of several experts can be combined in some fashion.

Another issue that is discussed in the literature (see Kadane and Wolfson 1998 for further discussion) is that of validating and comparing elicitation methods. There are several criteria that might be considered; the most important of these is *coherence*, that the elicited opinions obey the laws of probability (see *Probability: Formal*). In general, this should be considered a minimal requirement for any elicitation method. Other considerations are the *reliability* of the elicitation methods in producing stable reflections of the elicitee's beliefs and preferences; also, the elicitation method can be validated by an examination of whether it obeys *proper scoring rules* (i.e., does not systematically encourage the misrepresentation of beliefs and preferences). Some practitioners of elicitation, particularly in the field of meteorology, advocate the *calibration* of expert opinion, whereby elicited opinions are adjusted to reflect the elicitee's ability to correctly predict events. Subjective Bayesians typically object to calibration because subjectively held beliefs and preferences are not meant to be infallible. A final consideration given in the validation and comparison of elicitation methods should be given to the modeling of errors-in-elicitation. Some cognitive aspects of this are described in Poulton (1996), but very little statistical literature is available on the subject.

L. J. Wolfson

Elites, Anthropology of

The term elite, formerly an expression referring to a theological elect, came into circulation with its current meaning in the nineteenth century as mass society took shape in the West. Elites have been under-theorized and understudied in the social sciences, and thus the term has a certain vagueness: both 'traditional' and 'modern' societies are said to have elites, and the privileges of elites may be grounded in genealogy, land ownership, control of capital, bureaucratic position, educational attainment, or religious status, for example. The first to theorize elites were the Italians Vilfredo Pareto and Gaetano Mosca, each working independently in the late nineteenth and early twentieth centuries to develop a theory of hierarchy in modern society that was less abstract and less tied to the dynamics of capitalism than Marx's theory of class.

Anthropologists have not, until recently at least, evinced great interest in writing about elites, and there is hardly a field of elite studies in anthropology. The first generation of anthropologists, attempting to develop holistic descriptions of entire societies, was not interested in detaching elites from broader social wholes in order to focus on them and, in any case, many had been drawn to marginal societies in low-rent neighborhoods of the world system partly to escape their own privileged backgrounds at home. As more recent generations of anthropologists have developed an interest in colonial and post-colonial society, urban anthropology and repatriated anthropology, elites have still received surprisingly little ethnographic attention. There are many reasons for this, including practical obstacles, the historical conventions of the discipline itself, and the temperamental preferences of anthropologists. Elites are busy, important people who have the power to elude or obstruct anthropologists, and whose lives are usually unsuited to the anthropologist's classic (and time-intensive) technique of investigation—participant observation (Hertz and Imber 1995). (While it is easy to imagine anthropologists helping peasants with the harvest, spending hours with poor womenfolk while they cook and clean, or idling with urban streetcorner society, it is harder to imagine them sitting unobtrusively at board meetings, loitering in the hallways of the upper floors of the Pentagon, or being repeatedly invited to dinner with the Rockefellers.)

Anthropologists have also continued to neglect the study of elites for reasons of convention: the traditional division of labor in the social sciences has given anthropologists dominion over the geographically and socially marginal, and anthropology has historically developed as a discipline that explains to the center the logic of lifeways on the periphery. This convention retains a certain force even in the era of repatriated and postcolonial anthropology. There is also, finally, for many anthropologists a temperamental obstacle to fieldwork with elites: the traditional anthropological methodology of participant observation has historically demanded of anthropologists a reflexive sympathy for the people they have studied—largely poor and marginal people. This, combined with the liberal politics of most anthropologists, makes fieldwork with elites psychologically unappealing and conflictual.

Insofar as first and second wave anthropologists wrote about elites, they often studied them not so much as topics in their own right but as components of larger social wholes or as products of social processes that were themselves the principal object of analysis. Examples include Dumont's (1970) work on caste, Barth's (1959) monograph on patron–client relations among the Swat Pathans of Pakistan, Kuper's (1961) study of an African aristocracy, and Sahlins' (1958) work on chiefs and followers in Polynesia. Marcus (1983) observes that such work on elites tended to cluster in particular ethnographic zones where kinship—the core subject matter of early anthropology—was particularly important in understanding the dynamics of elite status: South Asia, marked by its caste system; the Pacific Islands, home to hereditary chiefs and 'big men'; Africa, peopled by hereditary chiefs and kings; and the oligarchies of Latin America. Work by first wave anthropologists emphasised the importance in sustaining elite status of kinship relations, marriage strategies, land inheritance, patron–client relations, and ritual—what we might call the preindustrial sinews of elite power.

As colonization, industrialization, and missionization transformed societies around the world, new sinews of elite power emerged. Accumulation of capital (not just land) became increasingly important, as did access to education, geographical mobility, and positions in the expanding bureaucracies of new states. In many colonial societies the power of traditional, usually hereditary, elites was challenged by the rise of new elites who owed their standing to Western education, positions in emergent state bureaucracies, and trading opportunities provided by the colonial en-

counter. The process of decolonization usually mobilized, or became ensnared in, rivalry between rising and falling elites but, over time, some sort of complex hybridization of old and new elites was often effected through, for example, intermarriage, the conversion of capital into land, and the Western education of chiefly offspring. (This process broadly re-enacted a similar development that took place in the industrializing societies of Western Europe where the ancient aristocracies and rising bourgeoisies learned over time to accommodate to one another through marriage, education, and financial alliance.) Processes of elite formation and mutation under and after colonialism are discussed by Ferguson (1990), Geertz (1963), Leach and Mukherjee (1970), Luhrmann (1996), and Vincent (1971).

As societies become more complex, bureaucratized, and marketized, the bases of elite power shift and new kinds of specialized elites (from physicists to investment bankers) emerge. One of the distinguishing features of complex industrial societies is that they have a more pluralistic constellation of elites than do their predecessor societies. Moreover, if the dominance of elites in 'traditional' societies was often expressed in direct, face-to-face contexts, elite dominance in industrial society increasingly is mediated by bureaucracies, investment markets, and educational systems, distancing elites from those below them. And if the privileges of elites in traditional societies were often brazenly hereditary, reproduction of elites in industrial societies is, in theory at least, less regulated by kinship. Thus, Marcus and Dobkin (1992), who studied traditional elites on the Pacific island of Tonga and dynastic families in the US, argue that, while kinship appears to define the transmission and reproduction of elite status for the Gettys just as much as it does for the Tongan aristocracy, the analogy is superficial and deceptive: for families such as the Gettys kin relations of inheritance constitute a shell that conceals the corporate and bureaucratic character of the contemporary dynastic family dependent, as it is, on lawyers and money managers for its functioning and reproduction.

Cohen (1981) points out that in industrial, bureaucratic societies recruitment to elites is generally advertised as meritocratic, yet principles of heredity often find a way to infiltrate and suborn processes of promotion ostensibly based on merit as members of elites transmit their privileges to their children. For example, private schools become a means of converting the wealth of one elite generation into the superior educational attainment of its children, allowing the circumvention of the meritocratic prohibition on the simple inheritance of elite position. Moreover, as both Cohen (1981) and Bourdieu (1984) argue, elites come to value taste and manners as signs of distinction when recruiting a new generation of leaders, and accomplishment in this realm is asymmetrically transmitted to the children of existing elites as they are subjected to esoteric training in manners and taste in informal social contexts within the family, in private clubs, in peer groups, and at private schools. Secret societies, such as the freemasons and the fraternities at elite universities in the US, can also play a role in short-circuiting the processes of meritocracy.

Anthropologists engaged in fieldwork in Western societies have tended, until recently at least, to ignore Western elites. Thus, for example, anthropologists in the 1950s and 1960s kept out of the lively, at times bitter, debate in sociology and among public intellectuals provoked by the publication of Mills's (1956) argument that, far from being a meritocratic society governed by a plurality of separate elites, the US was ruled by a single 'power elite.' According to Mills this elite class was integrated loosely by the backstage functioning of private schools, elite universities, private clubs, and the marriage market and had become adept at disguising its privileges and its degree of integration from the mystified masses. Instead of joining this debate on elites in US society, American anthropologists engaged in fieldwork at home at this time were busy writing about 'the culture of poverty' or, in a logical sequel to earlier fieldwork abroad, studying processes of acculturation and economic struggle in Western enclaves of ethnic migrants from Third World countries. To this day, repatriated anthropology produces far more studies of the marginal and powerless—welfare mothers, drug dealers, immigrant street traders, and so on—than of elites.

While it makes sense in terms of the historical conventions of the discipline that anthropologists would continue to seek their subjects on the periphery, albeit a periphery redefined, the anthropological tradition for studying down is problematic. It helps to ghettoize anthropology since those who prefer to study the marginal can more easily be written off as marginal themselves. It leaves a lacuna in anthropology's traditional boast to be the science that studies all of human culture, everywhere. Above all, while it is important for anthropologists to make the point that the poor and the marginal have cultures that have value and are worth studying in their own right, there is danger in an asymmetric ethnographic gaze that imposes the risks of anthropological surveillance disproportionately on the least powerful members of society. If one of the crutches of elite power is invisibility, anthropologists have an important potential contribution to make to democracy and public discourse, as well as to anthropological scholarship, in adapting and redeploying their traditional methodology for the study of elites.

A milestone in the recognition of these problems came, in a historical context where anthropologists were questioning their complicity with processes of domination from Vietnam abroad to the ghettoes at home, with the publication of Nader's (1972) article calling on anthropologists to 'study up.' Nader drew attention to the problems of imposing a special

visibility on the poor and powerless and appealed to anthropologists to shine an ethnographic spotlight on the functioning of power in the US. Her article is often misrepresented as a call for anthropologists to engage in bounded studies of elite cultures, where in fact she called for studies of 'vertical slices' of social life that would enable the analysis of hierarchical relationships between elites and others and dramatize the essential nature of those relationships for the grounding of elite status and power. This was a way of reworking the traditional holism of anthropology. However, if the first generation of anthropologists had subordinated the study of elites to the analysis of societies as social wholes, Nader's is a call for holism that puts the privileges and power of elites front and center.

Marcus (1983) and Marcus and Dobkin (1992) have also called for more anthropologists to study elites in the West and Marcus, as editor of the *Late Editions* series of edited volumes, has provided a forum for younger anthropologists to experiment in a variety of voices with article-length portraits of, among others, elite subjects. Marcus's own approach to studying elites differs in emphasis from Nader's. He is more interested in cross-cultural comparisons between the functioning of Western and non-Western elites, and he has called for a move away from structural analyses of elite power in society toward fine-grained ethnographic analysis of elite subcultures as, more or less, self-contained entities. His own work on dynastic families explores, for example, the way such families cultivate taste and display wealth, intergenerational relationships in wealthy families, and the social production of cynicism, eccentricity, and piety among the super-rich.

Recent years have seen a number of innovative studies of Western elites. Rose (1989), in a highly literary response to Nader's call to study 'vertical slices' of American life, juxtaposes vignettes from the lives of poor African-Americans in Philadelphia with scenes from the lives of business elites and the country gentry in Pennsylvania. Weatherford (1981) has written, in a somewhat popular vein, about the culture of the US Congress. Wedel (2001) has written a book that mixes investigative journalism and anthropology in its portrait of IMF and World Bank officials assigned to reform the economies of post-Soviet Eastern Europe. Pedelty (1995) has written a vivid account of the journalistic elite that shaped Western understandings of wartorn Central America in the 1980s, exploring the ways in which these journalists' articles are shaped in response to the interests of elites both in Central America and the US. Luhrmann (2000), author of a previous (1996) book on a post-colonialist elite in India, has written a fine study of the socialization of American psychiatrists—an increasingly important category of expert in the production of American culture and identity. Harding (2000) has written an ethnographic portrait of Jerry Falwell, bringing anthropological categories to bear on the analysis of a key player in the US religious elite, and Wulff (1999) has written about the culture of international ballet performers.

Some of the most rigorous and innovative ethnographic work on Western elites has appeared in the new field of science studies. This may be in part because scientists are supposed to espouse a culture of openness, thus making them easier to study from a methodological point of view (especially if they are clustered conveniently in laboratories). Also, scientists are what we might call marginal elites, being esoteric enough that they more comfortably fit the anthropological template of the exotic than do, say, lawyers and investment bankers. Relevant examples in the anthropology of science include Latour and Woolgar's (1979) study of the making of scientific facts in a biology laboratory; Traweek's (1988) investigation of particle physicists in Japan and the US; Gusterson's (1996) examination of the culture of American nuclear weapons scientists in California; Helmreich's (1998) portrait of artificial life specialists at the Santa Fe Institute; and Rabinow's (1996) ethnography of Cetus, a biotechnology corporation, which explores the conjoining of venture capital and scientific entrepreneurship in the remaking of the world. These ethnographies all broadly examine the socialization of scientists; the role gender, race, and class play in their cultural worldviews; and the construction of scientists' special authority as experts.

This new wave of studies of Western elites does leave some obvious, and rather large, gaps. We still await authoritative ethnographies of most government bureaucracies, of military elites, and of cultural elites from university professors to television producers. (The new field of cultural studies, which is emerging as a powerful interlocutor for many anthropologists, has, strongly influenced by the Birmingham School, shown more interest in popular culture, especially its reception, than in documenting the culture of the producers of culture.) Above all, we lack studies of business and corporate elites, these subjects having largely been surrendered to business schools in an unspoken interdisciplinary division of labor.

Recent years in anthropology have seen some experimentation with new modes of research and writing. We can expect the maturation of elite studies in anthropology to accentuate this trend. Given that elites are often geographically dispersed, busy, and difficult to access, we can expect modifications to the traditional ethnographic method as more anthropologists move to multi-sited projects and to supplement participant observation with archival work, interaction in cyberspace, and condensed formal interviews with informants met only once—a strategy I have elsewhere referred to as one of 'polymorphous engagement.' It is also surely no coincidence that many ethnographers of elites have abandoned the objectifying conventions of classic ethnographic writing for more humanistic, journalistic, novelistic,

or ironic styles of writing, since in elites we have informants who are also sophisticated and powerful readers of our work and will demand to engage with our theories and conclusions, often in public fora. Learning how to respond gracefully and honestly, but without losing anthropology's critical edge, is our challenge for the future.

Elites: Sociological Aspects

As commonly defined, elites are small groups of people who exert substantial power and influence over the public and over political outcomes. This power is based on the possession and control of various resources, including economic ones (capital and means of production), control of organizations, political support, symbolic means (knowledge, information, and the manipulation of symbols), and personal resources (such as charisma, or ambition). Some elite persons—those whose power is based on political support or charisma—are also referred to as leaders.

On this basis, the major elites in contemporary societies include political leaders (who in democracies are usually divided between the government and the opposition), the heads of the state bureaucracy, the military and the judiciary, the captains of business and industry, key media people (top journalists, editors, owners and managers of large-scale media organizations), trade union leaders, the intellectual–cultural–academic elite (influential writers, philosophers, publicists, and the like), religious or church leaders and leaders of civil society, of major interest groups, nongovernmental organizations and social movements (the latter are frequently referred to as non-established, counter-elites).

Vilfredo Pareto (1935), who introduced the term into the social sciences, defined elites as those who are most capable in any area of activity. But, as most commonly defined in the social sciences today, elites are not necessarily the best and the brightest; they are

simply those who, for whatever reason, have been able to gain the resources that lend them substantial power and influence. Occasionally the elite is equated with the upper class. However, by the above definition, elites are those who wield power, irrespective of their class background and socioeconomic status. In general, elites tend to stem from privileged class background, but not necessarily from the upper class. The top business elite belongs to the upper (capitalist) class. But other elites (e.g., trade union leaders, prominent media figures, church leaders) do not necessarily belong to that class, yet they still hold power, and therefore, elite positions.

Some elites command more power than others, and elites may thus be looked upon as a pyramid: at the top there are those who hold power at the macro, or national level—such as political leaders, and the top military brass. At the lowest level there are the elites of small units, such as heads of universities or local organizations. And in-between there are those who hold less power at the national level or hold power only in certain sectors or localites, such as the leaders of states or provinces (in a federal system) and city mayors, though the boundaries between the various levels are not sharply defined. The school of thought in the social sciences that focuses on the role of elites in society—or elite theory—has been concerned chiefly with top level or national elites.

1. *Classical Elite Theory*

Historically, elite theory developed as an alternative to class theory. While class theory, fathered by Karl Marx, stems from the middle of the nineteenth century, elite theory emerged only at the turn and the beginning of the twentieth century. Once it appeared, however, it did so with triple strength, under the aegis of the Italian classical social theorists Pareto (1935), Gaetano Mosca (1939), and Roberto Michels (1915).

The central idea of these founding fathers is, that all societies and organizations—including democratic ones—are divided into the few who rule and the many who are ruled. The ruling minority—dubbed by Pareto the governing elite or class, by Mosca the political or ruling class, and by Michels the oligarchical leadership—concentrates power in its own hands, uses it in its own interest, and then finds a formula to justify its rule. And the majority that is ruled, the masses, is largely powerless and has but little impact on policy outcomes.

To this Mosca adds that, according to democratic theory, majorities rule minorities. In fact, even in a democracy, the domination of an organized minority over an unorganized majority is inevitable. According to Michels, the very principle of organization spells oligarchy. And Pareto adds that although in principle governing elites are made up of those who excel, this is not necessarily so in practice. As long as a governing elite is composed of people with qualities of excellence and is open to absorb the most talented from the nonelite—while shedding the more degenerate of its own members—this ensures a circulation of elites, that keeps society in a state of equilibrium and gradual change. When this circulation is impeded, the equilibrium is upset and society becomes prone to violent upheavals.

According to critics, the notion that there are those who govern and those who are governed is self-evident. To transcend this truism, it would have to be shown that the governing elite has internal unity, which exacerbates its power. This, in fact, is the thesis of the, now classical, theorist C. Wright Mills. Mills (1956) sees even democratic (especially US) society as dominated by the top executive political, military, and corporate economic personnel, that together form a concerted power elite. At the bottom there are the masses, the powerless and apathetic receiving end of the power-elite's manipulation and rule.

Another critique leveled at these classical elite theorists was, that they overemphasized the similarity of elite rule in all types of regimes. Thus they had little to say on what still makes democracy (with all its iniquities) a distinctive regime. It fell to the lot of other theorists—known as liberal, democratic elite theorists—to fill this void. These included the German Max Weber who wrote at the turn and the beginning of the century, and surprislingly also Mosca in some later developments of his thought. In the post-war era they also included Joseph Schumpeter (1954), Raymond Aron (1968) and Suzanne Keller (1963), whose writings may now also be considered classical.

Rejecting the idea that democracy spells the rule of the people, and clarifying that it inevitably spells elite rule, these theorists still stress its distinctiveness. This lies not only in restrained elite competition and free elections that ensure the responsiveness of elites to the demands of the public, but also in the structure of elites. In a democracy, this is characterized by the plurality, autonomy and differentiation of elites, which enables them to countervail each other's power. These checks and balances increase the liberty of the public and the power-holders' responsiveness to it.

In opposition to this democratic elite theory, it has been argued that the virtues it attributes to democracy are more fiction than reality. Hence those who believe in them are overly complacent with respect to democracy, naively believing that 'the system that we ought to have is the very one that we do in fact have' (Pateman 1970, p. 16).

2. *Contemporary Elite Theories*

Such critiques have been one of the main causes of the fact that, since the 1960s, elite theory has been overshadowed by Marxist and neo-Marxist class theory. Yet elite analyses have not disappeared, and, indeed in quantity and variety have exceeded the classical writings on this topic.

Some of these new analyses—such as those by William Domhoff (1983), and Thomas Dye and Harmon Zeigler (1996)—may be seen as descendants of classical elite theory, in offering a skeptical view of democracy, albeit with a new twist. These observers of the US scene see the power of elites as exacerbated by their interlocking and consensus. They view popular elections as little more than rituals which lend the ill-informed masses sparce influence over policy. Indeed, it is the elites that preserve democracy, which works best when the masses are only minimally involved in politics. Intriguing as these ideas are, they lay themselves open to charges of excessive cynicism.

Such a charge is, in fact, implied by writers, such as Nelson Polsby (1985) and Giovanni Sartori (1987). These are representatives of the pluralist school of thought and they argue that democracies are distinguished by a plurality of elites, that occasionally are in coalition, and, occasionally, in opposition to each other. Such elites develop more links with the public and greater responsivenss to its wishes, than elites ever did before. Once again, swinging the pendulum to the other side, Robert Dahl (1985), who previously was a prominent pluralist, later took a different view in which, although in a polyarchy (i.e., democracy) there is a plurality of elites, the business elite is more powerful than the rest, and can make the government serve its interests.

Is it the case, then, that elites in Western democracies are plural, divided and in collision, or are they unified and in collusion with each other? An original scheme on this has been presented by John Higley and Michael Burton (1989) and some of their colleagues. According to Higley and colleagues elite configurations vary and have an impact on the structure of regimes. Disunified elites generate unstable regimes and ideologically unified elites give rise to stable autocratic regimes. By contrast, consensually unified elites—divided ideologically yet unified by their agreement on the rules of the political game—produce stable democracies.

Critics view this scheme as containing tautological elements (democracy prevails when elites adhere to its rules); but its proponents' response is that consensual unity historically always precedes the emergence of democracy. Accordingly, the major political turning points in modern history have been transformations of elites into consensually united ones. In any case the scheme is most useful for having produced a large number of studies of the emergence and development of democratic regimes.

Such developments, particularly transitions to democracy in various parts of the world, have also been the focus of other elite analyses. These concur that such transitions are usually crafted by elites. They take place where the previous elite oligarchy included some restricted competition between elites (Diamond and Linz 1989), through the forcible imposition of democracy by elites, or through compromises between contending elites (Karl and Schmitter 1991, Huntington 1991). At times they produce quasidemocracies, in which the elected elites' power is considerably greater than it is in representative democracies (O'Donnell 1994).

One widespread accusation, leveled at both classical and new elite theories, is that they are not only elite, but elitist theories, and that they applaud elite rule. A response to this charge has been made by a new version of democratic elite theory (Etzioni-Halevy 1993). This holds that the analysis of elites is crucial not as an endorsement, but as a scrutiny, of their power, without which it would be more pernicious. According to some, elites are the enemies of democracy. In fact, since elites are inevitable, all depends on their inter-relations. What makes democracy distinctive is the attempt to set them up as watchdogs for each other, through their relative autonomy, particularly that of the nongovernmental elites from the government.

This, indeed, is the central, implicit, metaprinciple of liberal democracy. It is nowhere so stated, but without it, the explicit principles of democracy, free competitive elections, human rights and civil liberties, would fall by the wayside. Without an opposition that is free from repression by government and not dependent on it for its livelihood, there could be no free elections. Without a judiciary that is exempt from government interference and cannot be dismissed by it, human rights could not be ensured. And without a media elite that cannot be gagged, freedom of expression, free elections, or human rights and civil liberties, could not be sustained.

Some of the main threats to democracy spring from the subversion of this metapricinciple as, even in Western countries, elites develop a close connection with each other. Thus, politicians frequently live in a cosy symbiosis with business magnates. A symbiosis has also developed between state elites and leaders of civil society, social movements and voluntary organizations.

The relative independence of such bodies has long been one of the hallmarks of democracy. But, recently, environmental movements have been institutionalized in parties, governments, and governmental organizations. And voluntary organizations let governments offload some of their responsiblities to them in return for funding. Thus, the boundaries between the state and civil society have been blurred and the latter can no longer serve as a check to government power. This puts the onus of preserving the watchdog metaprinciple of democracy more heavily on other elites, such as the media, which are not always well equipped to carry the burden.

3. *Recent Developments in Elite Analysis*

Elite and democratic elite theory, justifiably, has also been censured for paying insufficient attention to the

public, and to economic, class-based inequalities within it, particularly in Western (capitalist) democracies. Such inequalities and exploitation had long been the main theme of Marx-inspired class theory. However, with the breakdown of communism in Eastern and Central Europe, class theory has suffered a severe setback.

This opened an opportunity for elite analysis to incorporate socioeconomic inequality into its own domain. It did so by evincing a greater interest than before, in linkages between elites and the public, and in the impact of such linkages on both democracy and inequality. Such linkages involve a reciprocal relationship, whereby elites organize and promote the interests of certain constituencies, classes or groups within the public, which in turn support these elites. Linkages may be strong and clear, or weak and blurred. They may be direct, or through mediating bodies. Sustainable democracy relies on linkages that combine strength with extensive mediation (Pakulski 2000).

Much also depends on which groups within the public the elites link up with. Linkages between elites and the disadvantaged classes and groups within the public, are crucial for a stable democracy. For the disadvantaged—encompassing millions of people—cannot promote their own interests, unless they generate or adopt elites to represent them. And, unless the interests of all, including the disadvantaged, are represented in the political arena, there can be no democracy. The coupling of elites and the disadvantaged also makes elites struggle for a more egalitarian distribution of resources, and thus is essential in promoting progress towards greater equality.

This is, in fact, what happened in the West at the end of the nineteenth and the beginning of the twentieth centuries, as labor movement, union, and party-leaders linked-up with the working class and, to some extent, promoted their interests. At that time workers' wages rose, inequalities decreased, the working class gained the suffrage, and democracy was born.

Recently, in postindustrial society, the linkages between elites and the disadvantaged—those in the underprivileged labor market, the unemployed, the poor, the excluded—has become especially problematic. Together with insecurity of employment, this creates a destabilizing potential for democracy (Higley and Burton 1999).

At the same time, several elites have uncoupled from the disadvantaged. Labor-party leaders have turned their parties into 'catch-all' parties; leaders of social movements are more concerned with quality of life and identity issues, than with the redistribution of resources; and unions have been weakened and can no longer staunchly support the interests of the workers. This partial vacuum in elite–public linkages exacerbates inequality and insecurity. This, in turn, boosts fundamentalism and spurs the birth of populist and doubtfully democratic movements (Etzioni-Halevy 1997).

Another inequality is that between men and women in power positions. Until recently women were virtually excluded from such positions, even in advanced democracies, and this fact was largely ignored in elite analysis. But in recent decades women's presence in such posts has increased—even though they have not reached parity with men—and so has the attention paid to this issue in elite analysis. This analysis now shows that, to access elites, women must often offset the 'handicap' of gender, by even more privileged social background, and even greater human capital, than those of their male counterparts. Once in decision-making posts, women tend to have less hierarchical orientations than men; thus their increased representation in them constitutes a crucial factor in decreasing inequalities in society at large (Vianello and Moore 2000).

New times create new elites, and the new elite analysis also focuses on these. The transition from communism in Eastern and Central Europe has been led by elites and involved novel elite configurations. Yet a marked continuity of elite personnel has been widely noted, so that the pressing question is whether changes in elite values and behaviours have accompanied the transition.

Meanwhile, in the West the information society has generated new conglomerations of power in the high-tech, computer, and Internet centered fields; and the elites at their head have few visible links with the public. Further, globalization has given rise to transnational organizations—such as the International Monetary Fund and the European Union—and these have sprouted a second layer of elites beyond those of the state. These elites have the ability to shape people's life chances around the globe, yet they maintain but a minimal accountability to the public, to the detriment of democracy in global or transnational organizations. New transnational grassroots movements whose counter-elites would balance globalization from above with globalization from below, could vitalize transnational democracy.

Emergent Properties

Emergence and emergent properties are concepts that are used across many scientific disciplines. They are the key elements of a theoretical and methodological tradition—most prominently represented in the 1920s—claiming that the whole is more than the sum of its parts. This amounts to saying that the properties of a whole (systemic qualities) cannot be deduced by summing or averaging the properties of its components (nondeducibility thesis). Vice versa, the appearance of genuinely novel properties characterizing compounds or systems as wholes (i.e., emergent properties) cannot be solely predicted from knowing the properties of the constituents and their relations. Emergence theories are most elaborate in philosophical thought. However, an influential strand of twentieth-century social theory (Emile Durkheim, Talcott Parsons, Niklas Luhmann) borrowed some elements of this philosophical tradition and adopted the idea that the social (i.e., social organization at any level) should be regarded as an emergent property. Arguing against the powerful approach of reductionism, this sociological tradition asserts that systemic properties of the social world cannot be deduced from properties of the constituents (i.e., individuals) and their respective interactions. They need to be accounted for at the system level. In the latter part of the twentieth century, the scientific discourse about emergence has regained prominence in many scientific disciplines—not to speak of a veritable renaissance. More recent approaches to the understanding of emergent properties include, among others, the theory of deterministic chaos, complex-system theory, and theories of self-organization and self-referentiality. Interdisciplinary in orientation, they focus on the complex dynamics between interactions and relations at different organizational levels (multilevel analysis) and stress the coexistence of system concepts and constituent concepts in explaining composition outcomes. After a brief history of the concept in philosophical thought, the major theoretical discourses about emergence in the context of social theory will be discussed. Next, there is a brief discussion of the recent interdisciplinary approaches that incorporate the idea of emergence. Finally, methodological issues related to the measurement and the inference of emergent properties are discussed.

1. *The Philosophical Tradition of Emergence*

The concepts of emergence and emergent properties have a long philosophical tradition (see Stephan (1999) and Beckermann et al. (1992) for extensive reviews). Unanimously, the origins of the idea of emergence are attributed to John Stuart Mill (1974). Considered to be the classic source, Mill distinguished between two types of joint effect produced by the interplay of various causes (composition of causes). In the first type, the joint effect of several component causes is identical with the sum of the separate effects. With respect to the second type, the joint effect is heterogeneous to the separate causes. The properties of a system or a compound generated by the second type of joint effect were later to be labeled *emergent*. Offering an alternative to mechanism and vitalism, the 1920s may be regarded as the heyday of the philosophical tradition that grew out of Mill's fundamental insight.

It was in this decade that those later to become *classic* authors—Samuel Alexander, Conwy Lloyd Morgan, Charles Broad, and Roy Sellars—published their influential works. According to Stephan (1999), 'weak' versions of emergentism may be distinguished from 'strong' ones. The former loosen some of the

assumptions deemed to be essential for defining emergent properties in the latter versions. Both strands of theory assert that emergent characteristics of wholes are not the sum of the properties of their parts (nonadditivity). They cannot be understood by simply summing (or averaging) the behaviors of the constituents; rather, they must be described in terms of their own. The novelty thesis claims that in evolution genuinely novel (systemic) properties emerge. Examples are the advent of mind or reflective thought. In more abstract terms, this amounts to saying that emergent system properties are different in type from the properties of the system's constituent components. The two strands differ, however, with regard to the core assumptions of emergence theory—deducibility and predictability of systemic properties. Strong versions maintain that emergent properties are not deducible or predictable from the properties of the constituents and their relations (nonpredictability and nondeducibility). In this view, emergence may be characterized as the antithesis of microreductionism (Auyang 1998). By contrast, in weak variants of emergence theory, all systemic properties that distinguish a system from the qualities characterizing its elements must be regarded as candidates for representing emergent properties. The late 1960s and early 1970s saw a renaissance of ideas of emergence. Centering around the fundamental issue of the mind-brain relationship—the psycho-physical problem—Bunge (1977) and Popper and Eccles (1977) offered theories strongly drawing on the idea of emergent properties.

2. *Sociological Conceptualizations of Social Reality*

From its inception, sociological thought has been characterized by two dramatically different conceptualizations of social reality. In particular, these differences pertain to the fundamental understanding of the relationship between the individual and social organization. Methodologically, this problem may be couched in terms of the relation between the micro- and macro-levels—in other words, the micro–macro link. One tradition, most commonly referred to as the individualistic–reductionist position, asserts that the properties of the social at any level may ultimately be explained by the interplay between the properties of individuals (e.g., motives, preferences), who are the constituents of society. Having strong roots in the Scottish moral philosophers (David Hume, Adam Smith, Adam Ferguson), the development of twentieth-century social theory has been characterized by various attempts to explain social phenomena by the rules governing the behavior of individuals. Basically, this approach asserts that social organization results from individual actions. Fundamentally opposed to this view is the other sociological tradition, often classified as the collectivist position. Its basic assumption is that the social world constitutes a reality of its own. Historically, this position is closely intertwined with the demands of sociology as a young scientific discipline to claim its territory and to define its own true subject matter vis-à-vis already well-established disciplines. By asserting that society is a reality of its own, nonreducible to the rules governing individual behavior, sociology distinguishes itself especially from economics and psychology. Searching for the particular subject matter of sociology, proponents of this position asked about the novel qualities and the specificity of the social vis-à-vis other types of reality, such as the mental realm, the biological or physical realm. It is with this latter tradition in sociology that the ideas of emergence and emergent properties have been most commonly associated. For this reason, the historical development of the latter tradition is discussed below.

3. *The Sociological Tradition of Emergence: Society as an Emergent Property*

In late-nineteenth and early-twentieth-century sociology, the ideas of emergent properties are reflected in the conceptualization of society as representing a reality of its own endowed with separate characteristics nonreducible to the properties of its constituents (i.e., individuals). The sociological tradition that incorporates this assumption strongly draws on the thesis of emergence as nondeducibility. In the early days of sociology, Emile Durkheim (1938) most prominently advocated this approach to the understanding of social phenomena. In Durkheim's view, society is not solely the sum of individuals; rather, it is the *association* of individuals. Hence, it is the *nature of this association* that constitutes the decisive factors of social life and determines the proper characteristics of social phenomena ('faits sociaux'). This theoretical stance was epitomized in the famous methodological rules introduced by Durkheim (1938) according to which the social realm needs to be explained by social phenomena.

In modern sociological thought, developed in the second half of the twentieth century, general systems theory has advanced to one of the most influential currents, implicitly or explicitly advocating ideas of emergence (Parsons 1937, 1951, Luhmann 1995). With the Durkheimian tradition, systems theory shares the fundamental methodological conviction of the nondeducibility of the social world. Social phenomena at different levels of social organization (i.e., society, organizations, social groups) show novel properties that cannot be explained by reducing them to the properties of and interactions between their constituents (i.e., behavioral properties of individuals). Hence, a genuine *social* theory is needed to account for social reality as an emergent property.

This line of thought, advocated by Durkheim in late-nineteenth-century sociology, was continued in the mid-twentieth century by Talcott Parsons, albeit with some major modifications (Parsons 1951). For Parsons, the old problem raised by Hobbes about the origin of social order and social integration constitutes the fundamental sociological issue to which social theory needs to provide a satisfactory answer. The core of Parsons' answer to this fundamental problem is his thesis on the independence of institutionalized values and norms vis-à-vis the reality of individuals. The common system of ultimate values, constituting a reality *sui generis*, helps to establish order at various levels of social life and to prevent a free-for-all. In essence, Parsons declares common-value integration as the emergent property of social action systems. Parsons derives this conclusion from his systems-theoretical approach to the relationship between individual actors and social organization, whereby the starting point is the assumption that all reality realms constitute systems (i.e., the biophysical, personality, cultural, and social systems). Despite fundamental differences between various types of systems, they all share the system character as a common feature. By drawing a sharp distinction between the social system (the social reality) and the personality system (the human being), Parsons maintains that each system needs to solve its own particular functional problem (i.e., system stability), for which each system relies on self-regulating mechanisms. In the case of the social system, social order and social integration are the functional problems, and processes of socialization and social control are the self-regulating mechanisms. Despite their own system logics, the two systems interact with each other in such a way that each system constitutes the environment for the other. The interactions between systems and their environment include the mutual exchange of resources, necessary for each system to keep up its functional capacity (i.e., system maintenance). Within this systems-theoretical framework, the social system and the personality system mutually presuppose each other; they are of equivalent status. This implies that there is no ontological priority of one system over the other. Hence, the properties of the social world cannot be deduced from the rules governing the personality system. The society is thus an emergent property.

Within the tradition of systems theory, Niklas Luhmann (1995) has provided the latest elaborate attempt to conceive of social reality as a separate, nonreducible system, reproducing itself solely on the basis of its own elements. Sharing some common ground with Parsons' theoretical approach, Luhmann designs a systems theory that makes use of fundamental ideas developed in molecular biology. In particular, Luhmann applies the concept of autopoiesis advocated by Maturana to social reality. Arguing at a very high level of abstraction, social systems are autopoietic systems in as much as they are self-reproduced by their own components, which are defined as acts of communication. This amounts to saying that social systems operate on the basis of communicative acts engendering subsequent acts of communication. Hence, the social system is an independent, self-reproductive whole. Like Parsons' theory, Luhmann's approach attributes great significance to the strict distinction between the social system and the psychological system. These two separate systems reciprocally constitute the environment of the other, for any system needs appropriate environmental relations for its self-reproduction. Given the system–environment relationship, the autopoiesis of the social system is not conceivable without the autopoiesis of the psychological system and vice versa. In other words, the two autopoietic systems enable each other to operate. From this it follows that the two systems are equivalent (and not hierarchically dependent), which precludes the reductionist assumption that systemic properties of one system can be deduced from those of any other system. Consequently, social systems are emergent properties.

4. *The Renaissance of Ideas of Emergence in Late-Twentieth-Century Theoretical Thought*

In the latter part of the twentieth century, ideas of emergence have again attracted considerable attention in various scientific fields. Several new approaches, such as synergetics (Haken 1978) and other versions of self-organization theory (Krohn and Küppers 1992, Krohn et al. 1990) or chaos theory (Newman 1996), address interdisciplinary research questions at a relatively high level of abstraction that allude to problems raised in classical emergence theory. Examples of these research problems are the investigation of the spontaneous and self-confined emergence of new structures and systemic properties or the examination of predictability in chaotic dynamic processes. Interestingly enough, this body of research seldom refers to the tradition of emergence theory and the notion of emergence itself remains rather vague. This suggests that, for these theoretical approaches, the concept of emergent properties is used less as an analytical research tool and more as a guiding research idea.

This is most apparent in the booming field of theories of self-organization. Krohn and Küppers (1992), for example, provide a rather vague concept of emergent properties. They define emergence as the sudden appearance of novel properties that can be explained neither by the properties themselves nor by the relations of the elements involved, but rather by specific self-organizing process dynamics. To complicate matters, the notion of self-organization is also a shifting concept. Depending upon the strand of system theory, the meaning attributed to self-organization turns out to be completely different. Searching for the least common denominator, self-organization

may be understood as interactions between the components of a system and its organization that lead to modifications on both sides (Hejl 1990, p. 115). It follows that the dynamics of self-organization engender new structures endowed with emergent systemic properties. In theories of self-organization then, self-referential organization of systems and emergent properties are causally related. Within this theoretical framework, social phenomena, such as social networks and social movements, easily lend themselves to the conceptualization of emergent properties generated by self-organizing process dynamics.

The issues addressed in theories of self-organization discussed above may be generalized to include the problem of how to conceive of the relationship between microinteractions and macrostructures—in short, the micro–macro link. With respect to social theory, the great bulk of previous work adheres to either a bottom-up method (microreductionism) or a top-down method (systems theory). Both methods, taken by themselves, have their limits. The reductionist tradition in social theory must at least acknowledge systemic properties as marginal conditions of individual behavior. Vice versa, the collectivist tradition is often short of explaining many systemic properties. Against this background, the need for a circular movement of theory building when conceptualizing the micro-macro link (i.e., interlevel explanations) is evident. Hence, approaches that attempt to couple systems concepts with constituent concepts are in demand. A theoretical framework of this type 'simultaneously accounts for the behaviors of systems on one organizational level, the behaviors of their constituents on a lower level, and the relations between them' (Auyang 1998, p. 5). In this respect, the approach of synthetic microanalysis proposed by Auyang (1998) may be regarded as one example.

5. *Emergent Properties: Methodological Issues*

Methodologically, the question arises of how to assess emergent properties. The key to answering this question lies in the exploration of the link between the micro and macro levels of social phenomena. From this perspective, the claim that the whole is more than the sum of its parts amounts, first, to furnishing proof of the *specific assumptions* implied in either the 'strong' or 'weak' versions of emergence theory (see Sect. 1). According to the 'strong' version, properties at the higher levels of aggregation (i.e., the macro level) qualify as emergent, if they *cannot* be deduced or predicted from the properties of units at lower levels (i.e., the micro level). In the 'weak' version, they qualify, as long as they can be expressed as complex functions of the lower level characteristics. Second, the assessment of emergent properties must be based on evidence regarding the *impact* of system properties (i.e., contextual properties) on lower-level units and/or relationships that operate independently of the effects of any lower-level characteristics. Couched in more technical terms, the second requirement implies that the attributes of units operating at the micro level are a function of context (i.e., the macro level). The two tasks identified here to assess emergent properties address a measurement issue on the one hand and an issue about modeling techniques on the other. Each issue will be addressed in turn.

5.1 *The Measurement Issue*

'Strong' and 'weak' versions of emergence theory agree that higher-level properties that can be expressed as simple functions of lower-level attributes do not qualify as emergent. Examples include contextual characteristics defined as the sum, as a proportion or as the mean of lower-level properties (e.g., percentage of community residents above the age of 65 years; average income of regions). The two strands of emergence theory differ, however, with regard to the theses of deducibility and predictability. The 'strong' version claims that emergent properties are *global* attributes that are not expressible as functions of lower-level properties. This implies that system properties need to be measured at the system level as opposed to the level of system elements. One example of such an approach would be the description of political systems characterized by the degree of corporatism, whereby the measurement of corporatism would be based on expert judgement.

The measurement issue involved in 'weak' versions of emergence theory includes the application of complex rules of aggregation. Expressed as complex functions of lower-level attributes, system properties can be deduced or predicted from lower-level units. The income distribution characteristic of regional contexts—expressed by a complex function of individual incomes—serves as an example. A methodological perspective that is well suited to identifying emergent properties in line with 'weak' versions of emergence theory is *network analysis*, most prominently advocated by scholars such as Ronald S. Burt, Mark Granovetter and Barry Wellmann. This technique truly addresses the fundamental idea of the whole being more than the sum of its parts by focusing on *relational* characteristics and by introducing complex rules of aggregation. The social closure of elites, for example, cannot be inferred from the attributes of individual members of the elite. It is a property inferred from the *relational* attributes of the network members. Hence, the relational order of network elements (i.e., the structure) is a system property that truly qualifies as an emergent property. The second basic assumption of network analysis is the embeddedness of lower-level units in higher-level systems (i.e., networks) (see Granovetter 1985). This implies that lower-level outcomes (e.g., preferences, tastes, action orientations,

performance at the individual level) are mediated by higher-level system properties. This is to say that individual and collective actors respond to their social context. Couched in more technical terms, the notion of embeddedness addresses the issue of the additive and interactive effects of context on lower-level outcomes. This remark leads up to the second issue raised above, namely the modeling techniques required to assess emergent relationships.

5.2 The Impact Issue

To assess the effects of system properties measured at various levels of a hierarchical structure on lower-level outcomes, multilevel models (or contextual models) are the method of choice. A variety of models are used to specify the link between the macro and micro levels of social phenomena. While the names of the models and their statistical properties do differ (e.g., hierarchical linear model, random coefficients model, hierarchical mixed linear model), the basic idea is 'to analyze data that consist of multiple macro units (contexts) and multiple micro units within each macro unit' (DiPrete and Forristal 1994, p. 334). Within these models, two types of effect can be distinguished: main or additive effects and interactive effects. Main effects of higher-level properties on lower-level outcomes (e.g., behavior) provide evidence that context matters over and above the impact of any lower-level attributes. This indicates that the relationships identified through the effect analysis cannot be reduced to individual differences. Examples of substantive research along these lines include the contextual effects of schools and classes on student achievement or the impact of macro contexts, such as organizational structure and labor market segmentation, on career outcomes. The second type of effect involves interaction effects of properties measured at various levels of a hierarchical structure. The existence of cross-level interaction effects provides evidence of how higher-level properties (i.e., the macro context) affect the impact of lower-level attributes (i.e., those at the micro level) on the outcome of interest. Variation in the strength of the effect of micro-level properties on the outcome when system properties are included indicates the presence of relationships that can be qualified as emergent. The reason is that interaction effects involving cross-level components show that they are more than the sum of their parts. Substantive research employing this complex modeling strategy includes, for example, the ways in which country characteristics (e.g., economic development; policy programs) affect the influence of maternal education on the reproductive behavior of women.

Emigration: Consequences for Social Structure in the Sending Population

International migration is the movement of people across national boundaries. Emigration is international migration from the perspective of the migrants' country of origin. Emigrant flows are the

movements of emigrants with common origins or destinations, and emigrant stocks refer to the number of emigrants present in a destination. In many uses of the term, emigration involves a change in residence that is long term, although there is no single accepted definition of the length of time that a person has to be out of the country of origin in order to be considered an emigrant. Tourist or business related trips are not counted as emigration, whereas movements that involve a permanent change in place of residence are. Between these two extremes lies considerable ambiguity in deciding when an out-of-country movement becomes emigration. The United Nations defines a long-term emigrant as 'a person who moves to a country other than that of his or her usual residence for a period of a least a year (12 months), so that the country of destination effectively becomes his or her new country of residence' (United Nations 1998, p. 10).

Part of the ambiguity in defining emigration arises from the presence of circular international labor migration. The development and expansion of international communication and transportation networks has stimulated and facilitated the movement of labor across national borders by increasing global access to information on living standards and employment opportunities in high-income countries, and by lowering the time and monetary costs of international travel. Labor recruitment activities targeted at workers in low-income countries and state-sponsored guest worker programs have played an important role in generating and sustaining the international flow of labor. The same communication and transportation networks that facilitate emigration to high-income countries also facilitate return migration to emigrant places of origin. Recent approaches to emigration recognize the importance of return flows of information, financial resources, and emigrants. This article addresses the consequences in sending populations of both emigrant outflows and the return flows that emigrants generate. The consequences are divided into three broad groupings: demographic, economic, and social.

1. Measuring Emigration

Measuring emigration is difficult because it is a dynamic, duration-dependent process—a migrant is not necessarily an emigrant at the time of departure, but rather becomes an emigrant after a period of time in the country of destination. Although it is possible to measure intended length of stay at the time of departure, migrant intentions often change and not all international moves are legally sanctioned and thus documented at the point of departure or arrival. Many governments do not register departures or collect information on international migration flows. Lack of comparability across countries in the migration statistics reported makes it difficult to derive precise estimates of emigrant stocks and flows.

A number of approaches have been used to derive rough estimates of emigration using census and survey data. When emigrants from a country go to a small number of foreign destinations, information on place of birth from censuses conducted in the countries of destination can be used to estimate emigrant stocks and flows. Zlotnik (1992) used recent census data from countries in the Americas to estimate the number of emigrants from Latin American countries living in other countries in the region. Similarly, Hatton and Williamson (1998) used census data in major migrant receiving countries to estimate gross emigration rates in the second half of the nineteenth and early twentieth centuries for selected European countries. A second approach to estimating the magnitude of emigrant flows makes use of the demographer's balancing equation:

$$E = P_1 - (P_0 + B - D + I)$$

The number of emigrants (E) is derived as the difference between the enumerated population at the end of the period (P_1), and the expected population produced by natural increase ($B - D$) and immigrant additions (I) to the initial population (P_0). Baines (1985) used a variant of this approach to estimate emigration from England and Wales in the late nineteenth century. A third approach to measuring emigration makes use of questions in household surveys about the international migration of current household members and nonresident relatives. Woodrow-Lafield (1996) used this approach to derive estimates of emigration from the USA, and Bean et al. (1998) used it to derive estimates of emigration from Mexico to the USA. The first two census-based approaches capture long-term emigration, but miss many short-term emigrants who are not present in the destination at the time of the census. The survey-based approach misses long-term emigrants who no longer have relatives in their community of origin, but is more effective at collecting information on short-term emigration and return flows.

2. Emigrant Flows

Migration scholars identify three periods of major emigration in the modern world (Massey et al. 1998). The first period, from 1500 to 1800, encompassed the flow of European emigrants into areas of colonization in the Americas, Africa, Asia, and Oceania, as well as the forced emigration of African slaves into the Americas. The precise number of European emigrants during this period is not known, but the number of African slaves was close to 10 million. The mass migration of Europeans to the Americas in the nineteenth and early twentieth centuries marks the

second major period of emigration. From 1800 to 1925, more than 48 million people emigrated from Europe in response to economic dislocations created by economic development at home and the availability of agricultural land and industrial employment overseas (Massey et al. 1998). Major emigrant-sending countries were the British Isles, Germany, the Scandinavian countries, Italy, Austria-Hungary, Poland, Russia, Spain, and Portugal. The third period of major emigration began in the 1960s and continues up to the present. Emigration in this period is marked by a major shift in origins. Most of the world's emigrants now come from Africa, Asia, and Latin America. Many of the former emigrant-sending countries in Europe have become important emigrant destinations.

Most emigrant flows are accompanied by significant counterflows of returning emigrants. The percentage of emigrants who eventually return to their country of origin varies substantially by period, and by country of origin, and destination. During the early periods of European overseas emigration return flows were relatively small because of the high cost of transportation. However, as the cost of intercontinental transportation came down, return emigration rose. At the end of the nineteenth and start of the twentieth centuries the number of immigrants who left the USA to return to their countries of origin was equivalent to 30 percent of new immigration. While very few Russian and Irish immigrants returned, nearly 50 percent of Italian and Spanish immigrants to the USA returned home (Hatton and Williamson 1998). In the current period, the number of return emigrants in many national contexts exceeds the number of emigrants who remain in the country of destination. Emigrants are drawn back to their countries of origin by strong social ties at home, limited integration into the host societies—including legal restrictions on settlement put in place by the destination government—and the high purchasing power of emigrant earnings in low-income countries of origin (Appleyard 1998a).

3. *Demographic Consequences of Emigration in the Sending Population*

Permanent emigration represents a loss of population in the place of origin. Whether this loss translates into a long-run reduction in population size depends on the age and sex composition of emigrant flows, and whether birth and survival rates rise in response to the loss of population. Malthusian population theory suggests that a reduction in the population pressure on existing resources through emigration could trigger a rise in birth and survival rates in the sending population. A demographic response of this type would cancel out or reduce the impact of emigrant loss on long-run population size. The development context within which most contemporary emigration originates makes a rise in birth rates an unlikely response to emigration. The same forces of economic development and modernization that stimulate emigration also operate to reduce fertility in the sending population. In general, countries that have experienced high emigration show lasting effects on future population size. For example, during the peak years of mass emigration, 1864–1914, emigration losses reduced potential population growth by 40 percent in Norway and by 25 percent in Sweden (Lowell 1987, p. 5). In Mexico, cumulative emigration to the United States has reduced the expected population of major emigrant-sending states by almost 50 percent (Verduzco and Unger 1998, p. 427).

The long-run effects of emigration on population size stem from the fact that emigration entails not only the loss of the emigrant but the loss of the emigrant's descendants as well. The emigration of women who are ready to begin childbearing has a larger impact on long-run population size than the emigration of women who have completed childbearing. When emigration is selective of men, total fertility may also get below what it would have been because a greater proportion of women never marry. Ireland is an example of a country that experienced high rates of non-marriage among women due to the emigration of men.

The loss of emigrants and their descendants is associated with long-term or permanent emigration. Short-term emigration has separate but potentially significant effects on future population size. When emigration is temporary and sex-selective, it disrupts family formation and the pace of childbearing by delaying marriage and separating couples. Van de Walle (1975) provides evidence from the Swiss canton of Ticino of how the seasonal migration of men in the late nineteenth and early twentieth centuries stemmed population growth and led to low fertility by increasing the proportion of women who never married and by separating husbands and wives during their childbearing years.

4. *Economic Consequences of Emigration in the Sending Population*

The economic consequences of emigration for the sending population stem primarily from the outflow of labor and the return flow of emigrant earnings (remittances). When emigration is voluntary and motivated by economic reasons, emigrants are overwhelmingly drawn from the working-age population. For the sending country emigration reduces the supply of labor, which in turn leads to lower unemployment and higher wages for those workers who remain. Hatton and Williamson (1998) find evidence that emigration from Ireland in the nineteenth century had

precisely this effect—the departure of labor improved the economic conditions of non-emigrants faster than would have been the case if emigration had not occurred. Similarly, contemporary emigration in South Asia, much of which is directed toward oil-producing countries in the Middle East, has pushed up wages for skills that have become more scarce due to the temporary absences of workers (Appleyard 1998b). In addition to raising wages, emigration may induce the adoption of more advanced labor-saving technologies, and thereby speed up economic development (Simon 1989).

The impact of emigration on the aggregate supply of labor depends in part on the labor force participation of emigrants prior to departure and on the response of households to the loss of an emigrant worker's labor. For example, in Sri Lanka close to two-thirds of emigrant workers are female household workers, many of whom were not in the labor force before emigrating. The effect of this emigration on unemployment in Sri Lanka is therefore difficult to measure because many of these women would not be in the domestic labor force if they had not emigrated (Gunatilleke 1998). Households may also respond to the emigration of a household worker by increasing the economic activity of remaining household members. This intrahousehold substitution of work diminishes the impact of emigrant departures on the labor market. For example, in countries where female labor force participation is low and emigration is selective of men, the substitution of women's labor for men's would alleviate any possible labor shortages created by emigration and would thus leave wage rates unchanged.

The emigration of highly skilled workers represents a loss for the sending country in terms of public investments made in their education and in terms of the economic growth that the emigrants would have generated if they had remained. Known as the brain drain, the emigration of highly educated and skilled workers is a cause of concern in emigrant-sending countries. The loss of potential new employment due to emigration is expected to be greatest when the skills possessed by emigrants and non-emigrants are complements of one another, that is, demand for one set of skills is dependent upon demand for the other. Not all emigration, however, represents a loss of skills for the sending country. Many emigrants return, some with new skills which lead to increased productivity at home. Of course, not all skills learned abroad are transferable to origin labor markets because of national differences in the level of development and in the demand for distinct skills. Many jobs performed by emigrants in high-income countries also provide little or no opportunity for acquiring new skills.

Each year emigrant workers send home, or return with, a portion of their earnings. The transfer of emigrant earnings (remittances) has important economic consequences in the sending population. At the macro-level, remittances from emigrant workers have been a 'life saver' for the economies of some countries. In Bangladesh and Pakistan, both major emigrant labor sending countries, remittances constituted about 70 percent of export earnings during the 1980s (Shah 1998, pp. 24–5). During the 1990s remittances amounted to 50 percent of exports in the Dominican Republic, and in El Salvador remittances were nearly as great as the volume of exports (Lowell and de la Garza 2000, p. 6). In addition to being an important source of foreign exchange, remittances are a substitute for scarce credit, and remittances spent on goods and services generate new employment. In an analysis of the effect of emigration and remittances on the labor market in El Salvador, Funkhouser (1992) found that the strongest effect of emigration occurs through remittances and not through the loss of emigrant workers. Money earned abroad and spent at home creates investment and employment opportunities in the provision of goods and services that remittances are used to purchase. The labor market impact of remittances will be greatest in the local areas where remittances are spent. Market towns in emigrant-sending regions, for example, may benefit more from remittances in terms of employment growth than rural emigrant-sending communities.

At the household level remittances significantly raise consumption levels and the overall standard of living. The most common use of remittances after covering day-to-day living expenses is investments in housing. Aside from meeting a basic need, putting remittances into residential real estate is a popular strategy for storing the value of saved emigrant earnings when other forms of investment or savings are not viable options. Residential real estate can be used to generate rental income, and it can be converted back to cash by being sold. The heavy use of remittances for household consumption as opposed to investment in economic production has lead to pessimistic assessments by some analysts of the capacity of remittances to stimulate economic development. One common argument is that labor emigration to high-income countries and the return flow of emigrants and remittances create a condition of dependence on emigrant earnings in sending communities. Studies conducted in emigrant-sending communities from diverse settings reveal substantial variation in the relative use of remittances for consumption and investment purposes, however. In some communities remittances have played a key role in agricultural modernization, in others remittances have spurred the development of cottage industries which produce goods for domestic and export markets. The use of remittances for productive investments appears to be influenced by local access to productive resources. Greater numbers of return emigrants use remittances for investments in agriculture and entrepreneurial activities in communities where the expected returns on productive investments are positive.

5. Social Consequences of Emigration in the Sending Population

Many of the social consequences of emigration in sending populations are related, first, to the disruption of family life produced by temporary out-of-country absences, and, second, the diffusion of new ideas and behaviors brought back by visiting and returning emigrants. The emigration of selected household members leaves households divided across national borders. One of the consequences of the disruption of family life is a change in definitions of family roles and role relations. For example, in countries where male household members emigrate and female members stay behind, married women often become *de facto* household heads during their husband's absence, and take on many of the roles otherwise reserved for men. The experience of greater autonomy in economic decision making can produce long-run changes in household gender roles. The prolonged absence of a spouse or parent also places families under stress, resulting in increased rates of family disintegration and divorce and a weakening of family control over youths. On the other hand the periodic absence of household heads, whether male or female, does not always have negative repercussions for families. In many low-income countries temporary labor emigration is a standard part of life, extending back several generations. Under these circumstances, family systems evolve and adapt coping mechanisms to meet the basic needs of emigrant and non-emigrant members (Thomas-Hope 1998). Kinship networks are often an important source of support for households with emigrant members.

During their visits to destination countries emigrants are exposed to new ideas, behaviors, and lifestyles that they gradually and selectively adopt. These new ideas, experiences, and behaviors are transmitted back to family and friends in the community of origin through correspondence, telephone conversations, and most importantly through visits and return migration. Levitt (1998) calls the ideas and norms that emigrants bring home with them, social remittances. 'They include norms for interpersonal behavior, notions of intrafamily responsibility, standards of age and gender appropriateness, principles of neighborliness and community participation, and aspirations for social mobility' as well as 'expectations about organizational performance such as how the church, state, or the courts should function' (Levitt 1998, p. 933). The circular flow of community members back and forth between the sending and destination communities produces continuous, sustained exposure to destination norms and behaviors. Emigrants and non-emigrants in places of origin filter, transform, and adapt these norms and behaviors to meet their own needs and circumstances.

Emotion and Expression

Emotion can be expressed in the face, voice, posture, and gesture. Since Darwin, most researchers have concentrated on facial expressions. The scientific study of these expressions has been an important site for disputes over the existence of a universal human nature and the extent to which human culture is grounded in biology.

1. *What is at Stake in Discussions of Facial Expression?*

The nature and origins of facial expressions of emotion may not seem at first glance to be a matter of momentous concern for the social sciences and humanities. However, the emotions are widely believed to be a critical feature of moral agency, and are even more widely believed to be a critical part of esthetic response. If all healthy people display, recognize, and respond to the same limited number of emotional expressions, this suggests a similar uniformity in emotion itself. In that case, moral and esthetic judgments may have universal validity. Conversely, if humans expressions of emotion are as diverse as the concepts embodied in different languages and if humans can only understand the expressive repertoire of their own cultural group, this would seem to support cultural relativism about emotion and thus about ethics and esthetics.

A related debate concerns the extent to which emotional expressions can be given evolutionary explanations. If so, then the emotions they express are presumably also part of the evolutionary inheritance of humanity. The idea that emotions are the products of evolution has been used to argue for a range of highly controversial claims. One argument runs from the premise that emotions have evolved to the conclusion that emotions are universal. Another argument runs from the premise that emotions have evolved to the conclusion that emotions are biologically determined in the sense that that they cannot easily be altered by changing environmental factors. Because of the critical role of emotions in human social interactions, biological determinism about emotions supports the view that certain forms of social organization are biologically inevitable.

2. *The Origins of Research on Facial Expression*

The scientific study of facial expression began with the nineteenth century anatomical investigations of Bell (1844) and Duchenne (1867/1990). The most influential work of the nineteenth century, however, was undoubtedly Darwin's *The Expression of the Emotions in Man and Animals* (Darwin 1872). The book started life as a chapter of Darwin's *Descent of Man* (1871) but grew so large that it became a separate work. In *Descent*... Darwin aimed to show evolutionary continuity between human ethical behavior and animal behavior and also, via his theory of sexual selection, between the human esthetic sense and the esthetic sense of animals. In *Expression*... he aimed to show evolutionary continuity between the human and animal emotions by demonstrating continuity between the facial expressions of humans and animals. Darwin explicitly targeted Bell's claim that the muscles of the human face were created by God to express human emotions. This led him to argue that many movements that now express emotion were vestiges of previous ways of life. 'With mankind some expressions, such as the bristling of the hair under the influence of extreme terror, or the uncovering of the teeth under that of furious rage, can hardly be understood, except in the belief that man once existed in a much lower and animal-like condition' (Darwin 1872, p. 12). Some authors have denied that Darwin ascribed any current adaptive functions to emotional expressions (e.g., Fridlund 1994), but, to take just one example, Darwin argued that humans, unlike chimpanzees, open their mouths when terrified because, unlike chimpanzees, humans must breathe through their mouths when fleeing.

Darwin's analysis of the contributions of the various facial muscles to emotional expressions drew heavily on Duchenne and Bell, but he made substantial original contributions, particularly with respect to homologies between human and animal expressions. His conclusions conform closely to currently accepted views of the muscular basis of facial expression. Darwin also pioneered the use of photographs, including some images made by Duchenne, to test the ability of observers to infer emotional state from isolated facial expressions. Certain photographs elicited very general agreement from Darwin's subjects and he took these to show the 'true' expressions of the associated emotions. Photographs relating to facial expression are shown in Fig. 1.

Regrettably, Darwin only used photographs in England and relied on a less satisfactory technique to

(a)

(b)

study the expression of emotion in other cultures. He dispatched questionnaires to missionaries, traders and others, asking them about the facial movements used to express emotion by the people amongst whom they lived. Unfortunately, Darwin's questionnaire suggested which facial components he expected to represent which emotions and thus made it very likely that his observers would read the desired results into their observations. Darwin's failure to use photographic evidence in his cross-cultural research is puzzling when considered against the background of the extensive contemporary interest in ethnographic photography.

3. *The Affect Program Theory of Facial Expression*

Darwin's work on emotional expression was neglected for the first half of the twentieth century. Anthropolo-

gists such as Weston La Barre (1947) and Ray Birdwhistell (1963) argued that culturally specific emotional states were signaled in a culturally specific code of facial expressions and gestures acquired by the individual during their upbringing. This culturalist tradition was displaced in the late 1960s by a powerful revival in the Darwinian approach. Many of Darwin's specific findings about facial expression were confirmed and extended, most notably by the psychologist Paul Ekman and his collaborators (Ekman 1972). One famous experiment used subjects from the Fore language group in New Guinea with a minimum of prior contact with Westerners and their cultural products. These subjects were given three photographs, each showing a face, and told a story which was designed to involve only one emotion. They were asked to pick the photograph showing the person in the story. This method has the advantage that no translation of the names of emotions is needed. The subjects were highly successful in picking the photograph intended to express the emotion appropriate for each story. The New Guinean subjects were also asked to act out the facial behavior of the people described in the stories. Videotapes of their responses were shown to US college students. The students were generally accurate in their judgements of the emotion intended by the New Guineans. The six facial expressions that figured in these experiments were labeled surprise, joy, sadness, fear, anger, and disgust. These, and a seventh previously confounded with disgust and now labeled contempt, have become the basis of Ekman's influential revival of the Darwinian approach to expression.

Ekman conceptualizes facial expressions as key components of affect programs, complex patterns of facial and other actions controlled by the central nervous system and triggered in response to some specific stimulus (Ekman 1984). This conceptualization derives, ultimately, from the idea of a fixed action pattern as it figures in the classical ethology of Konrad Lorenz and Niko Tinbergen. These founders of the modern study of animal behavior rediscovered Darwin's work on the emotions and interpreted it as prefiguring many of their own ideas (Lorenz 1965). Emotions, they argued, were innate patterns of behavior that had evolved by natural selection. Darwin's emphasis on the vestigial nature of many human facial expressions was interpreted using the ethological concept of ritualization (Tinbergen 1952). Patterns of behavior that once served a practical function, such as the opening of the mouth and retching exhibited in disgust, have been retained and modified by natural selection because of their value as signals. Hence the primary biological function of facial expressions in humans is as a signal of the person's emotional state. The distinctive experimental paradigm of classical ethology is the deprivation experiment, which aims to show that an animal produces a pattern of behavior even when it is deprived of experiences that would seem necessary for the behavior to be learnt. The ethologist Irenaus Eibl-Eibesfeldt (1973) examined the facial movements of children born deaf and blind and showed that these children used the same patterns of facial action as other children to display their emotions. He concluded that these behaviors were part of humanity's evolutionary heritage.

Ekman and his collaborators have handled cultural differences in the expression of emotion with the concept of a display rule, a concept exemplified in another of their experiments. Twenty-five American and 25 Japanese college students were shown neutral and stress-inducing films while alone in a room. The repertoire of facial behaviors shown during the stress phase by the two sets of subjects was very similar. However, when an experimenter was introduced into the room and allowed to ask questions about the subject's emotions as the stress film was shown again, the facial behavior of the Japanese diverged radically from that of the Americans. Video analysis showed the momentary occurrence of negative emotional expressions and their replacement with polite smiles. An important feature of the display rule conceptualization of cultural differences is that the evolved expressions remain intact but interact with culturally specific behaviors to determine the observable pattern of facial action.

4. *Universalism vs. Relativism*

The research leading to the affect program theory and subsequent discussion have helped to clarify some of the issues about the universality of emotion. The affect programs have the same output across cultures, but they do not have the same input. There are some universal elicitors of affect programs in childhood, such as very loud noises, which elicit fear. There are also systematic biases in the conditioning of affect program responses that could lead to a convergence in the eliciting conditions for adult responses. The general picture, however, is that affect programs come to be associated with whatever stimuli locally fulfill a broad functional role, so that the fear affect program comes to be associated with whatever locally constitutes a threat, the disgust response with whatever locally appears noxious or unclean, and so forth. Distinguishing between the universality of outputs and that of inputs makes it clear that at least some of dispute between universalists and cultural relativists about emotion is merely semantic. Universalists regard two cultures as manifesting the same emotion when they respond in the same way to different stimuli. Relativists insist that having the same emotion means responding in the same way to the same things.

Further clarification results from distinguishing the question of whether emotions are pancultural (found in all cultures) from the question of whether emotions are universal (found in all healthy individuals). The types of evidence normally gathered by universalists

are designed to show that emotions are pancultural and have little bearing on the question of universality. Emotions might be pancultural but still be like blood type or eye color, with several different types of individual in each population. Models of the evolution of social emotions typically predict that competing types will be maintained in the same population through competition. It is surprising that the issue of whether emotions have evolved is still so strongly linked to the issue of whether there is a single, universal, human emotional nature.

Finally, the debate over universality could be clarified by abandoning the last vestiges of the traditional dichotomy between learnt and innate behaviors. Some critics of the affect program theory have argued that a biological perspective on emotion is inappropriate merely because the emergence and maintenance of emotional responses depends upon environmental factors. Conversely, evidence that emotions are pancultural and thus likely to be the products of evolution is still thought to imply that these emotions are genetically determined and resistant to modification by environmental changes. These inferences ignore the facts that the environment plays a rich and constructive role in the development of even the most stereotypically biological traits, such as bodily morphology or sexual behavior. Evolved emotions, like the rest of evolved psychology, will likely make use of many reliable features of the environment of the developing child in order to construct and maintain themselves. They will be open to cultural and individual variation as a result of changes in these features, as well as through genetic variation. Griffiths (1997) has suggested that questions of universality can often be usefully reframed in terms of the biological concept of *homology*: are two emotions in different individuals or cultures homologous, that is, are they modified forms of a response in a common ancestor of those individuals or cultures?

5. *Contemporary Alternatives to the Affect Program Theory*

Cultural relativism about emotions, now known as social constructionism, has undergone something of a revival in recent years (Harré 1986). The older relativist tradition rested its case on anthropological fieldwork. The modern revival relies less on empirical data and more on conceptual argument. Many social constructionists start from the widely accepted idea that emotions involve a cognitive evaluation of the stimulus. They argue that emotions will inherit the cultural differences in the way emotion stimuli are conceived. If two cultures think differently about danger, then, since fear involves an evaluation of a stimulus as dangerous, fear in these two cultures will be a different emotion. This argument does not impress universalists, many of whom will allow that the two emotions are interestingly different but maintain that their similarities are more than sufficient to make them the same thing, namely fear. As well as purely semantic disputes of this kind, relativists and universalists focus on different parts of the domain of emotion. The affect program states seem to require minimal cognitive evaluation of the stimulus via pathways that the neuroscientist Joseph le Doux has christened the *low road* to emotion (Le Doux 1996). Social constructionists often refuse to regard these isolated physiological responses as emotions, reserving that term for the broader cognitive state of a person involved in a social situation in which they might be described as, for example, angry or jealous. It is thus unclear whether the debate between contemporary social constructionists and their universalist opponents has a substantial factual dimension, or whether it reflects only a preference on the one side for tractable, reductive explanations and a desire on the other side to forestall the scientific neglect of the social, transactional aspects of human emotion.

The main contemporary alternative to the affect program theory is the paralanguage theory of emotional expressions, a view whose leading exponents are Fridlund (Fridlund 1994) and James A. Russell (Russell and Fernendez-Dols 1997). Paralanguage theorists argue that the affect program theory exaggerates the automated nature of emotional expressions and neglects their voluntary, performative aspect. They deny that facial expressions are involuntary expressions of discrete emotional states. Paralanguage theorists have accumulated considerable evidence of audience effects on the production of emotional expressions. They take this to show that expressions are produced for the benefit of the audience rather than to express the feelings of the person making the display. They question the affect program view of emotions themselves, as well as of emotional expression, arguing that emotional states vary continuously along several axes, rather than falling into a few discrete types. Paralanguage theorists argue that the experimental results of Ekman and his collaborators are largely artifactual. They are particularly critical of the use of forced choices from a list of emotion terms dictated by the experimenter. This procedure forces a range of responses to a range of facial signals into a few boxes defined by the experimenter. The critics argue that this cannot provide evidence for the existence of a limited number of stereotyped facial expressions, since this assumption is built into the experimental procedure.

Although paralanguage theorists criticize the experiments usually taken to establish the universality of emotion, some of them accept that emotional expressions have evolved and would therefore presumably expect the flexible signaling system they postulate to be at least substantially pancultural. Fridlund argues that an evolutionary perspective actually favors the

paralanguage view, since involuntary signals of true emotional state would be subverted by the evolution of dissimulation and deceit. While this is an important perspective on the evolution of emotional expressions, it does not constitute the decisive argument that Fridlund seems to suppose. Veridical signals do evolve in nature, often by making use of so-called *hard to fake* signals. The cost of being unable to suppress a signal of emotional state may be balanced by the advantage of being believed. A purely theoretical argument based on the evolutionary dynamics of signaling systems seems more likely to support the view that 'examples of emotional behavior lie along a continuum from expression to negotiation' (Hinde 1985, p. 989) than a purely expressive or purely manipulative picture of emotional expression.

6. *Conclusion*

Facial expressions of emotion are an important site for the debate between universalism and relativism because both sides believe that here they can offer substantial evidence for their positions. An examination of this evidence need not serve only to support one or other side of the debate. The actual details of emotional expression, its evolution, and its development in the individual can be used to question the validity of the dichotomies between biology and culture, fixity and malleability, universality, and idiosyncraticity which are assumed by both sides.

Emotion: History of the Concept

This article deals with the history of the concept of emotion, not with the validity or acceptability of particular interpretations or theories of emotion. It will, of course, be inevitable that the discussion will deal with theories of emotion, that is, where the concept is lodged. The emphasis is, in part, on the historical situation and development of these theories, which were situated in the sociocultural temper of the times. The story starts with a survey of ancient Greek thought and its successors, mostly in the context of insightful premature speculations that, in the fashion of the times, mix quasiscientific thought with practical, in this case ethical, considerations. We then jump to the Renaissance and René Descartes, with the not unexpected claim that the new sciences were replacing all that went before. This is followed by the scientism of the nineteenth century leading up to the last great philosopher-psychologist, William James, who was able to combine humanistic insights with scientific rigor. James and Wilhelm Wundt lead us into the modern period and the need for analysis and synthesis.

Early intellectual history was preoccupied with rationality, and when emotions were discussed they tended to be identified more with the magic and mysteries of human life. The Orphic mysteries dominated much of thinking; submission to the supernatural involved too many emotional attitudes to make it possible to speak clearly about feelings and emotions. In addition discussions of the feelings and emotions—when they did occur—were confounded with considerations of ethics and aesthetics. Emotions were

International Encyclopedia of the Social & Behavioral Sciences ISBN: 0-08-043076-7

discussed in the context of how to control and how properly to use them. They were part of a philosophy of life, and codes of behavior used the emotions as their foundation. This was especially true of the pre-Socratic thinkers but persisted long afterwards, after the Aristotelian interruption.

With notable exceptions, and Aristotle stands out among them, these discussions of the emotions from pre-Socratic to modern, i.e., Cartesian, days centered on their distracting influences on the intellect, on ways of controlling them (see, for example, Empedocles and Heraclitus). Later on, the emphasis in Plato and the early Greeks is on the intellect, how we know, and what we can know. But the theme of the distracting emotions was not forgotten and even medieval scholastics such as St. Thomas Aquinas were concerned with the way emotions interfere with pure thought and how one might control them.

In the *Timaeus* Plato had postulated three different faculties of the mind—thought, spirit, and appetite. This compartmentalization, and the previous positioning of the emotions as distinct from the mental, intellective faculties, was discarded by Aristotle. He unified the mind and its effects and influences. Mind cannot be conceived without the body and—importantly—the converse is asserted as well. This biological context allows Aristotle to consider feelings as natural phenomena. But Aristotle does not allow for simple, pure, affective processes. Rather he requires a cognitive element of a percept or idea, as well as an affective component of pleasantness/unpleasantness, and a conative effort or activity (cf. Hammond 1902).

The middle ages were in the hands of the scholastics and speculations about the emotions relegated them often to mere expressions of animal spirits and to a position very distinct from the spirit and the intellect. With the advent of Descartes and the modern age all that changed. In 1649 in his *Les passions de l'âme* (*The passions of the soul*), Descartes discarded the work of the ancients as 'defective' and emphasized the modernist credo to start afresh. Whereas his predecessors frequently had speculated on the number and character of the emotions that constituted the emotional life, Descartes was the proper seventeenth-century scientist and postulated six primary passions, with all the rest constructed of those six: wonder, love, hate, desire, joy, and sadness. This approach to passions has stayed with us unabated for three and a half centuries, though Descartes's love, desire, and wonder have fallen by the wayside to be substituted by other, more contemporary states. And the centuries have failed to solve the question of 'how many?'—the answer ranges between three and 18 (Ortony and Turner 1990).

The next major change in the conception of emotion came later in the seventeenth century with Spinoza's detailed analyses of the various emotions based on the insistence that they must be taken as natural and lawful phenomena rather than as a bothersome intrusion into mental life. In the next century Kant followed that trend and gave feelings the status of a special class of psychical processes—a distinction that held well into the twentieth century. Much of the nineteenth century was devoted to the detailed classification of the emotions—a refinement of the enumeration approach. Dominant among the classifiers was Wundt, whose system went from simple to complex feelings and then to true emotions. The composite feelings are often temporary; when permanent they represent moods. Combining composite feelings into a unitary whole results in the emotions. This simplified version does not do justice to a system where an emotion such as grief may be analyzed in terms of a half dozen or more types and tokens of feelings. The late nineteenth century occasioned several equally complex and in the end ineffective classificatory schemes. All this was brought to an end by a theory that arose in three different countries and dominated the psychology of emotion for decades to come—the James–Lange–Sergi theory.

The theory is generally attributed to William James, though the name of the Danish physiologist Carl Georg Lange is frequently included. James published his theory in 1884 in the journal *Mind*, followed by some elaboration in his *Principles of Psychology* in 1890 and an important defense in 1894. Lange published in a monograph in 1885 in Danish and two years later in German, and the Italian Guiseppe Sergi presented his ideas in a book on pleasure and pain in 1894, followed by a more specific treatment in 1896. There is no indication that any of the three had much knowledge of the others when they presented their ideas. In brief, James claimed that bodily reactions (including both autonomic and skeletal ones) were produced by some inciting fact and that the perception/feeling of these changes is the emotion. Lange similarly noted that the emotions were nothing more that the sensations produced by the vasomotor system, and Sergi noted that visceral/autonomic functions are stimulated directly and produce the emotions. And those three were not alone; there were similar suggestions from different parts of the globe. What was it about the end of the nineteenth century that engendered this particular point of view in such disparate places? Probably the commitment to an explicit materialism that pervaded scientific thinking. In psychology such an approach demanded implicitly that mental states should—whenever possible—be derived from observable physical events. The road went straight from physiology to experience, and it was not until the turn of the century that psychological theory languages were developed *sui generis*. In the process the definition of James's exciting facts that generated bodily reactions was neglected, though current thought has caught up with the question and primarily assigns these to cognitive evaluations. (For a discussion of these developments and the psychology of emotion during the subsequent century see Mandler 1979.)

With the advent of the commanding Jamesian position, the philosophy of emotion became an adjunct rather than the *avant garde* of emotion theory. For the next century philosophers would list, from different vantage points, specific factors as essential to emotion, such as: certain feelings, positive and negative cognitions, bodily sensations, facial and bodily expressions, and action tendencies. Increasingly psychological evidence was used to buttress one or another position. In the flavor of the century and in keeping with the complex common-sense meaning of emotion a Wittgensteinian position has often been invoked, which gives emotions the characteristic of family resemblances with one or more of the above factors relevant from case to case.

The Jamesian position demanded that for each different emotional experience there should be an appropriately different bodily/visceral precedent. However, a century of studies has failed to show any evidence that different emotional states are preceded by different bodily states. That fact was central in the extensive and crucial critique of the James–Lange position by Cannon (1927). Even though James did not restrict 'bodily events' to the viscera, Cannon noted that visceral autonomic changes were not differentiated or fast enough to account for emotional experiences, nor can visceral changes alone produce emotional experiences. It is this last observation that starts the bridge to the current scene.

In 1924, the Spanish physician Marañon had shown that productions of sympathetic nervous system arousal (by the injection of adrenalin) produced either descriptions of bodily symptoms or 'as if' reports, experimental subjects claiming they felt as if they experienced some emotions. Stanley Schachter picked up the thread imaginatively in 1962 when he (with Jerome Singer) showed that adrenalin injections together with the experimental induction of cognitive states related to specific emotions produced true emotional states or experiences. Essentially the Schachter experiments established what has since been called the 'constructivist' approach to emotional states. The states are the result of potentially independent cognitive and visceral/arousing events experienced as subjectively unified conscious emotions. The notion that cognitive factors played an important part in emotional life had been considered since Aristotle, but now became close to established gospel. The cognitive opening also made possible a new and wide variety of analyses of emotional phenomena and during the last quarter of the twentieth century many different theories of emotion emerged. (For a review of the state of affairs before the proliferation of theories, see Arnold 1970.) More important perhaps was the realization that these evaluative cognitions may well differ from one culture to another (see, for example, Lutz and Abu-Lughod 1990). A field that had been relatively quiescent during the earlier decades of the century erupted with new theories, several new journals, and new organizations. Emotion became—in some of these approaches—all-embracing, with some mental states devoid of any visceral involvement becoming candidates for emotional status. Given the large number of possible cognitive states, enumeration of emotional states became popular once again, though James, for example, had already argued that any such attempt reflected subjective sociocultural prejudices. As the number of theories multiplied, current fashions dictated neurophysiological projections as well as evolutionary speculations.

When the core of the emotion concept moved from ethics into the realm of science there arose an increasing insistence on the importance of visceral, i.e., sympathetic nervous system, activity as part of any reasonable definition of this common language concept. The nineteenth century showed that such activity can be dissociated from the other, cognitive, component of emotional experience. We are left with a question raised specifically in recent years: what—apart from an interminable list—in principle produced the visceral arousal. Questions about a principled source of all emotions had been raised in the nineteenth century by John Dewey in the US and Frederic Paulhan in France who noted that emotions are preceded by conflict, for example, among action tendencies. Current speculations about the source of visceral arousal have come from both psychological and physiological sources. Psychologically it has been proposed that any event or situation that is inconsistent with the individual's expectations (such as to continue some action or perceive an expected sequence) produced SNS arousal. What is proposed is a difference detector linked to the sympathetic nervous system (Mandler 1984, 1992). Physiologically, the research program has been in response to the question 'how is the initial state of bodily arousal evoked?' The most promising proposal is that 'the amygdala detects and organizes responses to natural dangers (like predators) and learns about novel threats and the stimuli that predict their occurrence' (LeDoux 1998).

Neurophysiology has been a widely favored discipline during the last decade of the twentieth century, and recent proposals have mirrored that approach to a psychology of emotion. At the same time there has been an increasing awareness of cultural determinants of different emotional states, and the concurrent realization that so-called cognitive determinants are reflections of sociocultural forces. Is it sheer *fin de siècle* optimism that we can look toward a new synthesis of a neuropsychology of arousal and a cultural analysis of cognitive values?

Emotion in Cognition

A view held by influential philosophers in the eighteenth century, and inherited by psychologists in the nineteenth century, was that mental life could be separated into three mental faculties: conation (will and action), cognition (thinking and knowing), and affect (emotion). In the twentieth century this distinction was reflected in two movements that each gave priority to one of these faculties: behaviorism to conation, cognitive psychology to cognition. In both affect was neglected. Recently it has become clear that neither conation nor cognition can be understood without understanding the influences of affect.

In this article the following is assumed: emotion (affect) and cognition can be distinguished for purposes of analysis, though in practice they are seldom separate. Emotion is often used as a superordinate category that includes both specific emotions such as happiness and anger as well as moods such as anxiety. Specific emotions are typically elicited by events, and usually have known objects: for instance one becomes angry at a particular person for a known reason. Moods are longer lasting and may be objectless (free floating) but their underlying mechanisms are the same as those of specific emotions. Cognition, which includes both conscious and unconscious processes, is the representation and use of knowledge in language, thinking, remembering, attending, perceiving, and the like. To understand emotion in cognition we can ask, therefore, how a specific emotion such as anger affects reasoning, how the fear-based mood of anxiety affects attention, and so forth.

1. *The Idea that Emotions Interfere with Rational Cognition*

Emotion has often been regarded as antipathetic to cognition as in the clichéd adage 'the heart versus the head,' as if emotions were storms that blow the ship of selfhood from its rationally calculated course.

In the Western intellectual tradition, suspicion of emotions was perhaps most clearly articulated by Darwin (1872), who argued that emotional expressions are actions that occur whether or not they are any use. He included the bristling of hairs when angry or frightened, and the curling of a lip on one side of the mouth in contempt which he thought was a vestige of baring the teeth in snarling preparation to bite. Had he been writing today, he would have pointed to the smiles and gestures people make when they speak on the telephone. For Darwin, emotional expressions were those actions that derive from our evolution as beasts, or from our individual development from infancy. They are leftovers from earlier times, which cannot be inhibited by taking thought: behavioral equivalents of the appendix in our digestive system which in distant ancestors had a function but which, in adult humans, has a function no longer. The implication is that such expressions, and by implication the emotions themselves, have a regrettable influence on adult cognition. In a notebook Darwin wrote: 'Our descent, then, is the origin of our evil passions!!—The Devil under form of baboon is our grandfather.' Although he would never have published this sentiment, the argument in his 1872 book is consonant with it. The atavistic quality Darwin ascribed to emotional expressions gave biological credence to a distrust of emotions as enemies of reason that had been voiced by Plato, then nurtured by the Stoics and many subsequent thinkers.

2. *Functional Conceptions of Emotion*

There is, however, another line of argument. It is that emotions are the essential guides of cognition. In Western thought, the line derives from Aristotle, who argued that emotions are evaluations: beliefs about what we value. This is the view that has prevailed in modern cognitive psychology. So an emotion is a psychological process that mediates between goals (valued concerns) and events. It is typically elicited by an appraisal of an event in the world that affects an

important goal or concern (see e.g., Oatley and Jenkins 1996).

Aristotle's main treatment of emotions is in his book *Rhetoric*, which is not so much about persuading people by sly means, as about reaching useful conclusions socially when no exact demonstration of the correct course of action can be made. If there were an exact demonstration—an unequivocal argument on some matter—says Aristotle, we should follow it. But without such a demonstration, there must be discussion, as occurs for instance in a law court or in politics. Now emotions become essential. They are aroused in people who listen to the case on this side and that. 'The emotions,' said Aristotle, 'are all those feelings that so change [people] as to affect their judgements, and are also attended by pain or pleasure. Such are anger, pity, fear, and the like, with their opposites.'

Most problems of practical human life have no fully rational solutions. Therefore different people need to represent different points of view, including their emotional implications. This occurred recently in political and media discussions of the Yugoslavian conflict: on one side the tragic fate of Kosovan refugees, on the other the terrifying effects of bombing on civilians. In such discussions, conclusions are reached that are not ideal, but are better than those reached without considering emotional implications or without thinking in a dialogical way.

Since the advent of cognitive science in the late 1950s, psychological conceptions of thinking have been dominated by the idea of search across a space of possibilities. In chess, for instance, one searches ahead across moves and their continuations. In reasoning, one searches across manipulations of a problem to reach a solution. But, as quickly became clear, most search spaces for real problems quickly become indefinitely large, so they elude simple search processes. Research attention was then drawn to heuristics that help to prune search trees.

Following especially from a paper of Simon (1967), emotions came to be seen as heuristics of this kind. Simon's argument was that although, at that time, computer processes ran without interference until they terminated, in any realistic example of cognition every possibility cannot be foreseen, and so unexpected events occur. A system is therefore needed to interrupt ongoing processes, so that a more urgent process can take control. Such a system corresponds with what we think of as emotion: the process of managing cognition in environments which, like the ones we live in, are never fully predictable.

2.1 Three Classes of Problem for Human Rationality

Simon stressed the unpredictability that derives from limitations of resources, but really the problem is more extensive. Outcomes of actions are not fully predictable for three classes of reasons. First, there is indeed the issue of resources: human mental models are always incomplete and often incorrect; time, movement, strength, etc. are also always limited. Hence the unexpected often occurs. Second, goals are often multiple and sometimes incommensurable, as is made clear every time the career aspirations of a politician are threatened by media exposure of questionable sexual goals. Moreover, even where goals are commensurable, as for instance when mediated by money, there is no principled way of deciding whether to maximize gains or minimize losses. Third, the human biological arrangement is to offset limitations of resources (the first point) by distributing cognition and action among several agents. This has allowed a huge net gain in the possibilities of agency as compared with what could be accomplished by the individual, as may be seen in the products of human culture. But the arrangement introduces a new domain of unpredictability because our knowledge of beliefs and plans of other agents with whom we interact is also limited. In general, then, although we should strive for rationality, fully rational thought and action in most of life is impossible.

A solution to these three classes of problems has derived from evolution: the system of human emotions as heuristics that manage priorities of action in environments that are never certain, when there are multiple goals, and when we interact with other people.

2.2 Definition of Emotion

A working definition of emotion is due to Frijda (1986): an emotion occurs when an event is appraised as relevant to a goal. It is a form of readiness approximately appropriate to the event that elicited it. It gives priority to some goals rather than others, and an urge towards action of a certain kind. It is often accompanied by distinctive types of thought, expression, and physiological response, and it can interrupt, or compete with, alternative courses of action. An example: imagine you are reading quietly at home when the phone rings with news of an accident to a close friend. You experience a hollow feeling in the stomach, and in anxiety you put all thoughts of reading aside. Mental processing is switched to the urgent concern for your friend, and you make plans about what you might do to help.

2.3 Emotions and Optimization of Cognitive Processing

Darwin's book on *Expression* can be read as a treatise on optimization of behavioral mechanisms that were each adapted to a particular environment at a par-

ticular phase of evolution or development. Behavioral mechanisms are acquired by accretion, and in general these mechanisms cannot be deleted. Any mechanism, then, may or may not be useful in future environments, and may or may not be adaptable to new purposes. Darwin saw that the adaptations of evolutionary change have occurred in a piecemeal fashion, over extended periods. His principal concern was to argue against the idea that humans are perfect creations, so he emphasized aspects of behavior that in adult human life are imperfectly adapted. A century later, the argument for evolution had been won. Simon accepted it, saw the optimization problem more generally, and recognized the functional place of emotions within it.

Emotions, on this view, are not antipathetic to cognition; they are its managers within a system of only-partly-adapted cognitive-behavioral mechanisms that operate in a world where perfect solutions are rare. Emotions are not especially enemies of rationality. Rather, human rationality is like an archipelago in a huge and changing sea. We can rationally choose to take the shortest route to some destination, rather than setting off in the opposite direction. As self-interested economic agents we can rationally choose the lowest price for a product. As friends, we can rationally do what we have promised, knowing that someone depends on us. But the sea of ignorance of the exact effects of our actions is large. Emotions are heuristics that bridge across the straits between the islands of what we know rationally how to do.

3. *Experimental Studies of Effects of Emotions on Cognition*

Since the 1970s, experimental studies of effects of emotions have been made in increasing numbers. A pioneer was Isen who induced mild happiness in people by testing a skill and telling them they had done well, or by giving them small gifts, or by having them watch comedy films. She found several types of effect. As compared with people in neutral moods, those made happy (a) were more cooperative for instance in making larger donations to charity and in helping strangers, (b) did better in some intellectual tasks such as creative problem solving, and (c) recalled happy rather than unhappy memories. One of Isen's most striking studies (Isen et al. 1987) was to have subjects watch a funny or a neutral film. She then asked them individually to solve a problem: to use only a box of tacks, a book of matches, and a candle, to fix the candle to a corkboard wall and light it. Less than 20 percent of subjects who watched the neutral film solved the task, but in one experiment 75 percent and in another experiment 58 percent of subjects made happy by the funny film solved the problem within 10 minutes. The tacks did not work to pin the candle directly to the wall. The solution was to empty the box of tacks, pin the box to the wall, and use it to hold the candle. Happiness, therefore, made cognition more flexible. In terms of optimization, happiness minimizes issues of safety (which are maximized by fear and anxiety), and it improves the search for unusual associations.

At about the same time Bower (1981) was experimenting with inducing emotions by hypnosis. In one experiment, he asked subjects to recall incidents from their childhood, moving haphazardly around their memory for 10 minutes and briefly describing each incident they recalled. Next day he asked them to classify the recalled incidents as pleasant, unpleasant, or neutral. On the following day, he induced either a happy or sad mood, and asked the subjects to recall again the incidents they had recalled previously and later categorized. He found that subjects who were put into a happy mood recalled substantially more incidents they had classed as pleasant compared with unpleasant. Subjects in a sad mood remembered slightly more of the unpleasant than the pleasant incidents.

Explanations for this type of phenomenon have shifted. Bower at first thought that the explanation was of state dependency: incidents of any arbitrary kind that are memorized in one mood state are more available for recall when the same mood state recurs. Results of many studies now imply an explanation called mood congruence: autobiographical incidents with a particular emotional meaning to the subject are more available to recall when that same emotion recurs.

Effects of the mood of anxiety have also been studied. Whereas sadness has large effects on memory, anxiety has its largest effects on attention. A typical effect is shown in the so-called Stroop task in which words are printed in different colored inks. In Stroop's original task, people were asked to look at words such as 'red,' 'yellow,' and 'blue,' and to name the color of the ink in which each was printed. People were significantly slowed wherever a word, e.g., 'red,' was different from the color in which it is printed, e.g., in yellow ink. The explanation is that attention required for the task of naming the ink colors is captured by the meanings of the words. In the emotional Stroop task, the words are not of colors but they are emotionally significant: words like 'cancer,' 'robbery,' and so forth. Where such words have special emotional significance for subjects, attention is captured, and such subjects are slowed in saying the ink color of the words. For instance, Foa et al. (1991) found that people who had been victims of rape were slowed in saying the ink colors of words related to rape compared with ink colors of words that were not so related. In general, methods such as this have indicated that people who are anxious attend selectively to issues of their anxious concern.

Many other laboratory findings and principles have been established. Emotion has also been shown to affect perception, categorization, and the represen-

tation of knowledge. Perhaps most widely it has been shown to affect tasks that involve reasoning and social judgements (Forgas 2000). Principles include the finding that happy emotions tend to make for cognition that uses short cuts or schematic solutions, whereas negative emotions tend to make for more careful, step-by-step, processing (Schwarz and Bless 1991). In terms of maximization and minimization, in environments that are experienced as safe and friendly, cognitive processes are switched to maximizing gains according to current goals, to cooperative plans, or to assimilating new information to current knowledge structures. Negative emotions signal that something has gone wrong in progress toward a goal. Processing is switched so that schemata can accommodate, and careful attention is given to events of the environment, and to consistency of internal models.

It is clear that the relations among emotions and cognition need to be understood at several different levels of processing (Teasdale 1999). It is also clear that interactions between emotion and cognition can be approached using experimental methods in brain sciences as well as in psychology. For instance, it has been found that people with lesions of the prefrontal region have experimentally demonstrable defects in emotional processing; they also show impairments in social planning as it affects friendships, employment, and the making of social arrangements (Damasio 1994). Although this association between emotion and social planning is consistent with much cognitive research on emotions, neurological findings such as this have been influential in enabling acceptance of emotions as guides of cognition rather than disturbers of rationality.

4. *Research in Psychiatric Epidemiology*

Though experimental studies in this area are robust, many of them neglect people's most pressing emotional concerns. This domain has, however, been explored in studies of people's cognitive-affective responses to emotionally important events and problems in their lives. Perhaps most significant in this area has been the finding by Brown and Harris (1978) of how clinical depression is typically caused. When people become depressed, they experience a range of cognitive changes, and typically come to regard life as hopeless and unsustainable, so that they cannot cope with daily tasks, and contemplate giving up life altogether. The immediate causes of such breakdowns are severely adverse events such as bereavement from loved spouses, children, or parents, or severe protracted difficulties such as marital conflict, or unemployment and consequent lack of income.

Comparably, people become clinically anxious in response to severe threats to their way of life and to their systems of previous belief. Although this is true for many kinds of clinical anxiety states, most striking in this regard is the syndrome of post-traumatic stress disorder, in which people who suffer war or civil disaster, have their lives and value systems upturned. Such people's cognitive systems switch chronically to states of hypervigilance, accompanied by vivid memory flashbacks to the disaster that occurred.

Cross-connections between experimental studies and research in psychiatry have been made (see, e.g., Power and Dalgleish 1997). For instance, depressed people have been found to suffer biases of memory towards recalling incidents of loss and defeat, and people who are clinically anxious show biases of attention that can be demonstrated on tasks such as the emotional Stroop test (see, e.g., Mathews 1993).

5. *Conclusion*

For a long time cognition was studied as if it involved merely the impartial representation and use of knowledge. But emotions are, as Aristotle argued, evaluations that mediate between concerns and the events that impinge on knowledge. They are guides of cognition, selecting among beliefs, arranging priorities among goals, directing attention, biasing access to remembered material, and providing heuristics that influence reasoning, judgement, and planning.

Emotion, Neural Basis of

In order to provide a fundamental basis for understanding the neural basis of emotion, it is useful to have a clear view of the events that give rise to emotions and the functions of emotion, for these help to define the input systems in the brain involved in producing emotions, and the output systems in the brain that are involved in expressing emotion. With this basis, developed fully by Rolls (1999, 2000a) the neural systems that underlie emotions are then considered.

1. *The Events that Give Rise to Emotions*

Emotions can usefully be defined as states produced by rewards and punishers. Rewards are stimuli for which an animal (including humans) will work, and punishers are stimuli that an animal will work to escape from or avoid. Rewards and punishers are reinforcers in that they alter the probability of behavior. Some stimuli are unlearned or primary reinforcers (e.g., the taste of food if the animal is hungry, or pain). Other stimuli may become reinforcing by learning, because of their association with such primary reinforcers, thereby becoming 'secondary reinforcers.' For example, fear is an emotional state which might be produced by a sound (the conditioned stimulus) that has previously been associated with a painful stimulus (the primary reinforcer.)

The different emotions can be described and classified according to whether the reinforcer is positive or negative, and by the reinforcement contingency. An outline of such a classification scheme is shown in Fig. 1.

The operation of the following factors enables a very wide range of different emotions to described:

(a) The reinforcement contingency (see Fig. 1).

(b) The intensity of the reinforcer (see Fig. 1).

(c) Any environmental stimulus might have a number of different reinforcement associations. For example, a stimulus might be associated both with the presentation of a reward and of a punishment, allowing states such as conflict and guilt to arise.

(d) Emotions elicited by stimuli associated with different primary reinforcers will be different.

(e) Emotions elicited by different secondary reinforcing stimuli will be different from each other (even if the primary reinforcer is similar).

(f) The emotion elicited can depend on whether an active or passive behavioral response is possible. For example, if an active behavioral response can occur to the omission of a previously rewarded stimulus, then anger might be produced, but if only passive behavior is possible, then sadness, depression, or grief might occur.

By combining these six factors, it is possible to account for a very wide range of emotions. It is also worth noting that

(a) emotions can be produced just as much by the recall of reinforcing events as by external reinforcing stimuli;

(b) cognitive processing (whether conscious or not) is important in many emotions, for very complex cognitive processing may be required to determine whether environmental events are reinforcing or not;

(c) emotions normally consist of cognitive processing which determines the reinforcing valence of the stimulus, and an elicited mood change if the valence is positive or negative; and

(d) and that stability of mood implies that absolute levels of reinforcement must be represented over moderately long time spans by the firing of mood-related neurons, a difficult operation which may contribute to 'spontaneous' mood swings, depression which occurs without a clear external cause, and the multiplicity of hormonal and transmitter systems which seem to be involved in the control of mood.

2. *The Functions of Emotion*

The functions of emotion can be summarized as follows.

(a) The *elicitation of autonomic responses* (e.g., a change in heart rate) *and endocrine responses* (e.g., the release of adrenaline). These prepare the body for action.

(b) *Flexibility of behavioral responses to reinforcing stimuli*. Emotional (and motivational) states allow a simple interface between sensory inputs and motor outputs. The new understanding is that some genes specify which stimuli are rewarding and punishing, and these stimuli are the goals for flexible actions. For example, genes specify that strong somatosensory stimuli produce a state of pain which animals (including humans) are built to perform actions to avoid or escape. The state produced by the painful stimulus is an emotional state which has the adaptive function of identifying and maintaining the goal for an action. This is an efficient design, for the genes need only specify the goals for actions, and not the actions themselves, so that the actions can be selected flexibly to meet the goals. It would be very inflexible and

Figure 1
Some of the emotions associated with different reinforcement contingencies are indicated. Intensity increases away from the centre of the diagram, on a continuous scale. The classification scheme created by the different reinforcement contingencies consists of (a) the presentation of a positive reinforcer (S+), (b) the presentation of a negative reinforcer (S−), (c) the omission of a positive reinforcer (S+) or the termination of a positive reinforcer (S+!), and (d) the omission of a negative reinforcer (S−) or the termination of a negative reinforcer (S−!).

inefficient for the genes to specify actions themselves. In this way, emotions provide an efficient interface between sensory systems and actions. The hypothesis is that our emotions correspond to the goal-specifying states arising from stimuli that genes have found it adaptive and possible to specify. Rolls (1999) provides in Table 10.1 the start of a list of some of the primary reinforcers that genes appear to specify, and thus an idea of how a wide range of different emotions have evolved because of their adaptive implications.

(c) Emotion is *motivating*. For example, fear learned by stimulus-reinforcement association formation provides the motivation for actions performed to avoid noxious stimuli.

(d) *Communication*. For example, monkeys may communicate their emotional state to others, by making an open-mouth threat to indicate the extent to which they are willing to compete for resources, and this may influence the behavior of other animals. This aspect of emotion was emphasized by Darwin (1872).

(e) *Social bonding*. Examples are the emotions associated with the attachment of the parents to their young, and the attachment of the young to their parents.

(f) The current mood state can affect the *cognitive evaluation of events or memories* (see Oatley and Jenkins 1996), and this may have the function of facilitating continuity in the interpretation of the reinforcing value of events in the environment.

(g) Emotion may facilitate the *storage of memories*. One way in which this occurs is that episodic memory (i.e., one's memory of particular episodes) is facilitated by emotional states. This may be advantageous in that storing many details of the prevailing situation when a strong reinforcer is delivered may be useful in generating appropriate behavior in situations with some similarities in the future. A second way is that the current emotional state may be stored with episodic memories, providing a mechanism for the current emotional state to affect which memories are recalled. A third way in which emotion may affect the storage of memories is by guiding the cerebral cortex in the representations of the world which are set up. For example, in the visual system, it may be useful to build

perceptual representations or analyzers which are different from each other if they are associated with different reinforcers, and it may be less likely to build them if they have no association with reinforcement.

(h) Another function of emotion is that by enduring for minutes or longer after a reinforcing stimulus has occurred, it may help to produce *persistent and continuing motivation and direction of behavior*, to help achieve a goal or goals.

(i) Emotion may trigger the *recall of memories* stored in neocortical representations. Amygdala back-projections to the cortex could perform this for emotion in a way analogous to that in which the hippocampus could implement the retrieval in the neocortex of recent (episodic) memories (Rolls and Treves 1998).

(j) Rewards and punishers, and the emotional states they produce, provide a common currency for the behavior selection process between competing alternative actions.

3. Brain Mechanisms of Emotion

3.1 Overview

Animals are built with neural systems that enable them to evaluate which environmental stimuli, whether learned or not, are rewarding and punishing, that is will produce emotions and will be worked for or avoided. Sensory stimuli are normally processed through several stages of cortical processing to produce a sensory representation of the object before emotional valence is decoded. For example, in the taste system, taste is analyzed in primates to provide a representation of what the taste is in the primary taste cortex, and this representation is independent of the reward value of the taste in that it is not affected by hunger. In the secondary taste cortex, in the orbitofrontal region (see Fig. 2), the reward value of the taste is represented, in that neurons only respond to the taste if the primate is hungry. In another example, in the visual system representations of objects which are view-, position- and size-invariant are produced in the inferior temporal visual cortex after many stages of cortical processing, and these representations are independent of the emotional valence of the object.

Then in structures such as the orbitofrontal cortex and amygdala, which receive from the inferior temporal visual cortex, associations are learned between the objects and the primary reinforcers associated with them, by the process of stimulus-reinforcement association learning. In the orbitofrontal cortex and amygdala emotional states are thus represented.

Consistent with this, electrical stimulation of the orbitofrontal cortex and amygdala is rewarding, and damage to these structures affects emotional behavior by affecting stimulus-reinforcement association learning. These brain regions influence the selection of behavioral actions through brain systems such as the ventral striatum and other parts of the basal ganglia.

3.2 The Amygdala

The amygdala receives information about primary reinforcers (such as taste and touch), and also information about visual and auditory stimuli from higher cortical areas (such as the inferior temporal cortex) that can be associated by learning with primary reinforcers (Fig. 2). Bilateral removal of the amygdala in monkeys produces tameness, a lack of emotional responsiveness, the excessive examination of objects, often with the mouth, and the eating of previously rejected items such as meat (the Kluver-Bucy syndrome). In analyses of the bases of these behavioral changes, it has been observed that there are deficits in learning to associate stimuli with primary reinforcement, including both punishments and rewards. The association learning deficit is present when the associations must be learned from a previously neutral stimulus (e.g., the sight of an object) to a primary reinforcing stimulus (such as the taste of food).

Further evidence linking the amygdala to reinforcement mechanisms is that monkeys will work in order to obtain electrical stimulation of the amygdala, that single neurons in the amygdala are activated by brain-stimulation reward of a number of different sites, and that some amygdala neurons respond mainly to rewarding stimuli, and others to punishing stimuli. The association learning in the amygdala may be implemented by associatively modifiable synapses from visual and auditory neurons on to neurons receiving inputs from taste, olfactory or somatosensory primary reinforcers (LeDoux 1996). Consistent with this, Davis (2000) has found that at least one type of associative learning in the amygdala can be blocked by local application to the amygdala of a NMDA receptor blocker, which blocks long-term potentiation (LTP), which is a model of the synaptic changes that underlie learning (see Rolls and Treves 1998). Consistent with the hypothesis that the learned incentive (conditioned reinforcing) effects of previously neutral stimuli paired with rewards are mediated by the amygdala acting through the ventral striatum, amphetamine injections into the ventral striatum enhanced the effects of a conditioned reinforcing stimulus only if the amygdala was intact (see also Everitt et al. 2000).

An interesting group of neurons in the amygdala (in, for example, the basal accessory nucleus) responds primarily to faces. They are probably part of a system which has evolved for the rapid and reliable identification of individuals from their faces, and of facial expressions, because of the importance of this in primate social behavior. Consistent with this, activation of the human amygdala can be produced in neuroimaging studies by some face expressions, and

Figure 2
Some of the pathways involved in emotion described in the text are shown on this lateral view of the brain of the macaque monkey. Connections from the primary taste and olfactory cortices to the orbitofrontal cortex and amygdala are shown. Connections are also shown in the 'ventral visual system' from V1 to V2, V4, the inferior temporal visual cortex, etc., with some connections reaching the amygdala and orbitofrontal cortex. In addition, connections from the somatosensory cortical areas 1, 2 and 3 that reach the orbitofrontal cortex directly and via the insular cortex, and that reach the amygdala via the insular cortex, are shown. as, arcuate sulcus; cal, calcarine sulcus; cs, central sulcus; lf, lateral (or Sylvian) fissure; lun, lunate sulcus; ps, principal sulcus; io, inferior occipital sulcus; ip, intraparietal sulcus (which has been opened to reveal some of the areas it contains); sts, superior temporal sulcus (which has been opened to reveal some of the areas it contains). AIT, anterior inferior temporal cortex; FST, visual motion processing area; LIP, lateral intraparietal area; MST, visual motion processing area; MT, visual motion processing area (also called V5); PIT, posterior inferior temporal cortex; STP, superior temporal plane; TA, architectonic area including auditory association cortex; TE, architectonic area including high order visual association cortex, and some of its subareas TEa and TEm; TG, architectonic area in the temporal pole; V1—V4, visual areas 1—4; VIP, ventral intraparietal area; TEO, architectonic area including posterior visual association cortex. The numerals refer to architectonic areas, and have the following approximate functional equivalence: 1,2,3, somatosensory cortex (posterior to the central sulcus); 4, motor cortex; 5, superior parietal lobule; 7a, inferior parietal lobule, visual part; 7b, inferior parietal lobule, somatosensory part; 6, lateral premotor cortex; 8, frontal eye field; 12, part of orbitofrontal cortex; 46, dorsolateral prefrontal cortex

lesions of the human amygdala may cause difficulty in the identification of some face expressions.

3.3 The Orbitofrontal Cortex

The orbitofrontal cortex receives inputs from the inferior temporal visual cortex and superior temporal auditory cortex; from the primary taste cortex and the primary olfactory (pyriform) cortex (see Fig. 2); from the amygdala, and from the midbrain dopamine neurons. Damage to the caudal orbitofrontal cortex in the monkey produces emotional changes. These include decreased aggression to humans and to stimuli such as a snake and a doll, and a reduced tendency to reject foods such as meat. These changes may be related to a failure to react normally to and learn from nonreward in a number of different situations. This failure is evident as a tendency to respond when responses are inappropriate, for example no longer rewarded.

For example, monkeys with orbitofrontal damage are impaired on Go/NoGo task performance (in which they should make a response to one stimulus to obtain a reward, and should not make a response to another stimulus in order to avoid a punishment), in that they Go on the NoGo trials. They are also impaired in an object-reversal task in that they respond to the object which was formerly rewarded with food. They are also impaired in extinction in that they continue to respond to an object which is no longer rewarded. Further, the visual discrimination learning deficit shown by monkeys with orbitofrontal cortex damage, may be due to the tendency of these monkeys not to withhold responses to nonrewarded stimuli.

The primate orbitofrontal cortex contains neurons which respond to the reward value of taste (a primary reinforcer), in that they only respond to the taste of food when hunger is present (which is when food is rewarding). It also contains neurons which learn to respond to visual stimuli associated with a primary reward such as taste, and which reverse their responses to another visual stimulus in one trial when the rewards and punishers available from those visual stimuli reverse. Further, these visual responses reflect reward, in that feeding the monkey to satiety reduces the responses of these neurons to zero. Moreover, in part of this orbitofrontal region, some neurons combine taste and olfactory inputs, in that they are bimodal, and are in 40 percent of cases affected by olfactory-to-taste association learning and by feeding the monkey to satiety, which reduces the reward value. In addition, some neurons in the primate orbitofrontal cortex respond to the sight of faces. These neurons are likely to be involved in learning which emotional responses are currently appropriate to particular individuals, and in making appropriate emotional responses given the face expression.

It has been found that another class of neurons in the orbitofrontal cortex of the monkey responds in certain nonreward situations. For example, some neurons responded in extinction, immediately after a lick had been made to a visual stimulus which had previously been associated with fruit juice reward, and other neurons responded in a reversal task, immediately after the monkey had responded to the previously-rewarded visual stimulus, but had obtained punishment rather than reward. Another class of orbitofrontal neuron responded to particular visual stimuli only if they were associated with reward, and these neurons showed one trial stimulus-reinforcement association reversal. Another class of neuron conveyed information about whether a reward had been given, responding, for example, to the taste of sucrose, or for other neurons of saline.

These types of information may be represented in the responses of orbitofrontal neurons because they are part of a mechanism which evaluates whether a reward is expected, and generates a mismatch (evident as a firing of the nonreward neurons) if reward is not obtained when it is expected (see Rolls 1999, 2000a, 2000b). These neuronal responses provide further evidence that the orbitofrontal cortex is involved in emotional responses, particularly when these involve correcting previously learned reinforcement contingencies, in situations which include those usually described as involving frustration.

It is of interest and potential clinical importance that a number of the symptoms of frontal lobe damage in humans appear to be related to this type of function; altering behavior when stimulus-reinforcement associations alter, as described next. Thus, humans with frontal lobe damage can show impairments in a number of tasks in which an alteration of behavioral strategy is required in response to a change in environmental reinforcement contingencies (Rolls et al. 1994; Damasio 1994). Some of the personality changes that can follow frontal lobe damage may be related to a similar type of dysfunction. For example, the euphoria, irresponsibility, lack of affect, and lack of concern for the present or future which can follow frontal lobe damage may also be related to a dysfunction in altering behavior appropriately in response to a change in reinforcement contingencies. At one time, following a report by Moniz (1936), prefrontal lobotomies or leucotomies (cutting white matter) were performed in humans to attempt to alleviate a variety of problems, and although irrational anxiety or emotional outbursts were sometimes controlled, intellectual deficits and other side effects were often apparent (see Valenstein 1974). Thus these operations have been essentially discontinued.

To investigate the possible significance of face-related inputs to orbitofrontal visual neurons described above, the responses to faces that were made by patients with orbitofrontal damage produced by pathology or trauma were tested. Impairments in the identification of facial and vocal emotional expression were demonstrated in a group of patients with ventral frontal lobe damage who had socially inappropriate behavior (Hornak et al. 1996). The expression identification impairments could occur independently of perceptual impairments in facial recognition, voice discrimination, or environmental sound recognition. Thus the orbitofrontal cortex in humans appears to be important not only in the rapid relearning of stimulus-reinforcement associations, but also in representing some of the stimuli, such as face expression, which provide reinforcing information. Consistent with this, neuroimaging studies in humans are showing representations which reflect the pleasantness of the taste and smell of food, the pleasantness of touch, and also of quite abstract rewards and punishers such as winning or losing money (O'Doherty et al. 2001.)

The behavioral selection system must deal with many competing rewards, goals, and priorities. This selection process must be capable of responding to many different types of reward decoded in different brain systems that have evolved at different times,

even including the use, in humans, of a language system to enable long-term plans to be made. These many different brain systems, some involving the implicit (unconscious) evaluation of rewards, and others explicit, verbal, conscious, evaluation of rewards and planned long-term goals, must all enter into the selector of behavior. Although poorly understood, the issue of emotional feelings are part of the much larger problem of consciousness, and may involve the capacity to have thoughts about thoughts, that is higher order thoughts (see Rolls 1999, 2000a).

Emotional Inhibition and Health

1. Introduction

Emotional inhibition constitutes part of a maladaptive interaction between an individual and their social environment. Emotional inhibition may be classified into genetic, repressive, suppressive, and deceptive inhibition and the extreme form emotional implosion (Traue 1998). Overt emotional inhibition generally is characterized by reduced expressiveness, unemotional language, and shyness, all of which is related to dysfunctional bodily reactions and may be adaptive in a short-term social stress situation. In the long run, emotional inhibition is likely to have a harmful effect on the individual, which may occur along any of three pathways: neurobiological, social-behavioral, and cognitive. Most psychotherapeutic techniques are directed at emotional behavior and experience and focus largely on changes in intra- and interindividual emotional regulation and the construction of meaning from emotional experience.

2. Emotion and Inhibition

Emotions may be considered transactions between individuals and their social environment. They give personal meaning to external and internal stimuli and communicate meaning from the individual to others. Emotions consist of interpretations of intero- and exteroceptive stimuli, intentions, physiological patterns of arousal, and motor behavior including overt emotional expressiveness. The interaction of these different components in the individual and the social and physical environment are mediated by the central nervous system (CNS). From a regulation point of view, emotional expressiveness has two important functions: first, it serves a communicative function by facilitating the regulation of person–environment transactions and, second, the feedback function of behavioral expressions controls the intra-individual regulation of emotion. This means that an experience

may be influenced indirectly by actively responding towards a negative emotional stimulus in the environment, in order to attenuate it, or directly through self-regulation. Thus, expressive behavior can serve simultaneously as a component of emotional processes and as a coping response.

Both psychoanalysis and neurophysiology advanced to the concept of inhibition in different contexts in the twentieth century. For many years, an inverse relationship between expressive behavior and autonomic responsivity has been documented, such that the inhibition of overt emotional expressiveness can lead to an autonomic over-reaction. This has been considered a significant factor in the etiology and maintenance of psychosomatic disorders. A number of early researchers in the first two decades of the twentieth century reported measurements of high physiological activity in subjects suppressing emotional expression. These studies led to the concept of internalization and externalization, where two behavioral coping styles for dealing with psychic tension were discerned: either behaviorally, outwardly directed, or physiologically, within the individual. According to this concept, the term 'internalizer' describes a person exhibiting a low level of overt expressiveness under stress yet a high level of physiological excitation, whereas an 'externalizer' is characterized by high expressiveness and a low level of physiological expressiveness in social situations. Different health models explain on internalizing and externalizing in terms of stress and coping or in terms of inhibition as physiological work. Over time, the work of inhibition acts as a low-level cumulative stressor. As with all cumulative stressors, sustained inhibition is linked to increases in stress-related diseases, and various other disorders such as cardiovascular and skin disorders, asthma, cancer, and also pain (Traue and Pennebaker 1993).

3. *The Model of Inhibition and Health*

A model explaining how emotional stress, under a given social situation, can trigger or modulate health disorders is described below (see Fig. 1). Health disorders and illness behavior are conceived as different, but related, processes, and distinct mechanisms may contribute dependently and independently to different aspects of a given disorder and its behavioral consequences (Traue 1998).

On a phenomenological level, emotional stress can occur on a severity dimension ranging from daily stressors, through more traumatic life events, to more chronic or severe psychotrauma. A common underlying factor in such situations is that each has to be coped with by the individual. Emotional stress can be considered to be processed by way of an '*inhibition-implosion*'-dimension (to implode means to collapse or cause to collapse inwards in a violent manner as a result of external pressure), modulated by dispositional factors (innate, personality, and socialization).

Of particular importance are innate and socialization factors. Possible individual differences in hypothalamic mechanisms and opioidergic pathways corresponding with increased vulnerability to stress have been suggested. Emotional processing relating to the inhibition-implosion idea has been discussed in relation to several topics such as control, suppression, Type C personality, repression, alexithymia, or ambivalence. Each of these concepts covers different aspects of overt emotional expressiveness from a personality or coping perspective. Inhibition is the most general term for the incomplete processing of emotional stress when these stressors induce bodily changes (physiological, endocrinological, or immunological) and the cognitive, emotional, and behavioral processing are dysfunctional such that subjective experience and spontaneous expression of emotions and action tendencies are separately or simultaneously attenuated and intra- and interpersonal regulation is disturbed. This process may be the result of innate or acquired behavior.

3.1 *Classification of Emotional Inhibition*

A classification of involved mechanisms differentiates between genetic, repressive, suppressive, and deceptive inhibition.

Genetic inhibition describes the genetically determined basis of behavioral inhibition. Studies working with young children have classified those children who were least able to initiate interaction in a social situation with other children and adults as behaviorally inhibited. Most children's degree of behavioral inhibition has been shown to be stable over a period of five years. In those children classified as inhibited, increased levels of arousal, norepinephrine, and salivary cortisol have been found.

Repressive inhibition refers to emotional processing with attenuated subjective experience of emotional arousal. Emotionally expressive responses in repressive inhibition could be based solely on the cognitive interpretation of the situation and are organized nonspontaneously. The individual, being unable to feel their own arousal, processes insufficient response-information for an appropriate response, which in turn decreases the need to express emotions or cope with an emotional stressor. In addition, the cognitive interpretation of the situation without the emotional component may be wrong or misleading. Prolonged bodily arousal and impaired coping could result. Repressive coping style is the best known model for repressive inhibition.

Suppressive inhibition is best circumscribed by suppression of emotional arousal. The emotional arousal is

Figure 1
Pathway model of emotional inhibition with neurobiological, social-behavioral, and cognitive pathways from stress/disposition to emotional processing and subsequent health disorders or illness behaviors (adapted from Traue 1998)

recognized by the individual, but spontaneous expressive and cognitive behaviors are suppressed involuntarily or habitually. Suppressive inhibition of emotions results from interactions between innate factors and socialization. For example, if individuals show increased responses under stressful encounters, they are prone to socialization conditions of punishment and negative reinforcement, initiating a learning history with decreases in spontaneous expressiveness and increases in bodily arousal.

Deceptive inhibition describes the phenomenon whereby individuals under emotional stress, aware of their bodily reactions and their urge for expressiveness, can suppress this need voluntarily or try to present a false response to a receiver. Whether an individual is pokerfaced or displays a false emotional response, such inhibition requires psychological energy, reducing the individual's coping capacity and providing additional stress.

In reviewing the psychophysiological and psychosomatic data, it might appear that emotional inhibition is always harmful. However, it should be noted that although the correlations between bodily processes and the above four forms of inhibition support such a notion, in certain circumstances inhibition could be beneficial for the individual and his/her relationship with the social environment. Inhibition becomes toxic when it is related, first, to physiological, endocrinological hyperarousal or immunological dysfunction, second to long-standing disregulation of emotions within the individual on a cognitive and behavioral basis, and third, if inhibition disturbs the individual's social relations.

Inhibition represents a risk factor for health under normal stressors. If the severity of the stressors is dramatically high, the mental and physical health consequences are inevitable. In traumatic stress situations like rape, criminal bodily attacks, or torture the victim may well lose control over strong emotional responses. The emotional responses of horror, panic, and loss of control could literally cause a violent breakdown in the mental and bodily systems. Such an

emotional implosion (Traue 1998) is observable in the symptom pattern of post-traumatic stress disorder (PTSD): cognitive and behavioral avoidance of trauma stimuli, numbing of general and emotional responsiveness (emotional anesthesia), detachment from other people, persistent symptoms of arousal like disturbed sleep, exaggerated startle response and somatic complaints (see *Post-traumatic Stress Disorder*). In addition, persons with PTSD suffer an increased risk of social phobia, major depressive and somatizing disorder (*DSM-IV*, American Psychiatric Association 1994).

The psychological, physical, and social symptoms in PTSD are a form of emotional processing involving an extreme form of inhibition. While inhibition generally develops over a long time span through interaction between innate and socialization factors, implosion can occur in a very short time as a result of a single and extreme man–made stressful event.

4. *Pathways from Emotional Inhibition to Health Disorders and Illness Behaviors*

Emotional stress modulated through innate, personality, and socialization factors can trigger, maintain, or worsen health disorders and related illness behavior through neurobiological, social-behavioral, and cognitive pathways. With respect to illness behaviors, the pathways include biases in symptom reporting, secondary gain by presented symptoms, subjective feelings of being impaired, pressure to seek medical help and social isolation.

4.1 *Neurobiological Pathways*

Emotional inhibition is strongly neurobiologically based. The behavioral inhibition system and the behavioral activation system have been discussed as possible neurobiological structures. Empirical evidence from between-subject studies shows that inhibited, repressed, or suppressed emotional expressiveness is linked to greater autonomic arousal, both under conditions of emotion induction and voluntary deception. There is rich empirical evidence for neurobiological correlates of inhibition in respiratory, cardiovascular, muscular, digestive, and immune functions. Immune functioning is of particular interest because it is the immune system that may be relevant in all sorts of infectious, allergic, and neoplastic illness processes. Inhibited style of processing upsetting events can compromise immune functions, resulting in higher serum antibody titers, decreased monocytes counts, and poorer natural killer cell activities. Other fields of research relevant to the neurobiological pathways of inhibition include hypothalamic-limbic overactivation, prolonged activation of physiological response specificity, hemispheric brain lateralization of emotion processing and faulty interhemispheric communication, the neuroregulation of action, and the behavioral activation and behavioral inhibition systems.

4.2 *Social-behavioral Pathways*

Several social-behavioral pathways connect inhibition-implosion to health disorders and illness behaviors. First of all, neurobiologically innate factors (shyness, behavioral inhibition, hypersensitivity, introversion) are superimposed by classical and operant conditioning in the socialization of an individual. Since individuals with these characteristics in early childhood are conditioned more easily, the process of socialization is of greater importance to them than it is to others. Under critical developmental conditions, the gap between emotional expressiveness and physiological hyperactivity may increase. A lack or deficit in emotional expressiveness will hinder interpersonal communication. It is thought that deficits in interpersonal communication disturb the development of emotional competence that is important for sharing experiences, maintaining psychological and physical contact, and adapting to the social environment (Rimé 1995). These are deficiencies in the healthy coping competencies that have been termed emotional intelligence. Other consequences of inhibited emotional expressiveness are disturbed social relations resulting in social isolation and a disrupted social support network.

Normally, persons respond to emotion-evoking stimuli with emotional expression, and such reactive expression is created by facial muscle activity and movements with reafferent neuronal signals in the CNS, which contribute to the individual's emotional experience. Subjective emotional experience does not, however, depend exclusively on this nervous input as claimed in the facial feedback hypotheses, but feedback does contribute positively to sensitivity towards the physiological aspects of emotion. If this sensitivity is disrupted, an individual will not perceive adequately increased muscle tension or other autonomic nervous system (ANS) reactions caused by stress, and consequently will not initiate healthy relaxing behavior. It has been demonstrated that the hypothesis of deficient perception of muscle tension holds for myogenic pain. These patients were significantly less able to judge the extent of their muscle strain than were controls.

It is conceivable that, under unfavorable circumstances, expressive behavior for mainly negative emotions like anger and aggressiveness is punished socially and thus justifiably avoided. The suppression of expressive behavior can be achieved by an additional increase in muscle activity. Such avoidance behavior or inhibition is very adaptable in the short

term, and it helps to modify a socially stressful situation. This reduction of emotional expressiveness is conditioned by the learning mechanism of negative reinforcement (the avoidance of punishment).

4.3 Cognitive Pathways

Memories and thoughts of emotional stressors are generally unpleasant. Increasing severity of the stressful encounter makes imagining the event painful or even unbearable in the case of traumatic experience. Most individuals attempt to suppress the thoughts surrounding traumatic events. As soon as the inhibition work begins, the urge to distract oneself and the mental energy put into this process fuels the images. Consequently, triggered intrusions and unwanted thoughts make life more stressful than before. In addition, thought control interferes with natural ways of coping such as sharing the experience with important others and thinking through the event. Therefore, inhibition may be dangerous because it hampers the individual who has suffered a critical life event in resolving the stressful experience cognitively and behaviorally.

As part of the inhibition process, individuals may tend to exclude the emotional content of the stressful encounter from their language representation of the event, called alexithymia, or low level thinking style. Although this may help to avoid negative emotionality in the short term, it hinders complete processing and integration of the stressful experience. The lack of integration into the self-concept makes an individual prone to the activation of fear networks. Finally, impaired or unfinished cognitive processing can make an individual prone to misinterpreting bodily symptoms. Instead of understanding bodily reactions as part of emotional responses, the individual conceptualizes the bodily reactions as symptom patterns and seeks medical help for illnesses. Badly advised medical treatment procedures result in iatrogenic diseases trapping the individual in a vicious cycle. Cognitive appraisal of a situation depends partly on facial feedback as a source of emotional information. When the expressive components of emotional reactions are systematically repressed by inhibition, the individual 'unlearns' an accurate assessment of stressful circumstances. This learning mechanism occurs because the estimated load of a stress situation is dependent not only on external features of the situation, but also on the subjective experience of stress-conditioned reactions. When, however, an inhibited person takes bodily reactions into account in the evaluation of a situation, their judgment will be impaired when the original physiological components of mainly negative emotions are interpreted as 'symptoms.'

In clinical studies, psychosomatic patients suffering, for example, from headaches have been found to report significantly lower stress levels than a control group, but showed nearly twice as much neck muscle tension as the controls. Although the arousal and muscle tension data indicated higher levels of stress, patients were unable or unwilling to report those stressors. It would appear that patients tend to interpret their stressors in terms of bodily symptoms, rather than underlying levels of stress.

5. Rituals and Therapeutic Interventions

Most societies seem to contain at least some implicit knowledge that emotional inhibition has negative health implications. The conflict resulting from the need for emotional regulation on the one hand and the need for disclosure, sharing, and catharsis on the other hand leads to a variety of cultural phenomena to solve this conflict. These include older universal cultural rituals (such as rituals of, grief, or lament), or religious acts such as confessions. The Wailing Wall in Jerusalem, where people have been going for centuries to deliver a written prayer, is possibly an example of an ancient disclosure phenomenon. Contemporary Western societies have introduced psychotherapy for enhancing emotional expressiveness. Here, talking or writing about emotions is encouraged, as is the acting out of emotions in role-plays. Assertiveness training aims at effective expression of emotion and catharsis-based techniques like confrontation are modern remedies for anxiety, PTSD, and the like. All of these techniques seem to have in common that they are directed at the construction of meaning from emotional experience. Culture, which may be construed as a subset of possible meanings, is therefore a very important mediating factor in this process. New approaches to cross-cultural psychology have proposed intercultural differences in emotional inhibition based on dimensions like masculinity–femininity, collectivism–individualism, uncertainty avoidance, and power distance.

Emotions and Health

Emotions have long been believed to play a significant role in health. However, definitive evidence on the nature of this role and the mechanisms involved is still being developed. On the one hand, patients often have emotional reactions to the diagnosis of serious or life-threatening illness, responses that can influence emotional as well as physical well being. On the other hand, emotions and their expression or inhibition have been linked with the development of various disease conditions. This article explores what is currently known about these links between emotions and health and the implications for both theory and intervention.

1. Background

Following a period dominated by behaviorism and stimulus-response approaches to behavior, there has of late been an explosion of interest in the emotions, their nature, antecedents, and consequences. Beginning in the 1980s, this interest has been brought about by a growing acceptance of a cognitive mediational approach to human behavior which goes beyond a simple stimulus-response model of human behavior to seeing behavior as being strongly mediated by internal psychological processes of which, of course, emotions are a part (Lazarus 1993).

At the most basic level, emotions are the affective or feeling states that people experience in response to external events, internal cognitions, or a combination of both. Beyond this, however, there are numerous controversies about the nature of human emotions. For example, there is debate over whether emotions are best described in terms of categories or dimensions, how many emotions can be delineated, and the ways in which emotions differ across cultures. These controversies, however, are beyond the scope of this article that specifically is concerned with the interrelationship of emotions and physical health. For the purposes of this article we will be concerned with emotions as feeling states which can be differentiated into identifiable emotions, are embedded in a social context, may be only experienced internally or also expressed outwardly, and are associated with identifiable patterns of physiological activity.

Work on emotions and health bears a close affinity to work on the relationship of stress to health (see *Stress and Health Research*) as well as work on personality and health (see *Personality and Health*). The relationship of emotion to stress has been delineated very persuasively by Lazarus (1993) who notes that the term stress has often been used to refer globally to negative emotional responses that people have to situations involving threat or harm and argues that stress should be understood as a subset of the emotions. This view has the advantage of bringing together two closely related but generally separate research literatures and allows for a more differentiated understanding of stress and its effects on health. The relationship of the work on emotions and health to that on personality and health derives from the fact that at least some of the personality traits found to be related to health are associated with emotion (Friedman 1990).

We begin our discussion with a consideration of the emotional impact of illness and then move on to a discussion of emerging evidence for the role of emotion in the development of disease.

2. Emotional Responses to Illness

Diagnosis with a chronic or life-threatening disease has been described as a crisis for patients which produces strong emotional responses. Patients diagnosed with serious conditions frequently experience intense feelings of fear, anxiety, grief, anger, and other emotions. These emotional responses often lessen with time as the person comes to grips with the condition but can lead to serious emotional maladjustment. Key determinants of quality of emotional adjustment appear to be age, the severity of the condition, coping strategies, and social support. Older patients appear to have less difficulty adjusting to disability than younger persons, perhaps because of an expectation of greater disability as one gets older whereas more severe disease is often associated with greater emotional upset. Further, coping strategies appear to be critical determinant of emotional adjustment. For example, positive adaptation to breast cancer appears to be facilitated by finding a sense of meaning in the experience of cancer as well as developing a sense of mastery and control over the disease and using downward comparison to help one feel good about how one is doing in the face of the disease (Taylor 1983). Finally, having supportive social relationships is critical to positive adaptation (see *Social Support and Recovery from Disease and Medical Procedures*).

Emotional responses to serious illness can also have important implications for the person's physical well being. For example, 10-year survival rates for breast cancer patients who responded to their diagnosis with feelings of helplessness, denial, or stoic acceptance

have been found to be substantially lower than those for patients who responded to their diagnosis with what has been termed a 'fighting spirit,' which included optimism in the face of their disease and a determination to do everything in their power to overcome the disease (Pettingale 1984).

3. Emotions and the Development of Disease

Emotions have also been linked to the development of a variety of disease conditions. In what follows, evidence is examined concerning emotions that are associated with a higher risk of disease as well as others which appear to be protective against ill health (see *Health Risk Appraisal and Optimistic Bias*).

3.1 Emotions as Health Risk

Not surprisingly, emotions associated with increased risk of disease are negative ones. Evidence has accumulated linking various negative emotions to the experience of ill health as well as the development of various disease conditions (Friedman 1990). Further, there is a tendency for the experience of different negative emotions to be correlated with each other and as such it makes sense to refer to a general tendency towards the experience of negative emotions. This tendency is known as negative affectivity and is closely related to the personality trait of neuroticism. A number of studies have found negative affectivity to be a common ingredient running through various health-related measures of stress, emotion, coping, and illness experience. As such it has been argued that findings relating such measures as life stress, pessimism, loneliness, low life satisfaction, and other measures of psychological distress to poor health can be explained, at least in part, as being a reflection of this general tendency to experience negative emotions and interpret experience in negative terms (Clark and Watson 1991).

Other evidence indicates that it is not just the experience of negative emotions that is associated with poorer health but more specifically the lack of expression of these emotions. Since the 1980s research evidence has been accumulating on the negative health effects of emotional inhibition. In particular, people with repressive coping styles as well as those actively inhibiting the expression of emotion have been found to have generally poorer health and to show negative psychophysiological as well as immunological changes as a result of suppressing the expression of negative feelings (Pennebaker 1995).

Although these general variables of negative affectivity and emotional inhibition are associated with poor health generally, there is also good reason to believe that a full understanding of the relationship of emotion to health requires examination of the ways in which specific emotions relate to health status and to specific disease conditions. In particular, the relationships of different emotions to specific health conditions are somewhat variable, suggesting at least a certain amount of specificity in the role of emotions in health.

Most likely the strongest relationship with health outcomes has been obtained for anger and its cognitive and dispositional counterpart, hostility. Even though anger and hostility can be conceptually differentiated they are discussed together because they are clearly closely related, measures of these two constructs generally share a common core of variance, and they are frequently discussed together in the research literature. Numerous studies have found significant associations between anger/hostility and deaths from coronary heart disease as well as mortality from all causes, an association that remains significant when other risk factors are statistically controlled. In the case of coronary heart disease this association has been described as being at least as large as those reported for more traditional risk factors for CHD such as cigarette smoking, high blood pressure, and high serum cholesterol (Miller et al. 1996). Anger and hostility also appear to be related to other disease conditions such as cancer and arthritis but the strength of these relationships appears to be somewhat weaker than that found with CHD. Interestingly, while it appears to be the expression of anger that is associated with CHD, the suppression of anger is associated with cancer (Friedman 1990).

Depression is a second emotional state with significant health implications. The most obvious association between depression and health is with suicide (see *Suicide*). However, depression has been found to have an association with a number of other medical conditions as well. On the one hand, there is evidence that depression is associated with an increased likelihood of conditions such as heart disease and cancer as well as with overall mortality (Wulsin et al. 1999). On the other hand, depression has been found to be associated with poorer prognosis for patients diagnosed with conditions such as AIDS, cancer, and heart disease. For example, work by Frasure-Smith et al. (1995) has found depression to be a significant predictor of mortality among cardiac patients whereas similar findings have been obtained for cancer patients (Pettingale 1984) and patients with AIDS (Patterson et al. 1996).

Relatedly, grief has been found to have significant health implications. Several studies have found increased illness as well as mortality among individuals who have been recently bereaved. This increased mortality has been found to be greatest in the first six months following bereavement and to derive from a number of causes including accidents, violence, heart disease, and cancer (Wulsin et al. 1999).

Finally, anxiety and fear have been found to have significant health implications. For one thing, anxiety can be converted into physical complaints through

somatization. For example, studies of patients' visits to physicians have found that a large portion of such visits are often the result of physical complaints with an emotional basis, often anxiety (Barsky and Klerman 1983). In addition, anxiety has been found to be associated with conditions as diverse as CHD, asthma, ulcers, arthritis, and headaches (Friedman 1990; Friedman and Booth-Kewley 1987) and severe fright has been linked to sudden death from heart attacks (Hafen et al. 1996).

3.2 Emotions as Protector of Health

The flip side of the coin is that positive emotions may be protective of health. Evidence for this is not as strong as for the effects of negative emotions but links are being established. As with negative emotions, there is a tendency for dispositional measures of positive emotion to correlate with each other, a construct termed positive affectivity. Positive affectivity is largely independent of negative affectivity and, whereas negative affectivity is closely associated with neuroticism, positive affectivity is closely related to extroversion. Current evidence indicates that on its own, positive affectivity is generally unrelated to health complaints. However, conceptually, positive affectivity is closely related to optimism and low levels of positive affectivity appear to be an important ingredient in depression. As such there has been speculation that it is the positive affectivity components of these emotional states that are responsible for their relationships to physical health (Clark and Watson 1991).

Perhaps the strongest evidence for positive emotions as a protector of health comes from work on optimism. Optimism refers to a person's tendency to look on the positive side of events and to believe that events will work out for the best. As such optimists can be expected to experience positive emotions more often than more pessimistic individuals. And, in fact, as noted, optimism is associated closely with positive affectivity. Research on optimism indicates that optimists tend to live longer, healthier lives than more pessimistic individuals and also to be less susceptible to viral infections, such as the common cold. In addition, optimistic cancer patients tend to live longer than more pessimistic ones and optimism is associated with greater immune system competence as indicated by the ratio of T4 to T8 cells (Peterson and Bossio 1991).

4. Mechanisms Linking Emotions and Health

As noted above there is accumulating evidence that emotions are significantly related to health and indications that emotional states may play a significant role in the development of disease as well as in the healing process. How can these relationships be explained? What are the mechanisms linking emotions and health? The answers to these questions are still emerging but a number of plausible hypotheses have been proposed. These hypotheses relate to both indirect and direct effects that emotions may have on disease processes.

4.1 Indirect Links Between Emotions and Health: The Health Behavior Connection

One possibility is that emotions influence health indirectly through their effects on behavior, particularly health behaviors. Numerous studies have noted that stress, which often includes emotional upset, is associated with poorer health behaviors. For example, higher levels of stress have been associated with higher levels of smoking as well as increased alcohol and drug usage and poorer eating habits. Specific emotions also appear to be associated with health behaviors. For example, there is evidence that higher levels of hostility are associated with greater consumption of cigarettes and alcohol as well as less physical exercise and poorer self-care (Smith 1992). It is well establised that these health behaviors are associated with poorer health outcomes (see *Health Behaviors*) and thus it seems highly plausible that emotions may well affect health outcomes in this manner.

4.2 Direct Links Between Emotions and Health: The Physiological Connection

There also appear to be direct physiological links between emotions and health. In addition to their experiential aspects emotions are very much physiological events. There has been much controversy over the years about the precise relationship of emotions to physiology, whether there are specific patterns of physiological changes that correspond to specific emotions, and whether the phenomenological experience of emotion precedes or is the result of such physiological changes, but there is no doubt that emotions are associated with a variety of physiological changes. These changes occur in a number of different bodily systems including the nervous, cardiovascular, respiratory, endocrine, and muscular systems and vary considerably in intensity. A substantial number of studies have attempted to chart these changes and relate them to specific emotions. Results from such studies have been mixed in that physiological changes found for specific emotions tend to vary considerably between studies and with the methods used for evoking emotion as well as measuring physiological changes. In many respects, this variation is not surprising given the complexity of physiological events and the metho-

dological hurdles in establishing their relationship to particular emotions (Cacioppo et al. 1993). However, there is no doubt that emotions are associated with substantial physiological changes and it seems highly plausible that these changes may mediate the relationship between emotions and health.

Although there is considerable controversy about the precise relationship between emotions and physiology, progress has been made in charting likely physiological pathways between emotions and specific diseases. Some of the most detailed evidence to date comes from work on the relationship of anger and hostility to cardiovascular disease. A number of studies have found that individuals high in anger and hostility tend to show heightened physiological, and particularly cardiovascular, responses to various stressors. Although results have not been entirely consistent there is evidence that individuals who are high in hostility, and who are thus more prone to the experience of anger, show larger stress-related increases in blood pressure, heart rate, and stress-related hormones than do individuals lower in hostility. This heightened physiological reactivity appears particularly likely when the person is faced with social stressors such as harassment or other social challenge and is considered by some to be at least a marker if not a causal agent for the future development of cardiovascular disease (Smith 1992). One possible mechanism is that increased blood pressure and catecholamine reactivity as a result of repeated episodes of anger may be related to increased likelihood of injury to the interior walls of blood vessels which in turns accelerates the process of atherosclerosis (Manuck 1994).

In addition to heightened reactivity in the face of stressors, it is also quite possible that high hostile individuals experience more situations evoking anger, either because they gravitate toward such situations and/or because their actions tend to evoke hostile responses from others. For example, there is evidence that high levels of hostility are associated with generally high levels of interpersonal conflict and low levels of social support. In addition, high hostility has been associated with the experience of more frequent and severe daily hassles as well as major negative life events. This tends to suggest a synergism between poor interpersonal relationships and high physiological reactivity which would further increase the high hostile individual's vulnerability to disease (Smith 1992).

Heightened physiological reactivity is one link between emotions and health but it is certainly not the only one. Another important link concerns the relationship of emotion to immune functioning. In this respect there is a growing literature showing that the tendency to experience certain emotions can affect immuno-competence, as can transient moods. First, indices of immuno-competence have been found to be lower among individuals with depressive symptomotology as well as among recently bereaved individuals strongly suggesting that dysphoric moods may lead to the suppression of immune functioning (O'Leary 1990). One possible explanation for this is that withdrawal responses and the generally more passive coping responses associated with helplessness and depression are associated with the activation of the hypothalamic-pituitary-cortical axis which leads to increases in cortisol output which in turn have the effect of suppressing immune functioning (Antoni 1987). Such processes have important implications for a variety of immune related diseases including cancer, AIDS, and autoimmune diseases. This may well be one of the reasons why individuals with a so-called 'Type C' personality, which includes the traits of being unassertive, patient, and unexpressive of negative emotions (see *Personality and Health*), all of which are related to passive coping, are more likely to develop cancer (Friedman 1990). Second, humor and positive emotions have been found to be related to increases in immuno-competence among other physiological changes. For example, several studies have found that laughter is associated with increases in concentrations of lymphocytes as well as increased natural killer cell activity and overall immune responsiveness, and a reduction in the secretion of cortisol. Similarly, studies on optimism have found that optimists have stronger immune functioning than do people with a more pessimistic attitude towards life (Hafen et al. 1996). Finally, there is growing evidence that the suppression and expression of emotion have both physiological and immunological effects. Inhibition of emotion has been shown to lead to changes in electrodermal as well as cardiovascular activity. Also, in addition to evidence cited above that suppression of negative emotions is related to reduced immune functioning, there is evidence from a growing number of studies that the expression of negative feelings as a form of catharsis can result in improved immune functioning. For example, several studies have now demonstrated that having people write or talk about traumatic experiences they have not disclosed to other people previously results in an increase in immune responsiveness. This occurs when they focus on the emotions involved but not when they focus only on the facts of what happened (Pennebaker 1995).

4.3 Common Underlying Factors Between Emotions and Health: Constitutional Vulnerability

A third possible link between emotions and health is that there may be common underlying factors for both emotionality and the occurrence of disease. For example, there may be genetic factors that influence, on the one hand, the emotions a person experiences and how those emotions are expressed and, on the other hand, the occurrence of ill health in general as well as specific disease conditions. As yet no such genetic links have been established but this does not

mean that they do not exist. With the rapid progress currently being made in the genetics of disease as well as work on the genetics of personality such links may well be established in the future.

5. Reducing Health Risk

The emerging pattern of linkages between emotions and health raises the question of what can be done to reduce the health risk from negative emotions and boost the benefits from positive ones. Three possibilities are considered here but these are best seen as only representative of interventions that may be effective.

First, psychotherapeutic techniques can be used to help people deal more effectively with negative emotions as well as boost positive emotions. Numerous techniques have been developed, and there is reason to believe that at least some of these may have positive benefits for physical health as well as mental health. For example, psychotherapy interventions have been shown to be effective in boosting immune responsiveness and improving physical health in both cancer patients and noncancer populations. Psychotherapy with cancer patients has been shown to reduce recurrence and increase five-year survival rates which is consistent with data showing that psychotherapy with a variety of medically ill patients can lead to improved health outcomes (Fawzy and Fawzy 1994). Of course, psychotherapy does more than simply reduce negative emotions and boost positive ones but such data, in conjunction with the evidence on the role of emotions in health, suggest the potential of psychotherapy for reducing the negative effects of emotions on health.

Closely related to these effects of psychotherapy in general is work showing the psychological and physical benefits of writing or talking about traumatic events. Research by Pennebaker and others has produced substantial evidence for the positive psychological and physical benefits of writing as well as talking about traumatic events. Overall, when people, ranging from university students to holocaust survivors, are induced to write or talk about traumatic experiences positive psychological benefits are found and there are reductions in harmful arousal as well as improvements in immune functioning and subsequent reductions in the number of times the person seeks medical attention. Such changes are particularly evident when the person writes or talks about traumas that had not been previously disclosed to others and when he or she writes about the emotions involved and not just the facts of the situation (Pennebaker 1995). This strongly argues for the health benefits of disclosure of negative experiences to others and suggests an apparently powerful way of reducing the harmful effects of emotion on health.

Finally, evidence on the role of anger and hostility in heart disease strongly argues for interventions directed towards reducing these potentially harmful emotions. A number of strategies have been suggested and there is evidence that teaching people to be aware of their feelings and then utilizing a series of strategies for dealing with difficult life situations can have positive effects both on the person's relationships and psychological adjustment and possibly on their physical health as well (Williams and Williams 1997). Definitive evidence on the effects of these interventions is not yet available but the results to date are promising.

6. Implications and Future Directions

Findings concerning the relationships of emotion to health are a prime example of the way in which psychological and social factors are closely intertwined with biological processes in determining one's health status. Disease is clearly a biological phenomenon but it is one that is strongly influenced by psychosocial factors. Also, phenomena such as emotions that are generally viewed in the realm of the psychological have a definite basis in biological processes. As such one cannot speak of psychological processes without consideration of the biological and vice versa.

Although the evidence relating emotions to health has been growing rapidly there are still many questions that remain to be answered. One major question concerns the degree to which specific emotions are related to specific disease conditions. There has long been speculation about such relationships but as yet there has been no clear resolution of this question. Whereas work on such topics as negative affectivity tends to suggest a general relationship between negative emotions and ill health, other work tends to suggest at least a degree of specificity. This is a question that needs further work and one which will benefit from a clearer specification of how one can best differentiate between different emotions both psychologically and physiologically.

Relatedly, there are still many questions about the mechanisms linking emotions and health. Evidence for the roles of physiological reactivity and immunocompetence in this linkage is growing but much remains to be learned. Exactly how is it that different emotions produce these physiological changes? What other biological processes operate in linking emotion to health? How are genetic factors involved in this relationship? These are fascinating questions that still remain to be addressed.

Finally, much remains to be done with respect to capitalizing on what has been learned in this area for improving health. Current interventions have been described but these would appear to only scratch the surface of what might be possible with respect to

harnessing psychological methods for improving physical health.

Emotions, Children's Understanding of

1. Theoretical Foundations

A *social constructivist* theoretical position is taken in this article on children's understanding of emotion, which means that children construct their understanding of emotional experience in the context of cultural beliefs, relationship transactions, and an affordant environment. The child's cognitive developmental level may be thought of as an organismic constraint on how and with what degree of complexity children construct their understanding of emotion. A *functionalist* perspective is also evident here in that how we come to understand our emotional experience is rooted in the goals that we have vis à vis our encounters with our environment (Campos et al. 1994). One of the more prominent aspects of western culture's views of how emotion 'works' is the emphasis on cognitive mediation of emotion or appraisal (e.g., Lazarus 1991). This western folk belief about emotions as stemming from one's thoughts and images derives from an emphasis on emotion as an internal, individual experience as opposed to a number of other cultures' emphasis on emotion as an interactive experience (Kitayama and Markus 1994). What do we know about children's acquisition of this belief, namely that emotion results from one's own cognition (as opposed to deriving from one's kinship system, from ancestral spirits, or from bodily illness)? Research undertaken by P. L. Harris (Harris 1989) suggests that in the preschool years western children demonstrate in their understanding of others' experience that the perspective or belief held by the other is significantly involved in determining how the other feels. As they move through middle childhood, children begin to invoke mental factors as well for how to change emotional experience. For example, Harris and Lipian (1989) interviewed children in boarding schools to find out how the children thought they could alleviate negative feelings such as home-sickness and sadness. Older children (age 10) were much more likely to cite such strategies as distraction, focusing on something positive, reinterpreting the situation, and so forth. Younger children (age six) tended to restrict their strategies to suggestions about how to change the situation rather than looking inward to seeing whether and how one might alter one's internal experience. This greater reliance by the older children on internal,

mental states as part of the 'emotional package' impacts on several critical features of emotion, among them which cues are used to identify emotions reliably, how emotional-expressive behavior is regulated, and importantly, how to cope with aversive emotions.

Goals play an important role in children's appraisals of what gives rise to emotions and feelings (e.g., Levine 1995, Wellman and Banerjee 1991). Liking or wanting something or the opposite, not liking or not wanting something, are prominent anchors in how preschool children determine how they or others are likely to feel. Such a goal orientation allows the young child to develop expectations for emotional experience and beliefs about 'the right way' to feel. Socializing agents, whether they are parents, peers, or the media, influence what is liked or not liked, and thus affect children's beliefs about how to feel when they do or do not get what they want. Harris (1995) has also focused on the role that children's cognitive skills have on their awareness of emotions relative to contexts. He makes an important distinction in children's understanding of intentional targets of emotions vs. causes of emotions. He contends that children primarily anchor their emotions in appraisal of the object, person, or event at which the emotion is directed (e.g., mad *at* you, scared *of* spiders), as opposed to the causal or precipitating event (e.g., a squabble between siblings leads to anger, finding a big spider in one's bed results in fear). The significance of this idea of intentional targets of emotions as a contextual anchor for children's understanding of their subjective emotional experience is important theoretically, for it points toward the transactional encounter between person and environment; that is, children construe their emotions as directed at something. Functionalist views of emotion as described earlier emphasize this goal-oriented nature of emotion as opposed to other theoretical positions that emphasize the biological causes of emotions.

2. Emotion Understanding and Skills of Emotional Competence

A useful way to examine children's understanding of emotion is to think of their acquiring a set of skills that facilitate their being able to pursue their goals efficaciously. My use of the term *emotional competence* is such a construct, and Table 1 lists those skills relevant both to emotional competence and emotion understanding (Saarni 1999). These skills are learned in conjunction with children's cognitive development and the social contexts in which they are engaged. I shall address children's understanding of emotion relative to each of these six skills, and in some cases refer the reader to other articles in the encyclopedia that are likely to provide more detailed coverage.

Table 1
Skills relevant to emotional competence and understanding

1. Awareness of one's emotional state, including the possibility that one is experiencing multiple emotions, and at even more mature levels, awareness that one might also not be consciously aware of one's feelings due to unconscious dynamics or selective inattention
2. Skill in discerning others' emotions, based on situational and expressive cues that have some degree of cultural consensus as to their emotional meaning
3. Skill in using the vocabulary of emotion and expression terms commonly available in one's subculture and at more mature levels to acquire cultural scripts that link emotion with social roles
4. Capacity for empathic and sympathetic involvement in others' emotional experiences
5. Skill in realizing that inner emotional state need not correspond to outer expression, both in oneself and in others, and at more mature levels the ability to understand that one's emotional-expressive behavior may impact on another and to take this into account in one's self-presentation strategies
6. Capacity for adaptive coping with aversive or distressing emotions by using self-regulatory strategies that ameliorate the intensity or temporal duration of such emotional states (e.g., 'stress hardiness')

2.1 Understanding One's Own Emotional Experience

Given that infants' emotional experience and the self-conscious emotions (e.g., shame, pride) are addressed in *Infancy and Childhood: Emotional Development* and *Self-conscious Emotions, Psychology of*, respectively, I shall focus on how older children come to understand that they can have multiple feelings directed at the same target or situation. Young children's experience of ambivalence has been found to be a sequential process with different appraisals attached to the polarized emotional responses. Research with older school-age children suggests that they have developed the ability to consider at the same time one set of ideas that is at odds with another set of ideas, enabling them to integrate opposite valence emotions (happy and sad) about different targets that co-occur in a situation (e.g., 'I'm glad I get to live with my dad, but I'm sad about not being able to live with mom too'). In early adolescence simultaneously opposite valence emotions

about the same target can be integrated (e.g., 'I love my dad, even though I'm mad at him right now for not following through on his promise'). In late childhood children also understand that emotions interact with one another; that is, a positive emotion following a negative one can ameliorate the negative feelings one had and vice versa. Similarly, older children report that memories of previous feelings can influence their experience of current emotions. It is not known whether younger children might experience simultaneously two (or more) emotions but can only cognitively construct an explanation about the experience that focuses on one emotion at a time. When children experience an intense emotion, they must also cope with their feelings and the eliciting situation. During this coping process, they may well begin to cognitively construct a more complex system of appraisals about the emotion-eliciting situation or relationship. Finally, younger children (preschoolers to about age seven) scan a situation for its emotional meaning and finding one, stop scanning. Older children do not exhaust the search for further possible appraisals that might yield multiple emotional responses.

2.2 Understanding Others' Emotional Experience

By late preschool, children can decode the culturally common meanings of prototypical emotional facial expressions, and they have learned as well common situational elicitors of emotions. During this age period they make steady progress in realizing that others have minds, intentions, beliefs, or what has otherwise been referred to as 'inner states.' At around 8–10 years of age they understand the need to take into account unique information about the other that might qualify or make comprehensible a nonstereotypic emotional response or a response that differs from how oneself would feel in the same situation. The attributions children apply to their expectations for which emotions are likely can be characterized by three dimensions: *stability*, which refers to the extent an event will recur; *locus*, which refers to whether the causes of emotion lie within the person (internal locus and thus stable) or in a context (external locus and thus variable). Another feature is the perceived *controllability* of the eliciting event. Different combinations of these attributions have been found to characterize different features of children's understanding of others' as well as their own emotional experience.

2.3 Understanding Emotional Lexicon and Scripts

Children's ability to represent their emotional experience through words, imagery, and symbolism of varied sorts allows them to communicate their emotional experiences to others across time and space, and these representations of emotional experience facilitate further cognitive elaboration and comparison with others' representations about emotional experience. Some of the developments in awareness of our own multiple feelings or in understanding others' emotions described earlier could not be undertaken without access to a language or representational system for symbolically encoding and communicating emotional experience. Research on early mother–child feeling-state conversations indicates that access to an adult who is interested in one's feelings may be pivotal to children having opportunities to talk about emotions and acquire a lexicon of emotion vocabulary. Mothers tended to use conversations about feelings as a functional way to guide or explain something to their children, whereas the children were more likely to use feeling-descriptive words simply to comment on their own reaction or observation of another (Dunn et al. 1991). Thus, they were learning to communicate their own self-awareness of feeling states to their mothers, who in turn were likely to communicate *meaningfulness* to their children by using guiding, persuading, clarifying, or otherwise interpretive feeling-related language. Other research has also documented that if families were characterized as high in frequency of anger and distress expression, the children were less likely to be engaged in discourse about feelings. But if the families were low in frequency of negative emotional expression, then when a negative emotional event did occur for the child, there was a greater likelihood of an emotion-related conversation to ensue between child and parent (Dunn and Brown 1994). Acquisition of emotion-descriptive concepts continues throughout childhood and into adolescence, but little research has examined these older age groups. One way that emotion language develops further in the school-age child and adolescent is evidenced in their greater ability to add variety, subtlety, nuance, and complexity to their use of emotion-descriptive words with others.

2.4 Understanding Empathy and Sympathy

With empathy children affectively share in another's emotional experience; with sympathy they understand another's emotional experience but are more detached from it. Some individuals experience vicariously another's emotion so strongly that it becomes aversive; they tend to focus on alleviating their own personal distress and generally are not likely to show prosocial behavior toward the distressed person. Preschoolers are capable of responding empathically to others' distress, and what continues to develop in their understanding is what to do if they are to respond prosocially and appropriately. As they learn more

subtle cues of emotion, their range for responding empathically or sympathetically is similarly extended. *Prosocial Behavior and Empathy: Developmental Processes* considers this topic in much greater detail.

2.5 Understanding of Emotion Dissemblance and Management of Expressive Behavior

Research has demonstrated that by 10–11 years, children understand that the expression of emotion, whether genuine or dissembled, is a regulated act. At this age they are able to make reference to the degree of affiliation with an interactant, status differences, and controllability of both emotion or circumstances as contextual features that affect the genuine or dissembled display of emotion. However, across all ages, the most common reason cited for when genuine feelings would be expressed was if they were experienced as very intense (and thus less controllable). When children are asked to explain why feelings are not genuinely expressed, four broad categories of motivation are apparent in their responses: (a) to avoid anticipated negative outcomes, (b) to protect one's self-esteem or to cope more effectively with how one feels, (c) to avoid hurting someone else's feelings, and (d) to abide by norms and conventions (e.g., rules of etiquette). By school entry children generally understand that how one looks on one's face is not necessarily how one feels on the inside. They can often provide justifications for how appearances can conceal reality, in this case, the genuine emotion felt by an individual. Many of these justifications included describing the intent to conceal one's feelings and to mislead another to believe something other than what was really being emotionally experienced. Children younger than six can readily adopt pretend facial expressions, but they are not likely to be able to articulate the embedded relationships involved in deliberate emotional dissemblance. These embedded relationships refer to how the self wants another to perceive an apparent self, not the real self. In other words, by age six children readily grasp that emotional dissemblance has as its basic function the creation of a false impression on others.

2.6 Understanding of Emotion Regulation and Coping Strategies

Two general patterns have emerged with regard to age: as children mature, they generate more coping alternatives to stressful situations, and they become more able to make use of cognitively-oriented coping strategies for situations in which they have no control. Embedded in both of these age-related patterns is greater cognitive complexity that is associated with becoming older: (a) the ability to appraise accurately when a situation is simply not under one's control; (b) the ability to shift intentionally one's thoughts to something else less aversive; (c) the ability to use symbolic thought in ways that transforms the meaningfulness of a stressful encounter or situation (reframing); and (d) very importantly, the ability to consider a stressful situation from a number of different angles and thus consider different problem solutions relative to these different perspectives. As to when these general developmental patterns in coping are clearly in place, it is likely that by 10 years old most children will have a fairly well-developed coping repertoire that includes the emotion-focused strategies of cognitive distraction and transformation. This assumes, of course, that the family lives of these children have been adequately supportive and that harsh traumas have not preoccupied the children's emotional resources such that inflexibility or dissociative processes have taken hold in the child's self- and emotion-regulation. In conclusion, children's understanding of emotion develops in tandem with their exposure to social situations in which emotions are elicited and with their cognitive development. Enhanced emotion understanding facilitates children's social competence and provides a buffer against pathology, whereas deficits in emotion understanding may function either as precursors to subsequent maladaptive functioning or as outcomes of pathology.

Emotions, Evolution of

The study of the evolution of emotion dates back to Charles Darwin. There are at least three different approaches to the subject in the current literature. The widely accepted 'basic emotions' view developed in the 1960s out of human ethology and the psychological and physiological study of emotion. The evolutionary psychology movement and the paralanguage or 'behavioral ecology view' draw in two very different ways on ideas that originated in behavioral ecology and sociobiology during the 1960s and 1970s to suggest amendments to this orthodox view.

1. *The Darwinian Legacy*

Darwin did not see his *Expression of the Emotions in Man and Animals* (Darwin 1872) as a theory of the evolution of emotion itself, because he defined emotions as subjective feelings. Following Herbert Spencer, Darwin distinguished the emotions as those feelings caused by external states, in contrast to those caused by bodily states, such as hunger and pain. Later evolutionary theorists have preferred behavioral and physiological definitions of emotion, with the result that Darwin's theory of the expression of emotions has been interpreted as a theory of the emotions themselves.

Darwin proposed three principles of the evolution of expression (see also *Emotion and Expression*). The most important of these was the 'principle of serviceable associated habits,' which is a straightforward application of Darwin's theory of instincts to the case of emotion. Darwin believed that instinctive behaviors derive from habits acquired by psychological reinforcement. The consistent acquisition of the same habit for many generations causes it to become a hereditary, or instinctive, behavior by the inheritance of acquired characteristics, in which Darwin was a firm believer. Most of the distinctive behaviors associated with particular emotions, such as the erection of the hair in fear, reflect long-since vanished lifestyles in which those behaviors were rewarded and reinforced in each generation until they were finally incorporated into the hereditary material as instincts. Darwin supplements this principle with two others, the 'principle of antithesis' and the 'principle of direct action.' His antithesis principle postulates an intrinsic tendency for opposite states of feeling to produce opposite behaviors. Darwin remarks of a submissive dog that:

> Not one of the movements, so clearly expressive of affection, are of the least direct service to the animal. They are explicable, as far as I can see, solely from their being in complete opposition or antithesis to the attitude expressive of anger (Darwin 1872, p. 51).

Darwin explains the behaviors left over after the application of these two principles as the results of the 'direct action' of the nervous system. Excess nerve energy built up in an emotional episode is released in behaviors such as sweating and trembling for no other reason than that it must go somewhere and that these channels are physiologically available for its release.

2. *The Ethological Tradition*

The founders of ethology saw themselves as the direct heirs of Darwin's work on mental evolution (Lorenz 1965). Their account of the evolution of emotion retains Darwin's principles, but reinterprets them to fit the theory of evolution as it emerged in the 1930s in the 'modern synthesis' of Darwinism and Mendelian genetics. The principle of serviceable associated habits is transformed into the ethological concepts of 'ritualisation' and 'derived activity' (Tinbergen 1952). Derived activities are behaviors that originally evolved for one purpose but were later selected for another purpose. Ritualized behaviors are derived activities that originally evolved to fulfill some practical function but which were later selected to function as signals. Thus, although piloerection in fear and rage does not make a human being appear larger to an opponent, it does communicate his or her emotional state. Derived activities require a special pattern of evolutionary explanation. They cannot be understood

purely in terms of the function they currently perform and the selection pressures that currently maintain them in the population. This is particularly obvious in the case of signals. Piloerection is not intrinsically better as a signal of fear than smiling or laughing. This particular behavior was selected as a signal only because it was already associated with certain emotional states in the distant past. It was associated with those states, not because it was a signal, but because it made the animal appear larger.

The concept of ritualization allowed ethology to reconstruct Darwin's principle of serviceable associated habits whilst avoiding his commitment to the inheritance of acquired characteristics. Darwin's descriptions of the psychological rewards that led to the reinforcement of emotional behaviors are equally plausible as descriptions of the original selective advantage of those behaviors. Darwin's other two principles are equally open to reinterpretation. The principle of antithesis is explained by the selective value of unambiguous signals. It is as important for a dog to signal that it wants to avoid conflict as for it to signal aggression. Hence there can be selection of behaviors merely because they look different from the behaviors that signal aggression. The principle of direct action was transformed into the ethological concept of a displacement activity. Early ethologists shared Darwin's view that instinctive motivations cause a build up of mental energy that must be released in some behavior or other. An example commonly given is that of an angry cat that is unwilling to attack and begins to wash itself. Niko Tinbergen remarks: 'I think it is probable that displacements do serve a function as outlets, through a safety valve, of dangerous surplus impulses' (Tinbergen 1952, p. 23). This wholesale reinterpretation of Darwin's three principles works so smoothly and allows the retention of so much of the detail of Darwin's work that the early ethologists seem almost unaware of the differences between Darwin's theory and their own (Lorenz 1965).

3. *The Affect Program Theory of Basic Emotions*

Darwin's detailed accounts of human facial expressions were confirmed and extended during the 1960s and early 1970s and many of his suggested homologies between human and primate facial expressions were confirmed. In addition, it became generally accepted that some emotional expressions, the so-called 'basic emotions,' are found in all cultures and have an evolutionary history at least as long as the history of the human species (Ekman 1973, see also Emotion and Expression). The basic emotions are usually referred to as fear, anger, disgust, contempt, joy, sadness, and surprise, although in normal usage each of these words has a much wider meaning. During the same period, the hydraulic metaphors that the ethologists had used to describe psychological processes were replaced by a computational model of emotion. Each basic emotion corresponds to an 'affect program' stored somewhere in the brain. When activated, this program coordinates a complex of actions that includes facial expression, autonomic nervous system changes, expressive vocal changes, and muscular–skeletal responses such as flinching or orienting. The concept of an affect program inherits many of the features of the earlier ethological concept of a fixed action pattern. Both concepts suggest that certain apparently complex behaviors are, in reality, atomic units of behavior that unfold in the same, stereotyped sequence whenever they are triggered. The affect programs are controlled by an 'automatic appraisal mechanism.' This is a specialized neural system that applies its own distinctive rules for stimulus evaluation to a limited set of data derived from the earliest stages of the processing of perceptual information. Considered together, the appraisal mechanisms and affect programs form a cognitive module in the sense favored by more recent evolutionary psychologists (Barkow et al. 1992).

The affect program theory retains two distinctive features of the earlier, ethological model of emotions. First, emotional behaviors are the inevitable and involuntary accompaniment to an underlying emotional state and as such are reliable signals of that state. Second, deliberate attempts to disguise emotions are subject to 'leakage' from the operation of the involuntary emotional response. Voluntary attempts to suppress emotional behavior can only operate by simultaneously using the muscles involved in the expression for some other purpose. They cannot interfere with the actual operation of the emotion module (see *Emotion and Expression*).

The affect program theory was accompanied by a distinctive theory of the evolution of the emotion system. The system was interpreted as an ancient form of cognition that had originally operated on its own and had later been supplemented by higher cognitive functions. This view was supported by MacLean's theory of the 'triune brain,' according to which the emotions are located in the 'paleomammalian' portions of the brain while higher cognitive functions are realized in newer, 'neomammalian' structures (MacLean 1952). The survival of these ancient forms of behavior control in primates was explained by their value as fail-safe responses ensuring that vital behaviors are performed whenever necessary even if that means they are performed too often. This view of the emotion system as a collection of primitive but reliable fail-safe mechanisms remains influential (Panksepp 1998).

4. *Sociobiology and the Emotions*

Sociobiology brought a new perspective to bear on the evolution of emotion in the 1970s and 1980s. It also moved the focus of investigation from the basic

emotions to the moral and quasi-moral emotions involved in human social interaction. Emotions such as trust, loyalty, guilt, and shame play an obvious role in mediating the competitive social interactions that were the focus of most research in human sociobiology. Numerous sociobiologists made brief comments to the effect that moral emotions must have evolved as psychological mechanisms to implement evolutionary stable strategies of social interaction (Weinrich 1980). Robert A. Frank suggested that the moral emotions evolved as solutions to 'commitment problems' (Frank 1988). A commitment problem arises when the winning strategy in an evolutionary interaction involves making a binding but conditional commitment to do something that would be against one's own interests if the condition were ever met. If such a commitment is to be credible, some special mechanism is needed which would cause the organism to act against its own interests. Frank suggests that emotions such as rage and vengefulness evolved to allow organisms to engage in credible deterrence, threatening self-destructive aggression to deter a more powerful aggressor. Conversely, emotions such as love and guilt evolved to allow organisms to engage in reciprocal altruism in situations where no retaliation is possible if one partner fails to reciprocate.

Sociobiologists criticized ethology for its lack of a theoretical framework with which to predict how humans would behave, accusing it of being little more than descriptive natural history (Barash 1979, Barkow 1979). In contrast, sociobiology seemed to make strong predictions that clashed with some aspects of the affect program theory of basic emotions. From a sociobiological perspective it makes no sense for organisms to possess involuntary expressive behavior. The application of evolutionary game theory to emotional behavior predicts that this behavior will be designed to manipulate the expectations of other organisms rather than to 'express' emotional states transparently. This theoretical argument has been used by some to reject the affect program view of basic emotions. Alan Fridlund has argued that emotional behavior should be regarded as a paralanguage of social signals whose production depends at least as much on an organism's social context as on its emotional state (Fridlund 1994). Fridlund and other paralanguage theorists have documented audience effects on the production of the basic emotions and have argued that this is inconsistent with the affect program theory. They have also tried to show that the classic facial expressions of emotion are not strongly correlated with underlying emotional state and that people rely more on context than on behavior in attributing emotions to others (Russell and Fernández-Dols 1997). It is unclear, however, that this data contradicts the predictions of the affect program theory. Signaling behavior exhibits audience effects in many organisms, such as domestic chickens, in which that behavior is presumably part of a highly stereotyped behavior sequence controlled by a relatively simple cognitive mechanism.

Mark Hauser has suggested that Fridlund's arguments bear on questions about the biological function of emotional behavior whilst the affect program model is concerned with the mechanisms that produce that behavior (Hauser 1996, pp. 495–6). In some places, however, Fridlund does seem to be discussing the nature of the underlying emotional processes and not merely their biological function. He argues that since emotions are signals and are produced because of the impact they will have on other organisms, a particular emotion defined behaviorally need not correspond to any particular motivational state (emotion) of the organism producing it.

5. *Evolutionary Psychology and the Emotions*

The evolutionary psychology movement of the late 1980s and 1990s has been less inclined than sociobiology to question the accepted view of basic emotions. The evolutionary psychologists believe that the mind as a whole is made up of modules that operate independently of one another. Like the emotion system, these modules operate on specific kinds of data using algorithms that differ from those used by other modules. Hence, evolutionary psychology endorses the affect program theory of basic emotions, but wants to go further, both by adding to the complexity of the known affect programs and by finding modular mechanisms underlying other emotional behaviors. John Tooby and Leda Cosmides suggest a number of cognitive and behavioral systems that they would expect to receive output from the affect programs, in addition to those currently known to receive such output (Tooby and Cosmides 1990). They also suggest that the affect programs will be elicited by simple, perceptual stimuli that have played a recurrent role in human evolutionary history. Current empirical research suggests, however, that few simple perceptual stimuli elicit affect programs in the absence of any individual experience of those stimuli. Most evolutionary influences on sensitivity to simple perceptual stimuli seem to take the form of learning preparedness: the relative ease with which one association is acquired rather than another. Genuine pan-cultural antecedents of emotion seem to be relatively abstract states of affairs having to do with the significance of a situation for the organism and requiring local knowledge to translate them into perceptible features of the stimulus situation (Ekman and Davidson 1994, pp. 144–77).

The leading evolutionary psychologist, David Buss, has argued for the existence of a module for sexual jealousy, one of the additional modules predicted by Tooby and Cosmides. Buss argues that sexual jealousy has simple perceptual elicitors such as unusual scents, changed sexual behavior, excessive eye contact, and

violation of rules governing personal space. 'These signals alert us to the possibility of infidelity, since they have been statistically linked with relationship loss over the long course of human evolutionary history' (Buss 2000, p. 45). The jealousy module uses special-purpose algorithms and, like the basic emotions, it functions as a fail-safe mechanism: 'failing to detect an infidelity was more costly than mistakenly accusing an innocent partner of betrayal. Evolution, as a consequence, forged a hypersensitive defense system, designed to sound the alarm not just when an infidelity has been discovered, but also when the circumstances make it slightly more likely' (Buss 2000, p. 224). When triggered, the module produces various forms of violence against female sexual partners, including, under certain environmental conditions, murder. A noticeable contrast between these recent theories and more traditional accounts of the evolution of emotion is the absence of the idea that emotions represent a more primitive form of behavioral control that can be contrasted to rational, planned action. The emotions are seen as just another cognitive module reflecting details of the environment of evolutionary adaptedness.

6. Conclusion

Current theories of the evolution of emotion all stem from the intellectual lineage stretching back to Darwin himself. There are a number of disagreements between current researchers, however. These include the number of separate, evolved emotions, the nature of the stimuli that produce evolved emotions, and a cluster of issues about the evolutionary function of emotional behaviors and their relationship to underlying emotional states, issues which are often discussed in terms of whether emotional behaviors should be primarily regarded as expressions or as signals.

Emotions, History of

1. Using the Past for New Understanding

This field of study builds on two assumptions. First, historians of emotion believe that emotion, the response to stimuli that combines physiological reactions and cognitive evaluations, plays a significant role in historical action. In this they differ from some historians who have argued, for example in interpreting rioting, that purely rational calculations underlie behaviors even when there are admitted emotional overtones such as anger or fear. Second, historians of emotion believe, and demonstrate, that emotions are subject to change, according to shifts in historical context. In this they differ from some researchers who argue that emotions are human constants, based on inherent biological and psychological factors, varying only by personality. Historians of emotion join anthropologists and many sociologists in seeing emotional standards and reactions as group variables, at

least in part. Whereas anthropologists mainly study different emotional configurations across contemporary cultures, historians of emotion deal with changes over time, venturing a periodization of key developments. Historians of emotion also contribute to emotions-study a concern for the social results of emotional standards, as opposed to purely personal qualities.

2. *Major Themes*

Historical research has become a significant contributor to the exploration of emotion and the role of emotion in larger social interactions. Although there are a number of different approaches to emotions history, and several different rationales, most historians agree in the focus on 'changes' in emotional standards and experience. They seek to chart what the changes were, granting that explicit standards, or what is often called emotional culture or emotionology, are easier to delineate than actual individual or collective experience. However, they demonstrate that standards themselves, have important results both in emotional life and in social and institutional behavior. Here, indeed, is one of the chief methodological pillars of the field. Historians also try to explain what the 'causes' of change were, which helps connect emotions to larger social developments. They are also eager to show what the 'results' were, not just in individual perceptions of emotions and capacities for display, but in other institutions and interactions.

3. *How the Field Became Explicit*

History cannot be written without dealing with emotional issues and expressions. Even before the rise of psychohistory—the application of psychological theories, particularly Freudian psychoanalytic concepts, to historical data—biographers often referred to emotional qualities of their subjects. Classic attempts to convey the larger spirit of a historical period, like Johan Huizinga's characterization of the waning Middle Ages, often included emotional dynamics, as did descriptions of reactions to wars or crowd behavior. With all this, however, the principal focus was not on emotion *per se*, but on emotion as a component of some other phenomenon.

The history of emotions received a considerable boost in the 1930s. The rise of social history in France, seeking to understand the experience of ordinary people in the past, involved exploring topics not previously part of the historical repertoire. Innovators like Lucien Febvre (1973) specifically called for research on emotions as part of the larger social history effort. At about the same time, German sociologist Norbert Elias sketched his theory of a 'civilizing process,' (Elias 1978, 1982) arguing that standards of self-control became more rigorous in Europe's upper classes in the seventeenth and eighteenth centuries. His primary focus involved physical behavior, such as eating habits, but his attention to more refined manners also involved discipline over emotion. Neither Febvre nor Elias generated an immediate response; indeed, Elias' theories are used currently more widely than ever before.

The development of psychohistory in the 1970s certainly called new attention to the historical exploration of emotion. Historians of childhood like Philip Greven (1977) and David Hunt (1970) thus explored the emotional impact of characteristic styles of childrearing in the seventeenth and eighteenth centuries, using psychoanalytic theory; Greven focused on the consequences of new styles of discipline associated with religious movements in colonial America. Most psychohistorians, however, concentrated primarily on biography, as in the classic study of Luther by Erik Erikson (1962). Still, historians influenced by Freudianism have continued to contribute, particularly when they have turned to larger cultural standards and individual experience around these standards. Generational emotional results of the experience of World War I have thus figured in some explanations of the rise of German Nazism (including the impact of father absence).

However, most explicit attention to emotions history resulted from a slightly different set of developments, in social history and related social sciences, as a framework established in the 1970s translated into explicit research from the mid-1980s onward. Social historians, now dominant in many areas of historical research, continued to widen their exploration of how ordinary people functioned in the past. A major extension of these inquiries, launched in France but spreading more widely, argued for inquiry into deeply-held values and assumptions—*mentalités*—concerning subjects such as death, community, or the forces of nature. Not surprisingly, attitudes about emotion quickly figured into this mix; sweeping studies of fear were one key result. English and American historians, for their part, broadened the investigation of family patterns into qualitative relationships among family members. In this vein they explored shifts in the definition and valuation of love, both marital and parental, and also changes in the ways anger was viewed in family life. Mentalities and family historians alike painted a distinctive picture of emotional standards in early modern—sixteenth to seventeenth century—European and American societies, compared to more modern norms. They also paid explicit attention to processes of change, particularly by the eighteenth century.

Two related strands of social history inquiry thus produced a new understanding of the extent to which past culture, and institutions like the peasant village or the family, could not be grasped without assessing the emotional dynamics involved. The same inquiry

underlined the extent to which emotional dynamics varied over time—with the historical period—and were therefore subject to explainable change.

Concurrently, various social scientists exploring emotion, began to probe the historical record as well, in this case with primary, though not exclusive, attention to more recent developments. American sociologists and social psychologists began to look at new emotional standards at work, as service sector jobs expanded in the twentieth century. They also investigated changing definitions of family-related emotion. While most anthropologists concentrated on painting rich, but fairly static pictures, of emotional standards in various societies, some began to build in attention to change. Thus Robert Levy, in his classic study of the Tahitians (1973), dealt with the impact of Western colonialism on Tahitian emotional culture, while Catherine Lutz (1988) in a variety of studies looked at shifts in emotion over time, while relying heavily on contemporary field work descriptions for her basic categories. A number of European sociologists, some strongly influenced by Elias' theories, began to examine changes in 'emotion management,' particularly in the twentieth century but in some cases over a longer sweep of time, focusing on ways emotional impulses were to be controlled. A Dutch group, in particular, worked on the emotional standards that accompanied more informal manners and relationships in the twentieth century. By the 1980s, explicit work in the history of emotion was well underway (see Wouters 1995).

4. *Gains and Gaps in Historical Research on Emotion*

Once launched, emotions history inevitably gained additional vantagepoints and emphases. The list of emotions historically explored now includes envy, disgust, joy (tentatively), grief, shame, and guilt, as well as the initial roster.

The takeoff of emotions history has also widened in terms of place and time—crucial indications of a project's significance in this empirically specific discipline. Thus several studies deal with changes and continuities in emotional standards and expressions in Chinese history. Historians addressing medieval Europe have generated an impressive literature, as in an important set of studies on anger and projects on wonder and empathy (Rosenwein 1998). Classicists are also dealing with love, in the context of further explorations of family history. The growing range still begs for expansion and connection. Changes within the Middle Ages need more explicit linkage to the patterns noted in the early modern centuries, while the Renaissance, as a possible period in emotions history, has not clearly surfaced at all. Geographical gaps are at least as obvious as the challenges in chronology and linkage. Specialists dealing with a number of key areas—Eastern Europe, Africa, Latin America, additional parts of Asia—have yet to generate focused histories of emotion, as opposed to more haphazard overlaps and connections with other topics like family life. Relatedly, key theories about emotional change—such as the civilizing process idea—have yet to be seriously tested beyond the Western context, so despite some speculation there is no consensus about possible applicability. Nevertheless, it is fair to say that the process of moving emotions history toward a full historical canvas is underway.

5. *Two Turning Points*

The most elaborate work, however, continues to emphasize developments in the USA and Western Europe. Here, in addition to broadening the varieties of emotions considered and the contexts in which they operate, historians and kindred social scientists have particularly emphasized two points of particularly revealing transformation. An important set of changes redefined emotional culture between the late seventeenth and early nineteenth centuries, with timing somewhat varying with the emotional configuration involved. A subsequent turning point intervened in the second quarter of the twentieth century, possibly a bit earlier in the USA than in Western Europe. Within this periodization framework a host of questions remain disputed or unanswered, but the framework itself has proved widely useful in explaining significant recastings of emotional guidelines and experience and in beginning to amass evidence about why emotions change and with what larger results.

In the early modern emotionological transformation, two factors propelled change. First, growing commercialization helped place new value on the family, as communities became somewhat more competitive. Family ties were alternatives to older, now frayed communitarian bonds. Same-sex friendships, by the same token, declined. Along with this, Protestantism, attacking the idea of special credit for celibacy, greatly improved the religious status of marriage (and, in destroying convents, made marriage more essential for women). By the seventeenth century Protestant writers urged emotional sharing in marriage. From these twin bases, actual emphasis on love as a key ingredient in forming and evaluating marriage measurably expanded by the mid-eighteenth century. A concomitant, noteworthy by this point, was a more systematic attack on anger in the family, as contradictory to love and also to the greater equality in human relationships being promoted by Enlightenment ideology. Jealousy was also redefined and more systematically reproached, particularly as the idea of a jealous defense of honor came under attack as uncivi-

lized. Growing emphasis on parent–child love, combined with further erosion of community controls, helped generate the growing reliance on guilt over shame in childrearing (Stearns and Stearns 1988). Techniques such as isolation increasingly supplanted both shaming and physical punishments, convincing children that love was temporarily interrupted and could be restored only by sincere repentance—often establishing guilt as a durable emotional enforcer of character standards. Grief, though more fully amplified in the nineteenth century, also followed from a greater emphasis on love, along with new beliefs that deaths should be brought under greater control. The apparatus available to commemorate death changed in order to accommodate growing grief needs (Rosenblatt 1983).

Emotional change also developed outside the family. The acceptability of sadness and melancholy declined, with people (initially, particularly men) urged to present a cheerful demeanor. More broadly, emotions were increasingly seen as operating under individual control, rather than sweeping through the body as an out-growth of physical humors. Correspondingly, responsibility for personal emotion management increased. Words like temper began to suggest a type of anger that should be controlled, while outright neologisms, such as tantrums, indicated a childish level of rage that could disqualify an adult from serious consideration (Stearns and Stearns 1986). The rise of new standards of disgust followed from cultural redefinitions of emanations from the body and from growing social inequality, with disgust used to mark and justify boundary lines between respectable and unrespectable people and situations (Corbin 1986).

Historians are still working out some of the implications of these changes, in altering the context of family life but also spilling over into wider public arenas. The transformation of criminal justice, shifting from shaming to imprisonment, clearly reflected the new commitment to guilt, for example, along with growing disgust at crowd reactions to public punishments. Ramifications of emotional change could reach into a wide spectrum.

Redirections in emotional culture between 1900 and 1950 were also extensive. Here, the dominant motifs are greater control over intensity plus growing informality in social relationships. Some historians also add an increasing democratization of emotional standards, with fewer systematic social divisions between respectable groups and others. Suspicion of intensity showed in several arenas. Anger, previously approved for men as a motivation for business and professional life (though dangerous in the home), was now more systematically reproved, with new techniques designed to defuse it. Grief was increasingly disallowed. Even more revealing attacks on intensity turned against too much stress on guilt, which might damage children's self-confidence. Maternal love, praised without major qualification in the nineteenth century, now fell victim to extensive criticism because of its overpowering qualities; mothers should keep their affection under tighter bounds. Romantic love, which had evolved toward increasingly idealistic statements in the nineteenth century, seemed excessive as well by contemporary standards; many prescriptive writers urged more limited, realistic emotional connections, while also freeing sexuality from some of the emotional commitment promoted in nineteenth-century advice literature (Seidman 1991, Stearns 1994).

The new concern about intensity was no accident, and it had some of the same range of effects noted in the earlier Western transformation. Causes centered on changes in economic structure, and therefore emotional functions, along with the rise of a new, psychologically-informed expertise. Growing consumerism urged emotional investment in acquisition and goods, and this diverted from some of the emotional investments that figured powerfully in the eighteenth and nineteenth centuries. Corporate and service employment required higher levels of emotional self-manipulation, in order to turn on a friendly smile and avoid bureaucratic confrontations. 'Impersonal, yet friendly' became a literal watchword in business training programs, with considerable emotional implications. At the same time, popularizing experts now referred to their psychological, rather than moral credentials, creating a picture of a more fragile mental structure than had previously prevailed. A recent study (Pfister and Schnog 1997) further probes the particular American fascination with psychological explanations and remedies, as a framework for contemporary emotional life.

The consequences of change involved, as with earlier redirections, both personal and social features. Americans became more nervous about emotional display, convinced that intensity reflected immaturity on their part; hence a recent study emphasizes a proclivity to check with others about onsets of jealousy, in order to provide a peer-mirror to guard against lack of restraint. Other studies (Salovey 1994) show the consequences of rigorous emotional control on the job, in distorting responses even in private relationships. Legal changes, including the rise of no-fault divorce, incorporated the growing belief that moderns should be able to keep anger and grief in check, in the most trying circumstances. Even changes in protest rates—the marked decline of labor strikes after 1958—derived in part from successful efforts to persuade workers that anger was childish, a reflection of personal flaw rather than a valid emotional response to objective problems. The reach of this new change in basic emotional style, in sum, was considerable.

Finally, amid growing constraints on certain emotional expressions, a recreational culture arose that provided some symbolic contrasts. Intense spectatorship, for example at sporting events, played off against

normal emotion management, and athletes and actors were allowed displays of anger, grief, or vivid camaraderie that were not usually countenanced—providing, in other words, what has been described as a compensatory surrogate culture.

Exploration of the two great transformations has involved the work of a substantial number of historians and historical sociologists. Inevitably, even in a new field, some disagreements have surfaced. Specific emphases and attributions of cause differ in the approaches to the early modern transformation. French work divides between explorations of distinctively Catholic features (as in the work on fear) and a sense that French emotional culture moved in harmony with other parts of Europe (as in the work on familial affections) (see Delumeau 1978). Divisions, though not outright clashes, also inform the work on the twentieth-century turning point. European sociologists have worked more on the process of 'informalization' than have their American counterparts, arguing that contemporary emotional relations work because people can assume successful incorporation of the rules of restraint (Wouters 1992). American historians accept this conclusion, in part, but additionally point to important new regulations and tensions. No coherent schools have emerged as yet, but there are fruitful debates.

Both of the great changes in emotional standards raise a host of questions, headed by the problem of social class. The rise of new standards of love in the eighteenth century involved a variety of social groups; proletarians, free from the constraints of property arrangements, may have moved early to emphasize a type of love more fully (Gillis 1985). But some of the standards particularly attached to the rising middle class. Emphasis on heightened emotional sensitivities between parents and children, for example, while no monopoly of a single class, moved into a bourgeois lexicon; and many observers criticized workers for failure to display the finer parental feelings. Changes in the twentieth century did have a democratic air, in that nineteenth-century attempts to downplay certain groups as impossibly crude noticeably declined. Romantic love was a case in point. American jurists in the late nineteenth century had been willing to allow lack of love as a valid reason for divorce for middle-class people, under the heading of mental cruelty, but they would not do the same for the working class because such emotional refinement was impossible at this level. In the twentieth century, however, the now-modified romantic love ideal was proclaimed for all. Still, issues of how particular emotional standards affected social classes are only now beginning to receive needed attention. One study, for example, shows how new hostility to the use of fear in childrearing, an American middle-class staple by 1900, captured Catholic working-class culture only in the 1950s. In other instances, middle-class prescriptions were not simply more slowly assimilated by other groups, but were positively defied, as in some of the more emotionally exuberant facets of twentieth-century African American culture (Stearns and Lewis 1988).

6. *Current Issues and Future Directions*

The success of historical work to date considerably adds to available information on varieties of emotional formulations and the ways values and emotions interact. It thus amplifies the constructionist approach to research on emotion, arguing that a significant part of emotional codes and responses vary with context—by place, but also by time period. The exploration of change and causation builds a further ingredient into constructionism, often missing from anthropological studies, in showing how one emotions variant may transform into another, responding to wider factors in economic, political, and cultural structure.

The historical agenda also raises problems, even aside from the range of areas and periods, and types of emotions, still open to this kind of analytical inquiry. The relationship between widely-prescribed cultural standards and other aspects of emotional experience—aspects that usually leave less explicit past records—is an obvious issue. Standards count in themselves: they affect social rules and practices, based on expected emotional behavior; they color evaluations of others and of self; and they unquestionably shape actual experience. Thus a culture that discourages romantic love—a common pattern in premodern peasant societies—almost certainly has less of it. But there are disjunctures as well, and historians must be sensitive to these. Among other things, emotional experience may vary somewhat less than standards do. Historians who initially assumed that the absence of explicit encouragement (indeed, the considerable explicit hostility) to marital love, in prescriptive materials before the seventeenth century, meant that there was in fact little, were assuming too much, and more recent researchers have improved on the evidence available in generating more nuanced statements of contrast and change.

A related issue, now happily beginning to gain constructive attention, involves subcultures. As noted previously, most emotions history to date has focused on mainstream standards issuing from dominant social groups. Various social classes, religious contingents, even age categories form emotional cultures of their own. Research in American history, particularly, is beginning to reveal patterns of emotionology in various religious and racial groups, and in the working class. These patterns sometimes link to mainstream trends, if with a certain chronological lag, but they sometimes deliberately run counter—as in the enthusiastic religious sects that arose around 1900 as an

antidote to growing mainstream hostility to emotional intensity.

Comparison also deserves more attention. The extensive focus on large transformations invite fine-tuning. Most research on both the early modern and the twentieth-century turning points has been either strictly national (just the USA or just France) or has assumed large transatlantic, Western trends. Yet we know that in the year 2000, in key particulars, regional patterns vary—the French get angry when jealous, the Dutch sad, while Americans scurry to get other people's opinions. We need explicit historical comparisons to determine when, and above all why, distinctions of this sort emerged.

History can also establish middle-level generalizations about emotional change, based on the accumulation of cases. We can begin to use partial models of the factors most likely to cause change, and about the length of time normally required between the introduction of widely-shared new standards, and actual changes in social arrangements and behaviors (including childrearing). It took about a century, for example, for warnings against scaring children with bogeymen stories to gain sufficient acceptance that the prescriptive emphasis could be cut back (after the 1920s). Thirty years elapsed between new strictures against anger in the workplace, and incorporation of the same standards in parenting advice; and almost 40 years between the new culture's inception and clear implementation in laws and protest levels. These are straws in the wind, toward more systematic statements about timing.

In what is still a new field of explicit research, despite promising results to date, dealing with empirical and theoretical gaps inevitably forms a challenging agenda for the future. Identifying subcultures has barely begun, for example in dealing with racial differences over emotional goals in the USA. Geographical omissions are troubling in themselves, and they limit opportunities for comparison. Even for the Atlantic world, where the literature is richest, comparative opportunities have barely been taken up. With all this, two additional challenges remain: further integration with history, and further integration with the other disciplines that examine emotion.

The number of historians interested in emotion has expanded steadily. But findings about emotional change are not usually incorporated into mainstream historical study. Family historians come closest to recognizing the importance of this topic, as an element for example, along with birthrates and the roles of family members, in establishing periodization. But the day when historians of protest or politics consider the role of shifts in emotional standards has not yet arrived. The connection is possible: at a time when the emotional reactions of American politicians are carefully scripted in light of the dominant emotionology, there is obvious invitation to explore mutual interactions between culture and political reactions in the twentieth century (Kofler 1997). The same holds for studies of sports or labor relations. While the record to date is tentative at best, there is reason to assume that fuller integration will occur, as historians become more comfortable with the idea that emotional standards shift and that shifts have important consequences.

The even greater challenge for the future is interdisciplinary. Historians of emotion have found ready audience among anthropologists, sociologists, and some social psychologists (particularly, of course, those theoretically wedded to a discursive, cultural-constructionist approach). But actual interdisciplinary projects, that would deal with change and impact in relation to current emotional manifestations, have yet to emerge. Mainstream psychology focuses primarily on invariant aspects of emotional display, such as facial expressions, and ignore issues of cultural variance and change (Harré and Stearns 1995). We lack the collaboration necessary to use historical analysis to help test the boundary lines between inherent emotional components and the role of cultural standards, yet precisely this collaboration constitutes a vital next step. Projects that would identify recent change and subject the emotional results to standard psychological scrutiny are possible—for example, the tentative signs, since the 1970s, of partial modification of the contemporary hostility to grief. But constructing the interdisciplinary apparatus that can handle such issues is no easy task, given the growing split between cultural analysis and scientistic psychology. The desirable agenda is obvious; its realization, distinctly problematic.

Even as things stand, the history of emotions is contributing not only to an understanding of emotion, but also to a wider assessment of emotion's impact on behaviors and social institutions. Too often, emotions research focuses on individual experience. Even in the short time explicit emotions topics have commanded their attention, historians have advanced the exploration of why particular emotional articulations matter—how they affect the experience of family life and friendship, how they connect to regimens at work, even—in some extensions currently being developed—how they can help shape new political styles. Historians will continue to probe emotional characteristics in the past, and particularly cases of significant change; but they will also be eager to fold emotion actively into our larger understandings of how societies function. Momentum continues to build in this active new disciplinary partner in emotions research.

Emotions, Psychological Structure of

As is the case with many concepts in the social sciences, the term 'emotion,' used widely in everyday language, constitutes a hypothetical construct, that is, a conceptual and operational definition of an underlying phenomenon that constitutes the object of theory and research. While laypersons use 'emotion' interchangeably with terms such as affect, feeling, sentiment, or mood, psychologists define the construct as a process of changes in different components rather than a homogeneous state. Furthermore, it is assumed that the differentiation of the emotions (e.g., into fear, anger, or joy) is based on specific configurations of changes in the components.

1. Components

Starting with Greek philosophy, there has been an uninterrupted tradition of postulating at least three major reaction components of emotion: physiological arousal, motor expression, and subjective feeling. These three components are often referred to as the 'emotional response triad.'

1.1 Physiological Arousal

The widespread notion that emotions upset the body's equilibrium state suggests that the presence of arousal or activation is one of the major preconditions for using the label 'emotion.' References to physiological changes such as temperature sensations, respiratory and cardiovascular accelerations and decelerations, trembling and muscle spasms, as well as feelings of constriction in internal organs are frequently part of emotion descriptions. The important role of neurophysiological changes in emotional episodes is due to the emotion-eliciting event disturbing ongoing homeostatic regulation and smooth behavioral coordination, and the preparation of appropriate adaptive responses (e.g., producing the necessary energy for appropriate actions such as fight or flight).

1.2 Motor Expression

The changes in facial and vocal expression, as well as in gestures and posture, during emotion episodes are also considered to be central components of the

emotional response. According to Darwin ([1872] 1998) these expressions are rudiments of formerly adaptive behaviors (e.g., clenching one's teeth as a rudiment of a biting response). Whatever their origin, most scholars have explained emotional expressions in terms of their communicative functions, broadcasting the reaction of an individual and its corresponding behavior intentions to other members of the group.

1.3 Subjective Feeling

The fact that individuals can verbally report a multitude of qualitatively different feelings, as encoded in a rich emotion vocabulary, constitutes the most important facet of emotional episodes for many scholars in the field of emotion. These internal sensations, often considered as necessarily conscious experiences, are often called 'qualia,' irreducible qualities of feeling that are unique to the specific emotional experience of a particular individual. More recently, it has been suggested that the feeling component of emotion can be conceptualized as a reflection of all changes in components during an emotion episode, that is, the results of event appraisal, motivational change, and proprioceptive feedback from motor expression and physiological reactions. It is important to differentially define the concepts in this fashion as the tendency to use emotion (the process as a whole) and feeling (one of its components) as synonyms results in confusion (Scherer 2000a).

1.4 Behavior Preparation

It has been argued that the classic response triad needs to be complemented by another component—behavior preparation or action tendencies (Frijda 1986, Scherer 1984). While both the physiological and expressive components imply the preparation of adaptive action in a general, often unspecific way, the notion of specific action tendencies being part of the response syndrome suggests a more explicitly motivational function. Emotions change ongoing goal-directed behavior and produce action tendencies that are specifically adapted to dealing with the environmental contingency that has elicited the emotional response.

1.5 Cognitive Processes

In the wake of the cognitive revolution in the social and behavioral sciences, there has been increasing recognition that emotions may have very strong effects on perceptual and cognitive processes such as attention, thinking, memory, problem solving, judgment, decision making, and the like (see contributions in Dalgleish and Power 1999). Thus, the emotional response syndrome also includes a cognitive component. It can be further argued that the emotion construct should not be restricted to the response components but should also include the specific characteristics of the processes that elicit and differentiate the emotions. Thus, proponents of appraisal theories of emotion suggest that emotional reactions are determined by the subjective evaluation of events with respect to their significance for the well-being and goal attainment of individuals (see contributions in Scherer et al. 2001). The recursiveness of the appraisal–response sequence (e.g., the evaluation of an event as dangerous may produce fear which in turn may affect the ensuing evaluation of subsequent events) strengthens the suggestion to include cognitive appraisal processes as a component of the emotion construct.

While the notion that emotions are syndromes of component changes is widely accepted, there is debate as to the relative importance of these components, particularly as to which ones should be considered as necessary and sufficient conditions for the occurrence of emotion. The components are expected to interact, that is, to influence each other. Thus, one issue of research concerns the possibility that motor expression may produce specific feelings or at least increase or decrease the intensity of subjective experience (as postulated by proprioceptive feedback theories; see Scherer 2000a for further detail).

2. Process

While it is customary to talk of 'emotional states,' emotion researchers generally emphasize that emotion is a process in time. Generally, research has shown that different emotions have different time patterns including differential duration and varying onset or offset patterns. What is seen as part of an emotion episode partly depends on the specific definitions proposed by a researcher. In what follows, a number of sequential phases or stages of typical emotion episodes are described. Emotions can be evoked by a number of different factors, including external events or behaviors, internal neurophysiological changes, or memory recall. All of these potential origins will be subsumed under the term 'stimulus event' (triggering an emotion episode). Since external events seem to be the most frequent elicitors, the description below is biased toward such types of stimulus events (e.g., a sudden noise that might represent an explosion in the vicinity).

Salient stimulus events are immediately evaluated by an automatic evaluation process on lower, subcortical levels of the central nervous system (CNS), focusing attention on the stimulus. This preliminary evaluation may result in orientation and/or defense

responses as well as in feelings of pain or pleasure. Stimulus events thus marked for requiring further, more controlled or effortful processing are subject to being appraised by evaluation processes on higher levels of the CNS, in particular the cortical association areas and memory (Dalgleish and Power 1999, Leventhal and Scherer 1987). In this phase, the causation of the event (i.e., the objects and individuals likely to be responsible), the process involved, the consequences to be expected, the implications for the well-being and the immediate goals of the individual, and the ability to modify the consequences or to adjust to them, are evaluated (a process described in detail by appraisal theories of emotion; see contributions in Scherer et al. 2001).

The appraisal process generally produces motivation towards an adaptive response to the event. Depending on the importance of the consequences to be expected, this urge may generate a primordial goal for the specific moment in time (e.g., survival or self-assertion), superseding all prior needs, desires, or goals. Once the consequences of the event and the individual's response potential are evaluated in at least a preliminary fashion, the current goal/plan hierarchy needs to be restructured. This stage can be called 'goal/need priority setting.' Next, action alternatives are examined with respect to the cost involved and the likelihood of success. The result of this selection produces more specific action tendencies or behavior preparation (Frijda 1986), enabling the organism to rapidly engage in a certain class of behaviors (e.g., mobilizing the necessary energy for fight or flight). In this phase, the internal monitoring of the event appraisal and the physiological and expressive reactions (as reflected in subjective feeling, see above) play a central role in determining the need for emotion control or regulation, inhibiting execution of the activated action tendencies. The next phase consists of behavior execution, that is, the triggering of motor commands that produce concrete overt behavior, in terms of instrumental motor behavior and verbal or nonverbal communicative acts. In many cases the individual will, during or after the emotion episode, probably talk about the emotional experiences with others (emotional communication).

So far, the description has focused on the part of the emotion process consisting of an individual's reactions to an event. In many cases this reaction is embedded in a social context (particularly when an interaction partner has provoked the reaction) and is only the beginning of an interactive process in which each reaction of one of the protagonists is a stimulus event that is likely to modify the emotion process. Examples are the escalation of anger or the soothing of sadness through the empathic response of another. This process of interpersonal emotion regulation or escalation has been well described in the context of marital interactions (Gottman 1993). In social interaction emotions, and particularly emotional expression, are often 'managed' in the pursuit of strategic goals such as self-presentation, intimidation, adulation, and so forth (Goffman 1959, Manstead 1991).

3. *Differentiation*

So far, the structure of emotion has been defined in terms of the underlying theoretical construct, in particular with respect to components and process. However, the problem of structure also arises when the differentiation of the emotions is addressed: How many emotions are there and what are they? This question is answered very differently depending on the theoretical stance adopted (see contributions in Ekman and Davidson 1994). Below, a number of major theoretical positions and their views on this issue are briefly described (see Scherer 2000b for greater detail).

3.1 *Dimensional Models*

The first explicit dimensional model was formulated by Wundt (1905) who used both introspective and experimental methods to study subjective feeling experiences. He proposed that feelings varied by their positions on three independent dimensions: pleasantness–unpleasantness, rest–activation, and relaxation–attention. This model strongly influenced early emotion psychology. It has an intuitive appeal since it has been shown that humans have a tendency to perceive all kinds of meaning in terms of valence (i.e., positive vs. negative) and activation (active–passive; see Osgood et al. 1975). Following this tradition, many dimensional theorists argue that the differentiation is sufficiently well described by one or both of these central dimensions. Dimensional models have been particularly successful in social psychological and neurophysiological approaches to emotion (see Scherer 2000b).

3.2 *Discrete Emotion Models*

Theorists in this tradition postulate a limited set of basic emotions such as fear, anger, joy, sadness, and disgust, characterized by a number of fundamental adaptive responses to prototypical events (e.g., fear/flight in response to an attack by a powerful enemy, disgust/avoidance in the case of spoiled food). Thus, the structure of emotion differentiation is given by prototypical, phylogenetically evolved adaptation patterns. Some models suggest that the differentiation and the number of fundamental emotions is determined by evolved neural circuits (circuit models; e.g., Panksepp 1998) or by phylogenetically continuous classes of motivation such as aggression or nurturance (motivational models, e.g., Plutchik 1980). Based on

Darwin ([1872] 1998), Tomkins (1984) suggested the existence of a small number of discrete, basic emotions in the form of neuromotor programs. Tomkins' suggestion has been extended by Ekman and Izard, who worked towards obtaining empirical evidence for theoretically derived consequences of discrete emotion theory, such as early ontogenetic onset of the discrete emotion patterns, discrete patterning of prototypical facial expressions, and universality of these patterns (Ekman 1992, Izard 1991). Theorists in this tradition have suggested that these basic emotions can be mixed or blended, thus explaining the large variety of emotion-descriptive verbal labels in many languages.

3.3 Meaning-oriented Models

Frequently, the semantic fields of terms in the emotion vocabularies of different languages are used to describe the structure of emotion, assuming that there is a mapping between semantic and psychological structures and categories. For example, lexical models try to define basic emotions as prototypical linguistic categories (e.g., a prototypical 'anger' category covering terms such as irritation, rage, being cross, etc.; e.g., Shaver et al. 1987) and to define each category by listing, as is the case in a dictionary, the semantic prerequisites and implications for the use of the word (e.g., in the case of indignation, 'being denied what one thinks one has a claim on'). Close to this view are social constructivist models claiming that the emotions are constituted or constructed by socioculturally determined behavior and value patterns, varying greatly over cultures. For example, it is suggested that certain emotions exist only in specific cultures or that a particular emotion has disappeared because of historic changes in cultural values and lifestyles. These models all suggest that the structure of emotion differentiation cannot be reduced to basic psychobiological patterns (i.e., a limited number of adaptive behaviors) but needs to be modeled on the basis of sociocultural meaning, often reflected in the semantic structure of the emotion vocabulary (see Scherer 2000b for more detail).

3.4 Adaptational Models

Theorists focusing on the way in which evolution may have equipped organisms to respond automatically to significant events have developed what can be called 'biological preparedness' models. For example, Öhman (1988) has developed a model that suggests that humans have unconscious detection mechanisms for stimuli that are potentially harmful (such as snakes and spiders). The automatic detection of such threat stimuli serves to efficiently prepare emergency reactions on the level of the autonomic nervous system (ANS). LeDoux's (1996) work shows that the neural architecture of the fear system (at least in rats) is optimally suited for the production of such rapidly and automatically elicited but relatively nondifferentiated responses.

3.5 Componential Models

Componential emotion theorists postulate that emotions are elicited by a cognitive (but not necessarily conscious or controlled) appraisal of antecedent situations and events and that the patterning of the reactions in the different response domains (physiology, expression, action tendencies, feeling) is produced by the outcome of this evaluation process. According to this view, the structure of emotion is the result of the dimensions or criteria used in the appraisal process to determine the meaning of the stimulus event to the individual and of the response patterns (facial and vocal expression, physiological symptoms) generated by the appraisal results (see the chapters authored or co-authored by Ellsworth, Frijda, Lazarus, Roseman, Scherer, and Smith in Scherer et al. 2001). Lazarus (1991) sees emotion structure as determined by appraisals on a small number of dimensions called 'relational themes' (e.g., 'loss of a cherished person or thing' giving rise to sadness). In contrast, the component process model proposed by Scherer (1984; see also chapter in Scherer et al. 2001) suggests that one can distinguish as many different emotional processes as there are differential patterns of appraisal results. However, it is suggested that there are modal emotion outcomes corresponding to universal organism–environment interactions (e.g., 'blocked goals') which tend to be labeled by short emotion terms (e.g., anger) in most languages. The other appraisal theorists adopt intermediate positions.

This review shows that the current psychological models of emotion vary quite strongly in their postulates regarding the structure of emotion with respect to focus on specific components, presumptions about the nature of the process, and the explanations offered for the differentiation of individual emotions. A two-dimensional coordinate system can be used to plot these structural differences among psychological theories of emotion. One dimension consists of the different components of the emotion syndrome, as described above: cognitive processes, peripheral physiological responses, motivational changes, motor expression, and subjective feeling. The second dimension consists of the different stages of the emotion process, as outlined above. Table 1 shows where in this space the models reviewed above can be located.

Table 1 illustrates the origin of some of the differences in assumptions about the psychological structure of emotion: The more a model is concerned with the output end of the emotion process (e.g., the selection of adaptive responses), the more it sees structure as being determined by the type of action tendency (e.g., a flight tendency characterizing the fear response). In contrast, the more a model focuses on

Table 1
Comparison of major emotion theories with respect to their focus on components and phases in the emotion process

The solid area, representing a particular type of model, is drawn across the intersections of components and phases that theorists in the respective tradition focus on most. The horizontal lines projecting from the solid areas indicate that a particular model includes in its theorizing at least some of the components/phases crossed by these lines.

the appraisal phases, that is, the input end of the emotion process, the less constrained is the presumed structure of emotion differentiation, allowing for a multitude of potential outcomes of the appraisal process. Obviously, it also matters which component of emotion a specific model focuses on. Models oriented toward the output end of the process tend to focus on the motivational (action tendencies) and motor expression components whereas those focusing on the input side highlight the cognitive component as being involved in structural differentiation. The table also allows one to determine which theories are committed to a psychobiological view (the models focusing on the physiological and expressive components, i.e., adaptational, motivational, circuit, and discrete emotion models) in contrast to those that lean more towards the phenomenological or sociocultural aspects of emotion (the models focusing on the subjective feeling component, i.e., dimensional, meaning, and constructivist models). Appraisal models tend to span the complete range of components. In spite of these differences, the claims of the different models are quite compatible once one allows for the fact that they focus on different components of emotion and different phases of the process.

4. Outlook

The explosive growth of emotion research in the last quarter of the twentieth century has produced both conceptual and methodological tools that promise to revolutionize the study of emotion. Largely confined to philosophical speculation based on verbal reports of subjective experience for much of its history, and hampered by terminological confusion, the study of emotion is increasingly based on a consensus concerning fundamental conceptual distinctions and employs methods that complement the traditional reliance on verbal report. In particular, the objective assessment of facial and vocal expression as well as of neurophysiological reactions allows a multicomponent approach to measurement that is likely to do greater justice to the complex structure of emotion episodes. Another promising development is the rapprochement between psychological and neuroscience approaches to emotion, with insights on the neural architecture of the emotion system, obtained through brain imagery, providing information on process characteristics. Our understanding of emotion processes has also been advanced by copious work on the development of emotion (see *Infancy and Childhood: Emotional Development*) and on affective disturbance.

Progress has been somewhat less marked with respect to the social functions of emotion: While there is much research on the influence of mood on social cognition, there have been only very few efforts to study empirically the role of emotion in social interaction. Phenomena like emotional contagion, affective influence, anger escalation, or emotional climate in groups constitute promising areas for future research on the social context of emotion processes.

Emotions, Sociology of

1. Introduction

In this article, a brief social history of the Western bias against emotions will clear the air for their current study. Works defining the beginnings of the 'sociology of emotions' are described; substantive topics addressed by the field are organized under a cybernetic macro–micro framework that emphasizes its contribution to sociology in general.

The sociology of emotions is premised on several recent observations that contradict popular prejudices. First, some constant emotional posture is necessary for mental functioning. Second, rather than depicting the asocial, idiosyncratic part of human existence that escapes through the seams of social organization, emotion is socially patterned and is a vital part of the maintenance of social organization. Third, rather than shaping the mere cultural display of biologically fixed emotions, in most cases, social processes are involved in their very constitution.

Definitions of emotion typically include organized mental states comprising cognitive appraisals, impulses to action, and to varying degrees, feelings. Hochschild (1983) likens emotions to senses that signal what is personally relevant about surrounding events. Scheff has cautioned that the attempt to define emotion is a rock on which many a ship has split. One difficulty is that emotion labels are often ideological. Contemporary American salaries for corporate executive officers averaging 400 times more than the lowest organizational worker can be viewed in terms of 'purely objective rewards for effectiveness,' self-interest, or greed.

2. The Recent Shift in the Western Evaluation of Emotion

Until the end of the twentieth century, Western society paid scant attention to emotions except to warn against them as a source of bias. The last quarter of the century however, saw a significant reversal from the devaluation of emotion to recognition of its crucial importance. Emotion, once seen as the enemy of rationality is now viewed as the foundation for our engagement in the world. Studies of brain trauma now identify certain emotional processes as necessary for rational choice-making and social adaptation. Artificial intelligence research reveals the importance of emotional predispositions in selecting what is relevant to a particular line of thought out of an unmanageable array of objective possibilities. Philosophers contend that 'emotion is what one sees the world in terms of.' Thus, emotion sets the very agenda for thought.

3. The Discursive Origins of the Word Emotion

The practice of carving affective experience into many separate subtypes and grouping them together as the same kind of psychic phenomena called 'emotion,' is relatively recent, and suspect to many scholars. The word did not appear in the Oxford Dictionary until 1580, after terms like 'self' and 'consciousness' lost

their negative connotation and individual experience became a subject worth attention. Before that, rage, love, and pity, etc. were not seen in terms of the broader category, 'emotions.' As the ascribed identities in the dark ages gave way to identities based more on achieved status, subjective experience became more relevant. Personal identity depended more on interpersonal skills and self-reflective behavioral control. People became more aware of, and interested in, their emotions.

Since antiquity, the more narrow term, 'passion,' stemming from 'pathos' and associated with suffering, referred to psychic events that overcame individuals. The broader term 'emotion' in France came from the Latin 'movement' or 'migration,' and meant that which 'moved' the person psychically. While this movement could now be for good or bad, the term still carried the connotation of persons torn between their hearts and minds (Sarbin 1986). This placed cognition as the exclusive link to reasoning with emotion as its threat. Thus, the implication of the term 'passion' still lurks in the broader word 'emotions.' Positive emotions such as awe, appreciation, gratitude, and determination are typically glossed over. Baily (1983) suggests that this is because emotion is used strategically as a discursive practice to account for, and excuse, untoward action. Nonetheless, sociological analysis depends on giving attention to a broad range of both dangerous and life-affirming emotions. All humans are emotional in the broad sense. Bureaucratic unease with emotion, is itself, emotion.

4. *Scientific Devaluations of Emotion in the Nineteenth Century and Lessons Learned*

William James (1902) and Charles Darwin (1955) set the scientific stage for the twentieth century depreciation of emotion. Darwin saw emotion as a vestigial remnant of the primordial bodily preparation for action. Its evolutionary survival lay only in its expression as cues to others; emotion had no current value to the individual. To James, emotion was primarily internal; it was essentially the body responding to the body, and not important in relating persons to the world. What lasted from James was the debated idea that an internal, defining substrate exists for major emotions.

Ironically the very 'subjectivization' of postmodern mentality that made the broad classification 'emotion' make sense and seem important has also led to distortions insofar as they are seen as self-contained, totally internal processes, independent of ongoing human action and particular social contexts. Emotions do not exist separated from action in an inner depository of the self, like cookies in a jar waiting to be discovered by inner reflection (Baumeister 1986).

With all the diverse emotional lexicons in the world, it is an illusion to insist that there is a distinctive process or state existing somewhere in the person that coincides with each emotion word. However emotion is viewed, its relation to cognition must be handled carefully. To the extent that the two can be separated, they are nonetheless highly interdependent; changes in one system produce changes in the other. Though they can be experienced in serious tension with each other, recent findings, alluded to above, have demonstrated the necessity of certain emotions for adaptive behaviors. Emotion and cognition are now seen, not in terms of their oppositional contrasts, but as parts of a single, though multivalent, system in human mentality.

5. *Origins of the Sociology of Emotions: 1975–80*

Particular emotions were, indeed, important to the classical sociologists (Marx and alienation; Weber and disenchantment, etc.). Their treatment, however, was not concerned with the light they shed on the broader social-emotional process in general (Smith-Lovin 1995). It was not until 1975 that American sociologists, for example, called for a study of emotion as a social process in its own right. In that year Arlie Hochschild (1975) argued that a purely cognitive view of human life was not sufficient for sentient humans. Her insistence that emotion was socially patterned was partly explained by her concept of feeling rules, i.e. culturally and historically variable norms defining what should be felt in various situations. Often these rules served ideological functions. While Foucault was stressing hegenomic power in forms of knowledge, Hochschild was stressing the hegenomic control of the heart. 'Emotion work' described the individual processes that maintained these norms. This occurs when actors feel a pinch between what they actually feel and what they feel they should feel. Techniques used to change emotions include surface acting to mask or enhance the emotion and deep acting wherein the actual emotion is changed. Recent studies also focus on how other persons encourage or cut off the actor's expression of emotion and in some cases, feeling itself.

Scheff's (1979) model of the emotional person allowed for the possibility that culture could violate inherent emotional needs. He stressed how culture provided, or failed to provide, the cultural rituals needed to purge the physiological build-up of distressful emotions. Such rituals evoked the distressful experience so it could be relived emotionally but simultaneously offer a new cognitively distanced perspective resulting in cathartic, 'aesthetic balance.'

In the following decade (Scheff 1990) refined his proposal that shame and pride were the most important human emotions, forming indicants of the

individual's social bond. This bond was the *sine qua non* for human adaptation. The current overemphasis on impersonal forms of social organization puts this bond in jeopardy and increases incidents of shame. Through a series of escalating shame–anger spirals, rage and violence emerges. Most conducive to violence is unacknowledged shame, that is, shame not identified as such by the actor. Observable shame markers are identified that manifest themselves independently of the actor's knowledge and allow for testable hypotheses.

Kemper's (1978) Power and Status Theory argued that 'social power,' the ability to force others' compliance against their will, and 'social status,' conceived as favors freely given, were critical dimensions determining emotional states. A person's 'structural' place in hierarchies of excesses or deficits along these dimensions automatically produced certain distressful emotions depending on whether one attributed the cause to one's self or others. At a minimum his deterministic scheme drew attention to the fact that a great number of emotions had to do with one's place on the social map.

Shott (1979) presented a theory that stressed the importance of emotions in voluntaristic social control. Prior research had stressed the importance of role-taking as a process that fused self-control and social control. Role-taking is the capacity to respond to one's own on-coming behavior as would others, and to use their anticipated response as a guide to further conduct. It had been understood as essentially cognitive. But cognition was not sufficient to ensure normative social control. Role-taking could as soon be used to manipulate others without the self-reflexive emotions of guilt, shame and embarrassment or the other-directed empathetic emotions of sympathy. The personal discomfort these emotions produced gave actors a personal stake in the avoidance of behaviors producing them. In these cases harming others is harming one's self.

In her focus on chronically failed emotion-work, Thoits (1990) coined the term 'emotional deviance.' The label of mental illness is often the result of reactions by others or one's self to the inability to feel appropriately. Sources of discrepant feelings are multiple roles, role transitions and unrealistic demands. Thoits expanded Hochschild's treatment of emotion-work strategies identifying points at which they could easily fail. She also drew attention to the emotional dimensions of coping behaviors and social support, the latter seen as emotion work on others. Support may not alleviate pain but it can help victims cope with it.

Assuming the close relationship between emotion and cognition, fundamentally diverse life forms and thus fundamentally diverse ways of thinking will produce important emotional differences. This is the basis for Social Constructionism, articulated by Rom Harré (1986). Like Baily, he sees the use of the term 'emotion' as a social strategy—a discursive practice used for identity maintenance. He does not deny bodily concomitants, or the perceived reality of the experience, but to him the physiology involved is not a 'natural sign' of a biological inner state. Instead, emotional experience is a function of diverse local languages and moral orders.

Denzin (1984) argued against the study of emotions as an abstract class, separated from the lived experience of situated individuals. Emotion was to be studied by narrative and as reflected in cultural reflections such as film.

6. *The Cybernetic Program for the Sociology of Emotions*

In 1985, the sociology of emotions was formally recognized as a subsection in the American Sociological Association. Several scholars independently suggested a cybernetic program for emotion studies. This balanced the cultural and structural shaping of emotions with equal attention to how individual emotional experience worked inadvertently to maintain, confirm and change the social arrangements that initially shaped them. This view is clearly illustrated by incest taboos shaping feelings of sexual attraction and disgust. Aggregate individual experiences of these sexual aversions confirm and maintain the kinship arrangements and feeling rules that shaped them in the first place. Without these feelings, the structures of kinship would collapse. The advantage of such an approach is that it allows for a detailing of the individual interactional processes that form the foundation of emergent structures. Without this, our theory of social structure becomes dangerously reified (Scheff 1990). Regardless of the emergent quality of structures, the detailed link between concrete people and institutions must be traced. Collins' (1984) conception of emotional energy emanating from 'interactional ritual chains' argues for a similar articulation between micro- and macro-levels.

7. *Cultural and The Social Structural Shaping of Emotion*

Emotions presented as culturally distinct include the Japanese amae, an accepted adult feeling of dependence and a desire to be cuddled that would make most Westerners uncomfortable. Legit is an emotion of the Philippine Llongots that combines achievement of group membership with force and creation. They feel legit when they 'take heads.' There would be little debate that certain cultures encourage and discourage certain emotional experiences and that these lead to important behavioral dispositions. Through history one can trace the emotional tenors of particular epochs

like the anxious prudishness of the Victorian bourgeoisie and the shift to the ambivalence of the more narcissistic discontent of today. Shifts in the incidences of swooning imply the degree to which culture socializes the body. Other examples of the cultural shaping of emotion include the literature on emotion and gender. Important here is the devaluation of emotion and the belief that women are inherently more emotional than men. There is no reason to think that men are not as in touch with their own perceived manly feelings as are women. Hochschild (1983) brought attention to 'status shields,' i.e. shared, interpretive dispositions that protect those of privilege against (a) the displaced feelings of others, (b) the negative interpretations of one's own emotional expressions, and (c) the conviction of others that one's emotions are unwarranted and not important. The undermining of women's anger by interpreting them as 'crabby' because of their menstrual period or otherwise 'hysterical,' is an obvious example of a structured lack of status shields. The aggregate of such interpretations serve male dominance.

Emotions are shaped by the ways whole societies are organized, as well as the organizations within them. As an example of the first type of shaping, Hochschild (1989) demonstrated how macro-level changes in women's entry into the workforce effected micro-level gender imbalances in feelings of gratitude between couples in the household. Because of traditional gender roles, men's relatively small contributions to housework evoked more gratitude than the larger contributions from their working wives. This resulted in a 'second shift' for women and interpersonal tension. The study of gendered inequalities in how much it takes to evoke gratitude has important implications for power relations in general.

In spite of the devaluation of emotion in many businesses and bureaucracies, they organize emotional processes unwittingly or consciously. Feelings can impede organizational efficiency but they are also necessary for it. Any workplace must deal with loyalty and disenchantment, stirrings about status and power, anxieties about keeping control and being controlled, pride, defensiveness, fear of change, and the comforts of the familiar. Emotional labor, according to Hochschild (1983), is the commercial exploitation of the principle of emotion work. The airline stewards she studied were paid to 'be nice' regardless of insults and paradoxically asked to be genuine. Loyalty can supercede error; receptionists and credit collectors are paid to make persons feel certain ways. Many studies deal with divisions of emotional labor in organizations and the simultaneous relations between formal and informal emotion rules. Hospitals must deal with protecting their staff from the anguish of patients and the different emotional roles played by practitioners and nurses. The emotion work necessary from female public defenders of rapists has also proved of interest to sociologists.

8. *Social Interaction and Emotions Supporting Structures*

Individual emotional processes acting as concrete support for structural arrangements most obviously include emotion work and the reflexive role-taking emotions. Below, other such processes are identified.

What persons care about determines emotion. Persons care about their identities. Identities are connected with social structure because they are embedded in social roles. Emotions will determine what roles are chosen as central to identities and resulting role performance will be affected by emotions (e.g., confidence) as well as producing them (e.g., pride). The emotional aspects of identity work are, then, simultaneously commitments to structural role performances. The work by Heiss and Smith-Lovin on affect control as well as that by Stryker and Serpe on identity theory describes this 'maintenance' process (Smith-Lovin 1995).

A crucial process in maintaining the Western belief that each emotion is an underlying physiological state is the 'documentary method.' This process underwrites the reality of socially constructed 'facts' by a circular logic. An unobservable belief (like the fixed existence of a certain emotion in the person) is presumed, and overt events are selectively used as evidence of its existence or explained away if they refute it. This process is especially evident in the interpretation of gendered behavior.

Empiricism, History of

There are almost as many empiricisms as there are empiricists, but what these views or approaches have in common is an emphasis on the importance of experience to the formation of concepts and to the acquisition of knowledge. The foil to empiricism is rationalism, which emphasizes instead the importance to thought and knowledge of material that is in some sense independent of experience. The range of empiricist positions is vast, from the shocking view that all we can think or know about are our sensations to the mundane claims that experience plays some role in the formation of some of our concepts and in the justification of some of our beliefs. Empiricism of some form may seem both obviously correct and obviously the correct philosophy for science on the grounds that it is clear that one can only find out about the world by observing it; but this innocuous looking thought has been disputed, and in any case many forms of empiricism go far beyond it in their claims. It is also unclear whether empiricism ultimately supports or undermines claims to scientific knowledge.

1. History

Empiricism is a hardy perennial in the history of philosophy. It was extensively discussed in antiquity, often with considerable hostility. Plato disdained it, partly on the grounds that observation can only provide information about a realm of appearances less important and indeed less real than a more abstract realm that we may be able to grasp through a form of thinking that does not depend on experience. Mathematics was a model of knowledge for many ancient thinkers, and this is perhaps the area where empiricism is least plausible, since mathematical proofs do not seem to depend on observation. Nevertheless, empiricism did have defenders in the ancient world, with Epicurus often cited as its first clear exponent. He held not only that observation is the only source of knowledge about the world but that, insofar as they are taken as sources of information about the appearances of things, the senses never lie.

Empiricism also had its advocates in the medieval period. St. Thomas Aquinas wrote that there is nothing in the intellect which was not previously in the senses, though by this he meant to endorse only concept empiricism and not a strong form of knowledge empiricism. Concepts can only be formed with the help of sensory images, but some knowledge—for example, some knowledge about God—is available by means of logical argument independent of particular observations. Empiricism is perhaps most strongly associated with three philosophers of the seventeenth and eighteenth centuries: John Locke, George Berkeley, and David Hume. These British empiricists developed versions of both concept and knowledge empiricism. In some respects Berkeley (1710, 1713) can be seen as attempting to purify Locke's (1700) view of its nonempiricist elements and Hume (1739, 1777) as attempting the same for Berkeley. Both Locke and Hume appealed to Newton's achievements in physics for inspiration: Locke presented himself as

Newton's underlaborer, 'clearing ground a little, and removing some of the rubbish, that lies in the way to knowledge.' Part of that ground-clearing operation consisted of a vigorous rejection of the claim that we are born with innate knowledge, a characteristic point of dispute between empiricists and rationalists (cf Mackie 1976). Hume characterized his own project more ambitiously, as an attempt to do for the human sciences ('moral philosophy') what Newton had done for the physical sciences ('natural philosophy'), by providing a theory that explained the creation and behavior of ideas. Berkeley was less influenced by the model of natural philosophy, aiming instead to combat skepticism and to support theism. The result was an exceptionally lucid statement and defense of idealism, the view that the only things that exist are minds and their contents. Locke had not taken this step, hoping to hold on to a material world even if our knowledge of its nature must be severely limited, but Berkeley argued that only idealism was compatible with the principles of empiricism. Hume was an idealist too, but made less of a fuss than Berkeley about this aspect of their philosophies, in part because Hume wished to avoid metaphysics, even of a negative sort.

In the nineteenth century, John Stuart Mill carried forward the tradition of British Empiricism from Hume, including his idealism, though in Mill's (1872) hands the position is normally referred to as 'phenomenalism.' Mill held that physical objects are 'permanent possibilities of sensation': to say that there is a tree in the quad at a certain time is to say either that someone is having an appropriate arboreal experience at that time or that they would have had one if they had been in the quad. Berkeley famously preferred to account for the existence of the tree when no human is observing it by appealing to God's constant observation, but in one or two passages he clearly presages Mill's counterfactual alternative, which appeals to possible human observations rather than to actual divine observations.

Mill went beyond his British precursors, however, in his treatment of mathematics, the most obvious candidate for nonempirical knowledge. Most empiricists have adopted the strategy of admitting that pure mathematics is nonempirical but denying that it provides worldly knowledge, claiming instead that it tells us only about the logical consequences of our definitions. Mill, however, maintained that mathematics, however pure, is empirically based, an inductive inference from pervasive regularities in our experience, such as those involving the manipulation of objects.

Twentieth-century empiricism remained inspired by science. Logical positivists and logical empiricists saw empiricism both as a way to understand scientific claims and as a way to make philosophy itself more scientific and less metaphysical (cf. Ayer 1936). They especially pushed the conceptual side of empiricism, for example, in the verifiability theory of meaning, whose motto was that 'the meaning of an expression is its method of verification.' On this view, the experiences that would confirm a claim also tell us what it means, and a claim which no course of observation could either confirm or refute is either a mere definition or metaphysical nonsense. Empiricism in this century has also been promoted by scientists themselves, in movements such as operationalism in the physical sciences and behaviorism in psychology. Another influential empiricist strain in this period has been Pragmatism, especially as developed by the American triumvirate of William James, Charles Saunders Pierce, and John Dewey, and more recently in a radical form that rejects definitions and meanings by Willard Van Orman Quine (1951).

2. *Concept Empiricism*

Empiricism about concepts is the view that our concepts derive in some sense from our experiences. Hume offered what has come to be a canonical version of this position, arguing that all our ideas are copies of preceding impressions, meaning roughly that every concept is a faint image of the experiences that cause it. Thus, to take a favorable example, our idea of the color blue is supposed to a faint image of the particular blue experiences we have enjoyed. For Hume, the copy principle was not just a fundamental fact about our cognitive economy but also a powerful philosophical tool. Constructively, the copy principle is supposed to allow us to analyze the content of an idea or concept, since by tracing ideas back to their source impressions we determine what that content really is. Destructively, the copy principle is supposed to expose empty talk or thought, since if a putative idea has no possible source impression, it must be devoid of content. The copy principle obviously requires some general demarcation between impressions and ideas. Hume draws it subjectively, in terms of the relative 'force and vivacity' of perceptions, recognizing the vagueness of this distinction, but trusting that we will all understand the difference between the vividness of what one sees as compared with faintness of memory and imagination.

Hume's most famous applications of his copy principle were destructive, part of his program to expose the emptiness of metaphysics. Thus, although he allowed that we do have an idea of the 'necessary connection' that is supposed to glue causes to their effects, the source impression reveals this idea to be purely subjective. For that impression is merely the feeling of expectation of a familiar effect when we see a familiar cause, something that is obviously only in our minds. We cannot conceive one thing making another thing happen: all we can conceive is a pattern of objects. Indeed although Hume often did write as if we could conceive of external objects, he seems to have held that the copy principle rules out conception of these too.

Hume's antimetaphysical fervor was taken up by the logical positivists of the first half of the twentieth century. They took statements rather than ideas as the unit of analysis, and held that a statement is meaningful only if there is some specifiable experience that would verify it. They made an exception of mathematics and logic, which were allowed to count as meaningful even though not empirical, but only because they consisted of definitions and their consequences rather than substantive claims. Since philosophical truths have often been supposed to consist precisely of nonempirical truths about the world, it is not surprising that the verification principle was supposed to sweep away great swaths of traditional philosophical doctrine, not on the grounds that such claims are false, but that they are literally meaningless, just noise.

As with Hume, the logical positivist program also had a positive side: for those statements that did manage to be meaningful, their meaning comprised the experiences that would confirm them. From this it follows that all claims are claims about experiences. Some tempered this extreme view by speaking of observable states of affairs rather than experiences, thus making the data public. In the hands of some behaviorists in the philosophy of psychology, this brought about a kind of reversal of the positivists' original, experiential doctrine, since now rather than analyzing all claims as claims about experiences, experiences and other mental states are analyzed in physical terms. On this view, the real meaning of the claim that someone is happy is not that the person is enjoying a certain kind of inner life, but that they are disposed to behave in characteristically happy ways. Hostility to this position is the source of the story of the behaviorist who, upon meeting another behaviorist in the street, proclaims 'You're fine, how am I?'

Concept empiricism has been extensively criticized in both its negative and positive aspects. The demarcation that concept empiricism attempts to draw between genuine concept or meaningful statement on the one hand and nonsense on the other depends on making reasonably precise the notion of a copy of an impression or the conditions under which evidence confirms a hypothesis. This has proven remarkably difficult so that, for example, familiar accounts of confirmation have been shown to have the consequence that everything is evidence for anything else, a result that would make all statements meaningful and is anyway obviously false. The other conspicuous weakness of concept empiricism concerns the specific meanings it attributes to statements that it rightly classes as meaningful. The attempt to reduce the meaning of a statement to the evidence that would support it typically both attributes meaning the statement does not have and leaves out meaning it does have. This comes out clearly in the case of scientific hypotheses that traffic in unobservable entities and processes. A hypothesis about the behavior of subatomic particles does not include as part of its *meaning* the diverse and indirect kinds of empirical evidence in its favor, while that meaning does include claims about unobservable particles.

3. *Knowledge Empiricism*

Knowledge empiricism is the view that all knowledge of the world is based on experience. Put negatively, this is the denial of *a priori* knowledge of the world. Empiricism here opposes rationalism, according to which the fundamental source of knowledge of the world is reason, not experience.

Critics of knowledge empiricism generate putative examples of *a priori* knowledge. Empiricists deal with these cases in several ways, claiming either that the statement in question cannot be known *a priori*, because it is unknowable altogether or knowable but only through experience, or that that the statement does not really provide knowledge *of the world*. Thus, when René Descartes, the great seventeenth century rationalist, claimed to know *a priori* of his own existence, Hume could respond that the only knowledge one has of oneself is of one's experiences, which are known through themselves. Mathematical knowledge is another popular area for rationalists' examples of the *a priori* although, as we have seen, Mill claimed that even this knowledge is ultimately empirical, resting on observations of the result of adding together and dividing apart physical objects. The more common empiricist treatment of mathematical knowledge, however, is to admit it does not depend on specific experiences but to deny that it is about the world. Both Hume and the logical empiricists admit that definitions or analytic truths—such as that a bachelor is an unmarried man—can be known to be true without experience, but maintain that these statements have no factual content. They then analyze mathematical axioms as definitions and treat everything that is derived from them as analytic truths which can be known without experience but tell us nothing about the world.

4. *Empiricism and Scientific Knowledge*

Alongside the question of whether there can be any knowledge independent of experience is the question of how far empirical knowledge may extend beyond the experience upon which it is based. Since Hume's seminal discussion of the problem of induction, it has become difficult to see how knowledge can extend beyond actual experience at all. It is neither surprising nor worrying that any nondemonstrative inference from experience might in principle go wrong; but Hume gave a remarkably resilient argument that we can have no reason whatever for extrapolating in one direction rather than in another, even when dealing

with everyday claims about the immediate future or the unobserved past and present. The nub of the problem is that any justification for the future success of our methods of prediction or extrapolation seems itself to rely on such a method, leaving us arguing in what is apparently a vicious circle, not unlike trusting someone solely on the grounds that he or she claims to be trustworthy. Thus empiricism has been a friend to the skeptic: if Hume is right, we have no more reason to trust the most sophisticated scientific predictions than tea leaves or entrails.

Even empiricists who, ignoring the Humean problem of induction, help themselves to inferences from past to future observations have had the greatest difficulty in showing how scientific knowledge is possible, since scientific theories appear to traffic in claims about entities and processes that are unobservable, not just unobserved. As we have seen, this is denied by the concept empiricists, for whom no claims about the unobservable can even be formulated, but few recent empiricists have been willing to go down this road. Instead, they have had to face the problem of the underdetermination of theory by data, developed with special force in the work of Pierre Duhem (1954) and Willard Van Orman Quine (1975).

The problem is that no matter how much evidence there is in favor of a particular scientific theory, there exist in principle many other theories, incompatible with the first yet compatible with all the evidence. This creates an epistemic stalemate that seems to block warranted inference to any claim that goes beyond what is observable.

Empiricists have attempted to deal with the underdetermination problem in a number of ways. Karl Popper (1959) adopted a radical solution that was designed to solve the Humean problem of induction as well. It was to deny that scientists need to indulge in nondemonstrative inferences at all. Instead, they are to attempt to refute their theories and then replace them by better ones, where this process relies only on a deductive inference from the falsity of a prediction to the falsity of the theory that entailed the prediction. This is empiricism in the sense that the rejection of a theory is determined by observational data. Popper is one of the few philosophers of science to have attracted the respect of a significant number of practicing scientists, probably because scientists appreciate being reminded of the importance of considering what sort of results would tend to undermine a hypothesis, but Popper's view has been severely criticized by philosophers. Falsifying an interesting and successful scientific theory is not nearly as straightforward as Popper would have scientists pretend. Moreover, even if Popper's methodology could be put into practice, it would still be a form of skepticism, since according to him we never have any reason whatsoever to think that any scientific theory or prediction is even approximately correct, nor can we have any reason to believe any claim about the future.

Empiricism continues to play an important role in the study of knowledge within science studies. One example is the 'strong program' in the sociology of knowledge, which rests on a kind of psychological empiricism. As David Bloor (1991) puts the matter, the strong program assumes that perception and thought are distinct but asymmetrically related: perception influences thought more than thought influences perception. Within the philosophy of science, a recent empiricist approach to scientific knowledge and the underdetermination problem is Bas Van Fraassen's constructive empiricism. Van Fraassen (1980) introduces a technical sense of 'acceptance,' where to accept a scientific theory is not to believe that it is true, but only that it is empirically adequate, where a theory is empirically adequate just in case everything it says about what is observable is true.

Constructive empiricism is the view that the aim of science is to discover theories that are empirically adequate, not theories that are true. The content of the theory that goes beyond its empirical claims is to be regarded as a model which may serve its function of generating true predictions without itself being a true representation of an invisible realm. Constructive empiricism thus appears to solve the underdetermination problem, since although the theories underdetermined by the data will be incompatible with each other, their empirical consequences, which is all the constructive empiricist would have us believe, may be compatible.

Constructive empiricism can thus be seen as a form of moderate skepticism, but it is still too skeptical for those who think that knowledge or at least reasonable belief about unobservable entities and processes is possible. Constructive empiricism also faces the difficulty of providing a nonarbitrary distinction between what is observable and what is not, a tricky problem faced in one form or other by almost all forms of empiricism.

Employers' Associations

Employers' associations are formal organizations which specialize in the aggregation, definition, processing, and promotion in the political arena of the collective interests and goals of a distinct social class defined by its dominant position in the division of labor and its power to invest in market economies. Although the term 'employers' associations' applies specifically to the role played in labor relations, while the term 'trade associations' refers to the role played in industrial policy, the former is often used more generally to identify any kind of business interest associations. It is in this broader sense that it is used here.

Employers' associations are representative voluntary organizations—i.e., they are led by elected leaders and managed by professional managers—with a permanent staff for the administration of associational activities and the delivery of associational services, a budgetary process for the acquisition of funds and the accountability of their use, and a set of specific criteria defining the rights and duties of members. They can be analyzed in terms of their organizational properties, i.e., the domain of representation, the internal structure, the resources, and the tasks performed, and in terms of their degree of organizational complexity and relative autonomy. As formal representative organizations, they differ from other forms of organizations working for business, like clubs, law firms, and public relations agencies, as well as from more informal types of business association.

Business is a powerful pressure group in contemporary society, and employers' associations are just one of the four major ways by which businessmen can exert power and influence, both individually and collectively, and both in the market and in the political arena. At the level of the individual firm, entrepreneurs and managers play a crucial role through investment, production, and employment decisions in the market—which shape the economic and political environment of government policies—and through lobbying and other forms of pressure politics. Collectively, businessmen can exert power in the market through agreements for controlling prices, market sharing, the allocation of raw materials, and in the political arena through collective political action by its own specific representative organizations. In fact, in spite of social cleavages and cultural differences among entrepreneurs, and in spite of the different roles they play in diverse organizational settings (large and small businesses, private and public firms, local firms, and multinational corporations), the business class often acts today as an organized collective actor through its own specialized representative organizations. Why does this happens? Or, in other words, why should capital owners and top executives, who possess the discretionary power to invest, develop a need for collective interest representation?

Historically, there have been three main reasons by which employers may be brought to politicize their interests and to form organizations. The first is that their power to invest can be challenged by workers' unions. In most historical instances, business efforts to organize and coordinate actions came as a response to prior attempts by workers to pursue their interests by collective mobilization. Employers' associations have concerned themselves with assuring a stable and reliable labor force, and with the setting of shared rules of the game in labor disputes in order to institutionalize class conflict. Trade unions have become their most important institutional partners.

A second reason for entrepreneurs to organize have been the attempts to avoid cut-throat competition on the market, to prevent—or at least limit—the access of foreign competitors to the domestic market, to form a common front vis-à-vis the suppliers of basic resources. In fact, while free competition is a basic feature of capitalist market economy, competition, when pushed too far, can generate crises and contradictions which threaten the viability of the system as a whole. Formal coordination rather than that spontaneously created by the market may be necessary through associational activity and through government action.

The last remark leads to the third main reason for employers to organize, i.e., the systematic effort to influence government economic policies: resistance to decisions which either limit the freedom to invest, or

aim at redistributing wealth, or tend to increase the state direct intervention in key productive sectors. Democracies are consensus-bound, and competing political parties try to win the electoral support of social groups larger than business through fiscal, welfare, and other interventionist policies aimed at economic redistribution. Such policies are feared by employers because, directly or indirectly, they may threaten their discretionary power to invest, and consequently, they stir a political reaction which often takes the form of business interest organizations.

These three reasons have combined in various ways in different historical contexts to foster business associability. However, since, as will be argued later, greater power in the market place goes together with greater difficulties in producing collective benefits, collective political action for business can be defined as a second-best choice (Martinelli 1991). Whereas, in fact, labor can exert power only through collective organization, capital can exercise power also if not collectively organized. Capital can to some extent release itself from its dependence on labor through technical change, but labor cannot release itself from its dependence on capital for employment. Since, while it involves considerable risks and uncertainties, collective action does not grant capital owners similar competitive advantages as economic action in the market place, business interests become politicized whenever the power to invest is no longer sufficient for them to realize their economic interests. Associate action is therefore a second-best solution.

1. *The Status of the Research on Employers' Associations*

Research on business and employers' associations is much less developed than research on the working class and trade unions, in spite of early movements to the contrary. As early as 1907, at the first meeting of the German Sociological Association, Max Weber argued for assigning a very high priority to the systematic study of patterns of associations in general and to the associative activities of business in particular, which he considered a significant new form of collective action. Descriptions of the political role of specific firms and individual entrepreneurs, and references to the working of business associations as part of general pressure groups studies, do exist; but specific studies on the strategies, organizational structures, resources, activities, and attitudes of associations devoted to the promotion and protection of employer and trade interests have been rare (Ehrmann 1957, Linz and De Miguel 1966).

Only in the last two decades of the twentieth century has the study of business interests associations been developed through the collective research work of a group of political scientists and economic sociologists (Schmitter and Streeck 1981, Lehmbruch 1984, Offe and Wiesenthal 1985, Windmuller and Gladstone 1985, Grant 1987, Sisson 1987, Coleman 1988, Martinelli 1991, Sadowski and Jacobi 1991). Research focused on business associability both in national systems and in industrial sectors was mostly framed in the paradigms of neocorporatism and organized pluralism.

A set of related research questions have been studied. The question of why should capital owners and top executives, who possess the discretionary power to invest, develop a need for collective interest representation, has already been discussed; three further sets of questions have been addressed by recent comparative empirical research. The first concerns the distinctive character of business associability, i.e., the ways in which entrepreneurs and managers form an interest group different from others, and what is specific about it. The second focuses on the logic of membership, i.e., what organizational arrangements are required, given the basically individualistic and competitive structure of business interests, for entrepreneurs and managers to be able to associate with each other and to form collective interest organizations. The third set of research questions focuses on the logic of influence, i.e., what is the role of employers and business associations in policy making, both in policy advocacy and in policy participation. In all these questions the main dependent variables are the organizational dynamics, and the strategies that business interest associations develop, both in their relations with their members, and with outside groups and institutions, for their collective action to be successful.

1.1 *The Distinctiveness of Employers' Associations*

In contemporary poliarchies business is a privileged interest; it differs from other interests because it can exert power directly through individual pressures or by collective organized action of business interest associations; and, indirectly, because of the crucial role entrepreneurs and managers exercise over production, investment, and employment decisions. The specific nature of entrepreneurs' collective action can be better appreciated by contrasting it with that of workers. As Offe and Wiesenthal (1985) argue, unions and business associations are different, because their respective collective actions are based upon two different logics. Unions' collective action is more complex, since the definition of collective interests of individual workers results from their interaction in the union; this leads to an ongoing contradiction between bureaucracy and internal democracy, aggregation of individual interests, and formation of a collective identity. Business associations have an easier task: they represent a pure form of individualistic rationality, because each member can perceive individually what is his interest, and the association's task is only the coordination of individual behaviors into the most

effective strategy. Besides, labor has no alternative modes of collective action, whereas business has.

This view has been criticized, because it underestimates the problems of organizing business (Schmitter and Streeck 1981). Business and employers' associations cannot be seen only as tools of market rationalization. Besides problems similar to those of unions, they have to confront further specific problems rooted in the diversity of economic sectors. Collective action for entrepreneurs is not easier; on the contrary, it is more difficult than for workers for three major reasons. First, business associations must organize actors who normally compete with each other and have less incentive to cooperate than workers. Second, entrepreneurial culture considers competition a core, legitimate value, whereas for workers it is often seen as a violation of the value of class and group solidarity; while an entrepreneur who pushes his competitors out of business is recognized by other entrepreneurs as an example of efficiency and success, a worker outbidding a fellow worker to get his job runs the risk of being ostracized for disloyalty and breach of solidarity. Third, business associations have to organize a range of interests wider and more complex than unions; their members are both buyers and sellers of factors of production, goods and services.

For these reasons, the problem of producing collective political benefits, as well as selective benefits in the form of specialized services for members, should be even more pronounced and more visible for employers than for workers.

1.2 Relations with Members and the Logic of Membership

As any representative organization, employers' associations must, first of all, be able to recruit members and win their allegiance and support. The task is not an easy one, first, because collective political action for business is second best, a choice to be taken only when the discretionary power to invest is no longer sufficient to realize its economic interests.

Second, this task is not easy because Olson's theory of the logic of collective action applies to employers' associations even more cogently than to other large interest groups. Why should a rational entrepreneur, belonging to a large group (where the link between the contribution of the single participant and the outcome of the action is very weak, as it is in an industrial labor dispute), bear the cost of the action—as in the case of lost production because of a strike—when he can benefit from it without participating in it? This is the reason why employers and business interest associations develop a wide array of activities and services, such as legal and fiscal assistance, constant information about laws and regulations, professional education and specialized training, and so on, which are used as selective benefits aimed at fostering continuing membership.

Third, business and employers' associations in the relations with their members face another fundamental problem, i.e., the management of diversity. Some potential conflicts between their members are due to competition, while others arise from relations of mutual exchange. In fact, the more homogeneous a business association is with regard to its membership, the stronger is likely to be the competition among its members in the market. On the other hand, the more heterogeneous a business association, the greater the diversity of interests involving rates of exchange between different functional areas or sectors of the economy (Schmitter et al. 1980).

The management of diversity can be achieved through organizational development, defined in terms of the capability to organize complexity and to obtain relative autonomy from the state. Comparative research has shown that employers and business associations are the more effective the more developed and encompassing they are in scope and purpose; the more external effects and interdependences they are able to internalize; the more specialized and coordinated they are internally; the greater is their control over their environment; the more safely their supply of strategic resources is institutionalized; and the greater is their autonomous capacity to act and to pursue long-term strategies regardless of short-term environmental constraints and fluctuations. The logic of membership requires an articulated organizational structure that is capable of adapting to fragmented and segmented interests, and of fostering internal social cohesion and awareness of common interests among its members. The management of the relations between the association and its members depends on the specific demands and perceptions, on the number and dimensions of firms belonging to a given economic sector or region, the location of firms, and the degree of competition of the relative markets, and the degree of interdependency among firms; all variables which can foster tensions between individual and collective interests, and which can therefore affect the success of business representation.

1.3 The Role of Employers, Associations in Policy Marking

Pluralist and corporatist approaches have both studied the role of employers' associations in policy making. The basic difference lies in the fact that the former approach tends to consider organized business as one political actor among others (although often more influential than others) and consequently to confine its role to policy advocacy in pressure politics, whereas for the latter business organizations are active both in policy making and in policy implementation as a private interest lobby, and as effective intermediators between their members and the state.

In policy advocacy, employers' associations compete with other actors—such as unions, consumer asso-

ciations, environmental groups—in the attempt to influence the agenda of public policies, the formation of their content, and the way in which they are implemented once agreed in parliament and by government. Employers' associations try to capture distributional benefits through exchanges with the state, providing information and pledges of political support. Basic requisites for successful advocacy are: the constant processing of specialized technical information about policy making, the skilful evaluation of the economic and structural effects of policy proposals on members; the ability to mobilize political support at crucial stages in the progress of a policy proposal (which in turn requires the maintainance of internal cohesion—not an easy task for employers' associations given the great diversity of interests within them); the ability to cultivate public opinion, and to win public support, by presenting the specific purposes of organized business as compatible with broader national goals (such as economic growth, more effective competitiveness of the national economy in the global market, and employment opportunities); and the ability to establish relations with members of legislatures and top bureaucratic officials and to become parts of policy communities and 'iron triangles.'

According to other scholars, employers' associations can assume a second basic role in the political arena: the active involvement in formulating and/or implementing public policies. In order to play this more complex role, employers' associations must be able to coordinate the complex range of information and activities that they are asked to assume by their members, by other organizations like trade unions, and by the state. They must be independent of both their members and the state, and in some cases they must assume responsibility for controlling their members' compliance with agreed policy and for sanctioning their behavior.

Organizational development—which is an important variable in the analysis of the logic of membership—is also relevant in the analysis of the logic of influence. In fact, organizational development is also linked to policy achievement: associations that possess a developed organizational structure, sufficient autonomy from, and authority over, their members and the state, and are legitimated by the state, can play an effective role in the political arena. In turn, demonstrating effectiveness in securing the implementation of agreements leads to the delegation of greater authority to an association, thus increasing its importance with respect to both its members and the state.

In some countries, employers' and business associations have actually acted as institutions of social regulation, alongside markets, public bureaucracies, and communities. Whilst the guiding principle of the market is dispersed competition, that of the community is spontaneous solidarity, and that of the public bureaucracy is hierarchical control, the guiding principle of employers' and other organized interests is organizational concertation (Streeck and Schmitter 1985).

The case of the economies of continental Europe provides an interesting case. Here, the renewed focus on the central role of the market and of large multinational corporations in today's global economy does not explain completely the complexity of institutional responses to the problems of economic governance and industrial adjustment. Business interest associations, together with large firms, international markets, and government agencies have been part of a balanced mix of coordinating institutions and regulatory mechamisms (Chiesi and Martinelli 1989). This regulation concerns both the external environment and relations with other collective actors, and the internal environment in which associations play a role of self-regulation and mediation among various business groups.

2. *Conclusion*

The logic of membership and the logic of influence remain the key issue in this study of employers associations. Emerging lines of research focus on the newly emerging supranational and transnational forms of interest intermediation, and the evolution of pressure politics in contemporary polyarchies. The weakenings of the nation state, and the increasing interdependence of productive and marketing processes, in fact induce employers' associations to take action beyond the national boundaries. The focus is on the adaptability of national interest associations, on search processes, on structural and behavioral modifications, on organizational learning, design, and engineering, in the context of globalization and of the formation of supranational political entities like the European Union.

Employment and Labor, Regulation of

Employment regulation consists of the legal rules and institutions that constitute and structure the employment relationship. Employment regulations determine the nature of the labor contract, the obligations of each party, and the legal means by which each party may press for advantageous terms. It includes not only affirmative interventions by the state into the employment relationship through statutes, administrative regulations, executive orders, or other acts of positive law, but also the background contracting rules with which a buyer and a seller of labor power, that is, an employer and an employee, form an employment relationship.

The content of employment regulation determines the parties' bargaining power vis-á-vis each other (Hale 1923). For example, legal rules determine whether workers are free to join together into unions or whether such actions constitute unlawful conspiracies. Legal rules also determine whether and under what circumstances workers can lawfully strike and picket, and whether they can use secondary pressure or appeals to the general public to support their position. In these and many other respects, the legal rules that govern the employment relationship have powerful distributional consequences.

The content of employment regulation is a product of the each side's relative power in the political process. Employers and unions operate as pressure groups, lobbying directly or indirectly galvanizing public opinion to shape the substantive law of employment in ways that will give them advantage. Legislatures and judges respond to the competing demands of employers and employees when they decide cases and enact employment-related statutes (Kennedy 1997).

In most Western nations, there are two types of positive employment regulations—regulations that directly determine specific terms of the individual wage bargain and regulations that legally empower labor and management to engage in self-regulation (Kahn-Freund 1983). Most northern European countries have detailed legal codes that specify many terms of the employment relationship such as mandated hours of work, safety conditions, and childcare leave policies. Most also have specialized labor courts. In Germany and France, terms negotiated between unions and employers can be transformed into generally applicable legal standards for an entire industry or region (Weiss 1987). In contrast, Great Britain relies primarily on the common law to regulate the employment relationship, and leaves many important issues concerning employment outside the law altogether (Wedderburn 1986).

Countries differ as to the content as well as to the form of their employment regulation. For example, some countries treat the individual employment contract as imposing affirmative duties on both the employer and the employee. For this reason, in most parts of Europe and Latin America, an employer violates the employment contract by firing an employee without good cause. In the United States, on the other hand, the employment contract is at-will, which means that employees who are terminated unfairly have no legal recourse.

Countries also differ as to what kinds of rights, privileges, and protections they give to organized labor. Some countries give very broad protection to labor organizing, picketing, and strikes, and some do not.

There are also significant differences between countries as to the role they give to organized labor

in corporate decision-making. Germany, France, and the Netherlands have statutes that mandate that employees be represented in their firms by elected works councils. Germany and Sweden mandate that employee representatives serve on corporate boards of directors in certain types of firms (Summers 1980). In Great Britain and the United States there are no statutorily-mandated participation rights.

This article traces the development of employment regulation in the United States. While the specific evolution of employment law in the US is unique, parallels can be found in many countries.

1. Early Employment Regulation in the United States

In the United States, employment was regulated primarily by the common law until the 1930s. Prior to the nineteenth century, there were very few workers' as we understand the term today. America's workforce was largely made up of skilled masters, journeymen, apprentices, indentured servants, and slaves and others in status relationships. The employment relationship in the United States was regulated under the common law of the master–servant relationship.

The master–servant law was hierarchical in structure and harsh in application. Servants were required to give masters not only labor power, but also obedience. The law condoned the use of corporal punishment against insubordinate or lazy workers. In addition, most states had statutes making it a crime for a worker to quit his or her job. Other conditions for employment—such as the hours of labor, the length of rest hours, the grounds for dismissal, and so forth—were set forth in statutes, leaving little to individual variation or private bargaining (Steinfeld 1991).

In the mid-nineteenth century, there arose for the first time a significant number of people known as 'free laborers.' Some were immigrants and former farm laborers who migrated to cities to become factory workers. Some were former slaves, indentured servants, and others in the status of bound labor who were converted into free labor by the passage of the 13th amendment and antipeonage statutes after the Civil War. And some were journeymen and apprentices who became free as craft guilds declined (Steinfeld 1991, Tomlins 1993).

Free labor was not as free as its name suggested. A number of common law doctrines made the worker dependent upon his employer. For example, under the 'entire contract' doctrine, if a worker left the job for any reason prior to its term, the employer was not obligated to pay for work already performed. The entire contract doctrine gave employers an incentive to treat employees harshly, with the hope that they would quit and forego their right to payment for work already performed. In addition, it was unlawful for one employer to entice workmen from employment at another establishment. Thus, worker mobility was curtailed (Orren 1991).

Toward the end of the nineteenth century, a new common law doctrine was applied to govern employment relationships that had no fixed term. Beginning in the 1880s, courts began to hold that a contract of employment of indefinite duration is terminable by either party at any time for any reason or no reason at all (see *Payne* v. *Western and A. H. RR Co.*, 81 Tenn. 507 (1884)). Under this 'at-will rule,' an employer was permitted to fire a worker at will, and a worker could likewise quit at will and nonetheless be paid for work performed. Thus at its inception, the at-will rule was a liberating reform for American workers. It was the beginning of the modern law of individual employment (Orren 1991)

While the law of individual employment was undergoing a fundamental transformation in the late nineteenth century, the law of collective employee action was not. At common law, unions were treated as dangerous and unlawful combinations. Throughout the nineteenth century, strikers and pickets were indicted for criminal conspiracy. Organized labor and progressive reformers organized political opposition to the use of conspiracy doctrine against labor. As a result of such pressure, by 1900 some state courts changed their approach toward collective labor action, and held that peaceful collective action by employees was lawful so long as the union's objective was legitimate (see *Plante* v. *Woods*, 176 Mass. 492 (1900)).

2. Early Labor Legislation and the Doctrine of Substantive Due Process

Before 1900, most labor law was state law rather than federal law. Some labor organizations successfully pressured state legislatures to enact legislation favorable to workers, such as legislation exempting trade unions from the conspiracy laws, guaranteeing workers payment of wages, restricting the hours of work, and providing health and safety protections for minors and women. There was no federal labor legislation in these areas. The Supreme Court adhered to a narrow interpretation of the Commerce Clause that said that Congress had no power to regulate private employment except on the railroads. In addition, in the early twentieth century, Supreme Court adopted a doctrine, known as 'substantive due process,' that said that legislative protection for labor rights and employment standards was a violation of freedom of contract and therefore unconstitutional under the Due Process clauses in the 14th and 5th Amendment. The doctrine was articulated in the cases of *Lochner* v. *New York*, 198 U.S. 45 (1905), striking down a state law establishing maximum hours of work for bakery

employees, and *U.S.* v. *Adair*, 208 U.S. 161 (1908), invalidating a federal law prohibiting railroad employers from discriminating against employees because of union membership.

Ironically, for the first quarter of the twentieth century, the only federal legislation that had generalized application to American workers was not labor legislation but anti-monopoly legislation intended to break up the trusts and to promote business competition. The Sherman Antitrust Act, enacted in 1890, declared illegal 'every contract, combinations in the form of a trust or otherwise, or conspiracy, in restraint of trade or commerce among the Several states' (15 U.S.C. X 1 *et seq*). At the time of its passage, proponents believed it was a business regulation that would help restore free competition to the product markets (Sanders 1999). However, in 1908, the Supreme Court held that the Sherman Act applied to labor unions, and imposed severe sanctions on union members for conducting a product boycott in support of organizing efforts (*Loewe* v. *Lawlor*, 208 U.S. 274 (1908)). The case was a bitter lesson for the labor movement, effectively ending the use of product boycotts in union organizing (Ernst 1995).

After 1908, the American Federation of Labor (AFL) began a legislative campaign to obtain a labor union exemption from the Sherman Antitrust Act. It joined forces with the Democratic Party in the congressional and presidential elections, and was rewarded for its efforts by the enactment of the Clayton Antitrust Act of 1914 (15 U.S.C. X 12 *et seq*). On the surface, the Clayton Act created an immunity for labor from the operation of the Sherman Antitrust Act. But in 1921, in *Duplex Printing Press* v. *Deering*, 254 U.S. 443 (1921), the Supreme Court gave the Clayton Act a narrow interpretation and held that it did not protect unions that were engaged in secondary activity from antitrust liability.

Despite the legal setbacks for unions in the 1920s, the railroad unions succeeded in obtaining legislation that gave them rights to organize and bargain collectively. After many decades of tumultuous labor relations and several unsuccessful regulatory attempts, the railroad unions and the railroad operators together drafted the Railway Labor Act of 1926. The resulting statute gave railroad workers a right to organize, protected them against dismissal for union activity, and imposed on unions and railroads a duty to bargain and to maintain the status quo while negotiations were in progress.

3. *The 1930s: The New Deal and the Origin of Contemporary Employment Regulation*

The 1930s was the decade of the Great Depression. With the election of Franklin D. Roosevelt and a Democratic Congress in 1932, the government embarked on an ambitious program of economic and social reconstruction called the New Deal that included affirmative steps to assist American workers.

The New Deal Congress passed three major statutes to address the problems of American workers. The first, enacted in 1932, was the Norris–LaGuardia Act, 29 U.S.C. XX 101 – 15, which declared that it was the public policy of the United States to support unionism and collective bargaining. The Act took away the power of federal courts to issue injunctions in labor disputes. Then in 1935, Congress enacted the National Labor Relations Act (NLRA), 29 U.S.C. X 150 *et seq*, which gave workers a legally enforceable right to organize, strike, engage in collective bargaining, and take other 'concerted action for mutual aid and protection.' The NLRA also established an administrative agency, the National Labor Relations Board (NLRB), to enforce those rights. And in 1938, Congress enacted the Fair Labor Standards Act, which established a minimum wage and set maximum hours of employment (29 U.S.C. XX 201 B 19).

The three New Deal labor statutes dramatically restructured the relationship between private employment and the state in the United States. All three were explicitly redistributive in their goals, and they all embodied the premise that it is legitimate, proper, and constitutional for Congress to legislate about the substantive terms of the wage bargain. Thus, they reflected a radical transformation in Congress' view of the capacity of government to intervene in the private economy (Irons 1982). Yet, the three statutes also retained a commitment to private bargaining as the core mechanism for establishing terms of employment.

There were also two important Supreme Court cases in the 1930s. In 1937, in *West Coast Hotel* v. *Parrish*, 300 U.S. 379 (1937), the Supreme Court abandoned the doctrine of substantive due process and instead upheld a state law setting maximum hours of work for women and children. That same year, the Supreme Court decided *Jones & Laughlin v. NLRB*, 301 U.S. 1 (1937), upholding the constitutionality of the NLRA and at the same time adopting an expansive definition of the Commerce Clause. These two decisions laid the groundwork for Congressional regulation of the private economy. They provided a constitutional foundation for the two-faceted labor law regime of the postwar era—legal support for collective bargaining and government mandated minimum terms of employment. As a result of the New Deal statutes, combined with rank and file determination and union organizing efforts, union membership increased from under 3 million in 1933 to more than 12 million by the early 1940s.

4. *World War II and the Postwar Period*

During World War II, the US government turned to private industry to help operate a wartime economy.

President Roosevelt also appealed to organized labor to help ensure labor peace. The unions agreed and gave a no-strike pledge in exchange for significant union representation on the War Labor Board and other government agencies involved with the war effort. After the war, the years of frozen prices and pent-up consumer demand fueled a major inflation. Unions, whose members' wages had been frozen for years, engaged in an unprecedented strike wave in an attempt to catch up with rising prices. Employers saw this is a propitious time to attempt to amend the NLRA and weaken its protections for unions. Employer associations waged a vigorous campaign and, in 1947, secured passage of the Taft–Hartley amendments. The amendments curtailed union power by prohibiting secondary boycotts, banning closed shops, and restricting union-only hiring halls.

In the postwar decades, unions continued to grow in numbers and strength. In 1953, the two competing federations merged to form the AFL–CIO. Throughout the 1950s and 1960s, unions successfully negotiated wage increases, cost of living clauses, health and pension benefit programs, and just cause dismissal protection for millions of American workers.

One area in which the labor movement made great strides was in the establishment of in-plant arbitration systems. Labor arbitration is a system of dispute resolution that uses a third-party neutral decision-maker, selected by the parties, rather than a judge or hearing officer to decide disputes that arise under existing contracts. During World War II, grievance and arbitration clauses spread to many industries with the active approval, and at times insistence, of the War Labor Board (Atleson 1998). After the war, arbitration clauses became widespread in the collective bargaining agreements (Stone and Van 1981).

Collective bargaining provided the primary form of employment regulation for American workers in the postwar period. However, the gains and protections obtained through collective bargaining only applied to unionized workers. In the 1960s and 1970s, Congress enacted employment laws that had general applicability. In 1964, the civil rights movement achieved the enactment of the Civil Rights Act which contained Title VII, 42 U.S.C. X 2000e – 17, a broad prohibition on discrimination in employment. Also in that decade, the labor movement succeeded in securing the enactment of the Occupational Safety and Health Act of 1970, 29 U.S.C. 651–687 and the Employee Retirement Income Security Act of 1974, 29 U.S.C. 1001–1461.

5. *The Decline of Unions and the Rise of Individual Employment Rights*

The New Deal system of employment regulation accomplished its redistributive goals throughout the postwar period. In that period, labor's share of national income rose and the labor movement held considerable political power. However, by 1979, that began to change.

The decade of the 1980s was a watershed for American workers. There had been a slow decline in union density from the mid-1950s onward, but in the 1980s union density plummeted as a result of increased employer opposition and changes in the interpretation of the NLRA that made it more difficult for unions to operate effectively (Stone and Van 1988). After 1979, for the first time since World War II, real wages began to decline. Average hourly and weekly wages declined by 11 percent between 1973 and 1990. At the same time, a wave of corporate takeovers and mergers produced massive employee dislocation. The three interrelated factors of union decline, wage decline, and job loss produced soaring rates of profit for corporations and hardship for American workers (Bluestone and Bluestone 1992, Kuttner 1997).

In response to the massive layoffs of the 1980s, state law-makers began to provide protections for the job security of individual employees. State legislatures enacted measures to provide protection for whistle-blowers, protection for privacy on the job, and other job-related rights. Also, some state courts began to carve out exceptions to the at-will employment rule and provide remedies for workers who were wrongfully dismissed. The expansion of individual employment rights in the 1980s shifted employment regulation from the federal government to the states. The shift corresponded with the demise of the union movement and the end of the redistributive impact of the New Deal system of employment regulation (Stone and Van 1992).

6. *The Prospects for Transnational Labor Regulation*

In the 1990s, unions further declined and income distribution became ever more unequal. At the same time, trade liberalization policies and the development of trading blocs introduced a powerful threat to domestic employment regulation—the threat of global regulatory competition. Businesses faced with competitive pressures from global trade or presented with lucrative opportunities for direct foreign investment to pressure national governments to weaken their labor standards and defer enforcement of the regulations they have. The threat of capital movement generates a downward spiral of deregulatory reforms. As a result of this regulatory competition, firms move around the globe like checkers, jumping from place to place to avoid onerous employment laws.

At present, the most pressing issue of employment regulation lies at the transnational level. Labor organizations and policy-makers in many countries have made proposals for a regime of transnational labor

regulation that could impose minimum global labor standards and thus limit regulatory competition. However, to date, none of them has been adopted. Instead, trade experts insist that labor considerations should not be included in trade agreements (Bhagwati 1994). Thus, the world trading system is evolving without any effective mechanism to protect labor standards, creating an unregulated global labor market in which companies can easily avoid domestic labor unions and national labor regulation.

In the emerging global labor market, employment regulation will not disappear, but it will be transposed. Just as in the early twentieth century, the doctrine of substantive due process served as an ideological barrier to state intervention in the labor contract, so too the present-day commitment to a form of free trade stripped of social concerns is an ideological barrier to the development of global labor rights. In this environment, employment regulation will occur through invisible mechanisms, subsumed in the emerging notions of property and contract, and will have the effect of exacerbating problems of inequality and social instability. Today's free trade orthodoxy threatens to prevent transnational actors from addressing social concerns, raising living standards, or redressing inequalities. An alternative regime of transnational labor regulation will be necessary if the emerging global economy is to promote social justice and protect the dignity of workers worldwide (Stone and Van 1999).

Encoding Specificity in Memory

The notion of encoding specificity was proposed, and has ever since been vigorously championed, by Endel Tulving. It is integral to his concept of an *episodic memory* system, which pertains to memories for personal experiences as opposed to mere knowledge (Tulving 1972). Tulving conceptualizes each episodic memory as embodied in a physical entity, referred to as a *memory trace* or *engram*, that serves to bridge the temporal gap between the episode and its recollection. According to the encoding specificity principle, the likelihood of a given cue eliciting recollection of the episode depends on how the episode was encoded into the trace.

Nowadays, it is easy to dismiss this notion as obvious, but at the time of its introduction around 1970 it was more commonly dismissed as obviously wrong. Key to this change in fortunes has been an increasing appreciation of the role of encoding, and in particular idiosyncratic encoding, in the memory process.

1. Idiosyncratic Encoding

Tulving and his associates were quick to credit Richard Semon with a biological rendition of the encoding specificity principle, and indeed of their entire conception of the episodic memory system (Schacter et al. 1978). But prior to this acknowledgment Semon was virtually unknown to psychology. By the time his views were translated into English (Semon 1921), mainstream American experimental psychology was taking an objectivist turn, and before long encoding was thought to add nothing to what could be objectively discerned from the stimulus conditions.

There were, of course, other approaches to psychology, some of which underscored the subjective nature of encoding. For example, gestalt psychologists used ambiguous figures to demonstrate that one and the same stimulus could result in distinctly different perceptions (see *Perceptual Organization*), and moreover they conceptualized memory for such perceptions as embodied in memory traces. Nevertheless, it was not until the adoption of the information-processing metaphor as the dominant model of cognitive psychology in the second half of the twentieth century (see *Cognitive Psychology: History*) that the concept of encoding assumed its current theoretical prominence.

Among the many demonstrations of the role of encoding in memory that came with the dawning of the information-processing era was Conrad's (1964) finding that an error in the written reproduction of a short visual sequence of letters tended to be acoustically similar to the correct letter. Thus, the letter S was 65 times more likely to be recalled as an F than as a B, despite not looking more like an F than a B. The implication is that performance in this task is mediated by inner speech, even though the letters are presented and reported silently. Such encoding is perhaps virtually universal under these conditions, but under other conditions encoding can be willful and idiosyncratic. The cocktail party phenomenon, for example, illustrates an ability to attend selectively to just one of multiple speakers. On the other hand, that such willful control is imperfect is shown by a special sensitivity to our own name spoken in what would appear to have been an unattended conversation. In this case, encoding is unwilled, yet clearly idiosyncratic.

Throughout the 1960s Tulving, among others, emphasized the hitherto neglected *recall* phase of *remembering*. Recall of an episode at any given time, he argued, depended on what was being encoded at that time, as well as on how the episode had been encoded into its memory trace (see *Memory Retrieval*). More particularly, he came to promulgate the encoding specificity principle—the dictum that recall of the episode depends on the relation between current encoding and the information available in the episode trace. Thus, the encoding specificity principle is best illustrated by experiments in which control is brought to bear on the encoding conditions prevailing at both the study and test stages of a memory procedure. A few examples warrant review.

2. Item-specific Context Effects

In a seminal demonstration of encoding specificity, Tulving and Osler (1968) presented a list of 'target' words (e.g., STOMACH, HEALTH, EAGLE), each being shown alone for some subjects (STOMACH), in the presence of a weakly associated 'cue' word for others (*empty* – STOMACH), and in the presence of two weakly associated cue words for yet others (*empty, hurts* – STOMACH). They then tested for recall of the target words. Of the subjects in each of the three study conditions, some were given free recall instructions (i.e., no specific cues), others were given one of the two cue words of each target word (e.g., *empty* – ?), and yet others were given both of the cue words (e.g., *empty, hurts* – ?). Subjects who saw cues at neither study nor test recalled, on average, 44 percent of the target words. The various groups of subjects for whom the cue, or at least one of the two cues, presented at study was also presented at test recalled an average of 60–62 percent of the target words, depending on the group. Subjects for whom no cue word presented during study appeared at test, or for whom the target words had been presented alone at study and tested with one or both of their cues, recalled an average of 29–36 percent of the target words, again depending on group. The authors drew the then-provocative conclusion that, 'specific retrieval cues facilitate recall if and only if the information about them and about their relation to the (to-be-remembered) words is stored at the same time as the information about the membership of the (to-be-remembered) words in a given list' (Tulving and Osler 1968, p. 599).

With the distinction between episodic memory and general knowledge yet to be drawn, it would have been natural to attribute the ineffectiveness of the extralist cues (i.e., words not presented at study but presented at test) to the weakness of their associations to the target words, and the effectiveness of the intralist cues to the temporary boosting of these associations in the study phase of the procedure. Evidence contrary to this account was provided by Thomson and Tulving (1970). In one of their experiments, target words were studied either alone (e.g., FLOWER) or in the context of a weakly associated cue (*fruit* – FLOWER), and tested under conditions of free recall (i.e., in the absence of explicit cues), or in the presence of the weakly associated cue (*fruit* – ?) or of a strongly associated extralist cue (*bloom* – ?), with a different group of subjects serving under each of the six combinations of study and test conditions. When no context words had been present at study, the proportion of targets recalled was, relative to conditions of free recall (.49), increased by the strong cues (.68) but not by the weak cues (.43). By contrast, when

weakly associated context words had been present at study, the proportion of targets recalled was, relative to conditions of free recall (.30), increased by the weak cues (.82) but not by the strong cues (.23). This pattern of results is not readily reconciled with what Thomson and Tulving called the hypothesis of associative continuity, whereby no distinction is made between episodic memory and general knowledge. It is, on the other hand, in keeping with a principle of encoding specificity operating within the realm of a distinct episodic memory system.

The critical finding in each of these two studies is the study–test interaction, which indicates that the relative effectiveness of different test conditions depends on the conditions under which the items were studied. Such interactions constitute the evidence for encoding specificity, and more generally for the premise of a distinct episodic memory system. In one of the many subsequent illustrations of study–test interactions (Fisher and Craik 1977, see also Morris et al. 1977), target words were presented in the context of either semantically or phonemically related words (*sleet* – HAIL or *pail* – HAIL). Recall was then measured in response to extralist cues that also were either semantically related or phonemically related to the target words (*snow* or *bale*). The semantically related cues were more effective than the phonemically related cues for words studied in the context of semantically associated words (.36 versus .22), but not for words studied in the context of phonemically associated words (.16 versus .18). This interaction is at variance with one particularly influential idea of the time, namely Craik and Lockhart's (1972) notion that memory for an item is determined by the depth to which it was processed, with semantic encoding being assumed to reflect greater depth than phonemic encoding (see *Memory: Levels of Processing*). Fisher and Craik suggested supplementing this idea with that of encoding specificity.

That specificity of encoding can occur entirely within the semantic realm is implied by the finding that a recall cue for an unambiguous target word may be more or less effective depending on its consonance with the context of the target word at study. Thus, *something heavy* is a more effective cue than *something with a nice sound* for the target word PIANO presented in the study sentence, 'The man lifted the piano,' but not for the same target word presented in the study sentence, 'The man tuned the piano' (Barclay et al. 1974).

Perhaps the most influential support for the encoding specificity principle has been the phenomenon of recognition failure of recallable words (see *Recognition Memory, Psychology of*). In his quest for a truly general theory of episodic memory, Tulving came to relinquish the widely held assumption of a qualitative difference between the 'copy' cue in a *recognition* test (i.e., the target word itself presented as a test item) and other kinds of memory cue, and suggested instead that the copy cue was, like any other cue, fallible, and so could prove ineffective even though another cue would be effective (Tulving 1983). To evaluate this suggestion, Tulving and Thomson (1973) presented three consecutive lists of 24 weakly associated word pairs (e.g., *ground* COLD, *head* LIGHT, *bath* NEED), and following each of the first two lists they re-presented in a different order the left-hand words as recall cues for the target right-hand words. The subjects expected to be tested the same way for the third list, and indeed they were, but not until they had engaged in two other tasks. First, they free associated to each of a sequence of stimulus words (e.g., *want*, *dark*, *hot*). Unknown to the subjects, each of these stimulus words had been selected as likely to yield one of the target words from the just-studied list (namely, NEED, LIGHT, and COLD, respectively). The subjects then looked over their free associates and circled any they recognized as a target from the study list. Finally, they were given the recall test they had expected, with the left-hand words from the third study list presented as cues for their respective paired words. A substantial proportion of the words produced in the free association task went unrecognized and yet were produced in the ensuing recall test. Across three experiments, the probability of a target free associate being recognized as a target was only about half that of its being recalled in response to the weak associate with which it had been paired. Subsequent research has shown this phenomenon of recognition failure of recallable words to be remarkably robust. Tulving and his associates have interpreted it in terms of the encoding specificity principle: the targets were encoded into memory traces in such a way that the traces tended to be more responsive to the context words with which the target words had been studied than to copies of the targets themselves.

This interpretation implies that level of performance on a recognition test may well depend on the congruence between the cognitive environments at study and test. Just such a relation was demonstrated at the very time the encoding specificity principle was being developed (Light and Carter-Sobell 1970). Subjects studied sentences that included a capitalized two-word phrase (e.g., 'The STRAWBERRY JAM tasted great') in anticipation of a memory test for these phrases. In fact, they were given a recognition test in which the test items were word pairs and the task was to decide whether the second word of each pair (JAM) had been included in the study list. Recognition of a target word was much more probable if its context was the same as at study (STRAWBERRY JAM) than if it was different (TRAFFIC JAM). Across various subconditions and experiments, probability of recognition, corrected for guessing, ranged between two and three times greater in the same context condition than in the different context condition.

Of course, *jam* is a homograph, as were the other target words in this study. According to the encoding

specificity principle, however, context may affect recognition of any word, and indeed context effects in the recognition of words that are not transparently homographic have been demonstrated. Thus, Tulving and Thomson (1971) found that a target word (e.g., WATER) studied alone was more likely to be picked out in a recognition test when presented alone (0.70) than when presented in the context of either a weakly (WHISKEY) or strongly (LAKE) associated word (0.49 and 0.59), and that a target word studied in the context of a weakly or strongly related context word (WHISKEY–WATER or LAKE–WATER) was more likely to be picked out at test when presented in the same context (0.85 and 0.88) than when presented alone (0.77 and 0.70) or in a different context (0.58 and 0.66).

Context effects in recognition memory have been shown to extend to nonverbal stimuli, such as faces. In one study (Watkins et al. 1976), subjects were shown photographs of unfamiliar faces, each paired with a descriptive phrase (e.g., *keeps tropical fish*, *drives an Italian sports car*, *works in cancer research*). The phrases and faces were then shown in a recognition test, with half paired as before and half re-paired. The subjects' task was simply to identify the faces regardless of context. Probability of identification was greater for same-context faces than for re-paired faces (0.84 versus 0.71).

In each of these examples, as with most other studies cited as support of the encoding specificity principle, encoding was controlled by manipulation of the physical environment. According to the thinking behind the encoding specificity principle, however, the effects of the physical environment are mediated by the internal, or cognitive, environment. Consistent with this premise, it should be possible to show, for example, context effects in recognition memory by having the subjects impose contexts in a purely mental way, and such effects have indeed been demonstrated. For example, if instructions in the study phase of a recognition memory experiment call for the mental filling in of irregular shapes with specified colors, then subsequent identification of the shapes, regardless of color, tends to be more accurate if they are shown filled in with the imagined color than with another color (Watkins and Schiano 1982).

3. General Context Effects

Memory may depend on the reinstatement of, not only item-specific contexts, but also general contexts shared by many or all of the target items (Davies and Thomson 1988). For example, there have long been claims of a beneficial effect of using the same room for study and test (Abernathy 1940, Smith et al. 1978; but see Saufley et al. (1985) for an example of a failure to replicate this effect). Similarly, an item encountered in the presence of a particular odor is subsequently more likely to be remembered in the presence of the same odor than in the presence of a different odor (Cann and Ross 1989, Angleton and Waskett 1999). In the same vein, recall has been found to be more successful when study and test are both on land or both underwater than following a study-to-test switch in these environments (Godden and Baddeley 1975). Also, memory tends to be more effective when drug or mood state at test matches that at study (see *Mood-dependent Memory*). And, like item-specific context effects, general context effects can be psychogenic. For example, adopting the perspective of a burglar or of a home buyer while recalling a story about an old house has been shown to differentially affect recall of such items as 'rare coin collection' and 'leaky roof' (Anderson and Pichert 1978) (see also *Schemas, Frames, and Scripts in Cognitive Psychology*).

4. Criticisms

Not all aspects of Tulving's account of encoding specificity are widely accepted. For example, its logic notwithstanding, there is little appeal to Tulving's (1983) argument that the interaction of study and test conditions precludes characterizing one episode as more memorable than another. We do not deny that Mother Teresa was a better person than Adolf Hitler just because in some ways (e.g., as an orator, artist, or military strategist) she probably was not, so why should we deny that some memories (e.g., my memory for the birth of my first child) are stronger than others (e.g., my memory for putting on my socks that same day)? More importantly, the very idea of episodes being encoded into discrete traces within a distinct episodic memory system is problematic. For one thing, it is an instantiation of Tulving's notion of availability. This notion has never been adequately operationalized (Watkins 1978), and consequently the distinction between encoding specificity and such process oriented notions as transfer-appropriate processing (Morris et al. 1977) is shaky at best. Also, the relation among traces has not been worked out. If, for example, memory for an item from a study list is represented in a trace, then how is memory for the list represented?

It is important to be clear that such problems refer to a particular conception of encoding specificity, and not to the idea itself. Indeed, in one guise or another, encoding specificity has become essential to contemporary interpretations of episodic memory.

Encyclopedias, Handbooks, and Dictionaries

According to one informed estimate, if a copy of every important reference work known in Western history were set side by side in chronological order, some three kilometers of shelf space would be required for their display. Ever since Plato and Aristotle first called for the assembling of what they named 'encyclopedia,' a challenge quickly accepted by one of Plato's nephews, Speusippus (d. 339 BC), intellectuals have tried to summarize and codify what they knew, either for general literate audiences or for specialized groups of colleagues. Of these three kilometers of systematized learning, those volumes that treat the social sciences would appear in only the last few hundred meters of material. This reflects both the fact that social science was not part of the trivium/quadrivium arrangement of classical and renaissance learning, and that official academic status was accorded these fields only during the twentieth century in most research universities.

The history of encyclopedias, handbooks, and dictionaries (designations which until at least the eighteenth century were used interchangeably) is distinguished not only by sheer quantity of printed material, but also by the quality of thinkers and writers who created and contributed to them. Pliny the Elder's *Natural History*, for instance, served as a model of organizing such material for 1700 years after its appearance in 77 AD, despite an odd mixing of fact and fancy throughout its 37 books. Francis Bacon devised in 1620 a huge encyclopedia of 130 sections which was never completed, but his mode of organizing knowledge was still consulted by Diderot and later compilers 130 years later. In 1817 Samuel Taylor Coleridge also put forth an ambitious reorganizing of all human knowledge, which he interestingly titled *Encyclopædia Metropolitana*.

The urge, then, to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West. Even in 551 AD when the love of knowledge and external conditions for its preservation reached an apparent nadir, Cassiodorus saw to it that the labors of the monastery he founded at Vivarium be dedicated principally to the preservation of worthwhile information, producing the two-volume *Institutes of Divine*

and Secular Literature. Vincent of Beauvois has long been identified as the finest encyclopedist of the Middle Ages, producing his *Speculum Majus* (*The Greater Mirror*) in 1244, made up of 10,000 chapters in 80 books, an achievement which held the field for sheer scope until the eighteenth century.

Alphabetical as opposed to categorically arranged encyclopedias began to appear at the end of the first millenium, although most have followed the latter rather than the former method of organization. The first grouping of all knowledge within a format that is recognizably modern, along alphabetical lines, was the *Grand Dictionnaire Historique* produced by Louis Moreri in 1674. The audience for such a work was already developed, for his venture went through six editions in the following 17 years, followed by still more editions in English.

Were Moreri and his contemporary compilers alive today, they would probably be astonished at the level of continuing interest in reference sources. Informed academic reference librarians and professional bibliographers now claim that we are living in a golden era of reference materials, especially if one uses sheer quantity of output as the vital measure of the gold standard. One director of acquisitions wrote of 'so many choices, so little money' regarding new reference books (Wilkinson 1997), and the editor of *The Book Review* of *The Library Journal* analyzed 'reference for a new age' with particular attention to the mesh of electronic and printed materials suddenly dominating publishers' catalogs (Hoffert 1996). A third expert notes that flashy graphics and other user-friendly alterations have attracted many first-time users to reference materials who before would have shunned their perceived complexity (Mantell 1997). Even a cursory look at the current availability of dictionaries, handbooks, or encyclopedias in the social sciences indicates that in some fields, for which before 1990 virtually no reference books (let alone CD-ROMs) were available, now have at their disposal a half-dozen fresh entries in the genre. And even at considerable cost, they are being bought by research libraries almost as a matter of course, just as the electronic forms have begun to encroach on printed versions. The latter may continue to exist into the twenty-first century, but will probably be relegated to the status of secondary resources, subordinate to the newer formats. Or they might persist as specialized bodies of information for ever smaller audiences. Overall, it is fair to say that the reference materials 'business' is thriving as never before, especially when measured by library acquisition budgets aimed in its direction, and the ultimate effect this outpouring may have on the way social science is conceived and used remains difficult to predict.

That said, however, no-one seems to be arguing that the latest entries into the reference book market are supplanting in quality of information or breadth of coverage some of the old standards. *The Encyclopedia of the Social Sciences* from the early 1930s will never be rendered entirely obsolete simply because so many of its contributors have themselves become the subjects of articles in later works. What was true in 1910 of the Eleventh Edition of the *Encyclopaedia Britannica*, still the nonpareil standard of reference works in English, is similarly the case for a range of earlier works. When authors close to the origin of a given field of research accepted invitations by reference publishers to write about their own scholarly innovations (e.g., Werner Sombart on 'Capitalism' in the *ESS*, Benedetto Croce's article on 'Aesthetics' or Edmund Husserl's on 'Phenomenology,' both in the 14th edition of the *Britannica*), later authors have been obliged to accept such statements as first-order expert testaments, beginning their reformulations from there. Surely some of this is going on today, for instance, in newer fields like 'cognitive neuroscience,' 'psycholinguistics,' 'psychobiology,' or 'economic psychology,' and a century hence these may well be accepted as foundational statements. But, for the time being, it is hard to distinguish the ephemeral from the more or less permanent when evaluating the raft of reference works that appeared during the last decade or so of the twentieth century.

It was not always so difficult to name the leading works to which scholars or novices could turn when searching for basic information regarding the social sciences, especially if one strays beyond the confines of the English language. There was a time, of course, when dictionaries, handbooks, and encyclopedias (which in Greek means 'general education') could have been viewed as a special genre of scholarly display, with Samuel Johnson's *Dictionary* (1755), Diderot's *Encyclopedia* (1751), or Voltaire's *Philosophical Dictionary* (1764) initially setting the tone for many modern versions that followed. As noted above, for some centuries prior to the Enlightenment, the words 'dictionary' and 'encyclopedia' were used synonymously, lacking precise meaning, e.g., when Rabelais around 1534 introduced the word into French literature, in *Pantagruel*: 'he has opened for me the true well and abyss of encylopedic knowledge' (*The Complete Works of François Rabelais*, University of California Press, 1991, p. 201). Though Rabelais meant simply 'knowledge' when using the term, within only 25 years a German, Paul Scalich, had published his *Encyclopaedia*, the scope of which conformed to today's usage. Since then, of course, untold thousands of such works have appeared in every major language.

But, unlike scholarly articles and books, rolling off the presses with merciless regularity, substantial reference works have until recently been rarely enough published that they eluded the standard procedure of critical appraisal brought to bear on most nonreference works. And they are hardly the innocent, bland summaries that the naive reader might take them to be. Each new entry into this crowded market must either claim to bring together for the first time a body

of knowledge which to that point had not been assembled by quite the same rules as those which constitute the 'new' rubric, or it must offer some other, less lofty advantage, such as lower price or ease of use. All of this is currently going in the world of social science publishing, and at an unprecedented rate, mostly owing, one suspects, to the huge composing advantages supplied by personal computers.

The positive result of the new technology lies in the superabundance of suddenly available reference resources, some of which will surely define for the first time entire realms of intellectual inquiry. A less sanguine prospect, however, is the burden this torrent of innovative materials places on those who must evaluate or use them. As the range of choices widens, the provision of useable criticism becomes ever more costly, and probably less reliable.

This was not always the case, at least regarding the social sciences. A fairly limited selection of well-known reference tools were at the disposal of researchers in the late nineteenth and early twentieth centuries, which gave this growing general zone of study a tidy coherence that today is all but gone. And whereas such an orderly presentation of knowledge, then common to a given discipline or subdiscipline, might today seem either unnecessary or epistemologically indefensible, for the founders of the social sciences (*Geisteswissenschaften*) over one hundred years ago, the task of proving to more established disciplines that intellectual coherence indeed existed within their upstart fields became a truly vital effort at self-preservation.

Within what we could now broadly call sociology, for example, systematizations appeared fairly early. This is interesting for a number of reasons, not least of which is the fact that sociology as a discipline was defined and taught (particularly in the USA) some time before its sister disciplines within the social sciences. It often played the role of *avant garde* as this new way of carving up the academic world began rearranging disciplinary boundaries. While many of today's practitioners are familiar, at least with the titles, of the *Encyclopedia of the Social Sciences* and *The International Encyclopedia of the Social Sciences*, or Robert E. L. Faris's *Handbook of Modern Sociology* (1964) or Neil Smelser's *Handbook of Sociology* (1988), most are not aware of this genre's substantial tradition, especially as produced in Europe. It is now commonly supposed that Faris's was the first handbook of American sociology to be published, since it was widely distributed at the time and was fortunate in appearing just as sociology became a 'growth industry' on campuses worldwide. But even some reviewers at the time knew better, e.g., Joseph Gittler's opening line in his review: 'With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one' (Gittler 1965, p. 335). But it must have seemed like much less of a 'milestone in the field of sociology' as the publisher had characterized the *Handbook* through its mailed advertisements to ASA members if one considers the substance of the reviews it received. The book was probably taken as a handy cribbing device for graduate students and young instructors, glanced at perfunctorily, then parked on the shelf with similar volumes which Rand McNally had become good at marketing.

As Gittler was hinting, the history of sophisticated handbooks that sought to introduce audiences to new trends of analysis is in fact long and distinguished, though it is quite true that only a few of them were in English. Carl von Rotteck and Carl Welcker edited the *Staats-Lexikon oder Encyclopädie der Staatswissenschaften* (1834–43), the oldest the author has found, adding up to fifteen volumes at 800 pages each. (Even though the social sciences hardly existed at that time, formally speaking, the subject matter in the *Encyclopädie*, as well as the other sources named below, included much of what we would now recognize as such.) In 1852 and 1853, Charles Coquelin oversaw production of the *Dictionnaire de L'économie Politique* in two volumes (1858 pages). Such works 'came dear,' as Dickens would have put it. The copy the author examined bore an inscription from September 1853, noting that the price paid in Piccadilly was £3.80, a very substantial amount of money at the time. Male manual workers in England then earned on average 9s.6d per week (or about £2 per month), with child laborers making perhaps 2s. per week, and domestic servants settling for much less (as per Caird's survey of 1851, reported in Burnett 1984, p. 29). Considering that the price of bread was around 1s. or more per loaf, or 11% of a week's salary, these early reference works would cost in today's terms the equivalent of two months gross earnings, or many thousands of dollars each, that is, if one were to apply every pence earned to the cost of the books! Meanwhile in Italy, Gerolamo Boccardo brought out *Dizionario Della Economnia Politica e Del Commercio: Cosi Teorico Come Practico* (1857) in four volumes and 2800 pages, an equally lavish item.

The predecessor to Weber's famous *Grundriss der Sozialökonomik* was Gustav Schoenberg's *Handbuch der Politischen Oekonomie* (1882–85) in three volumes. Surely the most important of these early handbooks was edited by Conrad et al., *Handwörterbuch der Staatswissenschaften* (1895), an enormous work in seven volumes and about 6000 pages. Supplements were added in 1895 and 1897 of 2000 pages, and later editions (1898 and 1909–11) included two versions of Weber's famous *Agrarverhältnisse im Altertum* (first translated in 1976 as *The Agrarian Sociology of Ancient Civilizations*), the initial version 27 pages long, the second 136 pages. Ludwig Elster, part of Conrad's team, published a shorter version of the monumental work in only two volumes (1898), merely 2100 pages in length. The French were not idle, with Léon Say and Joseph Chailley's *Nouveau Dictionnaire d'Economie*

Politique (1891/92), amounting to two fat volumes of 2800 pages, and a supplement in 1900 of 271 more. Finally, the famous Robert Harry Inglis Palgrave edited *Dictionary of Political Economy* (1894, 1901, 1910), which in its last version came to three volumes and 2500 pages. This was soon followed in 1897 by William D. P. Bliss' *Encyclopedia of Social Reform*, one volume of 1439 pages (1908). What all this shows is that the notion of social science compendia has been around quite a while, and that most of the nineteenth-century European models were enormous publishing achievements. With the new century, ambitions and costs both shrank considerably.

Although in the space allotted here it is impossible to offer even a succinct history of social science reference books, some sense of how they evolved over the last hundred years or so might be conveyed simply by means of mentioning some titles which seemed to define a given discipline at a particular moment in its development. I will begin with my own field, whose history is more familiar to me than the related disciplines.

1. *Sociology*

Despite its senior status as a university discipline of independent identity relative to most of the other social sciences, Sociology has not generated as many references works as one might therefore expect. Thomas Nixon Carver's *Sociology and Social Progress: A Handbook for Students of Sociology* (Ginn, 1906; 810 pp.) was remarkable for its earliness. Yet the first real encyclopedic effort in English came only in 1992 under Edward Borgatta's editorship (Macmillan, 4 vols.), a full century after academic departments bearing the discipline's name appeared in several midwestern universities. (Two previous efforts, one edited by the noted scholar Michael Mann, did not live up to their titles as 'encyclopedias' proper.) Other useful compendia include Smelser and Swedberg's *The Handbook of Economic Sociology* (1994) and Frank Magill's *International Encyclopedia of Sociology* (1995, 2 Vols.).

The first handbook expressly designed for sociology was Alfred Vierkandt's *Handwörterbuch der Soziologie* (1931), a mere 690 pages long, followed in 1956 by Werner Ziegenfuss' *Handbuch der Soziologie* at double the length. And in 1962 Rene König edited the famous *Handbuch der Empirischen Sozialforschung* in two volumes of 2000 pages. In the USA one could begin with *An Introduction to Sociology* edited by Jerome Davis and H. E. Barnes (1927, 1931), a 900-page collaboration by seven authors. *Trends in American Sociology* followed in 1929, edited by George Lundberg, Read Bain, and Nels Anderson, with substantial chapters on the history of sociology, theory, social psychology, culture, rural sociology, urban sociology, educational sociology, social work, applied sociology, and methods. In 1937 Prentice-Hall sold *Man and Society* for $3.75, a 787-page work edited by Emerson Schmidt that tried to introduce students to all the social sciences simultaneously, covering everything from human values to income distribution to social psychology (Herbert Blumer's memorable chapter). The Gurvitch–Moore volume, *Twentieth Century Sociology*, published just following World War II (1945), seemed to have widespread influence, despite its execrable typos and layout. Its most distinctive feature, in addition to chapters on all the subfields of sociology at the time, was a second section of 250 pages that dealt with sociology in France, the USA, Britain, Germany, Latin America, Italy, Spain, Russia, Poland, Czechoslovakia, Romania, and Yugoslavia. This should have inspired later handbooks, and may account for the volume's popularity, since a distinctly ecumenical flavor swept the academy worldwide following WWII. Its authors Burgess, Parsons, H. P. Becker, Sorokin, MacIver, Znaniecki, Gurvitch, Roscoe Pound, Merton, Wach, Levi-Strauss, Faris, Albert Salomon, Bastide, and so on comprise a list of distinguished scholars that has not been matched since in a collaborative volume. The first recognizably 'modern' compendium was Joseph Gittler's *Review of Sociology* (1957), with chapters by recognized authors on the topics that soon became the staples of introductory textbooks. (Georges Gurvitch edited *Traité de Sociologie* in 1960, two volumes and 1000 pages, which seemed to have little impact in the USA.) And finally, Parsons himself had a go with his *American Sociology* (1968), with chapters by many scholars now in the twilight of their careers but who then were the bedrock of the mainstream, as it were.

One could say many things along these lines about the Smelser *Handbook*, which, given its size and unique position within sociology at present, deserves more than passing attention. This is especially so regarding the 'theories' that are put forth in the opening chapters as constituting 'the' new streams. For instance, neither Walter Wallace nor Jeffrey Alexander, the chapters' authors, wishes to consider postmodernism as a fact of existential and scholarly life, and therefore each throws himself into a strange time warp. Peterson had characterized Faris' introduction to his earlier compendium as 'blindly benign' (Peterson 1965, p. 254), which seems perfectly correct, even when rereading Faris today. One could say something similar about the theoretical terrain that is gingerly walked over in opening chapters of the Smelser *Handbook*. A range of old beliefs, now diminished by criticism from philosophers and literary critics—some of whom, incidentally, number among our most influential 'social' theorists—are trotted out as if nothing substantial had occurred to Western culture since 1964. It is as if the 'self' about which Parsons wrote with such conviction is still out there doing what selves have 'always' done. The same could be said about the precritical notion of 'science' and 'rationality' that figures in both chapters,

but especially in Alexander's, as if definitions of rational action and societal rationality are not now in themselves enormously contentious topics. Such limitations begin to indicate the intellectual boundaries of compendia of this sort, even those written by top scholars, for the adventurousness which might pervade a monograph composed by the same authors is diminished when they turn their hands to 'general' statements. Since reference sources, by common consent, are supposed to offer a summary of 'established knowledge' in a specific field or subfield, their authors typically draw back from the perimeters of discovery and innovation. Therefore, such works almost always lag behind the leading edges of thinking and offer their users a snapshot of what was confidently held to be true a dozen or more years before they are published. And with the ever-increasing rate of change in global intellectual culture, this poses a problem, particularly for printed reference sources, which may be met only via constantly updated electronic versions.

Comparison of Smelser's *Handbook*, at the time of writing the most recent entry into the genre, with earlier versions must remain fairly rough. Its predecessors employed other sorts of authors, aimed at different audiences (those not yet effectively lobotomized by videocretinization), and seem to have been composed in an atmosphere of genuine wonder and hopeful discovery regarding what social scientific study might yield for intellectuals and for the social order that supported them. This kind of childlike hope decomposed after the Gurvitch–Moore volume in 1945 and was replaced by a somewhat defensive, stuffy scientism in later compendia that reflected sociology's struggle to survive McCarthyism on one hand, and literary criticism on the other. But such books, while high on scientific rhetoric, seemed correspondingly low on political self-examination and savvy, while also revealing a foreshortened understanding of the philosophical problems necessarily part of sociological study. Still, it is uplifting to read these older books because their authors were usually straightforward and unpretentious. They tended to avoid enormous claims for the discipline, and offered up its fruits with a direct and unembattled character that nowadays is harder to find. It is probably no accident that after years of sociology bashing at the highest levels of government, both in the USA and in Europe, the field should have put out a summary package for broad consumption in hope of regaining lost ground, both within the cloister and beyond its high walls. We shall see if it succeeds as part of the long process of recertifying the discipline for a public which has been told repeatedly that nothing good can come of thinking about social reality in the way 'we' do.

Dictionaries for sociology began with Constantine Panunzio's pamphlet, *A Student's Dictionary of Sociological Terms* (California, 1937), continuing with Henry Fairchild's *Dictionary of Sociology* (1944). Only in the late 1960s were a number of competing volumes added to this small shelf of sociological reference books, including those of Geoffrey Mitchell (1968, 1979), George Theodorson and Achilles Theodorson (1969), and Thomas Hoult (1969). With Raymond Boudon and François Bourricaud's *Critical Dictionary of Sociology* (1989), celebrated scholars from Europe entered the field for the first time, followed in the 1990s with new dictionaries by David Jary (1991), Nicholas Abercrombie (1994), Gordon Marshall (1994, 1998), and Allan Johnson (1995), the former three being well-known British scholars. American sociologists have not of late contributed substantially to this genre.

2. *Anthropology*

Of all the social sciences, anthropology has been to date the least well served in terms of general reference books. This seems odd given the nineteenth century's penchant for vast compilations of quasianthropological data, e.g., Frazer's *Golden Bough* or Herbert Spencer's *Descriptive Sociology* (in fact comparative anthropology) in 12 volumes. The earliest dictionary of sociology I have found has now become a standard, Charles Winick's *Dictionary of Anthropology* (1956), with several later editions. *Anthropology A to Z* (1963), edited by Gerhard Heberer, Carleton Coon, et al., was based on an earlier German compilation of several hands. A recent trend among publishers to name reference books after their firm is typified in *The Macmillan Dictionary of Anthropology* (1986) edited by Seymour-Smith. The implication of this general practice—that a source's value to the user is more or less guaranteed by virtue of a firm's prestige—is not necessarily realized in practice. The most recent entry is *Barfield's Dictionary of Anthropology* (1997).

The discipline came into its own so far as reference sources go when Honigmann et al. produced the 1300-page *Handbook of Social and Cultural Anthropology* (1973) at a period when the social sciences reached a zenith of appeal among college undergraduates in the USA. Two misnamed volumes are Hunter and Whitten's *Encyclopedia of Anthropology* (1976) and Barnard and Spencer's *Encyclopedia of Social and Cultural Anthropology* (1996), both books of modest size. An interesting twist appeared with Bock's *Handbook of Psychological Anthropology* (1994), an instance, ever more common, of a reference book seemingly anticipating an intellectual or disciplinary trend before it gains acceptance at the institutional level. Such a rubric might well surprise both psychologists and anthropologists, relatively few of whom typically relate their two fields in any intimate way.

3. *Cognitive Sciences and Related Fields*

As soon as it became apparent in the 1970s to policymakers, governmental budget specialists, and

academics that improvements in psychopathic or sociopathic conditions could be more cheaply and quickly realized through the use of drugs and related somatic measures—as opposed to 'talking cures' or other socially based interventions—those fields that stress the linkage between individual physiology and the social order experienced a sudden renaissance. What seemed a neo-Darwinian rage for simplification overtook large zones of inquiry within the social and behavioral sciences. This has become so much the case during the 1990s that physiological reductionism often seems the order of the day, nearly extinguishing the behavioral component in explanations for an ever broadening range of ailments, from alcoholism to schizophrenia to general criminality. Given this intellectual environment, it is hardly surprising that a range of new reference books appeared which positioned themselves along a continuum of biobehavioral explanation of social action, from crude sociobiological reductionism to subtle neurological analysis of brain function and behavior. Much of this new wave of work stirs up controversy because of its real or imagined political consequences, most famously exemplified by the raucous reception given Herrnstein and Murray's *The Bell Curve* (1994), both in the ordinary as well as the academic press.

Among many such books published in the 1980s and 1990s, several might be mentioned for their innovative qualities. Michael Gazzaniga edited *Handbook of Cognitive Neuroscience* (1984), complemented by Dunlop and Fetzer's *Glossary of Cognitive Science* (1993), brought to even grander fruition in Wilson and Keil's *The MIT Encyclopedia of the Cognitive Sciences* (1999). Not unrelated are Wyer and Srull's *Handbook of Social Cognition* (1984, 1994) and Van Hasselt and Hersen's *Handbook of Social Development* (1992). More traditional, and connected with a field the roots of which go back at least to Saussure's posthumous masterpiece, *Course in General Linguistics* (1916), is Florian Coulmas's *The Handbook of Sociolinguistics* (1997), and what amounts conceptually to its complementary volume, Morton Gernsbacher's *Handbook of Psycholinguistics* (1994). These interestingly hybrid fields will undoubtedly grow in the twenty-first century, and it seems now that a biosocial focus will stimulate at least as much theorizing and research as did the more purely sociopolitical analyses during the preceding half-century.

4. Economics

Unlike some of the newcomers mentioned above, economics (or 'political-economy' as it was first known) has a long history relative to other social sciences, dating at least to 1776 and the publication of Smith's *Wealth of Nations*. Reference sources therefore abound. Before economics became an academic area, many guides to financial matters existed, of course, for example *The Hand-book of Trade and Commerce, or, A concise dictionary of the terms and principles of trade, commerce, manufactures, commercial and common law, etc, with tables of money, weights, and measures*, published in London in 1840. We also know from sources like Marx's *Theories of Surplus Value*, his three-volume anthology of annotated excerpts from the history of economic theory, that the literature on economic matters was by the 1850s quite well developed. Reference works, however, did not apparently surface until somewhat later. Palgrave's *Dictionary of Political Economy* (1894) is perhaps the most famous, and John Joseph Lalor's *Cyclopedia of Political Science, Political Economy, and the Political History of the United States: By the Best American and European Writers* (1881–1884) is another early example. So was Frank Bower's *A Dictionary of Economic Terms for the Use of Newspaper Readers and Students* (1905), kept in print until 1951 under subsequent editors.

More obviously pertinent to the discipline as it now exists was Herwith Price's *Economic Dictionary* (2 volumes, 1926–29), published in Berlin, as well as John Todd's *The Mechanism of Exchange: A Handbook of Economics* (3rd edn., 1927) (which became *The Science of Prices* in a 4th edition [1935] before reverting to its orginal title in its 5th). Frank Bower's brief *Dictionary of Economic Terms* reached its 10th edition in 1936, while Horton's *Dictionary of Modern Economics* appeared in 1948. Beginning in the early 1950s, the number and variety of dictionaries and handbooks concerning economics exploded, keeping pace with undergraduate enrollments at large public universities in the USA and elsewhere. Sloan and Zurcher's went through five editions between 1951 and 1970, while J. L. Hanson's reached its 6th edition in 1986, having been in print for 21 years. The latest dictionaries of economics include those by John Black (Oxford, 1997) and Bannock et al. (Wiley, 1998). On a larger scale, encyclopedias of economics began to appear relatively late, with the *Guilford Encyclopdia of Economics* in 1973/74, the *McGraw-Hill Encyclopedia of Economics* in 1982 and 1994 (2nd edn.), and *The Fortune Encyclopedia of Economics* in 1993. O'Hara has reverted in his choice of title to an earlier time, perhaps for political as much as intellectual reasons, with *Encyclopedia of Political Economy* in two volumes (1999). Another new entry is K. Liou's *Handbook of Economic Development* (1998), which broadens the discipline's terrain by including the global dimension.

5. Political Science

One of the earliest general reference works in this area is *Political Dictionary, forming a work of universal reference, both constititutional and legal, and embracing the terms of civil administration, of political*

economy and social relations, and of all the more important statistical departments of finance and commerce (London, 1845–46) in two volumes. It is instructive that those fields which in the mid-nineteenth century seemed closely enough linked, empirically and practically, to be treated within a single work, have since the mid-twentieth century been torn asunder into mutually incompatible and incomprehensible camps of specialists, who have little to say to one another except at ceremonial occasions. This situation is not necessarily an advance in social knowledge. The 14-volume *American Annual Cyclopaedia and Register of Important Events … : Embracing political, civil, military, and social affairs* (New York, 1862–1875) does not take in political science *per se*, though it would surely have uses to the historian of the discipline. Already mentioned, John Lalor's 1882 *Cyclopedia of Political Science […]* is among the first to use the term in the modern sense. Another amalgamated volume that typifies an era unafraid to mix disciplines was William Bliss' *Encyclopedia of Social Reform: Including political economy, political science, sociology and statistics* (1897), some 1439 pages in length.

Dictionaries and lexicons of political science are as numerous as encyclopedias or handbooks are scarce. William Connolly's *Terms of Political Discourse* (1974) and Maurice Cranston's *Glossary of Political Terms* (1966) were produced by scholars who subsequently became well-known for other work. Joseph Dunner's *Dictionary of Political Science* (1964), Jack Plano's *Political Science Dictionary* (1973), and Roger Scruton's *A Dictionary of Political Thought* (1982) are several among a score of similar works, which, as in neighboring fields, have been increasing in number, length, and complexity. Works of larger scope, in terms of length as well as conceptual breadth, include David Miller's *The Blackwell Encyclopaedia of Political Thought* (1987, 1991), Hawkesworth and Kogan's *Encyclopedia of Government and Politics* (1992, 2 vols.), and Goodin and Klingemann's *A New Handbook of Political Science* (1996).

6. *Psychology*

Just as the number of undergraduate majors in psychology typically overwhelms those of all the other social sciences, with ratios often running five or six to one or higher, so with reference books attached to this enormous field. The most distinguished early survey was surely William James's *Principles of Psychology* (1890, 2 Vols.), in print continuously ever since, in full and abridged versions. Clark Murray's *Handbook of Psychology* (1885, 1888), James Sully's *Teacher's Handbook of Psychology* (1886, 1909, 5th edn.), and the *Handbook of Psychology* (1889–91, 2 Vols.) by William James's equally famous contemporary, James Mark Baldwin, were each substantial compilations, and helped give psychology a head start toward producing a unified view of the social world vis-à-vis its sister disciplines. More eclectic viewpoints were expressed in Geoffrey Rhodes's *The Mind at Work: A Handbook of Applied Psychology* (1914) (with help from the noted sociologist, L.L. Bernard) and in Leander Keyser's *A Handbook of Christian Psychology* (1928, 2nd edn.). By 1931, however, the field had become thoroughly professionalized, as exemplified by Anderson, Buhler, and A. Freud, et al., *A Handbook of Child Psychology* (1933, 2nd edn.), and its companion volumes in the Clark University series, H. Banister et al., *A Handbook of General Experimental Psychology* (1934, 1125 pp.) as well as Allee, Allport, et al., *A Handbook of Social Psychology* (1935, 1995 pp.). Somewhat less innovative were W. B. Pillsbury's *Handbook of General Psychology* (1942), Kimball Young's *Handbook of Social Psychology* (1946), or Lindner and Selger's *Handbook of Correctional Psychology* (1947). Specialization within the discipline had already reached such a pitch that in 1950 Norman Munn offered *Handbook of Psychological Research on the Rat* (first published in 1933 as *An Introduction to Animal Psychology*).

The 1950s were a boom period for psychology reference works of the larger scale, reflecting the discipline's ever-widening influence in Western societies, with at least six more 'handbooks' entering the market. In more recent times innovation has once again become commonplace, with books like M. Gazzaniga's *Handbook of Psychobiology* (1975), Raaig, Veldhoven, et al., *Handbook of Economic Psychology* (1988), and Crawford and Krebs's *Sociobiology and Psychology* (1987), which later became the *Handbook of Evolutionary Psychology* (1998). The last volume intimates a strong connection currently being forged between researchers with refreshed enthusiasm for neo-evolutionary doctrines on the one hand, and sociobiological explanations for behavior on the other. This general tendency—in some ways a repudiation of earlier causal models for social action and psychological states—has been given substantial impetus by the Human Genome Project and related studies that attempt to link physiology with behavior in an unmediated fashion.

Encyclopedias have also been a more regular feature of psychology's disciplinary life than in other fields. Early efforts included McKean's *The Encyclopedia of Psychology: A series of graphic descriptions of human characteristics …* (Brussels, 1928) and Philip Harriman et al., *Encyclopedia of Psychology* (1946). The 1970s exploded with new versions varying substantially in size and scope. Robert Goldenson's *Encyclopedia of Human Behavior: Psychology, Psychiatry, and Mental Health* (1970, 2 vols.) brought together supplementary fields, just preceding the herculean effort by Benjamin Wolman et al. (300 editors and 1500 authors), *International Encyclopedia of Psychiatry, Psychology, Psychoanalysis and Neur-*

ology which took up 12 initial volumes (1977) plus a supplement (1983) and surely set a new standard for comprehensiveness of these allied research areas. Wolman also edited a one-volume *Encyclopedia of Psychiatry, Psychology, and Psychoanalysis* in 1996. Another half-dozen encyclopedias of psychology proper appeared during the late 1970s and 1980s, that of Raymond Corsini's running to four volumes (Wiley, 1984); Frank Magill's reference book production team brought out the *Survey of Social Science: Psychology Series* (1993) in six volumes, grandly renamed the *International Encyclopedia of Psychology* when reissued and reset in 1996. (Magill and his specialty editors have produced like volumes for all the social sciences in his *Survey* series.)

Ever since James Mark Baldwin published *Dictionary of Philosophy and Psychology* (1901–05, 3 Vols.; new edn., 1928), there has never been a shortage of dictionaries for the discipline. The author has identified 35 in English alone, some of them of continuing interest simply for the peculiarity of their design, at least by today's standards, e.g., William Taylor's *Taylor's Dictionary of Bio-Psychology, Genetics, and Various Branches of Applied Psychology* (1925, 148 pp.), or Vergilius Ferm's *A Dictionary of Pastoral Psychology* (1955). Of the more standard fare—a score or more appear in most standard bibliographies—many were compiled by the same scholars who oversaw production of the encyclopedias named above, with the most lavish entries all appearing during the 1990s.

A. Sica

Endocrinology and Psychiatry

The term '*psychiatrie endocrinienne*' ('psychiatric endocrinology') was first coined by Laignel-Lavastine in 1908 at a psychiatric congress in Dijon. Since then hormones always have been viewed as magic bullets for the treatment of a variety of psychiatric conditions and even Sigmund Freud predicted that hormone treatment might one day replace psychoanalysis. The first systematic research in this field was conducted by the Swiss psychiatrist Manfred Bleuler, who attempted to establish a connection between psychopathology and the secretory activity of endocrine glands. Influenced by his mentor, the neurosurgeon Harvey Cushing from Boston, he first directed his interest toward the effect of pituitary-adrenocortical hormones that are excessively secreted in patients with an autonomous adenoma at the pituitary gland. This adenoma produces corticotropin in high amounts unrestrained by the high plasma cortisol concentration that would normally suppress corticotropin release

through negative feedback action. Bleuler defined the 'endocrine psychosyndrome' and his descriptions of the behavioral changes associated with endocrine dysfunction are still valid today.

This article illustrates how Bleuler's concept has been translated into hypothesis-driven research and how that has ultimately led to a novel pharmacology that holds the promise of better antidepressant treatments. In addition, some examples are given showing how peripherally monitored changes in hormonal secretion can be viewed as the readout of disturbed central neurobiology. Finally, the current status of several selected hormonal treatments is examined.

1. *Stress Hormones*

The majority of patients with Cushing's syndrome, whether this is due to high plasma corticosteroid levels caused by ectopic secretion or high-dosed corticosteroid treatments, develop mood disorders, some with psychotic features. Only in very rare instances do manic or schizophrenic syndromes prevail. Apart from these disturbances in mood and behavior, cognitive impairments are also observed. Cortisol was suspected to account for neuronal loss and damage because the hippocampus, a brain area critical for cognitive function and richly endowed with receptors to which cortisol binds (corticosteroid receptors), was found to be reduced in size in patients with elevated stress hormone secretion. Based on some simplistic concepts, the central actions of cortisol have been described as detrimental to neuronal viability. This impairment, however, is only true when extremely high corticosteroid levels are experimentally induced (Almeida et al. 2000). Under such conditions, which probably mimic the clinical situation only very rarely, glucose uptake by neurons could be reduced, thereby making neurons vulnerable to other insults such as hypoxia or increased neuronal firing rates (e.g., during seizures). Such neuronal damage does not occur in situations of stress-elicited hypercortisolism. On the contrary, corticosteroids are essential to coordinate the organism's ability to cope with stress and promote the interpretation and storage of novel information, as well as facilitating the extinction of behavior that is not relevant under the immediate highly demanding situation. Significantly, under certain circumstances corticosteroids can act as neuroprotectants rather than as neurotoxicants.

Much of the current confusion related to the excitement about the phrase 'stress is bad for your brain' stems from the different functions that the two corticosteroid receptor types, the glucocorticoid (GR) and the mineralocorticoid receptor (MR) may exert. As studies by Ron de Kloet and colleagues (1999) in Leiden, the Netherlands, have revealed, MRs play a role in behavioral reactivity during novel situations, whereas GRs are involved in the consolidation of learned information. Moreover, the neuroprotectant effect of naturally occurring corticosteroids is due to their binding at MRs, whereas synthetic corticosteroids, which selectively bind at GRs, render neurons susceptible to cell death. This does not negate the fact that continuous exposure to stress or acute serious trauma may have long-term effects, increasing an individual's risk of developing stress-related diseases such as depression, anxiety, sleep disturbances, or post-traumatic stress disorder.

Table 1
Common changes in stress hormone regulation of patients with depression

- The 24-hour secretory pattern of corticotropin and cortisol shows elevated values
- The urinary-free cortisol content is elevated over a 24-hour period
- Corticotropin-releasing hormone (CRH) is elevated in the cerebrospinal fluid
- Binding of CRH is reduced in the frontal cortex
- CRH is overexpressed in the paraventricular hypothalamus
- ACTH response to CRH is decreased
- ACTH and cortisol response is increased following CRH in dexamethasone-pretreated patients (combined DEX/CRH test)

One possible explanation is the long-term effect induced by stress hormones on gene activity. It is of note that GRs and MRs, once activated by corticosteroids, act as powerful transcription factors that bind at specific DNA sequences to activate or repress transcription of a manifold of genes. Hormone-activated MRs and GRs can also bind to other transcription factors and through this interaction indirectly modify the transcription rate of many genes that are not primarily hormone regulated. Stress-elicited hormone secretion and its consequences on gene activity represents a perfect model for the study of the influence of environmental psychosocial factors on gene expression in the context of the pathophysiology of depression.

While it is well-established that the risk of developing depression depends on a complex multigenetic predisposition, it is an equally well-founded fact that depression can be precipitated by life events. On a functional level, such life events are associated with an increased demand to maintain homeostasis. This condition is associated with increases in stress hormone levels, which exert activity at the level of gene expression by transforming GRs and MRs into transcription factors. Under these demanding conditions subtle changes in the genetic blueprint, e.g., single nucleotide polymorphisms, may no longer be compensated, resulting in the emergence of a clinical phenotype. Given that stress hormones account for such effects by transducing environmental challenges on the cellular and genomic level, it would seem worthwhile

Figure 1
Stress hormones and depressive symptoms

to consider the reuptake options available for intervention. To better understand the rationale for today's pharmacological strategies, the relevant facts about stress hormones are listed in Table 1. It is important to note that elevations of stress hormones or aberrant responses to neuroendocrine probes are not a byproduct of emotional stress associated with depression. As illustrated in Fig. 1, stress hormone abnormalities precede the occurrence of depressive psychopathology, and conversely, a gradual normalization of stress hormone regulation is followed by an improvement in depressive symptoms. This time-course pattern rejects the possibility that abnormal test results are secondary to depression. A more straightforward interpretation links regulation of the stress hormone system to the pathophysiology of depression (Holsboer 1995).

The key regulator of peripheral stress hormones is corticotropin-releasing hormone (CRH), a neuropeptide synthesized mainly in the nucleus paraventricularis of the hypothalamus, an assembly of brain nuclei that serves as a relay between brain function and peripheral autonomous and endocrine regulation (Holsboer 2000). From the hypothalamus, CRH is released into small blood vessels that allow transportation of CRH to the pituitary where it evokes the synthesis and release of corticotropin. This hormone enters the blood circulation and once it arrives at the adrenal cortex, cortisol is secreted, which regulates CRH and corticotropin release through a well-balanced feedback loop. Key elements in this circuit are corticosteroid receptors that when hormone-activated, serve as a break on genes coding for CRH and corticotropin. The corticosteroid receptor hypothesis of depression submits that the signaling through these receptor molecules is impaired, resulting in a number of changes of gene activity, including that coding for CRH. This neuropeptide is not only involved in organizing the stress hormone system—which is traditionally called the 'hypothalamic-pituitary-adrenocortical (HPA) axis, although it involves many other brain areas including those believed to be involved in the neuropathology of depression—but also coordinates a number of behavioral signs and symptoms that aid for adaptation to stress.

In transgenic mice continuous overexpression of CRH, as documented to occur in depression (see Table 1), leads to increased anxiety-like behavior and other symptoms reminiscent of depression (decreased appetite, sleep disturbance, loss of libido, etc.) (Steckler et al. 1999). Similar findings in rats to which CRH was administered also suggest that CRH precipitates behavioral changes compatible with anxiety and the symptoms of depression. Consequently, research has focused on the possibility of reducing these negative effects of CRH by blocking its receptors. After the responsible receptor had been identified as the CRH-R1 subtype, drugs were developed that are capable of

antagonizing the actions of CRH specifically at these receptors. Indeed, in animal studies it has been shown that anxiety-like behavior under stress conditions or under conditions of withdrawal from drug abuse disappears when CRH-R1 antagonists are administered. Moreover, stress-induced sleep disturbances disappeared in rats when the administration of the stressor is combined with the CRH-R1 antagonist. On a neurochemical level it has been shown that CRH overproduction in the brain is associated with blunted serotonin responses to stress, whereas genetic invalidation of CRH-R1 receptors results in increased serotonin release. This neurotransmitter is strongly implicated in the pathophysiology of depression, and most currently prescribed antidepressants such as fluoxetine, paroxetine, and citalopram work on the principle of the enhancement of serotonin release. This favors the hypothesis that blockers of CRH type 1 receptors may also work as antidepressants through the enhancement of serotonergic neurotransmission and the correction of excessive central stress hormone drive. These considerations have led to the first clinical trial of a CRH-R1 antagonist in depression and its results have confirmed that this hypothesis-driven research has led to a novel pharmacotherapeutic concept (Holsboer 1999).

2. *Sex Hormones*

The differences between men and women extend to neuroanatomy, with male brains having a higher volume of cerebrospinal fluid and grey matter. Women's brains are denser in grey matter, consisting of neuronal cell tissue and connection-making dendrites. It is believed that the proportional difference between grey and white matter accounts for the different performances in neuropsychological tests where men demonstrate better spatial skills, but women are more verbally proficient. Moreover, estrogens, women's key sex hormone, secreted from gonadal glands, may explain some of the functional gender differences. These can be studied in postmenopausal women, whose endogenous estrogen production is reduced. Studies using a brain imaging technique have shown that estrogen administration to postmenopausal women can activate a brain region responsible for storing phonologic information, which may explain why women score higher in language tests.

Changes in estrogen secretion have been related to many psychiatric syndromes ranging from schizophrenia to depression and Alzheimer's disease. While the lifetime risk for schizophrenia is equal for men and women, it has been found that the age at which affected men have their first psychotic symptoms is three to four years earlier than in women who, after the menopause, have a second peak of disease onset. The later onset of schizophrenia in women has led to the hypothesis that estrogens protract the expression of schizophrenic symptoms (Häfner et al. 1993). One possible mechanism involved is an estrogen-induced decrease in dopaminergic neurotransmission. This attractive hypothesis still awaits corroboration from therapeutic tests using estrogens in combination with neuroleptics. Further studies will also have to address the contradiction of estrogen-elicited increases in the density of serotonin type 2A receptors in the forebrain and the role of these receptors in the pathogenesis, as well as in the treatment of psychoses. Numerous studies have shown that serotonin type 2A receptor blockade is a fundamental pharmacological requirement for the new drugs termed atypical antipsychotics, such as clozapine or olanzapine. On the other hand, serotonin type 2A receptor density has been found to be diminished in patients with schizophrenia, which would be consonant with decreased estrogen secretion with age.

Estrogens are widely prescribed, mainly by gynecologists and practitioners to alleviate mood swings associated with the premenstrual syndrome (Schmidt et al. 1998). Comparatively little systematic research has been conducted, although most published trials have reported beneficial effects. Whether estrogens are also effective in major depression is controversial, and careful inspection of the available data casts doubt on the possibility that the documented effects of estrogens upon serotonergic (increase of serotonergic 2A receptors in the forebrain), noradrenergic, dopaminergic, and cholinergic systems may translate into a psychotropic action comparable to established antidepressant drugs. The situation is perhaps different in older women where endogenous estrogen production is reduced, or in women where massive changes in estrogen secretion have occurred. Postpartal depression is a typical example of this condition and in these cases estrogen treatment has been reported to be beneficial. Perhaps the most meaningful application of estrogens in women with depression is its use as an adjunct to standard antidepressant treatment. For example, estrogen replacement treatment in combination with fluoxetine was found to be superior to antidepressant monotherapy in women who were 60 years or older. Another study where postmenopausal women with severe major depression were treated with imipramine, and where to those who did not respond either to estradiol or placebo was added as adjunct, the investigators failed to observe an improvement by the hormone. In the light of this, mild dysthymic and depressive symptoms may respond to estrogen supplementation either directly through central neuropharmacological actions or indirectly through the beneficial effects of estrogen on peripheral bodily functions such as libido, hot flushes, skin crawls, rheumatic pains, etc. (Santoro et al. 1999).

Perhaps the most compelling influence of estrogen on brain function is related to memory, cognition, and the apparent protective effect of estrogens with respect to the onset of Alzheimer's dementia. Multiple epi-

demiological studies have suggested that estrogen replacement therapy may protect against, delay the onset of, or slow the cognitive decline associated with Alzheimer's disease. In these studies, women who took estrogen replacement once they reached menopause had a significantly decreased likelihood of developing Alzheimer's disease. A cautionary note, however, seems warranted as this correlation does not necessarily reflect a causal mechanism. In favor of a specific role of estrogens as neuroprotectants are the results of a number of experiments investigating the interaction of these hormones with β-amyloid, which is thought to be causal in the development of cerebral plaques. These are in combination with fibrillary tangles, a characteristic neuropathologic feature of Alzheimer's disease. Estradial was found to protect against β-amyloid-induced cell degeneration and to reduce the production of this β-amyloid. The protective effect does not seem to involve estrogen receptor activation but rather is related to the antioxidative actions of these steroid hormones (Behl and Holsboer 1999). This is a clinically pertinent observation because the decreased risk of developing Alzheimer's disease might be outweighed by the increased risk of, for example, breast cancer (Grodstein et al. 1997). It was shown that the antioxidant effect of estrogens is independent of the hormonal effects via estrogen receptors. This opens up the possibility of developing 'designer estrogens' to provide long-term protection against the common causes of morbidity and mortality such as osteoporosis, coronary heart disease, and probably against cognitive decline associated with Alzheimer's disease.

Male sex hormones have only received scant attention in psychiatry despite their widespread use as anabolic drugs. The best-established effects of male sex hormones, especially of testosterone, are related to their effect on sexual function. Sexual desire, intense sexual feelings, and sexual activity are reduced in males with pathologically decreased testosterone levels, and are restored with testosterone treatment. In young women without sexual dysfunction one single dose of testosterone can induce markedly increased sexual arousal irrespective of sex hormone secretory activity. However, men who are not hypogonadal, i.e., have normal plasma testosterone levels, but a decreased libido and erectile function, do not respond to testosterone administration. In other words, decreased sexual arousal and erectile impotence are not responsive to testosterone in men with normal sex hormone status. That male sex hormones play a role in aggression has been inferred from studies in prisons, in which violent criminals were compared with nonviolent inmates. Many, but not all, of these studies agree that violent criminals have higher testosterone concentrations in both plasma and cerebrospinal fluid.

Perhaps the more important question relates to the psychiatric risk of testosterone administration in dosages used by young men to improve athletic performance or personal appearance ('body builders'). A recent examination of the effects of testosterone on mood and aggressive behavior found notable adverse psychiatric effects in a subgroup of 16 percent of the study population, which was found to exhibit manic symptoms. From animal experiments a large number of interactions of testosterone with neurotransmitters and neuropeptides have emerged. These findings, however, give no hint as to why supraphysiological dosages of testosterone might induce manic symptoms in a fraction of otherwise healthy males. There is no documented evidence that patients with mania have elevated testosterone despite their increased activity levels, including sexual activity. Likewise, no data exist showing that testosterone is decreased in depression and that men with plasma testosterone levels within the normal range benefit from testosterone treatment.

What still needs to be investigated is whether male sex hormones are beneficial as neuroprotectants and, specifically, if they are beneficial in reducing the formation of β-amyloid, the protein related to Alzheimer's disease. It is of note that the brain contains an enzyme that converts testosterone into estrogen.

3. *Neuroactive Steroids—Dehydroepiandrosterone*

A special situation has developed with regard to dehydroepiandrosterone (DHEA), which has received disproportional media coverage and has been promoted as a 'fountain of youth.' This steroid was first described by Adolf Butenandt, who pioneered steroid biochemistry and who later received the Nobel prize in recognition of his work. DHEA is often thought to be a 'weak androgen,' which is incorrect as it is produced only to a small extent by gonadal glands and stems mainly from the adrenal cortex. The error possibly derives from the fact that testosterone and DHEA decrease with increasing age, whereas cortisol secretion increases. The increasing cortisol:DHEA ratio with age, however, reflects the fact that the part of the adrenal cortex from which cortisol is secreted (zona fasciculata) remains unchanged, while the part of the adrenal cortex from where DHEA is produced (zona reticularis) gradually undergoes apoptotic change with the consequence that the very high level of DHEA, which is present mainly as sulfate conjugate (DHEAS), declines (Arlt et al. 1999). Particularly low DHEAS levels have been recorded in patients under chronic stress or with serious health problems ranging from arthritis to HIV infection.

DHEAS is produced not only in the adrenal cortex, but also in the brain. Indeed, plasma DHEA concentrations in rats have been found to be lower than those in the brain and this is not due to the accumulation of peripherally produced steroid. In contrast, astrocytes and neurons are capable of synthesizing DHEA from pregnenolone, a common steroid pre-

cursor molecule and a derivative of cholesterol. Because nerve cells have the capacity to produce DHEA, this steroid is called a neurosteroid (Rupprecht and Holsboer 1999). The main effect of DHEA in the brain is its antagonistic effect on gamma-aminobutyric acid A ($GABA_A$) receptors. Based on this pharmacological property, several studies in animals and humans were initiated that observed the memory-enhancing effects of DHEA, compatible with the actions of other $GABA_A$ antagonists. The finding of a DHEA-induced increase in rapid eye movement sleep, which has been implicated in memory storage, is in accord with this notion. In the USA DHEA has become an 'over-the-counter' remedy for all ailments associated with aging, but this occurs in the absence of a solid database that would allow the use of DHEA in clinical treatment.

Another recent approach is an initiative in France where 280 men and women between 60 and 79 years received 50 mg DHEA or placebo daily for one year (Baulieu et al. 2000). The overall clinical impression obtained from the data of these healthy individuals was that this kind of replacement therapy has beneficial effects on bone and skin status as well as on several behavioral characteristics including sexual function. More refined analysis of this study, when available, will perhaps help us to identify the role of DHEA in preventive medicine. Until such data are made accessible to the public, DHEA will be considered by health care professionals as a 'lifestyle' drug. The only exception that relates to psychiatric conditions are studies where DHEA was administered to patients with depression where DHEA levels are low. Preliminary results from these studies noted an improvement in ratings of depression and aspects of memory function, supporting the notion that decreased DHEA levels are amenable to pharmacotherapy in selected cases.

4. *Thyroid Hormones*

There is a well-documented relationship between thyroid disease and psychiatric symptomatology. In patients with hypothyroidism, depressive symptoms are very frequent and disappear when thyroxine (T_4) or triiodothyronine (T_3) is given as substitution. These two hormones are secreted by the thyroid gland and act at the interior pituitary to inhibit thyroid-stimulating hormone (TSH), and at the hypothalamus to inhibit the synthesis and secretion of thyrotropin-releasing hormone (TRH).

At baseline, patients with depression are euthymic, i.e., they have normal T_3, T_4 and TSH levels. However, when the pituitary is stimulated with TRH, about 25 percent of the patients show blunted TSH responses, which correlates with the CRH-elicited corticotropin increases. The blunted TSH response is explained by chronic hypersecretion of TRH from the hypothalamus producing desensitization of anterior pituitary TRH receptors and ultimately reducing responsiveness to exogenous TRH. These laboratory findings do not suggest that hypothyroidism should be treated with thyroid hormones, which, nevertheless, have been used in various ways to treat depressive illness, mainly in combination with other antidepressants. In the treatment of depression, T_3 mainly is used because this hormone is the active steroid hormone in the brain, locally converted from T_4 by a brain-specific enzyme called deiodinase that removes one iodine atom from the thyroxine hormone molecule.

The finding that brain concentrations of T_3 are as high as those of T_4, whereas serum T_4 levels are 50 times higher than those of T_3 is a strong argument for a key role of T_3 in the brain. T_3 formation is increased by antidepressants that increase the aforementioned deiodinase enzyme activity. T_3 enters neurons readily and binds to nuclear receptors modulating the activity of many genes directly or through protein-protein interactions. As of yet it is entirely unclear which of T_3's neurochemical effects are involved in its beneficial effects on brain function. It is of note, however, that T_3 affects the serotonergic system as, for example, T_3 administration to rats increases basal serotonin levels in the forebrain. Similarly, T_3 has been found to induce subsensitivity of presynaptic serotonin 1A autoreceptors, proposed as one of the major mechanisms responsible for the antidepressant effect of selective serotinin reuptake inhibitors such as fluoxetine. In line with the special role of T_3 in brain function is the finding that psychopathological and neuropsychological symptoms of hypothyroidism respond favorably, if the patients receive a balanced combination of T_3 and T_4 instead of the usual T_4 monotherapy.

T_3 has been used in doses of 25 μg/day in combination with antidepressants and most reports claimed that adjunctive thyroid hormone treatment may hasten the onset of response (Newman et al. 2000). While most of these studies reported intriguing findings, they are preliminary and await confirmation in studies using current standard methods for efficacy validation. Another interesting approach using T_3 is the augmentation of the antidepressant effect in patients who have failed to respond to their current antidepressant therapy. Nonresponse, partial response, or failure to achieve stable remission frequently haunt practicing clinicians. Many studies exist reporting that T_3 can amplify the antidepressant effect thereby shifting nonresponders or partial responders into responders. A meta-analysis found that all T_3 augmentation studies could confirm that T_3 was more effective than placebo when combined with antidepressants. However, when more rigid standards were applied, e.g., randomized control design, etc., the significant difference between T_3 and placebo as potential augmentors of antidepressant action disappeared. Comparing all available augmentation strategies, it seems clear that T_3 studies have provided

the most convincing database and that this justifies a critical evaluation of T_3 dosage and duration of treatment in combination with new antidepressants.

5. Summary and Outlook

This article has taken a few examples of how neuroendocrinology has shaped psychiatric research, although hormone treatments have not yet entered clinical routine. Estrogen replacement therapy is well-established, but it is doubtful that it works as an antidepressant and its clinical usefulness in preventing Alzheimer's disease is not yet validated. Whether similar effects can be expected from testosterone replacement in men is an open question. DHEA treatment has received much attention, but its promise as a rejuvenating hormone still has to stand the test of time. Although not unanimously accepted, the most robust database exists for T_3 augmentation studies, which need to be corroborated by applying current validation standards for clinical trials. The most exciting development to date is the novel opportunity to interfere with drugs that block the anxiogenic and depression-like effects of CRH. Perhaps this new pharmacology can put hormone treatment back on the map in psychopharmacology.

Where will the future lead us? Classically, a neuroendocrine factor has been defined based on phenotypic changes. Entering the era of functional genomics, we will depart from studying one gene at a time and will rather apply a global approach, which will result in a dramatic expansion of our knowledge of gene sequences, expression profiles, and protein functions. From this rapidly progressing genomic revolution we can expect the discovery of many new genes in the endocrine systems. This will pave the way to the identification of new drug targets and the analysis of the genetic susceptibility of individuals to develop diseases where endocrine dysfunction, e.g., impaired stress hormone regulation, plays a role. Finally, if single nucleotide polymorphisms are mapped for gene areas of interest, customized therapies for the prevention of singularly detrimental effects of hormone dysregulation will become available. These new opportunities will establish a new platform where endocrinology works in partnership with psychiatry at a behavioral, functional, and genomic level.

Endogeneity: Methodology

The concept of endogeneity arises when a distinction is made between a dependent variable, to be explained, and independent variables, used as explanations. A variable is endogenous if it is the dependent variable. A variable is exogenous if it is used to explain variations in the endogenous variable. There are various forms of endogeneity, such as in recursive versus interdependent systems. The concept plays an important role in statistical analysis of social science data, sometimes but not necessarily called causal analysis.

1. *Endogenous vs. Exogenous Variables*

In several fields in the social sciences a distinction is made between endogenous and exogenous variables. A simple example may clarify. In studies of social inequality researchers try to explain differences in the level of education that people achieve. Education can be measured, for example, as years of schooling or as less than high school, a high school degree, and so forth. The goal of social science analysis will then be to figure out how the level of education achieved varies with other characteristics, such as a person's social background, sex, race, and more. Social background can be measured in terms of parents' socioeconomic status or income. An early example of this kind of analysis in sociology is Blau and Duncan (1967).

In this example, level of education is the endogenous variable. The variables used to explain variations in the level of education are called exogenous. More generally, the variables that show differences we wish to explain are called endogenous, while the variables used to explain the differences are called exogenous. Often this goes along with a causal imagery. Exogenous variables are thought of as causes, endogenous as their effects. But there is no necessary connection; one may use the terms without implying causality (Sobel 1995). A simpler terminology for exogenous and endogenous is independent and dependent variables.

This distinction between exogenous and endogenous variables is used almost universally in quantitative social science. It arises in statistical data analysis, as in large parts of sociology, political science, and psychology. It arises also in mathematical analysis of theoretical ideas, as in large parts of economics and some parts of political science. But the distinction clearly is of relevance also in more qualitative research, such as in fieldwork and historical research, though less often used explicitly in those contexts. The distinction is simply relevant whenever there is some phenomenon that the researcher is trying to explain, which then is the endogenous variable, and there are some explanatory factors that are used to explain the phenomenon, which then are the exogenous variables. For example, in Skocpol's (1979) study of social revolutions, two exogenous variables are the state and agrarian structures in a society, while the endogenous is whether a revolution occurs or not.

2. *Recursive Systems: Causal Chains*

The example above can be elaborated. Consider what happens once people have achieved a particular level or type of education. They then often enter the labor market hoping to find a job. But the kinds of jobs people can expect to get depend strongly on their education. Psychologists are not hired to build bridges and engineers are rarely employed to provide mental-health services to children in despair. So in a next step, in explaining the kinds of jobs people find, education becomes an important independent or exogenous variable. It was endogenous, but is now an exogenous variable for explaining the type of job, which then is the endogenous variable. But the job may in turn become an important factor, thus exogenous, in explaining the salary received, which then is the endogenous variable.

And so it may continue. A variable, which once was endogenous, may be exogenous in another setting. There is a technical term for such reasoning, not important in itself, but sometimes encountered (from Bentzel and Wold 1946; see Hausman 1998). The variables entering into the reasoning are said to constitute a 'recursive system': parents' socioeconomic status influences education, education influences the type of job, the type of job influences earnings and career opportunities, and so forth. In causal imagery, they make up a causal chain. And it may also be that parents' socioeconomic status not only influences education, but also the job their offspring gets, for example through the network ties parents may have to employers or others who make hiring decisions. So an exogenous variable may be exogenous not only to one of the endogenous variables but to several of them.

For a set of variables to constitute a recursive system, there can be no feedback effects between them. Education may influence the type of job. But the type of job can have no influence on education itself. That such is the case is almost always tautologically true, provided the problem is carefully framed. The level of education is determined chronologically prior to the type of job, so there can be no feedback effect. This does not rule out that expectations and desires about future jobs will influence the education sought. But expectations about the future are not the same as the future. Enough of us have desired to be glamorous rock stars, outstanding violinists, famous war generals, or influential academics. Some may even have sought educational tracks correspondingly. A few succeed, most end up other places than aimed for. But whatever education and training we acquire, it usually has some impact on where we end up, though not always enabling us to get where we aspired to.

3. Statistical vs. Mathematical Analysis

Often the analysis of the relationships between variables is statistical. Researchers then typically use multivariate statistical methods. One tries to assess the joint influence of, say, sex and race on earnings. The goal is to see how the average level of earnings varies with sex, race, and so forth, not to explain the outcome for each individual. Similarly, if the endogenous variable is the type of job, say blue-collar, white-collar, professional, etc., then the goal of the analysis is to figure out how the percentages falling into each of these groups vary with education, sex, race, etc. Statistical social science analysis is eminently Holmesian, taking its cue from Sherlock Holmes. He argued that 'while the individual man is an insoluble puzzle, in the aggregate he becomes a mathematical certainty. You can, for example, never foretell what any one man will do, but you can say with precision what an average number will be up to. Individuals vary, but percentages remain constant. So says the statistician' (Doyle 1986, p. 175). And though few quantitative social scientists would accept the statement that aggregate relationships are a mathematical certainty or that we can successfully predict aggregate behaviors, the gist of Holmes' comment is correct and agreed upon: We investigate what on average goes on.

If the analysis is purely mathematical, where one tries to explore theoretical ideas by means of mathematical tools, then the writer traces out the logical implications of the relationships between the variables. For instance, from the knowledge of how producers and consumers act and interact in modern economies, economists will specify several mathematical equations that try to capture elements of these actions and interactions. A goal can be to investigate, using the mathematical equations as an aid for reasoning, what the impact of an increase in the interest rate will be for consumption, production, and finally the national product. For example, increasing the interest rate may lead to a decline in home sales, leading to a decline in building of new homes, with correspondingly increased unemployment in the home construction sector, and so forth.

4. Interdependent Systems: Mutual Dependencies

In some settings two or more variables may mutually influence each other, sometimes referred to as being interdependently related, constituting an interdependent system. For example, the amount of schooling a person obtains may depend on her family behavior: whether she is married or not, and the presence or absence of children. Those who marry early and get children may decide not to pursue lengthy education. But vice versa, a person's family behavior may depend on her educational behavior, whether she is in school or not (e.g., Marini 1984). Being in school may delay family formation and getting children. In this example, family status is endogenous to schooling and schooling is similarly endogenous to family status. They mutually influence each other.

In the social sciences many attempts have been made to assess the strengths and even possible directions of such mutual influences. These vary greatly in how successful they are.

A number of approaches have attempted to use cross-sectional data, with information about variables at one point in time, to determine the strength and direction of causation between them. One may obtain information on the amount of schooling and family status of say people 30 years old. One then tries, using advanced statistical techniques, to disentangle how the two mutually depend on each other. Such attempts suffer from the drawback that they do not take into account the sequencing of and the temporal relationships between the variables. They can hence not be considered particularly successful (see Alexander and Reilly 1981).

An example may help. A woman may get pregnant at age 18, after finishing high school. This may lead to a shorter subsequent education. But the shorter subsequent education did not influence the event of giving birth at age 18. The expectation or intent of not obtaining additional education may have influenced whether to go through with a pregnancy at age 18, but as noted above, an expectation about the future is not the same as the future. The shorter subsequent education may, however, shorten the time before the person has a second child, which in turn may delay further education. At age 30, we may observe only the family status at that age, the number of children, and the education obtained so far. But unless one also collected data on the sequence of events as they unfolded over the life cycle, one cannot determine how childbirth influenced education and vice versa how education delayed or led to additional childbirths. Without a temporal relationship between values on two or more processes, mutual dependencies are hard if not impossible to assess (Petersen 1995).

It is therefore widely recognized that such interdependencies are best studied by means of dynamic models using over-time data, where the sequence and types of transitions are studied as they occur over the life cycle. This was already pointed out by Lazarsfeld (1948).

In the context of the present example, with over-time data on several individuals, one can investigate how family status at age 18 influences schooling status at age 19, and vice versa how schooling status age 18 influences family status at age 19. Suppose that family status has no impact on schooling status, so that marital status does not influence whether one goes to school or not in the next year. But suppose that schooling status has an effect on family status, so that it does matter whether you are in school or not for whether you get married or not in the next year. One would then say that schooling is an exogenous variable

relative to family status. This is the same as saying that family status is endogenous to schooling status. If they both impact each other, then both are endogenous to each other. Having figured out what happens at age 19, one can continue with analyzing the mutual influences of family and schooling status at age 19 on the same variables at age 20, and so forth. One can sequentially unravel how the relationships between the variables evolve over time. Bentzel and Hansen (1954) argued that mutual dependencies between two or more variables should be studied in such a manner.

There is an extensive statistical literature that addresses how to investigate which variables mutually influence each other, requiring access to over-time data as described above (Engel et al. 1983, Bergstrom 1984, Petersen 1995). Probably the best way to advance knowledge about which variables are endogenous and which are not is to collect careful data on sequences of event or variables (e.g., Tuma and Hannan 1984). No statistical technique can compensate for deficient data.

But no matter the kind of approach used or even favored, quantitative or more qualitative, the distinction between endogenous and exogenous variables is essential. Usually, there is some phenomenon in which we try to explain variations: the endogenous variable. Usually, there are some factors used to explain those variations: the exogenous variables.

Energy Economics

Energy economics is the field that studies human utilization of energy resources and energy commodities, and the consequences of that utilization. In physical science terminology, 'energy' is the capacity for doing work, for example, lifting, accelerating, or heating material. In economic terminology, 'energy' includes all energy commodities and energy resources, commodities or resources that embody significant amounts of physical energy and thus offer the ability to perform work. Energy commodities—for example, gasoline, diesel fuel, natural gas, propane, coal, or electricity—can be used to provide energy services for human activities, such as lighting, space heating, water heating, cooking, motive power, or electronic activity. Energy resources—for example, crude oil, natural gas, coal, biomass, hydro, uranium, wind, sunlight, or geothermal deposits—can be harvested to produce energy commodities.

Energy economics studies forces that lead economic agents—firms, individuals, governments—to supply energy resources, to convert those resources into other useful energy forms, to transport them to the users, to use them, and to dispose of the residuals. It studies roles of alternative market and regulatory structures on these activities, economic distributional impacts, and environmental consequences. It studies economically efficient provision and use of energy commodi-

Table 1
Physical properties of common energy resources and commodities

Resource/commodity	Energy form	Physical form	Timescale
Crude oil	Chemical	Liquid	Depletable resource
Refined petroleum products	Chemical	Liquid	Storable commodity
Natural gas	Chemical	Gas	Depletable resource
Processed natural gas	Chemical	Gas	Storable commodity
Coal	Chemical	Solid	Depletable resource; storable commodity
Trees/biomass	Chemical	Solid	Renewable, storable resource
Battery	Chemical	Solid	Storable commodity
Electricity	Electrical	Moving electrons	Nonstorable commodity
Wind	Mechanical	Moving gas	Renewable, nonstorable resource
Hydro	Mechanical	Moving liquid	Renewable, storable resource
Geothermal	Thermal	Solid or liquid	Renewable or depletable resource
Uranium	Nuclear	Solid	Depletable resource
Solar radiation	Radiation	Pure energy	Renewable: nonstorable resource

ties, and resources and factors that lead away from economic efficiency.

1. *Properties of Energy Resources and Energy Commodities*

Other than all embodying significant amounts of physical energy, energy resources or commodities vary greatly. They may embody chemical energy (e.g., oil, natural gas, coal, biomass), mechanical energy (e.g., wind, falling water), thermal energy (geothermal deposits), radiation (sunlight, infrared radiation), electrical energy (electricity), or the potential to create energy through nuclear reactions (uranium, plutonium.) They have differing physical forms. Crude oil, most refined petroleum products, and water are liquids. Water includes available energy only through its motion. Coal, most biomass, and uranium are solids. Natural gas and wind are gases, with wind including available energy based only on its movement. Geothermal energy is available through hot liquids (normally water) or solids (subterranean rock formations). Solar radiation is a pure form of energy. Electricity consists of electrons moving under an electrical potential.

Resources can be viewed as renewable or depletable. Some renewable resources can be stored; others are not storable. These issues will be discussed more fully in a subsequent section. Table 1 summarizes the energy form, physical form, renewable/depletable distinction for several common energy resources and commodities.

2. *Energy Conversion Processes*

A fundamental property of energy is expressed by the first law of thermodynamics: energy can be neither created nor destroyed (except through nuclear reactions transforming matter to energy.) Energy can be converted between forms, and human use of energy typically involves such conversions for human ends.

Energy conversion processes are basic to human experience. Fire, providing heat and light, is a process by which chemical energy stored in the fuel (say, wood) is converted to thermal energy and radiant energy. Chemical energy stored in wood is the result of photosynthesis, whereby plants convert energy in sunlight to chemical energy, stored in the plant material. Carbohydrates in food are converted within the human body to thermal energy and mechanical energy, providing body warmth and movement.

The industrial revolution was characterized by a change from the use of hand tools, using human mechanical energy, to machine and power tools. Machine tools allowed the conversion of energy in falling water to mechanical energy (water wheels), or the conversion of chemical energy in wood or coal to mechanical energy (steam engines) for industrial processes.

Humans now routinely harness complex sequences of energy conversion processes to provide desired services. Crude oil is separated into refined products such as gasoline, diesel oil, jet fuel, and heavy distillates, that embody chemical energy. Gasoline or diesel oil are burned explosively in internal combustion engines, converting chemical energy into thermal energy. Heated gases push engine pistons, converting thermal energy into mechanical energy. Some is lost as heated gases or as radiant energy. The mechanical energy moves the automobile and, in the process, is converted to thermal energy through friction within the automobile or between the automobile and the road or air. Some mechanical energy is converted to electrical energy by a generator in the automobile, to power electrical equipment. Some electrical energy is converted into chemical energy in the automobile battery. To start the car, chemical energy in the battery is converted to electrical energy which is then converted to mechanical energy to turn the engine.

Similarly, coal combustion converts chemical energy into thermal energy to create steam, which powers a turbine in an electric generating plant, converting the thermal energy into mechanical energy, and then into electrical energy. Electricity can power a motor (converting to mechanical energy), heat a room (to thermal energy), or light a bulb (to thermal energy, then to light). This energy is later converted to thermal energy, which ultimately is radiated into space.

Energy economics recognizes the fundamental physical realities that (a) no energy is created or destroyed, but that energy can be converted among its various forms, and (b) energy comes from the physical environment and ultimately is released back into it. Thus, energy economics is the study of human activities using energy resources from naturally available forms, through often complex conversion processes,

to forms providing energy services. Several issues of the demand for energy will be examined next.

3. Demand for Energy as a Derived Demand

Demand for energy is derived from wishes to use energy to obtain desired services. It is not derived from preferences for the energy commodity itself. Energy demand depends primarily on demand for desired services, availability and properties of energy conversion technologies, and costs of energy and technologies used for conversion.

For example, consumers use gasoline to fuel an automobile or other motorized vehicle, converting gasoline to mechanical energy for motive power. The amount of gasoline used is proportional to the miles the auto is driven, and inversely proportional to the efficiency by which gasoline is converted to useful mechanical energy, measured as miles per gallon (mpg) of gasoline used by the automobile. Demand for gasoline is thus derived from choices about distances vehicles are driven, and their energy conversion efficiencies.

Similarly, electricity is purchased by consumers only to perform functions using electricity. Typical electricity uses include lighting, refrigeration, space heating, air conditioning, clothes washing, drying, dish washing, water heating, and operating electronic equipment such as computers or televisions. Electrical energy is converted to mechanical energy (motors in refrigerators, air-conditioning units, vacuum cleaners), thermal energy (space heating, clothes dryers, water heating), or radiation (lighting, television, computer monitors.) Electricity demand is derived from demand for the underlying services—comfortable space, refrigeration, cleaning, entertainment, information processing.

In each case, efficiency of energy conversion equipment also determines energy demand. Typically, energy conversion equipment is long-lived—automobiles, air-conditioning units, refrigerators, televisions, computer systems, furnaces. Consumers or firms can usually choose among alternatives with various conversion efficiencies; such choices influence energy demand significantly. To the extent that consumers and firms purchase these units with an understanding of their conversion efficiencies, expectations of future energy prices can influence choices of particular equipment. For example, high natural gas prices can motivate consumers to invest in home insulation.

In general, increased energy prices reduce demand by reducing use of energy services and motivating selection of higher conversion efficiency equipment. For example, gasoline prices influence demand through vehicle miles and fuel efficiency of vehicles. Vehicle miles are influenced by cost per mile of driving, including per-mile gasoline costs, equal to the ratio pg/mpg (where pg is the gasoline price), and other costs. Increased gasoline prices lead consumers to purchase more fuel-efficient cars. Both factors imply that increased gasoline prices reduce gasoline demand, with the vehicle miles adjusting relatively quickly, and vehicular fuel efficiency adjusting slowly as vehicles enter the fleet. Except for firms selling energy resources or energy commodities, similar issues are important for industrial and commercial use of energy.

4. Demand Substitution among Energy Commodities

Some energy services can be provided by several different energy commodities. Homes can be heated using electricity, natural gas, oil, or wood, since each can be converted to thermal energy. Cooking can use electricity, natural gas, propane, wood, or charcoal. Thus, energy commodities typically are economic substitutes for one another: The demand for a particular energy commodity is an increasing function of prices of other energy commodities.

This substitutability of energy is made possible by, and is also limited by, the available set of energy conversion technologies. Typically, one conversion technology can be used only for a particular energy commodity. For home heating, a natural gas furnace cannot use oil, electricity, or wood. Because conversion equipment typically is very long lived, substitution among energy commodities occurs only slowly, and then only when new equipment is purchased. Short-run substitution can usually occur only if several energy conversion technologies are available simultaneously for use by particular consumers, for example, homes that have a central natural gas heating system plus portable electric space heating units. Thus, various energy commodities can usually be viewed as imperfect substitutes for one another, with much greater substitutability in the long run than in the short run.

The degree of substitutability can be altered sharply by the development of new conversion alternatives. For example, historically, automobiles were fueled only by gasoline or diesel fuel, but technologies currently being developed would allow them to be powered by electricity, natural gas, propane, hydrogen, or other energy commodities. Once such conversion technologies are commercialized successfully, gasoline and other energy commodities will become highly substitutable in transportation.

5. Is Energy an Essential Good?

In economics, an essential good is one for which the demand remains positive no matter how high its price

becomes. At the theoretical limit, for prices unboundedly high, consumers would allocate all of their income to purchases of the essential good.

Energy is often described as an essential good because human activity would be impossible absent use of energy: living requires food embodying chemical energy. Although energy is essential to humans, neither particular energy commodities nor any commercial energy commodities are essential goods. Particular energy commodities are not essential because consumers can convert one form of energy into another. Even the aggregate of all commercial energy cannot be viewed as an essential good. Experience from low-energy research facilities shows that an extremely energy efficient home needs relatively little energy. Solar energy could generate electricity or heat water. Travel could be limited to walking or riding bicycles. Solar-generated electricity or wood fires could be used for cooking. For high enough prices of purchased energy, demand for purchased energy by consumers could be reduced to zero. Thus, commercial energy is not an essential good.

6. *Optimality of Consumer Choice*

Debate is ongoing about the extent to which consumers understand conversion efficiencies of alternative technologies and act on this understanding, and the extent to which manufacturers of conversion equipment respond to consumer preferences. Labeling requirements have been one policy response to concerns that consumers otherwise would have insufficient information to enable them to choose among energy conversion equipment. New cars have stickers with estimates of mpg under different driving cycles. Refrigerator labels estimate annual electricity use and cost. The concern has led to the adoption of energy efficiency standards for household equipment, such as refrigerators, under the belief that labeling alone is not sufficient to motivate optimal consumer choices. Similarly, the imposition of corporate average fuel efficiency standards (CAFE) for automobiles is a legislative response to concern that, on their own, automobile manufacturers will make automobiles less fuel efficient than optimal. These behavioral issues and the appropriate policy responses have not been resolved fully in either the existing literature or the policy community.

7. *Depletable, Storable Renewable, Nonstorable Renewable Resources*

Based on the speed of natural processes, one can classify primary energy resources as depletable or renewable. Renewable resources can be further subdivided into storable or nonstorable resources. Renewable resources are self-renewing within a timescale important for economic decision making. Storable renewable resources typically exist as a stock which can be used or can be stored. Biomass, hydro power, and some geothermal, fall in this category. The amount used at one time influences the amount available in subsequent times. Nonstorable renewable resources—wind, solar radiation, run-of-the-river hydro resources—can be used or not, but the quantity used at a given time has no direct influence on the quantity available subsequently. Most energy commodities are storable (refined petroleum products, processed natural gas, coal, batteries), but electricity is not storable as electricity. Depletable resources are those whose renewal speeds are so slow that it is appropriate to view them as made available once and only once by nature. Crude oil, natural gas, coal, and uranium all fall in this category.

Table 2
US energy supply (domestic plus imports)

Sources of energy consumed in the US, 1999 (quadrillion BTU)			
Depletable resources		Renewable resources	
Coal	21.8	Hydroelectric power	3.4
Natural gas	22.1	Wood and waste	3.5
Petroleum: domestically produced	15.2	Geothermal	0.3
Petroleum: imported	22.5	Wind	0.04
Nuclear	7.7	Solar	0.08
Total depletable resources	89.3	Total renewable resources	7.4

Initially, all human energy use depended on renewable resources, in particular biomass resources used for food, heat, or light. In the United States, renewable energy—human, animal, water, wood, and wind power—dominated energy supply through the middle of the nineteenth century. Only during the second half of the nineteenth century did a depletable resource, coal, surpass renewable resource use. Crude oil and natural gas started supplying large quantities of energy only in the 1920s.

Now the dominant use of energy (other than as food) in developed nations is based on depletable resources, particularly fossil fuels. Table 2 shows that of the total sources of energy consumed in the United States in 1999, 92 percent was from a depletable resource and only 8 percent was from a renewable resource, of which almost all was hydroelectric and biomass (wood and waste).

But depletable resource use cannot dominate for ever. Once particular deposits have been used, they cannot be reused. Therefore, a future transition from depletable resources, particularly from fossil fuels, is inevitable. However, which renewable energy sources will dominate future consumption is not clear. And there is great uncertainty about the timing of a shift to renewable energy resources. Related is the unresolved question of future energy adequacy: will the renew-

able sources of energy be adequate to satisfy demands for energy, once the fossil fuel supplies move close to ultimate depletion? These issues will be examined further in the next section.

8. *Depletable Resource Economics and the Transition to Renewable Resources*

The study of depletable resource economics began with articles by Lewis Grey (1914) and Harold Hotelling (1931), which examined economically intertemporal optimal extraction from a perfectly known stock of the resource, with perfectly predictable future prices of the extracted commodity. Many, but not all, subsequent articles maintained the perfect knowledge assumptions.

The essential result is that under optimal extraction paths the resource owner recognizes (explicitly or implicitly) an opportunity cost, or rent, in addition to the marginal extraction costs. All information about the role of future prices and costs would be embodied in this opportunity cost. The competitive firm would extract at a rate such that the marginal extraction cost plus opportunity cost would equal the selling price for the extracted commodity. Price would thus exceed marginal cost, even if the firm were operating perfectly competitively. This opportunity cost would evolve smoothly over time. As the resource neared depletion, the opportunity cost and the marginal extraction cost even at very low extraction rates would together have increased until they equaled the commodity price, at which time extraction would cease.

In depletable resource theory, market prices would increase gradually to the cost of producing substitutes, reaching that cost only as the depletable resource were nearing depletion. Substitutes would be produced only in small quantities until near the time of depletion. Market forces would, automatically and optimally, guide commodity prices upward so that when the depletable resources were nearing depletion, commodity prices would have risen to a point at which the demands could be fully satisfied by the substitutes.

In reality, the economic cycle for depletable resources is far more complex and more prone to error and surprise. The cycle typically begins with innovations that allow the resource to be utilized. Technologies improve over time, partially guided by economic forces and public policy decisions, but often in somewhat unpredictable ways. Generally, the magnitude and location of the resource base remains unknown, and exploration is required to identify resource deposits. But exploration is costly. Therefore, typically it is optimal for companies to explore only until they find sufficient resources to satisfy their expectations of near-term extraction. These discovered resources—referred to as 'reserves'—typically are only a fraction of the resource base and do not provide reliable estimates of the overall size of the resource stock. Firms may extract optimally from the proven reserves but cannot know with any certainty the quantity or extraction costs of the undiscovered resources. Opportunity cost would depend on the future prices of the extracted commodity, but future commodity prices will themselves depend on future demand and supply, which in turn depend on uncertain future discoveries, and which are therefore very unpredictable.

With this additional complexity and uncertainty, although the opportunity cost concept remains important, it seems appropriate to focus more attention on responses of markets to random changes in technologies, reserves, and other market information. And it seems appropriate to abandon the notion that markets will automatically and optimally guide the system to a smooth transition to renewable resources.

One central result does remain, however. If there is only a limited stock of a resource—undiscovered plus discovered—then there will be only a limited number of years during which the resource can be extracted. Here, there is an important commonality between energy economics and ecological economics (see *Ecological Economics*). The typical pattern includes an initial period in which the resource is not used, before technology for extracting and/or using the resource is developed. Extraction rates rise over time, perhaps rapidly, as the technology develops and demand increases. Commodity prices would fall with falling extraction and finding costs. However, at some time, rising costs due to depletion of the resource start overtaking the decreasing costs due to technology advances. The extraction rate declines until ultimately all of the economical resource stocks are depleted. At that point, the consumers of the depletable resource must substitute some other means of satisfying energy service demand.

If markets work well, the renewable resources will then be available in sufficient quantities and at reasonable costs. A transition to renewable energy resources will have been accomplished successfully, and there will always be an adequate energy supply to satisfy all demands at the prevailing market price.

However, given the complexity and the uncertainty, it is not obvious that the transition will work as automatically, as smoothly, or as optimally as is suggested above. It may be that fossil fuels saved for the future will ultimately never be needed because substitute forms of energy become available at a lower cost and at an earlier time than expected. Or it may be that fossil fuels are depleted rapidly, but that costs of renewable resources remain well above expected levels, or that quantities of renewable resources are more limited than expected. In either case, in retrospect everyone might wish to have made very different public policy decisions.

Figure 1
World crude oil prices: nominal dollars and real dollars (1996), beginning of year prices

9. *World Oil Prices*

In 1973, energy markets were disrupted when war broke out between Israel and neighboring nations. Oil supply was reduced by some member nations of the Organization of Petroleum Exporting Countries (OPEC). At that time there was relatively little excess worldwide oil extraction capacity. Consumers and producers expected further disruptions. Therefore, the supply reductions led to disproportionately sharp increases in the world price of oil, increases that remained well after the war. Another price increase occurred in 1979. The price of Saudi Arabian light jumped from $2.10 per barrel (/bbl) at the beginning of year (boy) 1973 to $9.60/bbl at boy 1974. The boy 1979 price of $13.34/bbl was followed by a boy 1980 price of $26.00 per barrel. Not until 1986 did prices drop to levels consistent with the current levels. Prices are well above the pre-1973 levels, even when adjusted for inflation, and remain very volatile. Figure 1 shows these boy annual prices in nominal dollars and in 1996 dollars, adjusted using the US implicit GNP price deflator.

Many explanations have been offered for the persistence of the world price increases, including assertions that they simply reflected a realization that oil resources were being depleted, that they reflected only random movements, and that they reflect independent choices by various nations attempting to satisfy developmental goals. The most obvious explanation, that they reflect a collusive exercise of market power by OPEC members, is the best supported by economic data.

These sudden jumps in oil prices led directly to a wide range of economic impacts, and indirectly to impacts through governmental programs responding to the perceived crisis. Worldwide recessions followed both price jumps, partly caused by direct disruptions to industry, partly by reductions in real income of oil-importing countries, and partly by tight monetary policies imposed to decrease oil-market-induced inflation. Price and allocation controls were placed on refined petroleum products in the USA, resulting in widespread shortages, manifested by long gasoline lines. And prices of other energy resources and commodities increased significantly in response to the oil price increases.

The oil price increases and ensuing economic problems led to profound changes in energy policy and energy markets worldwide. For example, in the USA, President Nixon declared 'Project Independence' to reduce sharply US dependence on imported oil. Oil exploration and development increased extraction capacity throughout the non-OPEC nations, particularly in the North Sea (Norway and the UK), China, and Mexico. Energy 'conservation' programs were enacted to reduce energy demand, particularly for oil. For example, corporate average fuel efficiency (CAFE) standards were imposed on the US automobile industry. Public- and private-sector investments in renewable energy R&D increased sharply, with emphasis on solar, wind, geothermal, and hydro power. New national and international organizations were created, for example, the International Energy Agency (IEA) in Paris, and the US Department of Energy. Programs were initiated to reduce economic impacts of oil disruptions: the US government purchased large quantities of crude oil for storage underground; oil-importing nations agreed to IAE-monitored minimum levels of oil storage. Although some changes have been reversed—for example, investment in energy R&D has declined since 1986—oil policies, particularly for oil-importing nations, are still shaped by these profound changes in the world oil price.

10. *Energy Conversion Industries*

In addition, activities are associated with commercial conversion of energy from one form to another, particularly to electricity, from hydro power, coal, natural gas, oil, nuclear fission, wood and waste products, geothermal, wind, or solar radiation. Energy conversion industries, for economic success, must be able to sell their product at a price higher than the cost of energy commodities used as inputs plus per unit capital and operating costs of the facilities. Energy conversion is never perfectly efficient, and some input energy is lost into the environment. Therefore, the price per Btu of electricity must be substantially greater than the price of energy commodities used to generate electricity.

Technological advance can be very important. New technologies are becoming available that increase the conversion efficiency from natural gas or coal to electricity, and which can be expected to have lower operating and capital costs. Such technological

advances can be expected to bring prices of these energy commodities closer together over time.

In addition to these technological changes, there are important ongoing changes in economic structure of the electricity production and distribution industry, throughout the world. In many countries, state-owned industries generate, transmit, and distribute electricity. In others, private electricity suppliers are subject to special economic regulation. The reason for governmental ownership or control seems to stem from two factors. Electricity is fundamental to economic activity, and many people have not trusted private industry. Second, production, transmission, and distribution of electricity have shown significant increasing returns to scale, and the industry has been viewed as a natural monopoly. Fearful that an unregulated monopoly would exercise market power and overprice electricity, most nations have chosen to own or to control tightly the industry.

Recently, however, smaller geographically distributed electricity generating plants that could reasonably compete with one another, have become attractive economically. Thus, the possibility for competition in electricity generation has been recognized. In addition, it is now realized that an electricity utility sells two classes of product: electricity delivery services (wires), and electricity. Although these two classes of product traditionally were bundled together into a price per kilowatt hour of electricity, in principle, the two could be unbundled and sold by separate companies. Electricity delivery service is characterized by increasing returns to scale, but electricity itself is not. Therefore, the possibility is open for a competitive market structure to sell electricity to consumers, separately from the electricity delivery services.

In some localities this movement toward privatization and deregulation seems to be very successful; in others, it has not been. At the time of writing, there is an intense and heated debate about whether deregulation of the electricity industry is appropriate, and if so, what is the appropriate form of deregulation.

11. *Environmental Consequences of Energy Use*

Much important environmental damage stems from the production, conversion, and consumption of energy. Costs of this environmental damage generally are not incorporated into prices for energy commodities and resources; this omission leads to overuse of energy. Concern about this issue is common to energy economics, environmental economics (see *Environmental Economics*), and ecological economics (see *Ecological Economics*), with energy economics and environmental economics literature attempting to assign monetary valuation of the impacts, and ecological economics rejecting the idea that a monetary value could be placed on environmental impacts.

Environmental impacts currently receiving most attention are associated with the release of greenhouse gases into the atmosphere, primarily carbon dioxide, from combustion of fossil fuels. The three primary fossil fuels—coal, petroleum, and natural gas—each include carbon. During combustion, carbon combines with oxygen to produce carbon dioxide, the primary greenhouse gas. Carbon dioxide accumulates in the atmosphere and is expected to result in significant detrimental impacts on the world's climate, including global warming, rises in the ocean levels, increased intensity of tropical storms, and losses in biodiversity. Fossil fuels account for 98 percent of the US carbon dioxide net releases into the atmosphere, and 82 percent of the releases of greenhouse gases, measured on a carbon equivalent basis.

Energy use leads to additional environmental damages. Coal combustion, particularly high sulfur coal combustion, emits oxides of sulfur, which, through atmospheric chemical reactions, result in acid rain. Automobile gasoline combustion releases oxides of nitrogen and volatile organic compounds, which, in the presence of sunlight, result in smog. Electricity generating facilities often use large quantities of water for cooling and release the heated water into lakes or oceans, leading to local impacts on the ecosystem. Extraction of oil or mining of coal can lead to subsidence of the land overlying the extracted deposits.

Pervasive environmental impacts of energy use, absent governmental intervention, imply that significant costs of energy use are not included in the price energy users face. These so-called externalities (see *Environmental Economics*) lead to overuse of energy and provide strong motivation for interventions designed to reduce energy use.

Energy, Geography of

The geography of energy is concerned with the interrelationship between space and energy as the most important factor in human activity. The production, distribution, and consumption of energy determine all of the basic functions of our existence: work and production, housing, education, transport, communication, and even recreation. Accordingly, an energy chain (Chapman 1989, see also Brücher 1997, Scheer 1999) connects production and consumption, with various stages interacting with space, the environment, and society (Fig. 1).

1. *From Energy Chain to Energy System*

The use of all kinds of energy (e.g., heat, electricity) and energy resources (e.g., coal, oil) follows such an energy chain, giving it an individual profile. Take, for instance, the example of coal in the old mining areas (the numbers refer to Fig. 1). Underground mining manifests itself at the surface with various installations for the extraction (2) preparation (4), and processing (5) of the mined resource with each installation, connected by transport lines (3). After (possible) storage (6), coal is burnt to produce heat for the consumer (8) or transformed (7) into secondary energy (e.g., coke, electricity). All mining activities harm the environment in various ways through noise, pollution, surface subsidence, and heaps of mine-tailings. At relatively few locations, the high energy content of this fuel and the great labor intensity required to procure it has resulted in extensive conurbations (e.g., Ruhr (Germany), Midlands (UK), Pittsburgh (USA)). Mining is also an important political object, whether as a basis of energy supply and industry, or as a problem area characterized by economic decline. In comparison to the energy chains of other resources, like uranium, it is evident that there are not only substantial differences between them, but also between their specific impacts on space and on political decision making.

The generation of electricity from water power only, as in Norway, or the exclusive supply of energy by hydrocarbons, as in Saudi Arabia, are rare exceptions. Nearly every country has to use different resources and to combine their respective energy chains. Such an energy mix is based on availability, price level, socioeconomic structures, supply security, environmental protection, and so on. Furthermore, there is a need to adapt to the strategies of the nongovernment energy utilities and find an appropriate degree of acceptance by the electorate (e.g., 'green' anti-nukes in Germany). Given these and other considerations, every government shapes its own individual energy policy. The less energy a country owns (or estimates it owns), the more influential the impact of policy on the economy of energy will be; a good example for this is

Figure 1
Interactions between policy, socioeconomic and spatial conditions and the energy chain

the decision of France to produce a maximum of nuclear electricity.

In any given spatial-temporal situation the ecological, and technical conditions of energy supply, together with the energy policy and the utility structures, form a complex system with its specific impact on space. Referring to Debeir et al. (1989), (1991) and Chapman (1989) we call it an energy system. One can find examples based on slavery, on the steam engine, or on the power grid. In the wake of technical and economic progress, and with mounting requirements for energy and its changing forms of application, existing systems are being replaced by new ones. Such a transition from an old to a new system is always combined with a fundamental change in the interrelationship between the energy chain and space.

2. *Changing Energy Systems: From 'Energy from Space' to 'Energy for Space'*

Before the Industrial Revolution, energy was obtained exclusively from biomass (e.g., wood, food muscle power), from water and wind, and thus exclusively from the surrounding space. Was this not, ultimately, the decisive incentive for the historical conquests of territories? As the energy content of these resources is very low, there has always been a need to concentrate it: through irrigation and fertilizing, the grain harvest and thereby the human workforce can be increased. Similarly, a ton of charcoal holds twice the energy content of a ton of wood. Let us have a look at the energy system of the Romans. In their capital, up to half of the population was comprised of slaves, the 'engines' of antiquity. They were 'powered' by bioenergy derived from cereals supplied from the whole empire via a converging network of roads and shipping routes. Finally, the system destroyed itself through the excessive consumption of energy for transport over excessively long distances. This is the inherent limit of any energy system depending on space (e.g., charcoal, water mills, working animals; see Debeir et al. 1989, 1991).

A new system, the exact opposite of the former, permitted the breakthrough of the Industrial Revolution. Since then, energy has been gained mostly from fossil fuels, each with an increasing level of energy content, from coal to uranium. The resources are exploited at a restricted number of locations. From there, highly concentrated energy can be distributed ubiquitously by modes of transport fed by the same fuel. Finally, with electricity and the internal combustion engine it is possible to transform one form of energy into another and this at any point on the earth, as with a diesel generator in an isolated Amazon village. In the past, the target was to concentrate a low energy harvest from a limited space. Now, the main purpose is to maximize energy efficiency, which means overcoming with minimum loss the distance between production and consumption.

3. *The Subjects and Profile of a Geography of Energy*

Of course, the geography of energy subjects are characterized by great variety, for example: the energy

chain of the resources (e.g., uranium: from pitchblende mining to nuclear power station); the original energy systems of different countries (e.g., the interrelationship between resources, huge distances, and import-export in Canada, see Chapman 1989); the impacts of energy policy on space (e.g., supply in eastern Germany after reunification), or specific problems in the Third World (e.g., firewood in the Sahel). Of topical interest to the current situation is the competition between nuclear power, fossil fuels, and renewable energies, with regard even to global change.

The geography of energy is often considered as a part of industrial geography (see *Industrial Geography*). Thus, Chardonnet's work *Géographie Industrielle* (1962) includes a volume on *Les sources d'énergie*. Indeed, the production and transformation of energy comprise industrial forms of processing; a power station is as much an industrial plant as a steel mill. In terms of location factors, energy production is similar to industrial production. Nonetheless, even in some publications entitled 'Geography of energy,' such as George (1950), a specific profile is missing. As in industrial geography, these publications focus too much on the location problem, leading an individual energy resource like coal to be treated as if it were a branch of industry (see George 1950, Sevette 1976). In contrast to these earlier approaches, more modern concepts have also been developed: Fernie (1980), Curran (1981), and Chapman (1989), for instance, insist on the dominant influence of policy, and Chapman shows a new methodical approach oriented by the energy chain. Energy is also being increasingly judged as an important sector in geography (see Calzonetti and Solomon 1985). Nevertheless, the differences between the energy and industry sectors in structure, procedures, and interaction with spatial and socioeconomic conditions have not yet been sufficiently elucidated. There are at least five fundamental differences:

(a) Let us begin with the energy chain. In industrial processing too, there is a sequence of stages between the extraction of raw materials and the production of finished products. Industrial processing, however, lacks the imperative cohesion between the beginning and the end: one can produce an unlimited variety of goods out of steel, even in so-called 'footloose industries' (industries without special links to location). In contrast to this, moreover, all 'energy resources' (except for the raw materials for the chemical industry, like oil) are entirely transformed and conducted to an energetic end use, passing by stages on exactly calculated locations. Furthermore, unlike industrial products, consumed energy cannot be recycled.

(b) Three types of energy are line-bounded: electricity, district heat, and gas (except liquefied natural gas). Due to the varying demand during the day, the week and the year, but also according to changing economic trends, the load curve fluctuates continuously. Therefore, line-boundedness requires large, even supranational organizations for transport and distribution (e.g., the European 'Union pour la Coordination du Transport de l'Electricité') which are not needed by industry.

(c) Whereas industry produces innumerable goods, energy is generated and used in only very few forms. But as it is basic to all human activities, there is an extraordinary demand for energy resources. They are extracted in large amounts, transformed in huge facilities (e.g., power stations, refineries) and shipped by bulk transport systems over great distances (e.g., tanker, pipelines, power grid). Only very big utilities, if not state companies, can afford that.

(d) Enterprises of such dimensions are both the very sought-after political instruments of the governments and competing poles of political power themselves. While everyone feels concerned by energy policy (e.g., taxes, petrol price, and environmental protection), there is no comparable interest in an 'industrial policy.' In principle, inter-relations between policy and the energy sector are much tighter than with industry, as political power is always established on the control of energy. Political influence is omnipresent, on and between the different levels: the tensions regarding the deregulation of the European electricity market concern local and regional utilities as well as state companies (e.g., ENEL in Italy) and even the European Union.

(e) Only parts of the energy sector belong to the secondary sector: for instance, the preparation, processing, and transformation into electricity, coke or petrol. Simple mining, however, belongs to the primary sector, whereas transport, distribution, and supply are parts of the tertiary sector. Such a vertical structure, from the primary to the tertiary sector, is valid for each energy resource, from oil exploration to the petrol station, as well as for the big companies themselves.

It is true that these characteristics give an individual profile to the geography of energy. Nevertheless, the latter does not figure among the traditional fields of economic geography, in the manner of agricultural or transport geography, which are oriented by one of the three economic sectors. The geography of energy should rather be conceived of as an interdisciplinary area without sharp limits, focusing on the individuality of the energy sector. This individuality is determined by the fact that it embraces all three economic sectors, remains steadily under strong political influence, and interacts with space along the energy chain.

4. *Renewable Energies—To a New Energy System 'from Space'?*

The interrelationship between energy and environment is one of the central topics in current geographic research. Undoubtedly, the energy chains' cumulated emissions are by far the most serious cause of

worldwide ecological damage. Simultaneously, there is rising worry about the dwindling supply of resources. Against this background, we are witnessing a struggle concerning the forms of energy use (e.g., nuclear power), the markets (e.g., deregulation) and last but not least, the available reserves (e.g., recent wars in the Near East). Against this background, too, the need to increase the use of renewable energies is urgent. That has already caused conflicts between the established forces of fossil fuel economy and the pioneers of a new sustainable energy system (see Scheer 1999). Conflicts are also taking place on a second level. On the one side, the traditionally centralized, very lucrative supply systems based on sophisticated energy chains are easy to control by large enterprises or governments. On the other side, renewable forms of energy can be produced and used at the same location, as for instance through wind or solar photovoltaics on a remote farm. As there is no need for an energy chain, there is neither a basis for control or for much profit, wind and sunshine being free of charge and taxes.

It is too early to outline future scenarios. Possibilities for radical change are in the offing, however, not only in the energy economy itself but also in business structures and policy, with conflicts from the local to the global level. For the established companies, decentralized production and consumption of renewable energies would not only mean ruinous losses, but also a step out of the energy chain, and hence out of influence. Furthermore, the state would lose an instrument of political control. Thus it is not surprising that the traditional system is already adapting to a new one. The large companies, the oil multinationals at the head, are integrating renewable energies into their activities. They want to remain on the top technological level and to prevent a shortage of reserves. In addition, they are trying to conserve their business structures, their networks and, in this way, their control over the system. This is manifested too, in the resistance of large producers to decentralized power generation, as in the example of the resistance in Germany to providing an adequately high level of reembursement for feeding surplus energy from wind generated electricity into the power grid. There are obvious tendencies, too, to recentralize those dispersed microstructures, for instance, by assembling numerous wind turbines in Denmark in 'windparks'. This is also evident in gigantic plans to use nonpolluting hydrogen in densely populated industrialized countries (see Schaefer et al. 1997): The electricity needed for producing hydrogen by electrolysis should be generated by a renewable energy, too—why not by water power in Canada? From there, hydrogen could be shipped to specialized filling stations in European conurbations—via a new type of energy chain.

The transition from one energy system to the next is always slow and fluid; one is adopted without the former being completely abandoned. Preindustrial ways of using energy from biomass or muscles continue to be practiced, although almost exclusively in the Third World. Today we are again witnessing the signs of such a transition to a new energy system: a fundamental change from the rapid and definite exploitation of cumulated, but exhaustive reserves to the sustainable use of resources that are continuously 'recharged,' directly and indirectly, with solar energy. In a certain way, it is a return to a system of harvesting energy from space, as the cereals were for Roman slaves. It will be generated in small quantities at numerous dispersed locations, although with different methods and different degrees of impact on space than before the Industrial Revolution. The availability of resources as well as environmental constraints and policy will decide in the future to what extent and over which period of time fossil fuels can or must be replaced by renewable energies, and centralized generation be replaced by decentralized generation, respectively.

Energy Policy: International

Energy policy is a special sector of policy dealing with energy problems. Energy (i.e., the capacity to realize work) is an essential ingredient of the activity of human beings. The minimum average energy requirement for an adult human to stay alive is about 1,000 kilocalories per day. For an adult engaged in normal activities, it is about 2,000 kcal a day. To give an idea of the amount of energy involved in human activity, 2,000 kilocalories is the energy contained in a cup of petroleum; this is approximately the amount of energy the human body extracts from 1 kilogram of food which one eats every day.

The stages of development of man from primitive man (one million years ago) to today's technological man can be closely correlated with energy consumption as indicated in Fig. 1, which shows daily consumption of energy per capita for six stages in human development.

Primitive man (East Africa about 1,000,000 years ago), without the use of fire, had only the energy of the food he ate (2,000 kcal a day).

Hunting man (European about 100,000 years ago) had more food and also burned wood for heat and cooking.

Primitive agricultural man (Fertile Crescent in 5000 BC) was growing crops and used animal energy.

Advanced agricultural man (Northwestern Europe in AD 1400) had coal for heating, water power, wind power and animal transport.

Industrial man (in England in 1875) had the steam engine.

Technological man (in the US in 1970) consumed 230,000 kcal/day.

Starting with the very low energy consumption of 2,000 kcal per day, which characterized primitive man, energy consumption grew, in one million years, to almost 250,000 kcal per day. This enormous growth of per capita energy consumption was only made possible by:

(a) increased use of coal as a source of heat and power in the nineteenth century;

(b) use of internal combustion engines that led to the massive use of petroleum and its derivatives; and

(c) electricity generated initially in hydroelectric sites and afterwards in thermoelectric plants.

The world average annual per capita energy consumption is equivalent to 1,500 kg of petroleum equivalent; with a population close to 6 billion people, this corresponds to almost 9 billion tones of oil equivalent, valued at approximately 1 trillion dollars.

Figure 1
Stages of development and energy consumption

Figure 2
Evolution of GDP and energy in the OECD

To guarantee the supply and consumption of such huge amounts of energy is the subject of energy policy. In addition to that, there is a strong relationship between energy consumption and environmental degradation.

The energy–environment connection has been the object of many studies and it is sometimes possible to establish a cause and effect relationship between energy use and environmental damage. In 400 BC, for example, Plato mourned the lost forests, described by Homer centuries before, that had covered the barren hills of Greece. In this particular case, it was the use of wood, mainly for shipbuilding and forges to produce weapon that led to the destruction of the ancient Greek forests. A more recent example is the land degradation and desertification taking place in some areas of Africa because of the non-sustainable use of trees as fuel wood.

To harmonize energy consumption and environmental concerns is another facet of energy policies. Fossil fuel energy resources, such as coal and gas, are distributed unevenly across continents and countries. As a consequence, energy trade is an extremely important activity that involves not only the setting of prices, but of policies that regulate such trade. If we take the case of oil, more than 30 percent of the world's supply comes from the Middle East, which led to the formation of a cartel of countries that were the main petroleum exporters (OPEC). This cartel was able to raise the price of oil by a factor of 4 between 1973 and 1979, with very serious consequences for the world economy.

As a result of this crisis, several countries adopted national energy policies to protect themselves from undesirable dependence on Middle East oil imports; France, for example, dramatically expanded its nuclear program for the generation of electricity to replace coal and oil as fuels. The United States under President Nixon launched programs to reduce Middle East oil imports and President Carter introduced the expensive synfuels program to produce high-grade fuels from shale and coal, which were abandoned

Figure 3
Average energy demand by income segment (Brazil)

when the OPEC cartel lost its strong hold on oil supplies.

In the United States and Western European countries, another important energy policy launched was 'energy conservation,' which is a shorthand description for a series of technical fixes leading to a more rational use of energy. In the past, conventional wisdom led us to think that the growth of national income of a given country or region occurs through an increase of population, number of houses, automobiles, and domestic appliances with a consequent proportional increase in energy consumption. Such a perception proved to be wrong.

A number of 'rationalization' measures adopted by OECD countries after 1973 were very successful in 'decoupling' energy consumption and GDP (Gross Domestic Product) taken usually as a measure of economic growth (see Fig. 2).

Such uncoupling, at the aggregate national level, does not address the question of how different groups in society consume energy and what type of energy, which can be quite different as income grows. Figure 3 shows average energy demand by income segment in Brazil.

To address such problems, one needs special energy policies, such as subsidizing energy for the poor. Particularly conspicuous in the last few years are energy policies to address environmental concerns; such problems can be local, regional, or global.

1. Policies that Promote Sustainable Energy Futures

Energy policies to reduce local and regional environmental impacts have been in effect for a long time. Local pollution has to do with local governments, since it deals with clean air, fresh supplies of clean water, the removal and disposal of solid wastes and liquid effluents, street cleaning, etc. However in many developing countries, a large fraction of the population still lives among the rubble and residues that it produces, due to the lack of resources to remove waste and to build sewers and engineering works needed for the supply of water.

Regional pollution is caused mainly by automobiles, energy production, and heavy industry, which are inherent to more prosperous societies. Large cities and adjoining areas, such as Los Angeles, Mexico City, and São Paulo, have long been 'suffocating' under the pollution caused by the emissions and smog resulting from the burning of fossil fuels. Sometimes the amount of pollution produced is large enough to cause regional and even trans-border problems, such as 'acid rain,' some of which originates in the USA but is responsible for the destruction of life in the Canadian lakes. The same has happened to lakes in Scandinavia, due to industrial activities on the south of the Baltic Sea. Regional pollution has to be dealt with at the state or national level and eventually among a number of countries.

Global environmental problems and concerns are more recent, the most conspicious of them being the destruction of the stratospheric ozone layer by CFCs and the 'greenhouse effect.' These problems result from changes in the composition of the atmosphere and have little to do with national borders. The causes of such global problems are gases originating anywhere in the world and the problem can only be tackled at the international level.

The ozone layer problem was succesfully resolved by a concerted effort of a few countries that led to the Montreal Protocol. Subsequent decisions are effectively leading to the phaseout of CFCs from the face of the Earth. Other substances have been developed to replace them. The outstanding problem is the 'greenhouse effect' that is proving to be much harder to solve since the most important greenhouse gas is CO_2 (carbon dioxide), the unavoidable result of the combustion of fossil fuels that is responsible for 75 percent of all energy consumed in the world today.

The basic policy in this case is to reduce CO_2 production through improved efficiency in energy use and to search for proper replacements such as renewable energy sources. Appreciable success has been achieved in industrialized countries to reduce CO_2 emission mainly through rationalization in the use of energy. CO_2 emissions in those countries have levelled off since 1980 or are growing very slowly since then. In developing countries, however, emissions are growing at a fast rate.

The main policy instrument to solve this problem is the Framework Convention on Climate Change (FCCC) signed in 1992 during the Rio Summit and the Kyoto Protocol (1997) that adopted a binding resolution according to which industrialized countries, as a whole, would reduce their CO_2 emissions by 5.2 percent below the 1990 level in the period 2008–12. The United States accepted a reduction of 7 percent to their 1990 level. Since emissions have been growing by approximately 1 percent since 1990 in this country the reductions required would be much higher. Some estimates indicate that the reduction required will be approximately 25 percent.

In order to make it easier for industrialized countries to reduce their emission the Kyoto Protocol in addition to setting caps on emission for the industrialized countries has introduced features that could induce industrialized and developing countries to cooperate in reducing CO_2 emissions. They are the 'flexibility mechanisms' by which emission reductions in developing countries (or economies in transition, i.e., the former Soviet Union and countries of East Europe) can be counted as reductions in industrialized countries. In this category are 'Emissions Trading,' 'Joint Implementation,' and 'The Clean Development Mechanism.'

Emissions trading (ET) is the more general, market-based instrument. It enables achievement of limits at least cost by taking advantage of marginal cost differentials in emissions abatement among countries. Since greenhouse gases are a uniformly mixing global pollutant, both the damages from emissions and the benefit from emission reductions are independent of their origin. In order to minimize the cost of given global emission reduction, abatement should take place where the costs are lowest. (Emissions trading is defined in Article 16 bis and referred to in Article 3.10 and 3.11 of the Protocol.) It is restricted to trading among the Annex I countries (industrialized countries).

Joint Implementation (JI) limits emissions trading to developed countries that have accepted emission reduction commitments under the Kyoto Protocol, as listed in its Annex I. Countries that are certified to be below their national limits are allowed to sell greenhouse gas offsets to other Annex I countries who are above their own limits. The latter's motivation is the opportunity to meet their commitments at lower cost than through purely domestic actions (defined in Article 6, and referred to in Article 3.10 and 3.11 of the Protocol).

The Clean Development Mechanism (CDM) is an instrument for joint action on emissions reduction (and therefore trading) between the developed countries listed in Annex I of the Kyoto Protocol and developing countries, which are not listed in Annex I (covered in Article 12 and referred to in Article 3.12 of the Protocol). Article 12 of the Kyoto Protocol was the result of a political compromise. It conciliated two sharply opposing views that almost wrecked the Kyoto Conference in 1997. For some countries, an essential element for the Kyoto Protocol was emission trading based on adoption of mandatory reduction commitments by all countries. This feature was contained in a United States Senate Resolution, but was unacceptable to the developing countries. The creation of the CDM emerged as the solution.

In Annex I countries, there will be competition among the several mechanisms defined in the Kyoto Protocol to meet emission reduction requirements. The portion of resources allotted to each of them will prove to be an important internal problem to be resolved. The Kyoto Protocol left undefined what part of the emission reduction commitments could be met outside national borders through use of the flexibility mechanisms. A small percentage would encourage domestic action in Annex I countries, reducing the financial flow to developing countries. A larger one would discourage domestic actions and eventually tend to lead to an inordinate increase of emissions in Annex I countries. In all likelihood, the share for the CDM compared with other mechanisms will be determined by the market.

The Kyoto Protocol has not yet been ratified by the key industrial countries, but—if and when ratified—it might prove to be as effective as the Montreal Protocol in solving one of the most difficult global environmental problems of our time.

Engineering Psychology

As its name implies, engineering psychology is a branch of psychology that is concerned with design. In particular, it seeks to ensure that human capabilities, limitations, and tendencies are considered in the design of things people use—from ordinary consumer products to sophisticated technologies—with the aim of maximizing performance and safety. The colloquial term 'user-friendliness' captures the essence of this goal, and in pursuing it, engineering psychologists draw upon and contribute to many domains of psychological knowledge.

1. Interdisciplinary and Disciplinary Relationships

Throughout its history, which dates back to the Second World War era, engineering psychology has struggled to establish a clear identity. Partly this is a result of its interdisciplinary perspective and partly it stems from a confusing array of labels with which it has been associated. To appreciate the nature and current status of the specialty, therefore, it is necessary to sort out these relationships.

The core concept that engineering psychology shares with specialists in other disciplines—including some in engineering, computer and cognitive sciences, biomechanics, medical sciences, architecture, and gerontology—is that of the human–machine system: the idea that human and machine function as partners in a collective enterprise rather than as independent operators. Whereas design professionals typically focus on the efficiency and reliability of the machine component, and personnel specialists, on the proficiency of the human component (see *Personnel Selection, Psychology of*), the system perspective emphasizes the importance of their interaction. A machine that is difficult to use will result in poor system performance no matter how well it functions as a machine.

For example, airplane accidents officially attributed to 'pilot error' were at one time quite commonly found to involve misreading the cockpit altimeter. Since this instrument provided highly accurate altitude infor-

mation and rarely malfunctioned, it was beyond reproach from an engineering standpoint. From a human–machine systems standpoint, however, it was seriously deficient in that altitude readings were easily confused. Hence if a pilot under stress mistook 1,000 for 10,000 feet, it was as much the fault of the display design as it was of the human operator. Fortunately, this problem was diagnosed by engineering psychologists and corrected through human-oriented design (Sanders and McCormick 1987). The moral: good design requires joint consideration of human and machine characteristics.

The approximately 11,000 professionals who subscribe to this philosophy are known as 'human factors specialists' or 'ergonomists,' and despite a variety of disciplinary backgrounds, their shared interest has evolved into a discipline of its own (Van Cott and Huey 1992). In the USA, it is most commonly referred to as 'human factors'; in the rest of the world, as 'ergonomics.' Since nearly half of these professionals were trained as research psychologists, engineering psychology represents a substantial component of this interdisciplinary field. Within the field of psychology, however, where the number of professionals is well in excess of 150,000 and growing, it constitutes but a tiny specialty area—one that few other psychologists could readily identify. Moreover, larger, well-established specialties such as cognitive, experimental, educational, environmental, and industrial/organizational, (I/O) psychology have also developed an interest in design applications. For this reason, it has been suggested that the engineering psychology specialty is in transition and may eventually be absorbed into the others (Howell 1993). Its relationships with cognitive, experimental, and I/O specialties are particularly noteworthy as we shall now see.

2. *Background and Changing Emphases*

Although it had many precursors, engineering psychology emerged as a recognized specialty following the Second World War. During the war, teams of research psychologists and engineers had been assembled to investigate—and correct—problems such as the excessive number of accidents in certain aircraft, the difficulty of maneuvering large ships, and the failure of radar operators to detect critical signals. Most of the psychologists recruited for this purpose were academic scientists whose peacetime work had involved studies of basic human functions such as sensation, perception, motivation, and learning. Within the field they were known as experimental psychologists because they relied chiefly on the experimental methods of science in their investigations.

The success of these wartime 'human engineering' efforts, as they were called, had four noteworthy consequences. First, it convinced the engineers and psychologists who had been thrown together to rectify specific design problems that the collaboration had much broader potential. The engineers discovered that psychological knowledge is useful for design; the psychologists discovered new applications and directions for their research.

Second, it prompted transition of the psychology–engineering collaboration into peacetime applications. Military human-engineering units continued their research and development (R&D) activities, and extended their influence by writing user-oriented requirements into contracts for new systems, and by supporting civilian researchers. Consequently, some large military contractors (e.g., aircraft manufacturers) and civilian industries (e.g., The Bell Telephone system) saw fit to form human-engineering groups of their own. These groups comprised mainly of psychologists who reviewed plans and prototypes, defined usability requirements, and conducted research as a basis for setting those requirements.

The third consequence of the wartime human-engineering effort was the effect it had on the subsequent work of the participating psychologists. When they returned to their respective laboratories, many of them continued lines of research stimulated by their wartime activities, often under military sponsorship. For instance, Cornell University psychologist James J. Gibson developed a whole new theory of perception based on his wartime experience, one that revolutionized thinking on how we construct a three-dimensional world out of a two-dimensional retinal image (Gibson 1966).

The final consequence was the institutionalization of the amalgam of psychology and design with the establishment of the Society of Engineering Psychologists and the interdisciplinary Human Factors Society, both in 1958. Specialized journals (e.g., *Human Factors, Ergonomics*), graduate training programs, textbooks, courses, research laboratories, and consulting firms followed.

Then as now, the content of engineering psychology was dictated largely by the nature of the prevailing technologies and the accompanying task requirements for human operators (Howell 1993). At mid-century, humans exercised manual control over most systems, hence the focus was on the design of information displays (mostly dials), manual controls, and their interaction. The most relevant psychological knowledge was that involving sensation, perception, motor functions, reaction time, and perceptual-motor skill.

Today's technologies present operators with the daunting combination of more information, less direct control, and greater responsibility. Often the human's task is that of monitoring complex, powerful, highly automated machines and acting only when something goes wrong or there is reason to alter the program—a role commonly referred to as 'supervisory control' (Sheridan 1992). Consequently the psychological emphasis has shifted to more 'mental' topics such as attention, cognition, mental workload, information-

processing capacity, decision making, and problem solving.

Throughout its history, engineering psychology has maintained an active involvement in both science and application. When the literature provides a plausible scientific basis for a design decision, that knowledge is incorporated; when it does not, it prompts new lines of research. Some of this research seeks specific answers to narrowly defined questions, such as whether to use menus or icons in a particular software program (see also *Human–Computer Interaction*). Some, however, addresses much broader, more fundamental issues—such as the nature and limits of human attention—and in so doing expands the body of psychological knowledge.

In this regard, it is interesting to note that the work of engineering psychologists played an important role in a comprehensive 'paradigm shift' that overtook psychology, starting in the 1960s. At a time when the dominant psychological philosophy (behaviorism) held that mental events are unsuitable subjects for scientific investigation because they are not open to public inspection, British engineering psychologist Donald E. Broadbent and his colleagues were gathering data on radar operators that would culminate in a general model of how humans process information (Broadbent 1958).

Broadbent's model, particularly his theory of attention, was thus instrumental in the 'revolution' that rekindled psychologists' interest in cognition (i.e., mental processes). So, too, were contributions such as the Tanner–Swets theory of signal detectability (Swets et al. 1961), which established that the seemingly mechanistic task of sensing things includes an important cognitive element (decision making); *Hick's Law* (Hick 1952), which described human reaction time in terms of the mental operations required to translate a stimulus into a response; and a number of others. Because engineering psychologists dealt with applied problems such as detecting radar signals, interpreting messages obscured by noise, following moving targets, and remembering strings of letters and numbers, they found it necessary—and useful—to explore the mental functions that underlay these skills, thereby challenging the tenets of behaviorism.

Whereas engineering psychology's origins and current orientation are closely linked to experimentation (hence the experimental and cognitive branches of the field), it also has ties with another specialty—I/O psychology—that evolved from a very different tradition: psychometrics, or the measurement of individual differences. The experimental approach seeks to understand how the typical human functions under a particular set of circumstances—in the present context, in order to design for the modal user. The individual-differences approach seeks to develop measures (e.g., tests, questionnaires) that enable one to understand and measure how people differ—in the context of I/O psychology, in order to select and place them in jobs that best fit their knowledge, skills, and abilities (see also *Personnel Selection, Psychology of*; *Job Analysis and Work Roles, Psychology of*). Simply put, the former tradition tries to fit the machine (or work setting) to the human; the latter, the human to the machine (or work setting).

Over the years, the two traditions have drawn closer together philosophically and methodologically in recognition of the fact that both derive from the same basic model (complex goal-oriented systems) and seek the same end (achieving a good fit between the system components). I/O psychologists now include experimentation among the tools they use in organizational research, and engineering psychologists recognize that measuring individual differences is important for design because one size does not fit all. Increased ethnic and gender diversity among today's pilots, for example, requires rethinking a number of the cockpit design features that were geared to the fairly homogenous male pilot population of yesteryear. And our aging general population requires considering age-related differences in the design of consumer products, home-care medical devices, highways, and working conditions.

What is perhaps surprising is that despite these converging trends and the occasional reference of one to the other in modern texts, engineering and I/O psychology remain far apart in their institutional existence (Ilgen and Howell in press). There is very little overlap between their respective membership in professional organizations, journal content, graduate training programs, research efforts, or job titles.

The one notable exception is the content area of training in which both specialties have a long-standing interest. Engineering psychologists are particularly interested in the design and evaluation of devices (e.g., simulators, computer-based instructional systems) used for developing skills, whereas I/O psychologists are concerned with a much wider array of training issues (e.g., from simple job training to team building and even management or organizational development—see also *Simulation and Training in Work Settings*). It is worth noting, however, that whatever the focus, training constitutes a third strategic leg on the system performance stool—a complement to the design and selection strategies favored by engineering and I/O psychologists respectively.

3. *Engineering Psychology Today: Examples*

Whether or not engineering psychology survives as an independent specialty, the philosophy that it represents has clearly established itself within psychology and, by whatever name, design-oriented research will continue to grow. Thus it is important to grasp the essential nature of such research, and that is best done through examples. Two illustrations are presented below: the first, an example of fundamental research that was prompted by a design issue; the second, an

example of the application of existing psychological knowledge to a design problem. These examples also illustrate methodologies typical of engineering psychology.

3.1 Mental Models

Many technologically advanced systems have failed to perform as effectively as they might because the logic built into the machine component either is not transparent to the user, or is inconsistent with his or her conception of it, or both. That is, the 'artificial intelligence' and the 'human intelligence' involved are not congruent.

For example, computer-based systems designed to educate students in a particular subject matter (so-called 'intelligent tutoring devices') have often failed because they could not adequately diagnose the thinking behind the learner's answers and hence could not provide feedback in a useful form. And highly automated 'process-control' systems, such as those built into nuclear power plants, have encountered problems when something went awry because the humans responsible for diagnosing the fault were not sufficiently familiar with how the machine executed its control function. This was one of the many factors that contributed to the highly publicized accident at the Three Mile Island plant in 1979 (Rubinstein and Mason 1979).

Overcoming this limitation in the design of intelligent tutors, process-control automation, and other such systems cannot be achieved without an understanding of how people conceptualize the underlying physical or logical processes. Realization of this fact has led to a great deal of research on the mental representation of such structures, commonly referred to as 'mental models,' some of it aimed at specific applications and some at teasing out general cognitive principles.

A key requirement for either endeavor, of course, is devising ways to access private mental content—to describe these mental models and validate them. And that, in turn, has produced a number of new 'knowledge elicitation' and 'cognitive task analysis' techniques that are helping us gain a deeper understanding of human cognition (Cooke 1992). Some, known as 'process tracing' methods, involve collecting verbal protocols in a systematic way from individuals while they are performing a task, and then analyzing those protocols to infer the underlying thought processes. Others, such as the 'Pathfinder' technique and a collection of so-called 'policy-capturing' methods, deduce these processes using sophisticated statistical analysis applied to a lot of relatively simple judgments or choices required of the operator.

One technique, known as SAGAT, was designed explicitly to capture the operator's mental picture (or situation awareness') at various stages in the performance of highly complex tasks such as air-to-air combat or command decision making. This approach involves introducing systematic 'knowledge probes' at various points in the conduct of a simulated exercise, thereby piecing together the evolution of the operator's mental model (Endsley 1995).

Taken together, therefore, the design problems posed by the growing complexity of today's systems, plus the frequent disconnects between human and machine modes of thinking, has given rise to new insights into how the mind works as well as new methods for extracting that information.

3.2 The TADMUS Project

In 1988 a civilian airliner was mistakenly shot down by the USS Vincennes, a cruiser equipped with the latest intelligence technology, and the incident prompted international concern. It also prompted a Congressional investigation and a commitment by the US Navy to diagnose and rectify whatever went wrong. For many years, the Navy's Office of Naval Research (ONR) had been supporting fundamental research on human decision making—if fact, had been its leading sponsor. Therefore, ONR accepted the challenge of applying this vast body of knowledge to the general situation involved in the Vincennes incident, and the Tactical Decision Making Under Stress (TADMUS) project was born.

The aim of this project was to examine everything that was known about how humans make decisions; how their performance is affected by the complexities, uncertainties, and urgency (i.e., the stresses) typical of military 'command and control' operations; and how to ameliorate the effects of stress.

Needless to say, this ambitious goal called for—and received—a substantial investment in both time and money: more that $10 million was committed over an eight-year period, and the results were impressive. Drawing on basic cognitive literatures, hypotheses were developed and tested in a high-fidelity simulation of the shipboard Combat Information Center (CIC), and promising innovations were evaluated by operational personnel in research conducted at training sites, and even in actual shipboard demonstrations (Cannon-Bowers and Salas 1998).

At the end of the 1990s, TADMUS-based concepts on how to train teams to perform this vital function and sustain their performance, especially in the face of stress, were being incorporated into training curricula, and proven design improvements were being considered in planning the next generation of CIC interface equipment. The interface innovations include better (user-oriented) display of the massive amount of information available to decision-makers, and machine 'decision aids' to help them process this information rapidly and accurately. The literature on 'mental models' played an important role in both the training and design innovations.

In sum, the TADMUS project, mounted to address an urgent problem, has brought a wide variety of psychological knowledge to bear on that problem and, as a result, is virtually certain to result in improved CIC performance in the future. Moreover in the process, new knowledge was gained about team training, display for 'situation awareness,' decision aiding, and a number of other generic issues.

Viewed together, these two examples—mental models research and the TADMUS project—should provide ample material from which to construct a valid mental model of the specialty of engineering psychology as it exists today. Both its enduring features (the goal of improving human–machine systems, the bidirectional linking of design issues with psychological research, the multidisciplinary perspective, the driving role of technology) and its current focuses (cognitive functions; complex, heavily automated systems) are vividly illustrated. Additional sources of general information on engineering psychology can be found in two widely used texts (Wickens 1992, Sanders and McCormick 1987), the *Handbook of Human Factors* (Salvendy 1987), a chapter in the *Handbook of I/O Psychology* (Howell 1991), and chapters devoted to the topic that have appeared periodically in the *Annual Review of Psychology* (see Howell 1993).

English Revolution, The

The term 'English Revolution' refers to the profound changes experienced by the English political system from 1640 to 1660. Generations of historians have labeled this as one of the decisive political events of modern European history; at the same time it connected the social, political and religious changes of the sixteenth century with those occurring after 1660, up to the 'Glorious Revolution' of 1688–9.

1. Outline of the Debate on the English Revolution

Contemporaries such as the Earl of Clarendon, as a rule, did not use the term revolution (see instead he wrote *The History of the Rebellion and Civil Wars in England* (Macray W D (ed.) 6 vols. 1880, repr. London 1958). Although a generation later the word was added to the political vocabulary, it was applied to the events of 1688–9, that is, the overthrow of the Stuart monarchy, the succession of William and Mary and the new constitutional settlement. It was a foreigner, Francois Guizot, who, after the French revolution, was the first to refer to the events of the years 1640 to 1660 as the 'English Revolution' in his *Histoire de la république d'Angleterre et de Cromwell* (2 vols. 1854). At this time, liberal British historians such as Hallam and Macaulay were still describing those years as an untidy interruption in the process of the evolution of parliament and liberty, which had reached its first climax with the 1689 Bill of Rights. Then S. R. Gardiner developed his concept of the Puritan revolution (*The First Two Stuarts and the Puritan Revolution*, London 1876). His magisterial *History of England from the Accession of James I to the Outbreak of the Civil War 1603–1642* (10 vols., repr. New York 1965), which he later continued in his *History of the Great Civil War 1642–1649* (3 vols. London, 1886–91) and his *History of the Commonwealth and Protectorate 1649–1656* (3 vols. London 1894–1901), placed these

years firmly into the context of the heroic struggle of the English House of Commons against arbitrary monarchy. This Whig interpretation of early modern English history dominated for nearly a century, despite the vigorous attacks of Marxist historians such as Christopher Hill, who understands the English revolution as the violent replacement of a feudal society by a new capitalist order. This enhances the importance of the events which Hill regards as 'comparable in many respects with the French Revolution of 1789' (*The Century of Revolution 1603–1714*, Edinburgh 1961). Thus in Whig and Marxist accounts alike the revolution in general and the parliamentary cause in particular were progressive and dynamic, and thereby contributed to the patriotic myth of the distinctiveness and exceptionalism of English political tradition.

Such comprehensive views of a wide-ranging English revolution have been challenged fundamentally by recent scholarship. This new revisionism disputes the notion of an inevitable, long-term historical process of unfolding progress, culminating in the revolutions of the seventeenth century. Detailed research on events rather than trends, often concentrating on the regions rather than the capital, not only pointed to chronological fissures and contingencies, but also deconstructed the concept of a progressive parliament as the main historical agent. Every postrevisionist assessment of the English revolution must take care not just to repeat old paradigms, to avoid anachronistic conceptualization and to pass judgment on the basis of varied and often contradictory evidence.

2. *Origins and Causes*

Up to Stone's magisterial summary of *The Causes of the English Revolution* (1986) these have been placed into the context of the major economic and social changes of sixteenth-century England: the long-term inflation of the so-called price revolution, the secularization of the massive properties of the church in the wake of the Reformation, and new developments in trade and industry. All this contributed to the destabilization of the traditional social fabric, that is, to a temporary decline of the aristocracy and to a rise of the gentry wherever its members started to exploit their estates by the rules of an incipient capitalism. But no direct links between economic and social change on the one hand and the English revolution on the other have yet been established. Thus the latter cannot be labeled an early bourgeois revolution.

2.1 *The Long-term Crisis of the Constitution*

The political philosopher James Harrington (1611–77) attributed the outbreak of the civil war of 1642 to 'the dissolution of government' and this opinion has stood the test of time, remaining valid in the light of modern research. Since the Middle Ages the English monarchy has been based on the consent and co-operation of the political nation, that is those who, like the aristocracy, had an interest in participating in their country's politics, and possessed the means to do so. In this relationship parliament had served as the point of contact, giving its assent to the legislation of the crown and voting taxes to support its policies. This vital constitutional role had been confirmed and even strengthened during the Reformation, which had been effected by the King in Parliament. But towards the end of the sixteenth century this relationship began to disintegrate. The political elite was no longer willing to shoulder the rising financial and bureaucratic burdens of effective royal government, which represented the emergence of the early modern European state on the road towards absolutism. The structural weakness of the English monarchy became evident, when in the early years of the reign of Charles I, the more localist-minded members of parliament refused to meet the rising costs of war and thereby prevented the king from acting as a major player in the field of European politics in the age of the Thirty Years War. The crown, trying to bypass parliament's assent to taxation, mounted a constitutional offensive, which provoked a crisis of the constitution. Whereas the king and his advisers stressed the unlimited powers of the monarch, who ultimately was answerable only to God, the Commons accused them of trying to abolish the ancient English constitution and claimed to be the last bulwark of liberty. The conflict reached its climax when parliament forced Charles I to assent to the *Petition of Right* (outlawing nonparliamentary taxes, arbitrary imprisonment, and the billeting of troops) in 1628. Then, in 1629, the king dissolved parliament and declared that he would not call it again, but establish a government of personal rule.

2.2 *Conflict over Religion*

Historians always have agreed that religion was the cardinal issue of the English revolution, and John Morrill has recently described the English civil war as the 'last great war of religion.' With the final triumph of the Protestant Reformation, anti-Catholicism became the distinctive mark of English political culture. In the age of counter-Reformation Popery, especially in alliance with monarchical absolutism, was regarded as a constant threat to the ancient liberty of an English nation still haunted by the memory of the Armada. In the field of religion, transcending the limited sphere of the political nation, a wider public could be addressed and even mobilized. Contesting Popery promoted activism at all levels of society.

In this context the politics of religion implied momentous consequences, and contributed to the aggravation of tensions even more than the constitutional offensive of the crown. The king, as head of

the English church, gave the impression of undermining the Calvinist foundations of the Anglican faith when he obviously favored a novel Arminian stance in theology and worship. At the same time, under the protection of his Catholic queen, Catholicism gained influence at the royal court. Soon many contemporaries believed that their king was, if not the author, then at least the instrument, of a comprehensive Popish plot to subject England to papal rule again.

2.3 The Multiple Kingdom

Historians in search of the origins of the English revolution have only recently stressed the British dimension of the conflict. Since the accession of James VI of Scotland to the English throne in 1603, a regal union of both kingdoms had existed, and since 1541 the English monarch had also held the title of King of Ireland, reflecting the fact that the island had been an English colony since the Middle Ages. In addition to their different social and economic structures, the three kingdoms were separated by contrasting religious establishments, with the result that the repercussions of the English crown's religious policy were enhanced. When Charles I tried to adapt a radical Calvinist Scottish church to the doctrines and organization of the English Anglican Church, he provoked the armed rebellion of his Scottish subjects in 1639. This was to be an important precondition for the formation of effective English opposition to Charles I. In the face of English pressure to introduce the Reformation, the Irish had remained staunch Roman Catholics. In 1641, in view of the conflict between the king and the English parliament, they seized the opportunity to take up arms against their oppressors. This contributed decisively to the outbreak of the English civil war, which might also be called the war of the three kingdoms.

2.4 Charles I—the Personal Factor

The English revolution was not an accidental event because it took place in a political and cultural system, which could not stand crisis and strain. Nevertheless, its outbreak and course were also determined by certain elements of contingency, in the first place, the personality of king Charles I. Revisionist historians in particular have exposed the numerous political blunders of his constitutional and ecclesiastical policies, which finally led to the breakdown of the monarchy. This is, thus, presented more as a contingent event in itself than as the result of structural conditions and long-term developments. Yet his personality and his aims and actions were neither erratic nor contradictory. Right up to his end on the scaffold, they were linked to one single great purpose: the establishment and preservation of a monarchy, in which the king's powers would be limited neither by law nor by consent, because the ruler is answerable only to God. He always stood for absolutism and thus the quarrels he provoked raised fundamental issues, which form the subject matter of revolutions.

3. From Resistance and Rebellion to Revolution and Restoration

3.1 Stages and Turning Points

In 1639 the Scots rose against the ecclesiastical policy of Charles I, forcing the king to abandon his personal rule and to recall parliament in order to finance first the war and later the costs of military defeat. The unpopularity of his policies meant that he could command no following, either in parliament or elsewhere, and therefore had to give his assent to those statutes and measures which the opposition in parliament regarded as the necessary safeguards against royal absolutism and popery. They abolished the instruments of arbitrary rule and unparliamentary taxation, secured the position of parliament, and had the king's chief adviser, the Earl of Strafford, executed. This policy of enforced reforms changed from a defense of the traditional political order into a violation of the ancient constitution as soon as the leaders of parliament had to take precautions against a potential royal backlash and proposed to abolish the king's right to appoint ministers and control the army. Revolutionary aims like these soon alienated conservative members of the political nation, provided the king with a party, and finally opened the way for the escalation of the constitutional conflict between crown and parliament into civil war between Cavaliers and Roundheads (1642–5).

But even the military victory of parliament, which commanded superior resources, did not put an end to the conflict with the monarch. In the eyes of the majority of the nation there was no alternative to monarchy, and so even after defeat Charles was never willing to assent to, or even compromise on, the reduction of his royal prerogative. He counted on divisions among his adversaries and the second civil war in 1648 seemed to vindicate him, when risings of the royalists who were now supported by the Scots had to be put down. The confusion and turmoil of those years gave rise to and accelerated a process of political radicalization. The victorious army with its leading general, Oliver Cromwell, became the center of power, purged the House of Commons of those who still favored negotiation, and staged the trial and execution of the king (January 30, 1649). Together with the abolition of the House of Lords and the proclamation of March 17, 1649, in which parliament declared 'that the office of a king in this nation … is unnecessary, burdensome, and dangerous to the liberty, safety, and public interest of the people …' this marked the

climax of a political revolution in which the British monarchy was replaced by the republic of the Commonwealth.

At the same time new rifts opened between the more conservative 'Rump Parliament,' as it was called after the purge and the army which, in the field of religion, pressed for a 'godly reformation.' In 1653, Cromwell dissolved parliament by force and the Protectorate was established. Though parliaments still formed part of the new constitution laid down in the 'Instrument of Government', power rested with Oliver Cromwell, who became head of state as lord protector and his council. Thus, an only thinly veiled military dictatorship led the way back to the monarchy. After Cromwell's death in 1658 the revolutionary process came full circle when, with the overwhelming assent of the political nation, the Stuart monarchy was restored in 1660.

3.2 Forces and Factors

A common denominator of revolutions is the active role of the people, the masses applying 'violence from below.' Especially during the first stage of the English revolution, the populace of London repeatedly exerted pressure on the House of Lords and the king, whose assent was needed to sanction decisive reforms. They acted in accord with the leaders of the opposition in the House of Commons, who were able to organize mass demonstrations and petitions through a network of Puritan congregations. And when in December 1641 parliament published its program for radical political and ecclesiastical reform in the so-called 'Great Remonstrance,' this revolutionary move testified to the new revolutionary alliance between the representatives of the nation and a wider public. More than 20,000 sermons, pamphlets, and newsletters were printed between 1642 and 1649, opening up a public sphere for a general debate on religion and politics. New radical forces emerged, such as the popular democratic movement of the Levellers. This movement confronted parliament with a wide range of grievances, and, in its *Agreements of the People*, presented its drafts for a new written constitution, which was to guarantee every freeborn Englishman's birthright. And when the victorious army became a major factor in politics, this was also affected from below. Common soldiers elected agitators as their representatives to the council of the officers and declared that they were not a 'mere mercenary army,' but had the right of political participation.

In the end, the revolutionary regime was based on the minority in Cromwell's army that took an active interest in politics. This points to the extent to which, in consequence of progressive radicalization, the popular basis of support for the revolution was shrinking. But at the same time it was becoming more forceful, especially when linked to radical Puritanism, which, through the doctrine of predestination, could provide its members with the self-confidence that it takes to want to turn the world upside down.

4. Achievements

Because they refuse to take a long-term perspective and sometimes even try to separate the period of resistance and the civil war from the republican experience, many revisionists do not concede that the English Revolution in the long run secured the place of parliament within the framework of the constitution. But after a second attempt to establish absolutist rule in England had been averted by the resistance of the political nation in the Glorious Revolution of 1688–9, the introduction of constitutional monarchy, which had been proclaimed as the policy goal of the parliament of 1642, was finally achieved. Though it did not effect substantial social change, the English Revolution had unfolded the complete repertoire of political change: not only the right of resistance but also the idea of the sovereign people sitting in judgment upon the king, and the theory of individual rights and social contract as the basis for a written constitution. Thus, it both marked a decisive step in the process of political modernization (see *Modernization and Modernity in History*), and provided a case study for future revolutions, as the American struggle for independence was to show (see *American Revolution, The*).

Enlightenment

1. Definition and Meaning

Enlightenment is an epochal concept of modernity. It can be compared with others which preceded it such as Renaissance and Baroque, or followed like Romanticism, the latter mostly as its antithesis. The word *Enlightenment* is molded exactly on its German original, *die Aufklärung*, whose first conceptual definition is due to Immanuel Kant; in 1784 he had tried to explain the meaning of the word to the readers of a Berlin journal. The first point to be borne in mind therefore is that the term was condensed with theorical precision in a German area and that *Enlightenment* (second half of the nineteenth century) or *Illuminismo* (beginning of the twentieth century) were created as translations of the German term. But the concept of *Aufklärung* has had several metaphoric equivalents in European culture since the eighteenth century. The best known are linked to the term *light*, which in its turn is connected with *reason*: therefore Enlightenment was conceived from the very beginning as the *Age of Enlightenment*, emancipating reason, the time of man's coming-of-age. This is what Kant meant. Reason is a critical tool allowing man to get rid of prejudice, to change the world, dominating nature through science. Enlightenment is conceived as a culture of conscious change, that is of *reforms*, the secularization of a term which was originally in the singular and expressed a religious concept of modernity.

It does not mechanically coincide with rationalism, but it is one of its essential and critical moments. In fact a rationalistic conception of the world precedes Enlightenment and really belongs to the seventeenth century, as philosophers like Descartes and Spinoza could show. With them reason is a system, whereas with Enlightenment it becomes method. Reason becoming method is an essential point of enlightened epistemology, which not only uses Locke's empiricism, but also Newton's celebrated motto: 'Hypotheses non fingo.'

2. Times, Spaces and Routes

As for all complex epochal categories it is not easy to imprison it in a definite period of time or in space. The fact that the concept originated in a German area does not necessarily mean that the center of Enlightenment is linked to that environment. From a historiographic point of view at least three great European cultures claimed to have given origin and identity to Enlightenment: France, England, and the German world. As far as France was concerned, the capital of Enlightenment (light) was Paris, in the name of the *philosophes* and of the *Encyclopédie*, which synthesized its essential knowledge. London could not only boast Locke's and Newton's contribution, or the precocity of the *freethinkers*, and later the great lesson of Scottish intellectuals, but also its own political system, already based on the separation of powers, and above all on the rapid evolution of public opinion, favored by a free press. The Germans in their turn not only claimed that they had first created the conceptual condensation of the term, but also having given (through Leibniz, Wolff and Kant) Enlightenment a philosophy. Actually these claims implicitly conceal all the ideological processes of the following age, which perceived cultural identities on a national basis, in antithesis with Enlightenment, thus denying a fundamental presupposition, cosmopolitanism.

If one wants to understand the Age of Enlightenment today one has to put aside any simplification identifying center and peripheries, but accept its polycentric nature, which should be considered as a European and worldwide circulation of ideas, to which Kant attributed the choice of universal emancipation. This does not mean that one should ignore the diversities which induced some scholars to imagine the existence of various kinds of Enlightenment. A polycentric interpretation probably helps better than others to save the unity and the diversities of Enlightenment at the same time.

It is never easy to define the period of time enclosing a concept of epoch. If one compares the cultural events of France, England, and Germany with those of other areas from the Mediterranean sea to the north of Europe, one can take the 1680s, indicated by Paul Hazard as the beginning of the 'crisis of European conscience,' as a starting point, provided one does not fix dates or individual events. They are the years of the revocation of the Edict of Nantes, of the *querelle* between Ancients and Moderns, of the appearances in European culture of *Etrangers Symboles* ('foreigners symbols'), like the Chinese Mandarin, archetype of virtuous atheists. In England it is the period of intellectual maturity with Locke and Newton, but also of freethinkers like Anthony Collins and John Toland. Thomasius and Leibniz are the protagonists of the *Frühe Aufklärung*. In Holland refugees like Pierre Bayle and Jean Leclerc elaborate the tools of a great critical culture. Only slightly later the adventure of Giambattista Vico, Pietro Giannone, Alberto Radicati, di Passerano, and Ludovico Muratori has its beginning in Italy. As for the Iberian peninsula, the *décalage* is greater.

The 1730s and 1740s can be considered years of transition, with the important exception of Voltaire's and Montesquieu's France, who inaugurate the Age of Enlightenment. In England the radical culture of freethinking dies out, whereas the Augustan season asserts itself through Samuel Johnson. In Italy Radicati and Giannone succumb to the success of the erudites and of the enlightened catholics (from Scipione Maffei to Muratori). The latter's Spanish equivalent is Father Fejio.

The 1750s and 1760s are the season of Enlightenment at the height of its glory. The circulation of ideas links together all the European centers. Not only Paris, London, Berlin, or the cities of the great cultural mediation like Amsterdam and Geneva, but also Madrid, Lisbon, Milan, Naples, St Petersburgh, and Stockolm become involved in a close dialog. These are the days of the *Encyclopédie*, of the *Contrat Social*, of Cesare Beccaria's *Dei Delitti e Delle Pene*. Learned periodicals become journals of opinion. The first great reforms are introduced in the fields of economy, legislation, politics, and morals. Pombal's Portugal opens a confrontation with the Jesuits in which all the Bourbon states are going to be involved and will have an echo in the great European enlightened culture.

The network of Freemasonry develops the political language of a civil society, deeply entwining itself with all the other tools of European intellectual sociality. Reforming projects are most fruitfully nourished by Utopian ideals. Enlightened absolutism makes its tentative appearance in Austria, Russia, Prussia, Tuscany, Denmark, and Sweden. If sovereigns are drawing near to the philosopher's projects, there is also a fruitful exchange between enlightened culture and government's experience of a new generation of officials.

The 1770s and 1780s, when little by little the generation of the great representatives of Enlightenment (Voltaire, Rousseau, Diderot, D'Alembert, d'Holbach) disappears, tackle an Atlantic event like the American Revolution, which gave Europe first-hand ideological material on questions not yet approached, such as the self-determination of peoples, parliamentary representation, and federative connection within a republican model: liberty, democracy, and civil ethics as a shared and written constitutional project. Europe's boundaries widen with Russia entering the Mediterranean, and the inevitable modifications of the eastern balance. Historians like Edward Gibbon and law reformers like Gactano Filangieri take note of it. The models of reason change. Freemasonry itself, which Lessing thought the ideal tool to diffuse Enlightenment, lives a deep restlessness and the clash between operative rationality and taste for the occult and for mysticism. Raynal, who had enjoyed Diderot's collaboration, accuses the European colonial models, denouncing both their violence against other civilizations as well as slavery and the inclination towards despotism; he goes so far as to assert that the torch of freedom would be carried to Europe by a black Spartacus.

It is not easy to find an *ad quem* term. The beginning of the French Revolution, a starting point of an epochal crisis, is plausible beyond a logic privileging the French course. Some frontier areas are soon involved in the revolutionary turmoil. The process seems to take longer in Germany, England, Spain, Portugal, and Italy, not to mention in Eastern Europe. The French Revolution and war put a stop to the politics of enlightened absolutism. The crisis of enlightened culture and its transformation into something different (from Jacobinism to counter-revolutionary resistance) last through most of the 1790s. As for England—which experiences the first unsettling industrial revolution—it carries out and uncompromising war not only against the French Revolution, but against the Napoleonic Empire as well; and yet this does not modify its constitutional evolution, nor does it alter substantially the role of public opinion. This is true also with regard to the United States, which will later appear to an observer like Alexis de Tocqueville (*De la démocratie en Amérique*, 1835) as the most mature and complete project of the Enlightenment, from which the Europe of *Restauration* would have to learn freedom and democracy anew.

3. *Operative Tools and Fields*

An analysis of the categories of space and time connected with the concept of the Enlightenment implicitly shows its operative tools (reason, experience, criticism, scientific models, reforms, utopian tensions, theories of progress, and of public and private happiness). Each of these terms has its own internal dynamics, but also tends to adapt to highly differentiated realities. Enlightenment today does not appear so much like a clear unitarian philosophy, according to its reconstruction by Ernest Cassirer (1932), as like a process of general emancipation which moves hypothesis, possibilities, and strategies which might appear different and antithetic at first sight. This is clear from a brief analysis of its main fields of influence: religion, ethics, politics, economy, history, social transformation, and cultural change.

As regards religion, in the long term secularization had its roots in the first period of modernity (Humanism, Renaissance, Reformation, libertinism). Criticism of revealed religions is an important element of English freethinking in the early eighteenth century, with repercussions not only in Holland, but also in France and Italy. Materialism, pantheism (the term was coined by Toland in 1704), and the negation of the immortality of the soul involve both the protestant and the catholic world, as the religious adventures, destined to be defeated, of Jean Meslier, Giannone and Radicati di Passerano could show. The progressive reduction of magical, miraculous, and prophetic forecast practices are generalized as the refusal of superstition. Fruits of the application of critical models linked with philosophy and science, they create various intersections between faith and reason, from reasonable Christianity to enlightened catholicism, to natural theology, to deism. Tolerance, which is not only the cohabitation of different religious confessions on the same territory, but also the possibility (enunciated by Pierre Bayle) of individual conscience to err, without any church arrogating to itself the power of

constraint, is a good ground for testing important conquests. In the wake of a great juridical tradition Voltaire will take this battle into the very core of Enlightenment, elaborating for European public opinion the theoretical premises for the choices of Prussian, Austrian, and Tuscan enlightened absolutism.

D'Holbach's *coterie*, which represents the most radical experience of the French Enlightenment from a religious point of view (with two phases: the first an antichristian offensive; the second the elaboration of a social model where ethics and politics were separated from religion) is only one of the components, though the most aggressive and sensational, of the French and European Enlightenment. It is all too easy to underline its elitist nature, limited to a small group speculating on the complicity of European publishers interested in creating a flourishing market of clandestine books. One should not underestimate this aspect, after a scholar like Robert Darnton explained the relation between publishing and sedition, between forbidden books and crisis of political, ethical and religious social structures.

The most lasting result of the Enlightenment in this field was the widespread consciousness not only among laymen but among priests as well, including enlightened catholics, that religious choice mainly belonged to the private sphere. In this sense the most mature enlightened project had accepted and adapted for a larger civil society the rights of conscience proposed by Bayle at the time of the 'crisis of European conscience.'

4. *Emancipation, Reform and Utopia*

In its most essential and creative moments, each innovative choice of the Enlightenment was preceded by an ethical reflection which cannot be mechanically reduced to an individual reckoning of pleasures and sorrows. The utilitarian moral itself had imagined with Bernard de Mandeville that private vice could become public virtue; but in the middle of the eighteenth century it was perceived more as a tension to ensure the maximum happiness to the largest possible number of men. From this point of view the analysis of Montesquieu's works, of the 'economists,' of Pietro Verri, Beccaria, and Gaetano Filangieri are important because of the strong relation they establish with a new ethical project. The Scottish Enlightenment also starts from morals to discover economy and sociology. In fact one of the concepts most charged with future, that of 'civil religion' theorized by Rousseau in his *Contrat social*, was based on a profound thought of natural law (above all through Jean Barbeyrac) which had tried to set the field of man's rights and duties free from the traditional links of Patristics and Scholasticism.

Rousseau and Mably had transformed this inheritance and founded a new system of rights and duties of the citizen. The state was taking upon itself new tasks in the fields of instruction, cultural control and assistance, thus widening its public dimension and secular action; as a consequence religious choice would tend to become a private question, involving the intimate and inviolable sphere. The most significant lesson of the Enlightenment was not so much a lay morality opposed to the religious one, as the possible dialog on the field of citizenship between different kinds of ethic: a difficult project, continuously interrupted, which modernity has to tackle all the time.

Also from the point of view of political models the Enlightenment does not show a unified front, but a series of possible choices, from enlightened absolutism to the return of a republican culture, to the bureaucratic centralization of the 'well-ordered police state,' to constitutionalism, to debates on representation, to projects of direct democracy. Each of these terms in fact can be used to define very different experiences, unless there is the intervention of a contextual historical event. There is a sharp distinction, for example, between the forced modernization of Peter the Great, which is an example of reformism to the point that it attracted Voltaire's attention, and the strategies of 'enlightened' princes like Frederick II, Joseph II, Peter Leopold, and even Catherine the Great.

In the same way, with regard to republican thought, one should not confuse the patrician models of the republics which survived the success of absolute power (Holland, Venice, and Genoa), or the mannered republicanism one learnt by reading the classics, with the new republican tensions which arose as a consequence of the claims for freedom of the Poles, the Corsicans, the Genevans and above all the American colonies. But enlightened absolutism itself attracts or repels enlightened thinkers because of two equal possibilities. The first is the use of centralization in order to carry our reforming politics, where the accent was not so much on strength, however necessary to win resistance, as on the involvement in the project of new fields: law, politics, economy, religion, culture, together with the elimination of particularisms and unjust social relations. This implied the other necessity, that of transforming the model into constitutional forms. The process of emancipation, but also of adaptation to the complexities of the real world one wants to change, Enlightenment moves between the two poles analyzed by Franco Venturi (1971): utopia and reform, closely entwined. These two tensions vivify each other. But the course of the Enlightenment revolves round another two essential terms: freedom and democracy. The first term above all was the main object of Montesquieu's *L'esprit des lois* (1748). It is not possible here to go beyond a schematization recognizing virtue as the essential value of republics, as distinguished from honor, the real ethical and social cement of monarchies. Montesquieu does not choose among the different political forms. He only discards Asian

despotism and is very diffident against absolutism, which he wants to temper not only by separating the three powers, or through the binding strength of the laws, but also through the concrete presence of intermediate bodies, including the nobility.

The other term of reference for the political theory of Enlightenment is Rousseau. He opposes to eighteenth-century cosmopolitism the love for one's own country, which requires the practice of direct democracy. Rousseau's democracy is right for a small republican country. It does not admit representatives. Between majority and minority only the former represents the general will, because sovereignty derived from the social pact cannot be divided. The Genevan's challenge was even more complex: he questioned a developmental model of civilization based on the progress of art and science, but also on the basis of social inequality. Democracy was the courage to modify ownership, justice, and instruction. A large part of later political thought is linked to a comparison between Montesquieu and Rousseau, to establish a connection between freedom and democracy, the aspiration to absorb the Genevan's Utopian drive and transform it into a spirit of reform. An exemplary text is *Dei delitti e delle pene*, which questions the right to punish in an unjust society because it is unequal.

Various other experiences belong to Enlightened politics: cameralism, an administrative model mainly used by Prussian and Austrian officials; the physiocratic theory of legal despotism, in which a monarchic power guarantees certain natural laws, among which is ownership. From the above considerations it appears that the question of enlightened politics is narrowly linked with the question of law, which becomes 'science of legislation.' The weaker field was feminine political and cultural identity. For this question one would have to wait for Mary Wollstonecraft's adventure and her work on women's rights.

Economy becomes a science during the eighteenth century, evolving from late-mercantilist models. The physiocratic project established the essential points of the productive cycle based on agriculture and on free corn trade. If agriculture was the only wealth-producing sector, while transformation and circulation were the task of industry and commerce, taxing had to become progressive with respect to land, whose ownership was one of the fundamental natural rights. Adam Smith extended liberalism to sectors such as industry and commerce, which were not considered subsidiary, but highly productive. In this way the first strong perception of an industrial revolution under way in England became a theory. During the last decades of the century there was a return to protectionism.

What happens with economy could well be verified with other sciences, not only social and natural, but human as well. The Scottish school creates the premise for sociology, by studying social stratification or the concept of civil society. Economy itself, by defining a stages theory based on production forms, laid down the basis of anthropology. Consolidated disciplines like physics were renovated, as well as chemistry, geology, agronomy, and geography itself. Linneus and Buffon had reclassified nature, thus rendering it an open book. Natural history had given a common language to natural and biological sciences.

As for history, one can only register a change in some fundamental paradigms: the loss of the superiority of sacred history, the transformation of ecclesiastical history into history of religions, the emergence of the history of civilization within new models of universal history, the flourishing of civil history as institutional history, the first appearance of the history of science.

5. *Circulation and Practices: the Growth in Literacy*

If one examines this process from the point of view of cultural history and of general transformation of intellectual models, European and now world-wide circulation of ideas can be measured through parameters which are apparently external to intellectual history, but not unimportant. I am referring first of all to the international book market, but also to the creation of an incredibly large number of tools, thanks to which the consultation of books made possible, from public and private libraries to bibliographies, catalogs, abstracts, reviews. Book and newspapers have an almost universal circulation. In Europe and in America there has been an increase in literacy. The world of potential readers has expanded not only thanks to the advent of the middle classes but because the distance between male and female instruction tends to diminish in urban spaces. Somebody called this the revolution of middle class readers. Even reading habits change; there is a greater tendency to undirected reading, not linked to learned professions but to the consumption of leisure time. The demands of the new readers also bring about a change in genres. The novel has an incredible development, offering as it does to all classes means for education, identification and escapism. Among the forbidden books of the second half of the eighteenth century, the *philosophique* and *pornographique* genres often follow the same semiclandestine circuits, thus contributing to the modification of the cultural and ethical general models of society. Music and theatre as well are often fields for ideological formation and dispute. Journalism follows in the tracks of this expansion of the book market, and from the objectivity of abstracts, which are made for a public of learned people, moves to the subjectivity of journals, the concision of reports. Journals of opinion are essential for the formation of this new

international public sphere which discovers languages, interlocuters, and spaces. To this sphere belong the salons, public, and private spaces at the same time. Intellectual sociality takes a number of forms, from the old and new academies, to clubs, to cafés, down to the taverns where conversation and gossip are a way for dilating news. The Enlightenment–Academies relation is supported by a rich bibliography, starting with Reinhard Koselleck's (1959) work which laid down the basis for a more through analysis of the links between Freemasonry and Enlightenment. The former is now considered the privileged center for the formation of the political language on which the assemblary model of the French Revolution will be created.

Many centers of intellectual communication reverse the prevailing male image one received when analyzing the concept from the point of view of intellectual history. Women are present in the famous French salons, where they have a personal control over an ephemeral though socially important genre like conversation. They start being accepted in some lodges and academies, their role thus changing from that of consumers of books and newspapers (also of a literature for women, produced by men) to that of writers. Firstly, they occupy the space of women's literature, then they take and active part in the journalistic debate. The inclusion of women in the public sphere does not alter the fact that their role is still subordinate. Women's writing often tends to self-identification, but it remains unfinished, secret. And this corresponds to a social model which is prevalent in male Enlightenment. Rousseau, who had put the question of public education of the citizens, had kept women separate; Filangieri himself had followed suit. This explains the novelty of Wollstonecraft's denunciation. In fact the public sphere created by High Enlightenment seems to be threatened by new classes joining the world of writing and communication, forming an international Grub street and living on collaborations and translations. The creation of a more aggressive political language, and of the use of reason both as prophecy and announcement of the crisis, breaks the balance of the previous generations which had reached the highest levels of intellectual communication in the academies, in the teaching and in the publishing world. In this phase women seem to live less apart. The fact remains that on this question Enlightenment as emancipation was a partial project delegated to the future, because it had not fully accepted the other half of its universe.

6. *Building an Epocal Concept*

Finally it should be said that the French Revolution, whilst celebrating the Enlightenment as its parent, strongly contributed to its interruption first of all because what had survived as *idéologie* had to adapt to the heavy Napoleonic tutelage and stabilization, and secondly because the behavior and the propaganda of Napoleonic France were experienced by the European cultures as a violence which forced them to find anew their national, religious, and identifying roots. This explains why part of Romanticism set itself up as an antithetic culture to the Enlightenment which was considered responsible for the political conditions in Europe. Friedrich Meinecke had spotted the opposition between cosmopolitism and the national state (1908). While new problems required new kinds of culture, certain fundamental values, after being driven underground during the *Restauration*, after the Napoleonic age, sprang up again in all the moments of opening to freedom and democracy which are scattered in the history of Europe. In French history the ideological elaboration of the Third Republic renewed the strong link between Revolution and Enlightenment again, the latter being dragged by the former.

The twentieth century, however, really needed to reflect on Enlightenment again, having a critical period troubled by nationalistic, fascist, and totalitarian cultures which threatened liberty, democracy, and equality. These threats were answered by Cassirer's (1932), Becker's (1932), Hazard's (1935, 1946) and many other's meek projects. From these roots there originated an important historiography (Venturi (1971), Gay (1967), Koselleck (1959), Pocock, Darnton, Jacob (1946, 1980), Roche and many others) which to this day has an echo in the International Society for Eighteenth Century Studies and in the dense network of National Societies. Margaret Candee Jacob has written about a 'Radical Enlightment,' which was masonic, pantheist, and republican. John Pocock (1999), more recently, has located in the English world a 'Conservative Enlightenment,' while Jonathan Israel (2001) widens the chronological terms of a European 'Radical Enlightenment' and 'its making of modernity,' starting from 1650.

There are also many publications on the limitations, deficiencies and responsibilities of Enlightenment in the evils of modernity, to begin with T. W. Adorno and M. Horkheimer (1947). But in the light of the dramatic problems of our times many evoke the necessity of a further Enlightenment, of a future of Enlightenment which will resume the interrupted project. One can well imagine that it will inevitably be a new one, because the past can give inspiration, but not necessarily return. It is true, however, that we must find our own answers to emancipation, freedom and Utopia for a world otherwise risks being an icy globality without universalism.

Entertainment

Entertainment is play, but play put on display. In the modern, Western or Westernized world plays and games have become commodities for sale in that special branch of economic life called show business. There is no limit to the media, the art forms, or the genres that might be marketed by the agents of show business, but within television and music the label 'light entertainment' marks the quintessence of entertainment: ease, lightness, cultural expressions with no other aim than pleasing as long as the program or the piece of music lasts. Entertainment, in the modern sense of the word, may thus be defined as the commercialization of the pursuit of happiness.

Late in the reign of Queen Elizabeth I, Sir John Harington wrote a *Treatise On Playe* (Harington 1968), where he defines play as 'a spending of the tyme eyther in speeche or action, whose only end ys a delyght of the mynd or the speryt.' In Elizabethan culture play developed into commercial entertainments, and Harington's definition corresponds with most modern definitions of play and entertainment. His distinction between entertaining words and entertaining actions also seems to correspond with the ancient Roman distinction between *jocus* (cf. joke) and *ludus*, but anachronism and ethnocentrism may lead to a distorted understanding if the modern concept of entertainment is projected onto cultures distant in time or space. Thus, during the Empire the Roman plays assumed explicit political functions. An operative definition of entertainment must therefore include a discussion of the interaction between history, structure, and functions in the emergence and the enjoyment of entertainment.

1. Play and Entertainment

'Only when playing is man fully man,' Friedrich Schiller declared in his manifesto *Über Ästhetische Erziehung*, and his words are echoed in Johan Huizinga's (1937) influential book *Homo Ludens*, where it is claimed that all cultural institutions are derived from play. Huizinga's sketch of the history of the concept of play, however, shows that the meaning varies from culture to culture. Thus, in ancient Greek

the verb indicating 'play' literally meant 'doing what children do' (which raises a parallel problem of historical and cultural differences in the definition of childhood). In spite of the risk of anachronism and ethnocentrism, Huizinga presents the following general definition of play: it is an activity that is freely chosen, taking place in a space and time separated from the ordinary world, operating by fixed rules or by a general 'rule' of fictiveness, and leading to results, which are uncertain and unproductive. If freedom is fundamental to play, this would exclude the medieval carnivals since they were linked to a social and religious calendar, and it is indeed very likely that Huizinga's definition of play itself is tied to modern, liberal society. If this is so, the process of secularization is what makes possible the transfer of forms of religious ritual to forms of play and entertainment, and this again implies that what appears to be the same activity actually is perceived very differently according to cultural norms.

One of Huizinga's critics, Jean Henriot (1989), has suggested that a theory of play should consider the development of the idea of play rather than the practices of play. At the individual level the child learns to consider certain activities or certain attitudes towards these activities as play, and at the social level people learn to distinguish between for instance education, work, politics, war, and play.

Ideas such as play, work, etc. govern our perception of society, and play may even be interpreted as one of those ideas in which society reflects on itself. Henriot advocates a historical definition of play, but he also notes that it is always characterized by detachment and mental lightness, and here he comes close to Georg Simmel's sociological perspective. Simmel suggests that all social processes may be considered as content and as form, and in play the forms are articulated for their own sake, while the content is suspended: in an entertaining conversation the aim is not to convince the other, the pleasure of verbal exchange is the only aim; and in a quiz-show the aim is not to get an answer to a problem, the playful reproduction of social forms known from the church (catechization) or the school (examination) is the only aim. The word 'entertainment' actually refers to play as a source of 'sociability' (Simmel). It is derived from Latin: *inter* means 'among' or 'in between' and *tenere* means 'to hold,' and therefore the meaning of entertainment is 'to hold something mutually' or 'to keep something up.' Entertainment is a social relationship and is concerned with social relations. Play has its origins in the fact that people cannot be alone, as La Bruyère stated in his *Caractères* [1688], and one of the pioneers of modern entertainment, the composer Jacques Offenbach emphasized the importance of mutual support by declaring that his dream was 'to found a share holding company of mutual insurance for the prevention of boredom' (Kracauer 1976, p. 101).

Undoubtedly there are great differences between cultures as to the degree to which a culture can or may distinguish between the contents and the forms of its everyday practices, but Simmel's perspective offers the possibility of a mediation between a historical and a formal understanding of play and entertainment; it indicates in what sense Huizinga was right when he saw a connection between play and the other cultural institutions; and it explains why play or play-like activities have been so influential in the description and interpretation of cultures distant in time as well as space from Mikhail Bakhtin and Emmanuell Le Roy Ladurie on the Renaissance carnival to Clifford Geertz on Balinese cock-fighting.

2. *Bread and Circuses*

In Western culture spectacles, circuses, mimes, etc. go back to antiquity. The idea of the ludic, i.e., the playful, is derived from the Roman concept of *ludus* (chariot races); and the idea of the aleatory, i.e., the hazardous, is derived from the Roman word for dice. In the course of Roman history it is possible to follow a restructuring of religious rituals—such as gladiatorial fights in connection with funeral rites—into cultural forms much closer to the modern idea of entertainment. Even though the giant spectacles of the Roman Empire functioned as part of a system that should solidify and glorify the status of those in power, they have become immensely powerful models for modern entertainment and modern critique of entertainment. Juvenal's verdict on a social policy that replaced the active political commitment of its citizens by the passive reception of 'bread and circuses' has inspired a 'mythology of negative classicism', i.e., comparisons of the development of modern society with the social decay of classical Rome (see Brantlinger 1983, p. 18). Just as the Romans staged enormous sea battles, mythological or historical, so English imperialism was supported by show business in gigantic reproductions of the imperial wars in the colonies, for instance the wars in South Africa staged as Savage South Africa. Colosseum has become a popular name for modern establishments within show business, and Las Vegas of course boasts a Caesar's Palace.

3. *Carnival*

In the Middle Ages, Roman festivals such as the Saturnalia and Lupercalia metamorphosed into the still-existing tradition of carnival. Entertainment is often characterized as recreation, and re-creation is what characterizes the carnival. The rural and pagan carnival would recreate the natural world, the Christian carnival would recreate the religious community, and the urban carnival would recreate the power and splendour of the city—or different groups and corporations within the city. During the carnival the

world is turned upside down, and in this period of creative chaos the sense of community is reanimated.

In contrast to commercial entertainment however, the participants in the carnival were not free to choose their leisure, and therefore their performances cannot be called pure entertainment. From the perspective of the church or the city council who presided over the event, the aim of the carnival was to make the different groups of society accept hierarchy. The function of the blasphemous words and gestures was to frighten people away from changing society or at least to restrict their demands for social and spiritual change to the carnival season.

That the authorities could use the carnival is the only plausible explanation of their pivotal role in staging the processions and plays of the carnival. But as long as the carnival lasted the situation was potentially open, the functions and the future of society were put at stake, and the safety valve might turn into an explosive political risk. Mikhail Bakhtin (1968) emphasizes the emancipatory aspects of the carnival in his influential book *Rabelais and his World*, while Emmanuelle Le Roy Ladurie in his *Le Carnaval De Romans* shows the confrontation between disciplining forces and rebellious forces within the carnival.

4. *Courtly Diversions*

In Europe in the sixteenth, seventeenth, and eighteenth centuries the ways of popular culture and elite culture separated. Politically, as power became centralized the powerful made a spectacle of themselves through fireworks, pageants, and allegorical plays, while reducing their subjects to spectators. Economically, the Reformation and the rise of the middle classes, who knew that time was money, was accompanied by a war against idle leisure.

To the aristocracy as well as the middle classes, the experience of time, the abstract and empty time of the clock, became a new social experience, but while the aristocracy actively cultivated a culture of pastimes and diversions, the puritan middle classes rejected all pastimes that would divert their attention from work. While the aristocracy in an oblique way became the pioneers of modern entertainment, the puritans just as obliquely shaped the pattern of modern cultural critique.

The culture of *divertissements* at the French court developed as the process of centralization and the politics of absolutism changed the 'nobility of the sword' into courtiers. Leisure time at court became a psychological as well as a political problem. To aristocrats used to fighting, hunting, etc., life at court was inactive and boring, and they had to do something to pass away their time. Diversions would compensate for the lack of activity and power and at the same time the entertaining discussions, dances, etc. would create a social bond between them. The intricate equestrian displays known as *carrousels* epitomized this domestication of a warrior class through entertainment. A trace of this historical development may still be seen in the predilection for a lavish, baroque style in merry-go-rounds and other fairground architecture.

5. *Commerce and Buying Fun*

In the eighteenth century the word entertainment (or in Germany: *Unterhaltung*) had a breakthrough, but this was in reference to private or domestic entertainment. The expansion of the book market contributed to changing the private home into a sphere of entertainment, and in so far as stories of love or adventure were written for the market, the principle of publicity entered the private sphere. The court was replaced by the market as the provider of entertainment, and these entertainments were open to everyone with sufficient money. In 1725 Daniel Defoe noted that writing had become 'a very considerable Branch of the English Commerce' (Watt 1957, p. 55), and an increasingly popular genre such as 'the penny dreadful' indicates the importance of the market. In the Scandinavian languages the word commerce became synonymous with having fun.

However, at the beginning of the nineteenth century Joseph Strutt wrote *The Sports And Pastimes of the People of England* (1801) in which it is obvious that the idea of public entertainment for a general public was only beginning to get a foothold. In his table of contents the pastimes are divided according to time, place, and social group: 'Rural exercises practised by persons of rank,' 'Rural exercises generally practised,' 'Pastimes usually exercised in towns and cities, or places adjoining to them,' 'Domestic amusements of various kinds; and pastimes appropriated to particular seasons.'

In contrast to premodern entertainments the break with hierarchy was a general feature of the modern culture of entertainment. When Philip Astley (Speaight 1980) founded the first circus at Westminster Bridge in 1770—gathering itinerant showmen, jugglers, clowns, and acrobats under the same roof, with riding masters as a tribute to aristocratic culture—he addressed his public as 'the Nobility, Gentry and others.' But he, as well as other entrepreneurs within show business, soon learned that it would pay off to put the 'others' in the foreground. If the new entertainment industry used amusements of the old aristocratic culture, they would inevitably democratize the diversions of the past. Søren Kierkegaard made 'leveling' a key concept in his analysis of modern, urban culture; Georg Simmel wrote of 'leveling' in his analysis of 'The Metropolis and Mental Life' from 1903; and in 1913 Georges d'Avenel published a book

on the leveling of amusements in modern times: *Le nivellement des jouissances.*

6. *The Mass Entertainment Industry of the Nineteenth Century*

According to Asa Briggs (1960) five conditions stand out for the development of a mass entertainment industry in the nineteenth century. First, a large and concentrated urban population. Second, sufficient money to buy regular, cheap entertainment. Third, sufficient leisure time to make a commercial exploitation possible. Fourth, urban transportation systems to take the public to the places and palaces of entertainment. Fifth, the application of technology to entertainment. The money, the leisure time, the transportation, and the technology making mass reproduction possible are self-evident preconditions for the rise of a mass entertainment industry. The process of urbanization, however, needs some further comment.

In the nineteenth century the concentration of the urban population was preceded by an uprooting of people—from the countryside, from tradition, etc.—and the isolation of the individual in the middle of the urban crowd called forth a need for the mental support of entertainment. Just as the popular culture of fairy-tales, carnival, etc. had given form and meaning to the culture of the preindustrial society, the mass entertainment industry shaped a sense of community between urban dwellers, who could no longer rely on time-honored traditions or pre-established social relations. Boredom may be termed the cultural disease of the nineteenth century. Similar to the boredom experienced at the courts of the seventeenth and eighteenth centuries, this was the psychological reflection of a loss of cultural meaning, a loss of a common cause. A recurrent theme in nineteenth century literature was the characterization of boredom (*ennui*, *Langeweile*) as a modern invention, a modern monster, the constitutional evil of the century (see Sagnes 1969). In the same year that the cosmopolitan Georg Carstensen opened the Tivoli Gardens in Copenhagen, Søren Kierkegaard published his *Either-Or* with an ironical chapter on boredom as the source of all creation including the Creation, and as a remedy to this boredom he suggested public entertainments on a grand scale.

The grandest scale was represented by the city itself and the crowd, and urban life became a leading motive in all kinds of modern entertainment: panoramas such as the London Colosseum showing a panorama of London as seen from the cupola of Saint Paul's Cathedral, crime and detective stories, melodramas, music (from Offenbach's 'La vie parisienne' to the role songs of the music halls). Many of the new establishments of entertainment were even constructed as small cities, for instance panoramas with their spectacular 360 degree representations of cityscapes; world exhibitions; amusement parks such as the Tivoli Gardens; and zoological gardens with gates, walls, streets, squares, and animals living in cages shaped like buildings from their native countries.

City life was entertaining in itself, as witnessed by cafés, promenades, show windows, etc., and the appeal to visual pleasures was noticed by most observers. Charles Lamb wrote of the spectacle as the essence of the city; Théophile Gautier declared that the era of purely visual spectacles had arrived; and in the 1880s a new and abundant use of the terms 'show' and 'show business' (see Nasaw 1993) marked that visual turn of entertainment which has continued with film, television, and even music videos in the twentieth century.

7. *A Map of Modern Entertainment*

A map of modern entertainment may take as its starting point the minimizing expression: 'only entertainment.' This expression indicates two things: (a) that entertainment has become a specific sphere in society, and (b) that entertainment has no importance. As a specific sphere, as 'show business,' entertainment differs from play although it is based on forms of play. And as a sphere of activities allegedly of no importance, entertainment differs from art although the absence of intentions may be seen as an extreme version of the esthetic attitude defined by Kant as 'disinterested pleasure.' However, the reduction of entertainment to 'only entertainment' may be interpreted as an effort to deny or exorcise the real importance of entertainment in modern society: as a substitute for religion, as a purveyor of a new mythology, as a part of politics, and as a key sector in the economy.

As mentioned above, boredom seems to have been the mental reflection of the processes of modernization, which changed the status of religion, politics, economy, and private life. Uprooted from traditional social ties, modern man was thrown back on himself. Entertainment, however would offer a reconstruction of social ties based on the elementary experiences of the body and the gaze. Circus, melodrama, waxworks, the whole showbusiness, literally show that the body and the gaze are the stuff entertainment is made of. On one hand the concept of diversions indicates that entertainment literally should divert attention from this boredom. On the other hand entertainment became an institution or a cultural practice which should shape the relationship between the individual and modern life, the mass and modernity.

Play is the basis of entertainment and similarly to play, the forms of entertainment may be divided into four categories, each articulating a specific relation between the individual and society—or the mass and power. Following Roger Caillois (1967) the main forms of entertainment may be interpreted as four different ways of handling the oppositions between

identification and alienation and activity and passivity (or action and passion).

(a) Activity and identification are leading principles in chariot races, chivalrous tournaments, and sports as well as in the shooting parlors of the amusement parks, and in the narratives of action and adventure whether told in novels, films, or TV shows. Just as the hero does, the audience identifying with the hero seeks the recognition of their identity in the hero's victory. The characteristic emotional experience of action, adventure, and competition is suspense, which gives the reader or spectator a vicarious feeling of taking part in the action.

(b) Passivity and identification are leading principles in all games of chance, in horror stories, etc. The heroes are more often than not victims, and if they end up as winners it is not by their own merit. Identification therefore does not consist in recognition of their name but in identification of the number which makes them winners. The characteristic emotional experience of this type of entertainment is the thrill, which gives the reader or spectator a vicarious feeling of being victimized or saved by alien forces.

(c) Activity and alienation are leading principles in all kinds of theater, masquerades, variety shows, literary parodies, etc. The heroes here take on the heroic or villainous or just different persona of another person, and if they gain a name, it is through their talent for making themselves another person. The whole gamut of feelings is of course invited by this type of entertainment.

(d) Passivity and alienation are leading principles in slapstick comedy, in many kinds of music and dance, in swings, merry-go-rounds, roller-coasters, etc. The heroes here hand over themselves and their destiny to impersonal forces, and in contrast to the gambler do not look for any profit but the pleasure of vertigo. Even though emotional distance from the capers and clowns of all sorts is one of the enjoyments of comedy, the readers or spectators who give themselves over to laughter are also looking for the pleasure of losing control.

Even though play often involves a gathering of onlookers, it is not, as in public entertainment, based on a division between actors and spectators. This division of course complicates any mapping of emotional investments and gains. In action and adventure the investments of reader or spectator parallel the hero, whereas in comedy the investments of the reader or the spectator are characterized by their contrast to the troubles of the 'hero' (i.e., the fool or the clown). And even though a horse race confronts parties in a competition where they can only rely on their own skill in their endeavor to be named winners, the spectators may very well make it an occasion for gambling. The map thus needs further elaboration, but already this provisional map shows the possibility of describing and comparing forms of entertainment across the different media. What they have in common are typical, and sometimes stereotypical, ways of staging self-experience and social bonds.

8. *Entertainment Now*

After 1900 show business has developed exponentially with the new media, but now the system of genres and types seems well established. Sampling, parody, and similar kinds of recycling indicate a growing familiarity with the world of entertainment. Also a new entertainment form such as computer games is characterized by using the formulaic worlds of adventure, crime, gothic tales etc. In spite of computer cafés, this medium also confirms the trend toward privatization and even individualization of entertainment: the radio made it possible to enjoy a symphony on the sofa, the television set made the sitting room into a cinema, the transistor radio and the home video made it possible for individuals to chose when they would enjoy a specific program, the Walkman made the individual into a closed electronic circuit. In contrast to this process of extreme individualization a number of new entertainment forms offer the pleasure of being a member of a crowd: rock festivals, sport events, cult movies. Entertainment no longer forms a distinctive sphere, or it is at least often discussed as an aspect of education, politics, work, or even war (wargames). If entertainment is a dramatization and an interpretation of modern life, this invasion of the other spheres of social life may reveal a growing need for understanding how society—in Simmel's words—is possible.

Entrepreneurship

The entrepreneur is the head of the firm and coordinates the factors of production; introduces new methods, processes, and products and creates opportunities for economic growth; bears the risks connected with his or her activities; and, enjoys power and high status in capitalist market societies. Entrepreneurs predate capitalism and do exist in socialist and other alternative economic systems, but are especially associated with that economic system more than any other.

The term entrepreneur is only one of the concepts used to designate leadership in business and overlaps with others, such as capitalist, employer, investor, owner, manager, producer, chief executive, bourgeois, investor, work-giver, profit-maker, boss, businessman, and businesswoman. Each of these labels stresses one aspect of leadership in business institutions and of the relations with a variety of stakeholders, but the concept 'entrepreneur' seems the most encompassing and rigorously defined.

The very origin of the word 'entrepreneur' must be traced to the realm of war rather than of economic competition, although in a war for gain rather than for power or honor. The first references to the word appeared in sixteenth-century France, where it defined the fortune captain who hired mercenary soldiers to serve princes, leagues, or towns for pay. It was only later, in the eighteenth century that the concept applied to 'peaceful' economic actors who either undertook contracts for public works, or introduced new agricultural techniques in their land, or risked their own capital in industry.

The first theoretical accounts of the entrepreneurial function appeared in the second half of the eighteenth century with Cantillon and Turgot, who stressed the willingness to accept the risk and uncertainty inherent in economic activity as the key distinctive feature, a concept which was later developed by Knight in the twentieth century. Adam Smith and mainstream economics did not emphasize the specific role of the entrepreneur—with the notable exceptions of Jean Baptiste Say—who defined the entrepreneur as the person who combines the factors of production for profit, putting himself at the center of several relations among capitalists, workers, technicians, merchants, and consumers—and John Stuart Mill—who separated the entrepreneurial function (the payment for which is profit) from that of providing capital (the payment for which is interest). It was, however, Joseph Schumpeter, who above all, conceptualized entrepreneurship as innovativeness, thus giving it a dynamic quality lacking in earlier formulations.

Contemporary economics assumes that entrepreneurial services are highly elastic and that failures in entrepreneurship are due to maladjustments to external market conditions and to lack of economic incentives. Only a few economists analyze more deeply the concept of the entrepreneur, conceiving him or her as a middleperson between markets, or a gap-filler alert to new opportunities. The study of entrepreneurship is thus more developed within other disciplines: sociology, business history, psychology, and anthropology.

1. *The Classical Theories*

The classical interpretations of entrepreneurship by Marx, Weber, and Schumpeter are framed into broad, ambitious studies of economic dynamics and cultural change which, although sometimes not convincing and in need of empirical verification and substantial revision, generally avoid the pitfalls of comparative static models and often ask the right kind of questions.

Marx's contribution to the study of entrepreneurship does not lie so much in *Das Kapital*'s (1867) abstract model of the capitalist mode of production, as in the analysis of the capitalist labor market and factory system, and in the historical sketch on 'primitive accumulation,' where he traces the processes of disenfranchising of labor from feudal and corporate ties and the transformation of land, merchant, and money capital into industrial capital; as well as in the

accounts of the events of 1848 and 1870 in France, where the different strategies of the various components of the bourgeoisie, such as industrial and financial capital, are analyzed. On the whole, in spite of its methodological errors—first of all the reifying of its economic model into more or less universal laws—Marx's analysis of the rise and the internal dynamics of capitalism played an important role in future works by Weber, Sombart, Schumpeter, and many others (both Marxists like Dobb, Sweezy, the 'dependencia' theorists, and non-Marxists like Polanyi and Barrington Moore), by identifying a set of basic structural conditions of a capitalist economy, where entrepreneurship can develop.

Weber's study of entrepreneurship is couched in his analysis of the interplay between religious ethos and modern rationalization in the rise of capitalism. The entrepreneur is clearly distinguished from his historical predecessors in traditional economies by virtue of his rational and systematic pursuit of economic gain, reliance on calculation measured in relation to this economic criterion, the extension of trust through credit, and the subordination of consumption in the interest of accumulation. These are the elements of the rational economic actor's 'instrumental rationality' (*Zweckrationalitat*), by which he or she establishes a systematic relationship between preferred goals and the most suitable means to achieve them. In his ponderous essays on the economic ethics of great world religions published in the *Archiv für Sozialwissenschaft und Sozialpolitik* and in his major work *Wirtschaft und Gesellschaft* on the relations between economy and society, Weber argued that the advent of ascetic Protestantism provided an especially fruitful breeding ground for the mentality of economic rationality, since through a complex process material success is a sign of ascetic realization.

Weber's analysis has been variously and sometimes convincingly criticized; but his most significant and lasting contribution lies, as Brigitte Berger (1991) puts it, in 'his ability to show how the expansion of "instrumental rationality" characteristic of the modern entrepreneurial phenomenon also impelled—slowly and incrementally, through the efforts of individuals and groups in their everyday activities and practices—the formation of distinctly modern institutions in all spheres of life, the public as well as the private.' The degree to which the forces of rationalization responsible for dislodging individuals from their embeddedness in nature, religion, and tradition continue to shape contemporary and future developments is the study of some current researchers, particularly those influenced by Kellner.

The classical interpretations of Marx and Weber are relevant, but Schumpeter is the theorist of entrepreneurship 'par excellence,' who provides the most thorough analysis of the entrepreneurial function. The analysis of entrepreneurship is at the center of Schumpeter's theoretical system. The entrepreneurial function is the key variable in his theory of development. He defined it as innovation, the introduction of a new combination of the factors of production (land and labor) that, when combined with credit, breaks into the static equilibrium of the circular flow of economic life and raises it to a new level. The entrepreneur changes the conditions of supply, combines existing resources in new ways, and thereby sets up a new production function. Entrepreneurship does not imply the requisite of property, is not based on the assumption of risk, and does not require belonging to a business organization. Schumpeter stressed the revolutionary character of the entrepreneur (and sometimes portrayed him with the same unilateral admiration as Marx showed for the revolutionary proletariat). But the conception of entrepreneurship as 'the function of innovation' opens the door to the critique that he exaggerates the importance of a function that seems potentially open to every person in business. To counteract this critique, Schumpeter drew on a range of sociological and psychological insights to demonstrate the entrepreneur's exceptional role and qualities.

Entrepreneurship, he argues, calls for a specific type of personality and conduct, which differs from the economic man. The entrepreneur takes advantage of rationally based components of his or her environment, such as money, science, and individual freedom, and he or she orients his or her conduct to rational values, but he or she is not the average product of bourgeois culture, which defines rationality from the narrower viewpoint of calculating one's short-term advantage. The entrepreneur acts on the basis of an autonomous drive to conquest and struggle, to achieve and create for its own sake, and also to establish a family dynasty. He or she is a bold leader, capable of thinking the new and grasping the essential, willing to act quickly, to understand by intuition, and to forgo the psychological resistances and social criticisms that always arise when new and innovative behavior is regarded as deviant and dangerous. This sets him off from the routine manager. While having some elements in common with religious and military leaders of the past, the entrepreneur is, however, the leader of a rational and antiheroic culture, and as a result does not excite the charismatic feelings and collective enthusiasm of those who make or defend whole civilizations.

Entrepreneurship is a specific historical phenomenon, which rests on the premise of a separate economic sphere differentiated from others. In previous epochs, the entrepreneurial function was fused with others in the actions of religious, political, and social leaders. In any historical society there is leadership, defined as the capacity to conceive and lead the making of innovations. What changes in the different historical contexts is the privileged sphere where leadership is applied, the one that is related to the core function for the survival and development of that

given society. Entrepreneurship is the specific historical form that leadership assumes in capitalism, its distinctive (and even essential) feature, closely linked to the bourgeois class. The bourgeoisie is the leading class, because bourgeois families have performed the innovating and leadership role in the economy and because they acquire, consolidate, and transfer prestige, power, and wealth to future generations.

The fate of entrepreneurship is closely linked to those of the bourgeoisie and capitalism. The conception of entrepreneurial innovation as the key element of capitalism implies that the weakening of the role of the innovative entrepreneur is seen as a basic factor—along with the fading away of bourgeois institutions—of the crisis of capitalism. Schumpeter predicted the progressive decay of the entrepreneurial function by virtue of the routinization of innovation in large oligopolies, which would render the entrepreneurial function superfluous and undermine the basis for continued bourgeois dominance. It is the very success of the capitalist firm that undermines the system.

Schumpeter's identification of the fate of the nineteenth-century entrepreneur with that of capitalism is largely responsible for his faulty prediction of the collapse of this system. In reality, capitalism has proved capable of fundamental transformations through that process of 'creative destruction' that Schumpeter had clearly perceived, but underestimated. Several different brands of capitalism exist, which proved compatible with the existence of very large firms and with state intervention and control of the economy.

In spite of his limitations, Schumpeter is the most influential scholar of entrepreneurship. Although often in a rather sketchy way, he asked the most relevant questions and provided important theoretical insights.

2. *The Multidisciplinary Approach to the Study of Entrepreneurship*

In recent decades entrepreneurship has been studied by various disciplines and through different approaches that were influenced by the classical studies, and particularly by Schumpeter's theory. For most economists—with notable exceptions from Schumpeter to Kirzner—the question of entrepreneurship is not problematic; entrepreneurial activities will emerge more or less spontaneously, as an instance of rational profit maximization, whenever economic conditions are favorable, such as availability of capital, labor, and technology, factor mobility, and access to markets. Other social scientists, mostly sociologists, social-psychologists, business historians, and anthropologists, tend to see entrepreneurship as a more problematic phenomenon, deeply embedded in societies and cultures; they focus on the influence of, and the mutual interplay among noneconomic factors, such as cultural norms and beliefs, class relations and collective action, state intervention and control, organizational structures, bounded solidarity and trust, deviant behavior and marginality status, and motivations for achievement. They also study how different historical and geographical settings may call for markedly dissimilar forms of entrepreneurship. Economic historians have pointed out that the personality type and behavior characteristics of last-century business leaders bears little resemblance to their counterparts of today. Comparative sociologists have shown strong differences in entrepreneurial roles and styles across countries and with regard to the firm's size and to the stages in the firm's life cycle.

Different disciplinary paradigms provide a first basis for classifying major approaches to the studies of entrepreneurship and management. Underlying these different approaches are the two fundamental dimensions of: (a) system variables versus actor variables (or, in different terms, macroanalytical models versus microanalytical models), and (b) structural versus cultural variables.

Metaphorically we can say that for entrepreneurship to emerge it is necessary that the 'seed' should find the appropriate 'ground.' Certain scholars focus on the seed, i.e., either on specific psychological traits of entrepreneurial personalities or on their social characteristics. Other scholars focus on the breeding ground, which is analyzed either in its structural factors (types of markets, factors of production, class and ethnic relations, state planning, etc.) or cultural factors (business ethics, social approval of economic activity, etc.). Others, still, emphasize the specific relation between the actor and the situation.

3. *The Entrepreneurial Personality*

Schumpeter argued that entrepreneurship calls for a specific type of personality and conduct, which differs from the simple rational conduct of the economic person. Psychological and sociopsychological studies focus on the distinctive traits of entrepreneurial behavior and personality. McClelland's comparative study tries to answer the question of why some societies are more likely to produce entrepreneurs than others. His major conclusion is that childhood experiences create in certain individuals a particular psychological factor, what he calls 'the need for achievement,' which is responsible for economic growth and decline. The inculcation of the achievement motive is due to child-rearing practices that stress standard for excellence, self-reliance training, maternal warmth, and low father dominance. In Western industrialized nations children internalize in family socialization attitudes and symbols which favor a higher need for achievement than do children raised elsewhere, and many of the high achievers have become entre-

preneurs. In underdeveloped countries McClelland finds fewer people with a high need for achievement; besides, of this smaller number, most go into fields other than business and industry. This interpretation of the motivational structure of entrepreneurship has rather overt normative implications; governments interested in economic growth should produce more high achievers by breaking traditional patterns and emphasizing other-directedness and should motivate the high achievers to enter business and industry. McClelland's need for achievement theory raises serious methodological problems and risks to be tautological; yet, because it is easily testable, it has fostered a large number of empirical researches.

In general, psychological approaches are questionable since they either tend to make economic activity too much a function of personality, underplaying the role of contextual influences, or to establish too simple a correlation between micro (personality) variables and macro (economic and sociological) variables. Gerschenkron (1962) criticizes this type of theory, arguing that the normal variation in child-rearing practices and in IQ will produce enough potential entrepreneurs in every society; the critical questions are the institutional factors that are available for entrepreneurial action.

A more sophisticated theory of the relation between socialization and entrepreneurial personality is that of Hagen (1962), who tries to answer both the questions of who the entrepreneurs are and why they come more often from certain social groups. Hagen's model combines a psychoanalytical interpretation of the entrepreneurial personality with an analysis of his or her condition as a member of a group that is deviant from the cultural norms of the larger society. According to Hagen, entrepreneurs tend to come from groups that suffered from withdrawal of status respect (i.e., groups who perceive that their purposes and values in life are not respected by other groups in society whom they respect and whose esteem they value). The loss of status by the social group leads to the breakdown of the family authority and is the trigger mechanism for changes in personality formation. However, the outcomes can be very different. Status withdrawal may only lead to sentiments of anger and anxiety and to retreatism. Or, in situations where the mother rejects the husband-father and shows an attitude of protective nurturance to her child, she may foster individualism and the development of a creative and self-reliant personality. Several generations are required to overcome social blockage, but then entrepreneurs can emerge.

The weakest point of Hagen's theory is that his attempts at verification are limited to a few historical cases. Yet, at least for the part based on status withdrawal, his model can rely on empirical evidence of disadvantaged minorities in complex national societies that contributed disproportionately to entrepreneurial activity and economic development (like the Jews and the Protestants in Europe, the Samurais in Japan, the Parsees in India). Hagen's model is in some way the *trait-d'union* between the psychological and the sociological approach; he considers macro-sociological variables, such as status withdrawal and social marginality, but only insofar as they influence personality development.

4. *The Social Context of Entrepreneurship: Marginal or Privileged Status?*

The context where entrepreneurship emerges has been studied with regard to: either the social position of the entrepreneurs (marginal/deviant or privileged), or the cultural values and attitudes that can favor it, or the structure of risks and opportunities. Sociological conceptions of entrepreneurship in terms of deviance and marginality status have a longstanding tradition. In *Der Moderne Kapitalismus* (1916–27, 1987), Sombart remarks that the creativity and the ability to break traditional values and patterns which characterize the capitalist entrepreneur can be found in all peoples, social groups, and religions, but that they are more frequent among the members of certain minorities, such as the heretics, the strangers, and the Jews. These groups are not completely accepted in the societies in which they live; they can therefore avoid more easily than others the traditional values and norms that regulated economic behavior in premodern Europe. Because of their minority status—both tolerated and oppressed—they tend to develop specific skills in the commercial and financial activities they are allowed to practice; and because of their acute sense of diversity, they maintain a strong group solidarity, which favors trust and therefore credit among the members of the group.

Building on both Sombart and Schumpeter, Hoselitz (1963) argues that entrepreneurs are deviant because of their ambiguous social position. Marginal groups such as the Jews and Greeks in medieval Europe, the Chinese in Southeast Asia, and Indians in East Africa, are peculiarly suited to make creative adjustments in situations of change and to develop genuine innovations in social behavior, because they act in a hostile social milieu, where prevailing attitudes are against innovation; they are excluded from political power so they concentrate on business; and being left outside the dominant value system, they are subjected to lesser sanctions for their deviant behavior.

More recent works on ethnic communities (Ward and Jenkins 1984, Waldinger et al. 1985) and women (Goffee and Scase 1985) follow a similar 'positional' approach. Structural factors within the larger society, such as racism, sexism, and credentialism, through processes of exclusionary closure create 'outsiders'; but some of these people form 'feeder groups' from which new entrepreneurs emerge, as in the case of

South African Indians who, embedded in organic networks and communities, were remarkably successful in circumventing the massive legal and political constraints of apartheid.

In their study (1992) of how Dominican and other immigrants 'made it' in the American economy Portes and Min Zho emphasize bounded solidarity and enforceable trust as sources of social capital, which do not stem from shared value orientations, but from the position of the ethnic minorities in the wider social structure. Citizens of China, Korea, or Cuba do not display any exceptional solidarity or *bienfeasance* in economic transactions when they are in their native countries. Such benefits stem from their being the members of an identifiable social minority in the host country. Bounded solidarity is created among immigrant customers, workers, and investors because they are treated as foreigners, and have a heightened awareness of the symbols of common nationhood. Enforceable trust is based on the ostracism of violators, cutting them off from sources of credit and opportunity in the ethnic economy.

The social marginality approach can be challenged on two grounds: on structural grounds, by those who argue that dominant classes in society can produce entrepreneurs more than marginal groups can, because of their access to economic, political, and social resources; and on cultural grounds, by those who stress core values and social approval as requisites of entrepreneurship. Social marginality and ethnic solidarity certainly play a role in the formation of entrepreneurship. But historical and comparative research on developed countries—both early industrializing countries (like Great Britain and France) and 'latecomers' (like Germany, Italy, and Japan)—show that most new entrepreneurs come from the already 'privileged' status groups of preindustrial societies, such as merchants, landowners, and wealthy artisans, who possess both the material and intellectual resources for economic achievement. Dobb's thesis of the revolutionary role played by yeomen and independent artisans (1946), Pirenne's analysis of the role of merchants in the formation of the urban bourgeoisie (1914), and Brentano's view of the acquisitive aristocracy as a protocapitalist class (1916), are all instances of the importance of social groups that occupied well-established positions in the 'traditional' societies and which paid a key modernizing role. Although in different ways, studies of modernization and of the world economy by Barrington Moore (1966), Bendix (1978), Wallerstein (1979), and others, show the importance of socially established classes in entrepreneurial formation and consolidation.

Even in a more open society as the United States, the contribution of immigrants and lower classes to the formation of entrepreneurship has been exaggerated. Scholars as different as Mills (1945) and the business historians of the Harvard Center for Entrepreneurial History (Miller 1952) found a rather stable recruitment pattern: most of the business elite in the period of the great American industrialization (1870–1910) came from landowning or entrepreneurial families, whereas lower classes contributed between 10 and 20 percent of the membership. A similar critique of the popular origins of entrepreneurs in industrialized countries comes also from major studies in social mobility (Lipset and Bendix 1959).

More recent studies of the relationship between entrepreneurship and social stratification focus on the social and cultural specificities of women entrepreneurs (Goffee and Scase 1985); and stress the importance of the middle classes as a breeding ground for small entrepreneurs. Martin and Norman (1970) argue that small entrepreneurs are particularly suited to contemporary society, because of facilitating conditions both on the supply side of entrepreneurial talents, and on the demand side of services requiring new market niches. And Bechhofer and Elliot (1981), see them as the true custodians of the traditional values upon which the capitalist social order was built (passionate individualism and independence, the moral evaluation of work, laissez faire competition, and the belief that inequality is the result of differential distribution of talent and effort).

5. *Entrepreneurship and Culture*

Studies stressing cultural context variables are indebted both to Weber and Schumpeter. The classical exposé is Weber's comparative analysis of religious ethics and economic action in the rise of capitalism. Schumpeter inspired the historical research of the Harvard Center for Entrepreneurial History. Neo-Weberian research focuses on the degree to which the forces of rationalization responsible for dislodging individuals from their embeddedness in nature, religion, and tradition continue to shape economic growth and social modernization. Following Weber and Parsons (and in a similar vein to Marshall Berman's perceptive study of modernity, 1982), scholars like Peter Berger, Brigitte Berger, and Kellner (Berger et al. 1973), stress the typical cognitive style that distinguishes modern consciousness, such as instrumental rationality and the propensity to combine and recombine activities for the achievement of calculated ends. Brigitte Berger's cultural approach to entrepreneurship argues that economic growth develops from the 'bottom up,' not from 'top down': ordinary individuals, competing with one another for achieving a variety of goals (including economic profit and self-advancement), create in their everyday activities, practices, habits, and ideas the basis for other distinctly modern institutions to emerge that may mediate between them and distant, large-scale structures of society.

Evidence for this cultural approach is found in various empirical researches, including: Martin's

(1990) analysis of the role of Protestant sects in generating a dynamic process among segments of the urban poor in contemporary Latin American cities that fosters entrepreneurial activities; Redding's study of the relation between basic aspects of Chinese culture—such as Confucian ethic and family attitudes—and the entrepreneurial behavior among overseas Chinese (1990); Landa's thesis of the entrepreneurial success of ethnically homogeneous middlemen groups in Africa and in Southeast Asia (1991).

These types of study can be challenged on various grounds. First, these studies often make some confusion between the hegemonic culture and marginal groups' subcultures: sometimes it is the contrast with the core cultural values which is presented as a cause of entrepreneurial success; some other times it is the convergence with the core value of instrumental rationality. Second, the concept of culture is often stretched so far as to include social interaction in general and all sorts of social networks, without paying attention to structural variables like patterns of solidarity, class, status and power relations, legal norms, and state arrangements and policies, which fundamentally affect social interaction. Third, cultural explanations can be accused of having little predictive power since they are invoked only after a particular group has demonstrated its economic prowess; and of being ultimately tautological, since if a certain minority is successful, it must be because it originally had, or later acquired, the right values.

Another approach that is framed in the cultural paradigm is the social attitudes (or cultural legitimation) model, developed by the members of the Harvard Center for Entrepreneurial History, such as Landes (1951), Sawyer (1952), and Cochran (1949) and by sociologists such as Lipset (1967).Comparing the United States and Latin America, both Cochran and Lipset explain differences in economic development in terms of the degree of legitimation of entrepreneurship. Cultural norms, role expectations, and social sanctions can either favor or hinder innovation. Comparing France and the United States, both Landes and Sawyer maintain that the different pace and degree of economic development in the two countries were due to their different historical heritage; while in France the feudal heritage had left a consistent residual of social attitudes hostile to entrepreneurship that limited the recruitment of entrepreneurs, in the United States the absence of a feudal past had allowed the growth of a sociocultural context which was especially receptive for innovation and entrepreneurship.

In a well-known debate, Gerschenkron (1962) refutes Landes and Sawyer's thesis by arguing that the error of giving too much importance to social attitudes lies in assuming the existence of a homogeneous and generalized value system in society. As counterevidence Gerschenkron brings the cases of eighteenth-century France's *fermiers généraux* and of nineteenth-century Russia's emancipated serfs, who became entrepreneurs in spite of an unfavorable cultural environment. Gerschenkron's critique is framed in his theory of the different paths to economic development; according to him, different countries develop through a different mix of what he calls the 'institutional agents' of development, such as private entrepreneurs, merchant banks, and governments.

6. *The Entrepreneur in the Structure of Risks and Opportunities*

Both nonmainstream economics and the situational approach to the study of entrepreneurship focus on markets as structures of risks and opportunities. Mainstream accounts of economics—like those by Knights and by post World War II development economists—assume economic actors to have knowledge of all the opportunities open to them and to behave in a fixed, rational, maximizing way, once appropriate incentives are introduced. But, when these assumptions are relaxed, and market segmentation, ignorance, impeded factor mobility, and pervasive administrative controls are taken into account, the 'extraordinary' role of the entrepreneur becomes apparent, as does the need to analyze more carefully the factors that can favor his or her formation. The most interesting contemporary interpretation of this kind is Kirzner's approach.

Under the influence of Schumpeter, Mises, and Hayek, Kirzner (1973) points out that human action is meaningful only in relation to the purposes, plans, and expectations of the actor; it is partly guided by maximizing criteria, but alertness, creativity, and judgment—the typical features of the entrepreneur—also influence what we do. For the market process to emerge, an additional element is required that is not comprehensible within the narrow conceptual limits of economizing behavior, that is entrepreneurial action. This action is favored by an appropriate system of economic and social incentives, such as profit, fame, prestige, power. Entrepreneurial competition is a discovery procedure of profit opportunities, and the competitive system is a fundamentally social process, dependent on the free interplay of individuals.

Pushing Kirzner's conception further, Lavoie (1991) argues that the theory of entrepreneurship could more fully account for economic change if it were built on the hermeneutical theory of language and culture. According to him, any individual interpretive process is embedded in culture and meaningful only in relation to culture. Lavoie adheres partially to methodological individualism, only insofar as it assumes that the social whole has no purpose, but is a complex resulting from the choices of the participating individuals. But he rejects its other assumption, shared by most economists, that the rational action of the isolated individual serves as the foundation of the analysis of

markets. Individual minds are interdependent parts of an integral process of cultural dynamics; they could not exist in isolated, cultureless, brains devoid of language. With Lavoie, we come full circle, back to culture.

By the mid-1960s, scholars from diverse disciplines contributed to what is known as the situational (or social development) approach. Instead of looking at the institutional conditions of entrepreneurship, they asked themselves what actually an individual does when being an entrepreneur. Some, like Glade, and Greenfield and Strickon, give primacy to social action over structural context; others, like Gibb and Ritchie, stress structural context over social action.

Glade (1967) starts criticizing McClelland and Hagen's models as instances of comparative statics, describing social behavior in two contrasting types of system, one underdeveloped and the other developed, which are both in a steady state; what they lack is a theory of change which explains the transition from one state to the other. Glade maintains that actors make choices and decisions within social settings that are opportunity structures changing over time. The integral features of any given situation are both an 'objective' structure of economic opportunity and a subjective capacity of participants to perceive and act upon such opportunities. Entrepreneurs are individuals who can recognize the new opportunities and take advantage of them, without losing them to others.

Glade's situational analysis to the study of entrepreneurship has been criticized and elaborated upon by Greenfield and Strickon (1986). They propose using Darwinian biology as a metaphor for the study of change; as Darwin rejected typological, essentialist biology, they reject fixed types of entrepreneurship—the analogue of the immutable species—and recognize existing diversity of behavior within specific human populations (or communities), which at its extremes encompasses innovation and novelty. These diverse behaviors interact with their environments, to produce outcomes that are evaluated both by the actor and others. Those innovations judged more advantageous in terms of the standard prevailing within the group may be selected, learned, and imitated, with the result being the establishment of a statistical pattern. Society, culture, religion, politics, and economics are not seen as entities with a reality of their own, but as statistical patterns abstracted from the variable behaviors of the members of specific communities.

An attempt to combine the situational approach with that of reference groups is the social development model exemplified by Gibb and Ritchie (1982). Entrepreneurs change continuously in terms of the situations they encounter and the social groups to which they relate. It is their interactions with specific social contexts and reference groups which produce distinctive ambitions and behavior. The wide range of influences and interactions makes it impossible to define a single entrepreneurial model, but it does not prevent the development of typologies of entrepreneurs, like the one they develop, where four types ('improvisers,' 'revisionists,' 'superceders,' and 'reverters') are identified as being at the center of different sets of influences.

7. *An Integrated Approach to the Study of Entrepreneurship*

The conclusion we can draw from the state of the art of the research on entrepreneurship is that the most interesting studies are often located at the borders between disciplines, such as those by economists who reject simple rational models and recognize the influence of social interaction and culture, or by sociologists and anthropologists who reject oversocialized conceptions of man and take into account the strategies of individual actors. The most convincing interpretations are those away from the extremes of the actor-system continuum, which dismiss oversimplified views of the interaction between the actor and the systemic context.

A recent example of this integrated approach, close to my own view, is that expressed by Aldrich and Waldinger in their essay on ethnic entrepreneurship (1990). It focuses on such diverse variables as structure of markets, access to ownership, state policies, group characteristics, predisposing factors, and resource mobilization. As for types of economic environments that might support new immigrant entrepreneurs, they identify core urban markets increasingly abandoned by large food retailers, markets where economies of scale are low, markets affected by instability or uncertainty, markets for exotic goods; as for access to ownership, the relevant conditions are the level of interethnic competition for jobs and businesses, patterns of residential segregation and succession, and state immigration and labor market policies; as for group characteristics, predisposing factors, and resource mobilization, they focus on selective migration trends, settlement patterns, culture and aspiration levels, ethnic social networks, and organizing capacities. Although Aldrich and Waldinger's preference is for structural and institutional variables (like market niches and group resource mobilization) over cultural variables (like group cultural heritage), they are willing to take into account all covariables which can reasonably affect entrepreneurial formation in ethnic communities.

What is needed in future research on entrepreneurship is a multidisciplinary comparative approach, capable of integrating the analysis of the context (market, social structure, culture) with a theory of the actor (both individual or collective) with his or her motives, values, attitudes, cognitive processes, and perceived interests.

Entrepreneurship, Psychology of

Small and medium sized enterprises are important for the economy because they are the major agents of economic growth and employment (about 99 percent of the European companies are small or medium sized and they provide 66 percent of the working places, European Council for Small Business newsletter, 1997). They add jobs faster than bigger companies in the developed and underdeveloped world. Small-scale firms are highly adaptable and able to act quickly and innovatively.

Psychological approaches to entrepreneurship have experienced a revitalization recently because of the future importance of small-scale entrepreneurs and because the entrepreneur is at the boundary line of individual work psychology (personality, work activities, etc.), organizational psychology (founders of the organization have an enormous influence on it), and market psychology (economic activities in the market). Many organizational issues, for example, the influence of human resource practice, can also be studied in entrepreneurs. Essentially, all aspects of psychology are implicated when studying entrepreneurs (Rauch and Frese 2000).

Relevant literature in this area is distributed in many outlets and can be found in such diverse journals as the *Journal of Applied Psychology*, *Academy of Management Journal and Review*, *Administrative Science Quarterly*, *Journal of Small Business Management*, *Journal of Business Venturing*, *Entrepreneurship Theory and Practice*, *Journal of Management*, *Small Business Economics*, *World Development*, *Strategic Management Journal*, *Organization Studies*, and there are many articles in conference procedures such as *Frontiers of Entrepreneurship Research*, and *International Council of Small Business Conference Proceedings*.

Figure 1
The Giessen–Amsterdam Model of small business owners' success

1. *A General Psychological Model of Entrepreneurial Success*

Figure 1 presents a general psychological model of entrepreneurial success. It helps us to organize this contribution, and also has some controversial implications. For example, it does not hypothesize any direct links from personality, human capital, or environment to success because we assume that there is no success without actions. Actions are mainly determined by goals and strategies. Therefore, according to this model, psychological strategies of actions are the bottleneck through which all of entrepreneurial success is accomplished or not accomplished. The model can also be used to understand the different levels of analysis: one can differentiate the organizational level and the individual level of the firm owner with regard to each issue in Fig. 1. The level of analysis issue has a slightly different meaning in the area of entrepreneurship because company size determines which level is the adequate one. In large companies, the right level of analysis is the organizational level, in small firms, the firm owner is typically the source of action of this firm. When there are only four or five employees in a firm, the owner usually has a much stronger impact on company policy, company culture, and the company's actions than in larger firms and an individual level of analysis can be used profitably for these firms.

2. *Definition Issues: Entrepreneurs, Business Owners, and Other Concepts*

There is no agreed-upon definition of entrepreneurship. Moreover, founders and owner/managers are a highly heterogeneous group that defies a common definition. Probably the best strategy is to use a behavioral definition because it does not make any further assumptions of success, growth, or failure (e.g., Hisrich 1990): entrepreneurship is the study of founders/managers of organizations. However, one should also be open to the fact that there is a growing interest in entrepreneurship within large organizations.

3. *Characteristics of the Entrepreneur*

It is necessary to separate the emergence and the success of entrepreneurs. There may be different processes by which a person decides to become an entrepreneur and by which a person achieves entrepreneurial success (Utsch et al. 1999). Personality characteristics may be more important for the decision to become a founder than for success.

3.1 *Personality and Emergence of Entrepreneurship*

McClelland's (McClelland and Winter 1971) early work suggested that need for achievement should be higher in people who start a business. This is indeed the case as a quantitative review shows (Rauch and Frese 2000). A similar result appears for locus of control (Rotter 1966). Business owners have a slightly higher internal locus of control than other populations (Rauch and Frese 2000). Other studies have found a high degree of innovativeness, competitive aggressiveness, and autonomy (Utsch et al. 1999), Protestant work ethic beliefs (Bonnett and Furnham 1991), or risk taking (Begley and Boyd 1987). The literature about the emergence of entrepreneurship highlights that entrepreneurs are different from managers and other groups.

More recently, researchers developed more sophisticated personality concepts that match the personality variables with the behavioral requirements of an entrepreneur, for example, the Entrepreneurial Attitude Scale (EAO), which consists of achievement, self-esteem, personal control, and innovation (Robinson et al. 1991) or task motivation theory (Miner et al. 1994).

3.2 *Personality and Success*

The most frequently studied personality characteristics were need for achievement, internal locus of control, and risk-taking. A quantitative review showed a weighted uncorrected mean correlation of 0.13 between need for achievement and success. It is important to note that there is a reduced variance in these samples because of the fact that emergence is also related to the achievement motive (Rauch and Frese 2000). Studies showed that achievement motive could be enhanced and that this leads to a higher success in business (e.g., McClelland and Winter 1971). A similar relationship with success also appeared for locus of control (Rauch and Frese 2000). In contrast, high risk-taking is not or even negatively

associated with business success (Rauch and Frese 2000).

3.3 Personality Reconsidered

Thus, there are differences between entrepreneurs and managers, and correlations between personality and success, but these correlations are not high. It is, therefore, understandable that criticisms of a personality approach have appeared.

However, both approaches—the personality proponents and its critiques—have overlooked the significant advances that have been made in personality research during the last 20 years that need to be made useful for entrepreneurship research. The most important issue is certainly that specific behaviors (such as starting up a business or using a certain approach to the market) works only through mediating processes (cf. the Giessen–Amsterdam model in Fig. 1). For example, planning mediated the relationship between achievement orientations and success.

Second, the personality variable has to be specific enough to predict specific (entrepreneurial) behavior. For example, Miner et al.'s (1994) task motivation theory explained 15–24 percent of variance in growth measures.

Third, interaction models suggest that one looks at which personality trait helps in which environment. Thus, one would have to look at interactions of personality with environmental conditions.

Finally, no one personality trait will ever have a strong relationship with success because success is determined by many factors.

4. Human Capital

Human capital theory is concerned with knowledge and experiences of small-scale business owners. The general assumption is that the human capital of the founder improves small firms' chances of survival (Bruederl et al. 1992). Human capital acts as a resource. However, human capital theory studies usually assume that experiences are translated into knowledge and skills. This assumption is problematic, however, because length of experience is not necessarily a good predictor of expertise (Sonnentag 1995). Therefore, it is not surprising that human capital factors, such as length of managerial or industry experiences or education, are not strong predictors of success, although in large-scale studies they usually are significant (Bruederl et al. 1992, Rauch and Frese 2000).

5. Goals

One can distinguish between goals related to the start-up of an enterprise and goals related to the existing enterprise. Goals or motives for becoming self-employed can be categorized into push and pull factors. Push factors imply that a current situation (e.g., the job or unemployment) is unsatisfying, pull factors are related to desires for being independent and doing what one likes to do. While there are differences among entrepreneurs, there is little evidence that goals related to developing a business are related to success (Frese 2000).

6. Strategies (Content, Process, Entrepreneurial Orientations)

From a psychological perspective strategies are directly related to goal-oriented actions. It is useful to distinguish between three dimensions of business strategy: content, process, and orientation. All three strategy dimensions can in principle be crossed with another.

First, strategic content is concerned with the type of business decisions vis-à-vis the customers, suppliers, employees, products, production factors, marketing, capital, competitors. Studies in this area are often done by economists although psychological issues are important as well, for example, how to convince banks to give credit, active strategies on the market, for example in developing a niche product, and so forth.

Second, the strategic process is concerned with formulation and implementation of strategic decisions (Olson and Bokor 1995). One issue is planning, which is related to success (Schwenk and Shrader 1993). Frese and his co-workers (Frese 2000) have recently presented a theoretical typology of psychological strategies that are differentiated along the dimensions of proactivity and planning. Planning strategy implies that a top-down planning process is used that is also highly proactive. Critical point planning implies that an important issue is planned but other issues are not. It is proactive and involves a smaller amount of planning. Opportunistic strategy implies very little planning but a high degree of proactivity: one looks out for opportunities and takes them without any detailed planning beforehand. Finally, the reactive strategy implies that one is neither proactive nor planning: one simply reacts to the demands of the situation. The latter is negatively correlated with success in various countries (four African countries), while all others are positively correlated with success (Frese 2000); however, the relationship between planning and success depends on the situation to a certain extent. A Dutch longitudinal study has also shown that there is a reciprocal determinism from a reactive strategy to failure and from failure to reactive strategy (Van Gelderen and Frese 1998).

Third, orientation implies an attitude towards one's strategy: why a strategy is played out. Lumpkin and Dess (1996) conceptualized entrepreneurial orientation to consist of five dimensions: innovation, pro-

activeness, risk-taking, autonomy, and competitive aggressiveness. Covin and Slevin (1986) showed among others that entrepreneurial orientation was highly related with company performance ($r = 0.39$, $p < 0.01$). The relationship between entrepreneurial orientation and success may also be contingent on environmental and organizational factors.

7. *Environmental Conditions*

Each enterprise is nested in a specific environment. The task environment can be divided into three bipolar dimensions: complexity, dynamism, and munificence. Complexity describes the homogeneity versus heterogeneity of an environment. In a complex environment it is more difficult to get and to consider all the necessary information than in an easy environment. Dynamism describes the variability and unpredictability of the environment. Munificence falls into two subconcepts: ease of getting customers and ease of getting capital.

Sharfman and Dean (1991) showed that munificence had no significant relationship with performance, but complexity and dynamism were positively related to success. Thus, an unfavorable environment—the dynamic environment—has positive consequences. According to Swaminathan (1996), organizations founded in adverse environments have a higher initial mortality rate. But beyond a certain age, the surviving organizations had a lower mortality rate than those founded in a more friendly environment.

8. *Other Issues of Psychological Entrepreneurship Research*

There are other psychological issues that have not been studied as much as the ones discussed above but that are potentially interesting (see Rauch and Frese 2000). Among them are the effects of networks, information search activities to get feedback, and organizational life cycle models. Moreover, there are leadership issues and one can study whether visionary leadership, communication, delegating, and performance facilitation are related to success. Social psychological and cognitive factors are most likely related to entrepreneurial outcomes, such as values and culture, attributional theory, and problem-solving styles. Other issues of this type are concerned with learning, minorities, human resource management, learning and training, feedback processing, transition from business founder to manager, financing, organizational culture, and others. One fascinating topic is the issue of making psychological entrepreneurship research useful for developing countries.

9. *Conclusion*

Psychological approaches to entrepreneurship are fascinating both for entrepreneurship and psychology. Entrepreneurship can profit from this interface between business and psychology because psychological variables are clearly related to entrepreneurial entry and success. Psychological variables (most notably action-related concepts) function as mediators in the process that leads to success (e.g., strategies). For psychology, entrepreneurship is interesting because it combines the following features.

(a) The level of analysis question is related to the dynamic of enterprise growth; in the beginning, a small scale enterprise is best described by looking at the owner. However, in somewhat more mature enterprises, the level of analysis has to change because more delegation, management, and implementation are necessary.

(b) Some interesting organizational hypotheses can better be studied with small-scale entrepreneurs than with large organizations. A good example is the study of contingency theories. Small-scale enterprises are more coherent than larger ones and, therefore, contingency models can be tested better.

(c) Even large organization attempt to mimic small enterprises, and stress intrapreneurship, innovation, and personal initiative. There is no doubt that future workplaces will stress innovation and personal initiative more strongly and we need to know how small-scale entrepreneurs act.

(d) Interdisciplinary cross-fertilization takes place in this area.

We have reported a number of different models in this review; they are often presented to be contradictory. For example, some people have pitted personality approaches against human capital approaches. As Fig. 1 shows, we assume that they coexist and can influence each other (e.g., IQ has an influence on the development of skills and knowledge). An integration of various approaches to make real headway towards understanding a societally important phenomenon—entrepreneurship—is called for and should produce challenging research.

Environment and Anthropology

Anthropologists have been concerned with interaction between human populations and their environments since the middle of the nineteenth century. Early treatments were largely in terms of environmental determinism, replaced increasingly from around 1900 by 'possibilist' approaches which specified only a constraining role on society for environmental factors. A major paradigm throughout the twentieth century has been that of *ecological anthropology*, informed by conceptions of ecology which have been to varying degrees Darwinian, emphasizing the inter-relationship of social, cultural, biotic, and physical variables within a system, and centrally concerned with the concept of adaptation. This essentially positivist program has been augmented, and in part superseded, since the 1980s by one which uses interpretative, cognitive, and sociological approaches to understand peoples' perceptions of nature, environmental problems, and collective responses to them. These methodologies are not easily brought within the framework of ecological anthropology, and in recent years the term *environmental anthropology* has appeared as a more inclusive description. Approaches to human ecology which are concerned only with the biological characteristics of populations are not dealt with in this article.

1. *From Sociological Possibilism to Cultural Ecology*

During the first four decades of the twentieth century, anthropological theory was dominated by the ideas of Emile Durkheim (1858–1917) and Franz Boas (1858–1942), for whom environmental factors were for the most part secondary, and who accorded them a permissive rather than a determinant role. Nevertheless, the period saw the appearance of a number of classic studies, including Boas's own study and that of Mauss and Beuchat on Eskimo patterns of settlement.

The first explicit use of the concept of ecology in anthropology is found in the work of Julian Steward (1902–72) during the 1930s. For Steward, the concept of cultural adaptation is paramount, and the key adaptive strategies of a particular culture are located in a core of social institutions and technical arrangements directly focused on food-getting. The recognition of distinctive subsistence strategies provided the basis for the delineation of cultural types, which Steward maintained evolved multilineally, rather than in the unilinear fashion advocated by many nineteenth-century thinkers. In a modified form, Steward's ideas have continued to be influential, through the work of scholars such as Robert Netting. However, his theory of cultural ecology (see *Ecology, Cultural*) depends on a definition of adaptation, and a division between organic and superorganic levels of

explanation, and between a core of key adaptive traits and a neutral periphery, which recent writers have rejected.

2. *The Influence of Bioenergetics and Systems Ecology*

Advances within biology linked to the notion of ecosystem, the empirical measurement of energy flow, and the employment of the language of cybernetics and systems theory, led during the 1960s to a new formulation of ecological problems in anthropology. The special character assigned by Steward to the superorganic was passed over in favor of a view of human behavior in many respects functionally equivalent to that of other animals. Descriptions of ecological interactions began to involve computations of carrying capacity (see *Human–Environment Relationship: Carrying Capacity*), and estimates of energy transfer and efficiency (Ellen 1982). Adaptation became a matter of webs of mutual causality. In particular, there developed an interest in the way in which cultural institutions might serve to regulate certain systems of which human populations are part. All of these trends are demonstrated in the seminal work of Rappaport (1968), undertaken among the New Guinea Maring.

The technical and conceptual shortcomings of such approaches have been criticized in retrospect: inadequate samples and indices of what constituted success and adaptation and a theoretical naivete wedded to a prevailing sociological cybernetics which underestimated the difficulties of defining system boundaries (and thus of demonstrating feedback loops), and which neglected the role of historical contingency. This contributed to a skepticism concerning the more extreme proposition that certain kinds of small-scale society have built-in mechanisms for maintaining environmental balance through homeostasis. Although, other things being equal, it does seem that small populations with limited equipment and resources have benign effects on the environment (temptingly but erroneously interpreted as 'harmony'), for some in the environmental movement the inspiration offered by such cultures has led to a degree of idealization of the extent to which the values of particular nonindustrial and animistic peoples equate with environmental practices.

This debate has been particularly apparent with respect to the native peoples of North America. However, debunking the existence of 'ecological Edens' is not to downplay either the extent of the interconnections between apparently esoteric aspects of culture and the pragmatic well-being of subsistence systems, or the manifestly sophisticated knowledgeability of many nonindustrial peoples. Two studies which capture the former in a powerful way are Lansing's (1991) analysis of the linkage between the Balinese temple hierarchy and irrigation decision-making, and Richards' (1985) demonstration of the long-term rational behavior of Mende rice farmers in Sierra Leone. Both vindicate traditional local knowledge as against that of successive external bureaucracies, and thereby provide an antidote to top-down development programs. This general trend is evident in the growing literature on indigenous environmental knowledge (e.g., Warren et al. 1995) (see *Indigenous Knowledge and Technology*).

Some human systems *do* maintain a degree of integrity and are relatively well defined, while it is both practically and intuitively a relatively simple matter to isolate 'systems' which make sense of the data and which may be used in the investigation of a wide range of problems. Recognizing the openness of human systems is not inconsistent with employing some notion of closure to determine what universe of variables to examine. The arbitrary and analytic character of most boundaries, together with the reality of exogenous intrusions of varying types, magnitudes, and origins, does not inevitably mean accepting a notion of receding causation or infinite regress whereby the critical determinants always seem to lie outside the local system being examined—a view which comes dangerously close to providing no explanation at all. Vayda (1983) has sought to circumvent the problem by advocating a 'progressive contextualization' focusing on particular locally-significant 'people–environment interactions' and placing them in increasingly wider and denser contexts without making prior assumptions as to what the context might be. However, all explanations presume some kind of context and boundary (Moran 1990).

3. *Neo-Darwinist Approaches*

One response to the perceived deficiencies of systems approaches has been inspired by economic formalism and neo-Darwinism, both characterized by methodological individualism. This trend is evident in studies emphasizing how people actually cope with environmental hazards (Vayda and McCay 1975) (see *Environmental Risk and Hazards*), and in optimal foraging theory (Winterhalder and Smith 1981) and evolutionary ecology (Borgerhoff 1991). In this latter, adaptation and change are seen as providing an indefinite number of alternative strategies for enhancing reproductive fitness and survival depending on particular environmental circumstances. Such approaches have been criticized for their simple-mindedness at the level of ethnographic analysis, for using 'social' to mean no more than observable interactions between conspecifics, and for their failure to understand the cultural significance of subsistence, or to consider that the organization of consciousness might be relevant. However, more recently it has been acknowledged that the role of genes is more complex:

enabling the generation and sustenance of diverse kinds of social relationship and permitting (but not determining) the effective factors which contribute to their formation. At the same time, the properties of human social interaction themselves are seen to condition the adaptive value of strategies adopted; individuals thus adapting to the constraints of the social environment in which they develop, and the outcome of consumption influencing the value of alternative patterns of production.

4. *The Ecological and the Social as Mutually Constitutive but Separate Systems*

A second response to the difficulties of 'ecological functionalism' has been to explicitly disaggregate post-Stewardian general ecology, to speak instead of humans being simultaneously involved in nonconflateable ecological and social relations, and to play down possible causal connections between the two. In this model—most clearly stated in the work of Ingold (1986b)—ecological relations are those represented by material flows between individual organisms, and abstract and culture-bearing social relations are those established between persons through consciousness. Here the social and the ecological are co-extensive; both intra- and interspecific interactions simultaneously have social and ecological aspects. For example, predation is an ecological relationship of extraction with consequences for the flow of energy and materials; hunting—which may refer to exactly the same activities—on the other hand is constituted through social relations of appropriation and exchange. Natural selection operates at the level of ecological rather than social relations, within an effective environment of conscious internal representations and plans for action. In this model, consciousness lies beyond (rather than within) the field of ecological relations, social institutions and relationships never being incorporated within adaptationist or other Darwinist explanations.

One difficulty with this approach is a metaphysic which prevents the effective engagement of the social and ecological and which sidesteps the issue of adaptation. How one might influence the other, and how we might measure and compare different entities or sets of relations remains the major problematic of ecological anthropology, and one rarely, and then inadequately, addressed. There is plenty of empirical evidence to suggest that the social and ecological have measurable effects one upon the other. By emphasizing the continuity of the social landscape, such an approach fails to acknowledge the need in any one analysis to draw boundaries around datasets and thus create 'systems' of interacting parts which provide insights into existential reality. Such a view places renewed emphasis on the essentially social determination of modes of subsistence, acting, at most, as a filter for the expression of an underlying ecological dynamic.

5. *Historical Ecology*

A third recent approach, both in biology and anthropology, has been to reject synchronic ecology in favor of analyses which are historical in orientation, emphasizing contingency and process at the expense of the systemic and functional. At the highest level of abstraction, there has been expanded emphasis on the evolution of social and ecological systems (Ingold 1980), and on the co-evolution of genes, species, and culture (Durham 1991), focusing on positive feedback. Work in historical ecology has been concerned with, for example, historical demography (Netting 1981), the environmental causes and consequences of systemic collapses such as that of the classic Maya (e.g. Atran 1993), and the way particular human groups first make and then manage their environment (Crumley 1994). Some of the most dramatic studies have been with respect to tropical forests (Sponsel et al. 1996), long thought of as a byword for the most pristine of global ecosystems, and consequently the most vulnerable to human impact. Yet other studies have focused on how particular well-known functionalist theories of environment–social organization linkage might better be explained through particular histories (e.g. Kelly 1985). Such developments in anthropology have proceeded very much in parallel with the new emerging environmental history.

6. *Perceiving and Conceptualizing the Environment*

Another major area of growth since the late 1970s has concerned how people conceptualize the natural world, what they know of its objective properties, how this relates to the decisions they make about environmental information, and which of this might be used in pragmatic development contexts (see *Nature, Concepts of: Environmental and Ecological*, *Environmental Cognition, Perception, and Attitudes*). Research in this area has grown exponentially over the last decade, and the shape of the problematic altered so much that it is impossible to do justice to the subject here. There has been a spectacular growth in ethnobotany in particular (see *Ethnobiology*), in studies of indigenous knowledge with a view to countering top-down development models (e.g., Richards 1985) and making development policy more effective, and studies in the cognitive organization and cultural representation of natural kinds, and the concept of nature more generally (Descola and Palsson 1996). Research on the environmental knowledge of local peoples has shown how in looking at, say, the relations between humans and domesticates, cultural selection is important, strengthening the case for reconceptualizing

human evolution as the systemic co-evolution of both interdependent species, and of objects and their cultural images.

The emphasis on cognition, on how different cultures represent and 'construct' their worlds, the questioning of the objective notion of system, and developments in modern biology, have led to the emergence of a critical questioning of what is meant by the terms 'nature' and 'environment' (e.g., Ellen and Fukui 1996). Increasing knowledge of the extent to which even hunter-gatherer populations can modify their surroundings and the growing literature in historical ecology has led to further erosion of the nature–culture divide. A persuasive anthropological critique of the organism–environment distinction is to be found in Ingold's borrowings (e.g. 1986a) from the ecological psychology of Gibson (1979): the concept of environmental niche as a set of affordances, and the idea that organisms fit the world to themselves rather than being 'constructed' by them.

7. *The Environment as a Political Agenda*

The development of anthropological and social science theories of human ecology over the last 30 years has taken place against the backdrop of an emerging political agenda, one which has intruded into ecological theorizing, as in discussions on 'indigenous environmental knowledge' (Milton 1996) (see *Ecology, Political*). Under the guidance of figures such as Garrett Hardin and Kenneth Boulding, economic thinking has been placed in a more biospheric context, and the 'growth model' rejected both in relation to advanced industrial and developing societies. Practical concern for environmental degradation, the profligate use of finite resources, the calculated advantages of 'alternative' technologies, and anxieties about biodiversity conservation have spawned theories of sustainable development (Oldfield and Alcorn 1991, Redclift 1987). It has led to the interrogation of definitions of 'sustainability,' asking at what level systems are sustainable (local, regional, say); whether economic, ecological, cultural, and social sustainability are compatible; whether long-term ecological sustainability is to be preferred to shorter term economic sustainability; whether we want to sustain some aspects of a system at the expense of others (say, biodiversity over sustainable food production); whether we wish to sustain systems which derive their dynamic from human interventions rather than change an environment through conservation, and so on (see *Sustainable Development*). Some writing in this vein is distinctively Utopian; some is concerned with practical matters of implementing specific controls; some seeks to modify the existing world-system though retaining capitalist relations of production; other writing seeks a rapprochement between Marxism and environmentalism; and some seeks to interrogate the very notion of 'environmentalism' (e.g. Milton 1996). A specific but well-articulated debate in this subfield concerns what Hardin had called 'the tragedy of the commons,' the ecological consequences of economic development on the management of collectively owned resources (McCay and Acheson 1987). Specific substantive issues which have contributed to our understanding here include that relating to pastoralism and overgrazing (Homewood and Rodgers 1987) and the extent to which foraging is a sufficient lifestyle to survive in tropical rainforests (Headland 1987).

8. *Merging Paradigms*

Understanding the way in which human ecological relations interact with social consciousness is increasingly seen to require the simultaneous application of two apparently antithetical approaches: one which emphasizes the systemic character of interactions looked at spatially and in the short-term, and one which emphasizes linear change in the long-term. The first is about ecological and social context, the second concerns biological and cultural history (including, but not exclusively, the working out of the key mechanisms of natural selection and cultural adaptation). Human action in the environment is, therefore, inevitably the product of a subtle combining of genetic and cultural process. While these are historically the product of previous action, they go on to contribute to the context in which further action takes place, and neither culture nor environment, neither genes nor social relations, are independent variables.

It should be noted that approaches which confine the environment to relativistic internal conceptions, methodologically undermine the notion of environment as an objective backdrop or set of relations, the basis of ecological analysis hitherto. It is necessary, therefore, to recognize that ecological and social relations have both an existence externally as part of the context, and internally as part of a system of ideas and meaning. There is, if you like, a kind of 'triple duality' (pace Giddens): a theoretical notion of context and process, an empirical recognition of genes and social consciousness, and a methodological distinction between objective environment and its various cultural conceptions. All of these interact recursively to reproduce and to change the systems of which they are part.

Moreover, material relationships between humans (those we describe as economic) are predicated by a notion of value, and value which is not reducible to matter is based on a cultural division of tasks, on exchange between persons rather than individual biological organisms, and which can affect material transactions, including the flows of energy, nutrients, objects, and information between individuals of the same species. Through the increasing dependence on value, culture, and consciousness in human production and consumption, the economic becomes differentiated from the ecological, and as—through

exchange—economic relations become more separated from other status relations in local social formations, so the economy as a separate phenomenal form emerges.

The relationship between *Homo sapiens* and the environment cannot be reduced to essences or imperatives—not environmentalism, biologism, sociologism, nor ecologism. Ecology, as human ecology, cannot ever be an autonomous discipline, except in the limited sense of an understanding of the dynamics of human populations in their ecological context. Ecology is rather a problematic—a discursive practice—which brings into focus the articulation and integration of several fields of knowledge, skills, and disciplines.

Environment and Common Property Institutions

The twentieth century witnessed many efforts to increase the sustainability of natural resource systems through reforms of property-rights systems. Many of these reforms have not achieved their intended outcomes. Instead, some have generated counterproductive results. Since many reforms of property-rights systems are based on a conventional theory of how property-rights systems affect the incentives of those using natural resource systems, the multiple failures need to be viewed as evidence for an insufficient theoretical understanding of the relationship between diverse forms of property and the incentives and behavior of resource users. The currently accepted theory is based on idealized models of private property and government property. Researchers frequently equate common property with the absence of any property rights.

1. Conceptual Confusion

The debate about the relative merits of government, private, and common property has been clouded by

three confusions. Different meanings are assigned to terms without clarifying how multiple aspects relate to one another. The sources of confusion relate to the differences between (a) common-property and open-access regimes, (b) common-pool resources and common-property regimes, and (c) a resource system and the flow of resource units.

1.1 The Confusion between Common-property and Open-access Regimes

Open-access regimes (*res nullius*)—including the classic cases of the open seas and the atmosphere—have long been considered in legal doctrine as involving no limits on who is authorized to use a resource. If anyone can use a resource, no one has an incentive to conserve their use or to invest in improvements. If such a resource generates highly valued products, then one can expect that the lack of rules regarding authorized use will lead to misuse and overconsumption. Some local grazing areas, inshore fisheries, and forests are effectively open-access resources, but there are many fewer than presumed in contemporary policy literature.

Some open-access regimes lack effective rules defining property rights by default because the resource is not contained within a nation-state or no entity has laid claim successfully to legitimate ownership. Other open-access regimes are the consequence of conscious public policies to guarantee the access of all citizens to the use of a resource within a political jurisdiction. The concept of *jus publicum* applies to their formal status but effectively these resources are open access. A third type of open-access regime results from the ineffective exclusion of nonowners by the entity assigned formal rights of ownership. In many developing countries, the earlier confusion between open-access and common-property regimes has paradoxically led to an increase in the number and extent of local resources that are effectively open access. Common-property regimes controlling access and harvesting from local streams, forests, grazing areas, and inshore fisheries have evolved over long periods of time in all parts of the world, but have rarely been given formal status in the legal codes of newly independent countries.

As concern for the protection of natural resources mounted during the 1960s, many developing countries nationalized all land and water resources that had not yet been recorded as private property. The evolved institutional arrangements that local users had devised to limit entry and use lost their legal standing as a result of the national government claiming ownership. The national governments, however, lacked monetary resources and personnel to monitor the use of these resources effectively. Thus, resources that had been under a *de facto* common-property regime enforced by local users were converted to a *de jure* government-property regime, but reverted to a *de facto* open-access regime. When resources that were previously controlled by local participants have been nationalized, state control has frequently proved to be less effective and efficient than control by those directly affected, if not disastrous in its consequences.

1.2 The Confusion between a Resource System and a Property Regime

To add to the confusion, the term 'common-property resource' frequently is used to describe a type of economic good that is better referred to as a 'common-pool resource.' Traditional examples of common-pool resources include fisheries, water systems, and grazing lands. The Internet is an example of a common-pool resource enabled by modern technology. All common-pool resources share two attributes of importance for economic activities: (a) it is costly to exclude individuals from using the good either through physical barriers or legal instruments and (b) the benefits consumed by one individual subtract from the benefits available to others (Ostrom et al. 1994). Recognizing a class of goods that shares these two attributes enables scholars to identify the core theoretical problems facing all individuals or groups who wish to utilize such resources for an extended period of time. Using 'property' in a term that refers to a type of good reinforces the impression that goods sharing these attributes tend everywhere to share the same property regime, a notion that is empirically incorrect.

Common-pool resources share with public goods the difficulty of developing physical or institutional means of excluding beneficiaries. Unless means are devised to keep nonauthorized appropriators (those who harvest from the resource) from benefiting, the strong temptation to free ride on the efforts of others will lead to a suboptimal investment in improving the resource, monitoring use, and sanctioning rule-breaking behavior. Second, the products or resource units from common-pool resources share with private goods the attribute that one person's consumption subtracts from the quantity available to others. Thus, common-pool resources are subject to problems of congestion, overuse, and potential destruction unless harvesting or use limits are devised and enforced. In addition to *sharing* these two attributes, particular common-pool resources *differ* on many other attributes that affect their economic usefulness including their size, shape, and productivity and the value, timing, and regularity of the resource units produced.

Common-pool resources may be owned by national, regional, or local governments, by communal groups, or by private individuals or corporations, or they may be used as open-access resources by whomever can gain access. Each of the broad types of property regimes has different sets of advantages and disadvantages, but at times may rely upon similar operational rules regarding access and use of a resource. Examples exist of both successful and unsuccessful efforts to govern and manage common-pool resources by gov-

ernments, communal groups, cooperatives, voluntary associations, and private individuals or firms (Bromley et al. 1992). No automatic association of common-pool resources exists with common-property regimes or with any other particular type of property regime.

1.3 The Confusion between the Resource and the Flow of Resource Units

Common-pool resources are composed of resource systems and a flow of resource units or benefits from these systems. The resource system (or alternatively, the stock or the facility) is what generates a flow of resource units or benefits over time. As mentioned above, examples of typical common-pool resource *systems* include lakes, rivers, irrigation systems, groundwater basins, forests, fishery stocks, and grazing areas. Common-pool resource systems may also be *facilities* that are constructed for joint use, such as mainframe computers and the Internet. The resource units or benefits from a common-pool resource include water, timber, medicinal plants, fish, fodder, central processing units, and connection time. Devising property regimes that effectively allow sustainable use of a common-pool resource requires some rules that limit access to the system and other rules that limit the amount, timing, and technology used to withdraw diverse resource units from the resource system. Both types of rules are essential if a resource and its flow are to be managed sustainably.

1.4 Property as Bundles of Rights

A property right is an enforceable authority to undertake particular actions in a specific domain (Commons 1957). Property rights define actions that individuals can take in relation to other individuals regarding some 'thing'. If one individual has a right, someone else has a commensurate duty to observe that right. Schlager and Ostrom (1992) identify five property rights that are most relevant for the use of common-pool resources, including access, withdrawal, management, exclusion, and alienation. These are defined as:

(a) Access: the right to enter a defined physical area and enjoy nonsubtractive benefits (e.g., hike, canoe, sit in the sun);

(b) Withdrawal: the right to obtain resource units or products of a resource system (e.g., catch fish, divert water);

(c) Management: the right to regulate internal use patterns and transform the resource by making improvements;

(d) Exclusion: the right to determine who will have an access right, and how that right may be transferred; and

(e) Alienation: the right to sell or lease management and exclusion rights (Schlager and Ostrom 1992).

Private property is frequently defined as being the equivalent of alienation. Property-rights systems that do not contain the right of alienation are considered by many policy analysts to be ill-defined. Further, they are presumed to lead to inefficiency since property-rights holders cannot trade their interest in an improved resource system for other resources, nor can someone who has a more efficient use of a resource system purchase that system in whole or in part (Demsetz 1967). Consequently, it is assumed that property-rights systems that include the right to alienation will be transferred to their highest valued use.

Instead of focusing on one right, it is more useful to define five classes of property-rights holders as shown in Table 1. In this view, individuals or collectivities may hold well-defined property rights that include or do not include all five of the rights defined above. This approach separates the question of whether a particular right is well defined from the question of the effect of having a particular set of rights. 'Authorized entrants' include most recreational users of national parks who purchase an operational right to enter and enjoy the natural beauty of the park, but do not have a right to harvest forest products. Those who have both entry and withdrawal use-right units are 'authorized users.' The presence or absence of constraints upon the timing, technology used, purpose of use, and quantity of resource units harvested are determined by operational rules devised by those holding the collective-choice rights (or authority) of management and exclusion. The operational rights of entry and use may be finely divided into quite specific 'tenure niches' (Bruce 1999) that vary by season, by use, by technology, and by space. Tenure niches may overlap when one set of users owns the right to harvest fruits from trees, another set of users owns the right to the timber in these trees, and the trees may be located on land owned by still others. Operational rules may allow authorized users to transfer access and withdrawal rights either temporarily through a rental agreement, or permanently when these rights are assigned or sold to others. 'Claimants' possess the operational rights of access and withdrawal plus a collective-choice right of managing a resource that includes decisions concerning the construction and maintenance of facilities and the authority to devise limits on withdrawal rights.

2. Can Proprietors as well as Owners Manage Common-pool Resources?

'Proprietors' hold the same rights as claimants with the addition of the right to determine who may access and harvest from a resource. Most of the property systems that are called 'common-property' regimes involve participants who are proprietors and have four of the above rights, but do not possess the right to

Table 1
Bundles of rights associated with positions

	Owner	Proprietor	Claimant	Authorized user	Authorized entrant
Access	X	X	X	X	X
Withdrawal	X	X	X	X	
Management	X	X	X		
Exclusion	X	X			
Alienation	X				

Source: Ostrom and Schlager (1996, p. 133)

sell their management and exclusion rights even though they most frequently have the right to bequeath it to members of their family (see Berkes 1989, Bromley et al. 1992, McCay and Acheson 1987).

Empirical studies have found that some proprietors have sufficient rights to make decisions that promote long-term investment and harvesting from a resource. Place and Hazell (1993) conducted surveys in Ghana, Kenya, and Rwanda to ascertain if indigenous land-right systems were a constraint on agricultural productivity. They found that land users having the rights of a proprietor as contrasted to an owner in these settings made as efficient investment decisions and were as productive. Other studies conducted in Africa (Migot-Adholla et al. 1991, Bruce and Migot-Adholla 1994) also found little difference in productivity, investment levels, or access to credit as well as in land tenure regimes and intensity of cultivation (Turner et al. 1993). In densely settled regions, however, proprietorship over agricultural land may not be sufficient (Feder et al. 1988, Feder and Feeny 1991). In a series of studies of inshore fisheries, self-organized irrigation systems, forest user groups, and groundwater institutions, proprietors tended to develop strict boundary rules to exclude noncontributors; established authority rules to allocate withdrawal rights; devised methods for monitoring conformance; and used graduated sanctions against those who did not conform to these rules (Agrawal 1994, Blomquist 1992, Schlager 1994, Lam 1998). 'Owners' possess the right of alienation—the right to transfer a good in any way the owner wishes that does not harm the physical attributes or uses of other owners—in addition to the bundle of rights held by a proprietor. An individual, a private corporation, a government, or a communal group may possess full ownership rights to any kind of good including a common-pool resource. The rights of owners, however, are never absolute. Even private owners have responsibilities not to generate particular kinds of harms for others. In conventional theory it is always presumed that owners will manage the resources they own efficiently. This does not mean, however, that owners are more likely than proprietors to manage resources in a sustainable manner. Sustainability requires restricting the use of the flow to the 'sustainable yield,' which may or may not be the efficient level (Clark 1980). Thus, the private owner of a common-pool resource may efficiently 'use up' a resource when the value of the flow is high and the future is discounted at conventional levels.

The world of property rights is, thus, far more complex than simply government, private, and common property. These terms better reflect the status and organization of the holder of a particular right than the bundle of property rights held. All of the above rights can be held by single individuals or by collectivities. Some communal fishing systems grant their members all five of the above rights, including the right of alienation (Miller 1989). Members in these communal fishing systems have full ownership rights. Similarly, farmer-managed irrigation systems in Nepal, the Phillippines, and Spain have established transferable shares to the systems. Access, withdrawal, voting, and maintenance responsibilities are allocated by the amount of shares owned (Martin and Yoder 1983, Siy 1982, Maass and Anderson 1986). On the other hand, some proposals to 'privatize' inshore fisheries through the devise of an Individual Transferable Quota (ITQ) allocate transferable use rights to authorized fishers but do not allocate rights related to the management of the fisheries, the determination of who is a participant, nor the transfer of management and exclusion rights. Thus, proposals to establish ITQ systems, which frequently are referred to as forms of 'privatization', do not involve full ownership.

Further, all three types of owners may fail to manage common-pool resources in a sustainable manner. The possibility that individuals who jointly own a resource system and govern and manage that resource in a sustainable manner has only been seriously recognized the 1980s. Prior to that there were many individual studies that documented individual 'success' cases, but these were treated as relatively unique cases and not representing any more general phenomena. While the number of successful instances of self-organized resource systems now appears to be very large, it is also the case that some communities do not organize themselves to develop indigenous property rights systems. When the resources they jointly use are valuable, the lack of self-organization can, indeed, lead to tragic overuse, if not the destruction of the resource system. Thus, the question of why some groups organize and

others do not organize is key to an understanding of common-property institutions and the environment.

3. *On the Origin of Self-governed Common-pool Resources*

Recent research, thus, challenges the generalizability of the conventional theory that predicts that no one will organize to ensure the long-term sustainability of a jointly used natural resource system. While the conventional theory is generally successful in predicting outcomes in settings where appropriators are alienated from one another or cannot communicate effectively, it does not provide an explanation for settings where appropriators are able to create and sustain agreements to avoid serious problems of overappropriation. Nor does it predict well when government ownership will perform appropriately or how privatization will improve outcomes. A fully articulated, reformulated theory encompassing the conventional theory as a special case does not yet exist. On the other hand, scholars familiar with the results of field research substantially agree on a set of variables that enhance the likelihood of appropriators organizing themselves to avoid the social losses associated with open-access, common-pool resources (McKean 2000, Wade 1994, Ostrom 1990, Baland and Platteau 1996). Considerable consensus exists that the following attributes of resources and of appropriators are conducive to an increased likelihood that self-governing associations will form.

3.1 *Attributes of the Resource*

3.1.1 Feasible improvement. Resource conditions are not at a point of deterioration such that it is useless to organize or so underutilized that little advantage results from organizing.

3.1.2 Indicators. Reliable and valid indicators of the condition of the resource system are frequently available at a relatively low cost.

3.1.3 Predictability. The flow of resource units is relatively predictable.

3.1.4 Spatial extent. The resource system is sufficiently small, given the transportation and communication technology in use, that appropriators can develop accurate knowledge of external boundaries and internal microenvironments.

3.2 *Attributes of the Appropriators*

3.2.1 Salience. Appropriators are dependent on the resource system for a major portion of their livelihood or other important activity.

3.2.2 Common understanding. Appropriators have a shared image of how the resource system operates and how their actions affect each other and the resource system.

3.2.3 Low discount rate. Appropriators use a sufficiently low discount rate in relation to future benefits to be achieved from the resource.

3.2.4 Trust and reciprocity. Appropriators trust one another to keep promises and relate to one another with reciprocity.

3.2.5 Autonomy. Appropriators are able to determine access and harvesting rules without external authorities countermanding them.

3.2.6 Prior organizational experience and local leadership. Appropriators have learned at least minimal skills of organization and leadership through participation in other local associations or learning about ways that neighboring groups have organized.

4. *The Importance of Larger Political Regimes*

It is important to stress that many of these variables are affected strongly by the type of larger political regime in which appropriators are embedded. Larger regimes can facilitate local self-organization by providing accurate information about natural resource systems, providing arenas in which participants can engage in discovery and conflict-resolution processes, and providing mechanisms to back up local monitoring and sanctioning efforts. Perceived benefits of organizing are greater when users have accurate information about the threats facing a resource. The costs of monitoring and sanctioning those who do not conform to rules devised by users are very high, when the authority to make and enforce these rules is not recognized. Thus, the probability of participants adopting more effective rules in macro regimes that facilitate their efforts over time is higher than in regimes that ignore resource problems entirely or, at the other extreme, presume that all decisions about governance and management need to be made by central authorities. If local authorities are not formally

recognized by larger regimes, it is difficult for users to establish an enforceable set of rules. On the other hand, if rules are imposed by outsiders without consulting local participants in their design, local users may engage in a game of 'cops and robbers' with outside authorities.

5. Conclusion

The conventional theory of common-pool resources, which presumed that external authorities were needed to impose new rules on those appropriators trapped into producing excessive externalities on themselves and others, is now considered a special case of a more general theoretical structure. For appropriators to reformulate the institutions they face, they have to expect that the benefits they receive from an institutional change will exceed the immediate and long-term expected costs. When appropriators cannot communicate and have no way of gaining trust through their own efforts or with the help of the macroinstitutional system within which they are embedded, the prediction of the earlier theory is likely to be empirically supported. Ocean fisheries, the stratosphere, and other global commons come closest to the appropriate empirical referents (Ostrom et al. 1999). If appropriators can engage in face-to-face bargaining and have autonomy to change their rules, they may well attempt to organize themselves. Whether they organize depends on attributes of the resource system and the appropriators themselves that affect the benefits to be achieved and the costs of achieving them. Whether their self-governed enterprise succeeds over the long-term depends on whether the institutions they design are consistent with design principles underlying robust, long-living, self-governed systems. The theory of common-pool resources has progressed substantially during the second half of the twentieth century. There are, however, many challenging puzzles still to be solved.

Environment and Development

1. Environment and Development

Since the 1950s people have become increasingly aware of problems like marine oil-spills, wildlife extinction, and pollution. However, before the early-1970s few, except ecologists and other environmental scientists, were familiar with the terms 'environment' or 'development.' Today it is generally accepted that for development to be successful it must be environmentally sensitive (Barrow 1995).

2. The Term 'Environment'

'Environment' may be defined as the total external conditions and influences affecting the life and fortunes of organisms, effectively 'the parameters of life.' It is shaped by living and nonliving elements that often interact in complex ways, making it a challenge to understand and predict future situations. The study of these interactions, 'ecology,' was founded as an academic subject in 1869 by Ernst Häckel, became established by the 1930s, and underwent an expansion in the 1970s. Ecology has been described as 'scientific natural history' and, along with 'environment,' became familiar to the general public in the early 1970s. The media often uses the term ecology loosely as a label for environmental concern (for example, an 'Ecology Party was launched in the UK in the early 1970s).

Humans often adapt well to the environment they live in, and may be able to modify it to better suit their needs. Sometimes they are uncomfortable, fail to improve or even sustain conditions, or cause environmental degradation and then have to move away or suffer. A given environment may offer more opportunities than others but, ultimately, there are limits to human activity. If humans can satisfy their needs on a sustained basis without damaging the environment they may be said to have achieved 'sustainable development.' There are often many workable development strategies that could be pursued, some 'fit-in' with nature and at the other extreme others boldly change conditions. Wise development should also assess and prepare for environmental threats (see *Environmental Surprise*; *Environmental Risk and Hazards*). Agriculture is essentially an attempt to modify natural environments by inputs of energy (human labor or fuel-based mechanization), technology, and knowledge to sustain higher outputs of food or other crops.

People often talk of 'their local environment' or an 'alpine' or a 'desert environment,' but there is essentially only one global environment or biosphere. The biosphere can be subdivided into a vast number of more or less interacting 'ecosystems' (each a recognizably distinct assemblage of organisms adapted to particular environmental conditions). The ecosystem is the basic functional unit of ecology (see Miller 1990).

3. The Term 'Development'

Attempts to define 'development' reflect the current values of those making the definition, it is therefore difficult to agree one definition that is universally accepted and precise. Some see it as a learning process, others argue it is 'positive social transformation.' Another definition that is widely accepted in the West is: *an ambiguous term for a multidimensional process involving material, social and organizational change, accelerated economic growth, the reduction of absolute poverty and inequality*. There is some overlap with *modernization*, so that a group of people could develop yet remain unmodernized, or vice versa. Modernization is generally accepted to be a change toward a 'modern' economic, social and political system developed in Western Europe and North America between the seventeenth century and present. Many in the arts, sciences, philosophy, and social argue that there have been signs of a paradigm shift since the mid-1960s, away from modern to *postmodern* development, involving less support for a mechanistic, reductionist and compartmentalized approach to the world's problems, in favor of a more *holistic*, multidisciplinary stance. (A researcher adopting a holistic approach seeks to study the whole, which may be more than the sum of the parts, so exploration of linkages and interactions is as important as studying component parts.) Whether the approach to development is

modern or postmodern in character, it will meet difficulties if it does not make optimum use of environmental opportunities, heed physical and socioeconomic limits, and prepare for possible hazards.

4. Attitudes Toward Environment and Development

Peoples' perception of development affects their exploitation of the environment. It is frequently argued that a faulty attitude toward development leads to environmental misuse and socioeconomic problems for humans (Crump 1991) (see *Environmental Cognition, Perception, and Attitudes*; *Nature, Concepts of: Environmental and Ecological*).

4.1 Attitudes Toward Environment and Development from Prehistoric Times to the Nineteenth Century

Before humans developed a sedentary lifestyle and their numbers increased beyond a few persons per square kilometer, environmental damage was largely temporary and limited. People moved on before pollution or erosion became too bad and, with the probable exception of some game animals, seldom overexploited resources (see *Human–Environment Relationship: Prehistoric*). Although it has always been important to recognize natural threats and opportunities, the need to be concerned about environment and development has mainly grown as people have settled and multiplied, and as industry and technology have caused new impacts. By roughly 3000 BC around the Mediterranean the struggle to survive had led to forest clearance, soil erosion, and loss of fauna through hunting enough for several ancient chroniclers to record environment and development problems. One Roman geographer even recognized a link between the expansion of free trade and exploitative agriculture damaging the land.

Peasants, with few alternatives to fall back upon for survival, have often evolved sustainable livelihood strategies and sound rules of stewardship to ensure common resources were used without being degraded. Other social groups: the very poor, refugees, and the greedy have often exploited and damaged the environment in their struggle to survive or to profit. The poor may be forced to sacrifice sustainable livelihood and future opportunities to survive in the short term unless given aid; those driven by greed or commerce cause havoc through environmentally insensitive ethics (see *Environmental Conservation*: *Ethical Concerns*).

In medieval Europe the prevailing view was that the universe reflected Divine Perfection, consequently there was little attempt to think about development or tolerance for those who did. After the Renaissance some explored the possibility of shaping secular human development; for example, Thomas Moore published *Utopia* in AD 1516. By the mid-sixteenth century Europe's merchant class had grown in influence, possibly assisted by the spread of Calvinistic ethics (Weber 1958). There was a growing, relatively liberal, capitalist economy and an increasing interest in science and rational study. From the mid-eighteenth century this commerce and scientific reason, together with an Industrial Revolution and urban migration had caused huge changes of attitude, a shift to what has been termed the 'modern' outlook.

This modern, western civilization is often accused of particular insensitivity toward the environment. However, there are environment and development problems in virtually all societies: in atheistic, Christian, Islamic, Buddhist and Hindu countries (the latter, some claim, are more 'in-tune' with nature), regardless of whether the economy is socialist or free-enterprise capitalist. The intensity and type of environment and development problems may vary with the impact of commerce, technology and population growth, but they are found everywhere and pose a global challenge.

Beyond the spreading cities, degraded farmlands and forests of Europe and eastern North America several islands began to suffer damage to biota and environment by the eighteenth century. For example, by the 1760s legislation was being enacted to try to protect forests on Tobago, Mauritius, and St. Helena, and many other islands were in need of such controls. Even oceanic fisheries, seal and whale stocks were coming under pressure by the early-nineteenth century (see *Human–Environment Relationship: Carrying Capacity*). Nevertheless, few people could yet see the world's frontiers closing, if there were problems they were sure there was plenty of new land and resources to move on to. There were also naturalists in Europe and the Americas who raised public interest in the natural environment (an early example being Gilbert White's 1798 study of nature; reputedly the fourth-most published English language book) (for writings on the development of environmental attitudes see Wall 1994).

4.2 Attitudes Toward Environment and Development from the Nineteenth Century to the 1940s

By the nineteenth century the dominant attitude adopted toward development in the Western nations was that, whenever possible, the environment should be exploited, and unspoiled areas were wasted or even threatening and should be 'tamed.' As the nineteenth century progressed the idea that humans could ultimately conquer environmental problems became established. Achievements between 1830 and 1930 seemed to confirm such beliefs, as engineering and science made huge progress. But as pollution and overcrowding of industrial cities increased (see Ponting 1991) and as scientists learnt more, it became clear that controlling the environment would not be as

easy as had once been hoped, and that there was a growing need for better stewardship and development ethics.

In Europe, Russia and North America concern about growing cities, pollution and the clearance of forest and wilderness prompted a diverse group of intellectuals, romantics and 'proto-anarchists' to question the way development was progressing (these included Thoreau 1854 and Kropotkin 1899). These intellectuals shared a concern about the moral and ethical issues associated with development and environmental degradation. Some saw the need to value nature for the inspiration and solace it could give which might help improve the human character. While more utilitarian environmentalists argued for a return to closer proximity to nature, and for development to establish decentralized, cooperative communities that would offer an escape from what was being inflicted by large scale industrialization and increasing state control.

The idea of protecting the environment against development existed here and there long before the nineteenth century, around the world people have protected certain plants or animals, forests or areas for practical or religious reasons, establishing sacred groves, hunting parks, holy trees, and taboos which help ensure rational and sustainable use of common resources (see Berkes 1989). By the early- to mid-nineteenth century a growing number of naturalists, hunters, and foresters could see that what had once seemed limitless lands and resources were being degraded so they set up societies to promote conservation, and lobbied for laws to protect wildlife, forest and soil. National parks and reserves began to appear in the USA, Africa, India and other countries, and a number of forestry services were established. In the USA *preservationists* like John Muir worked to establish unspoilt wilderness reserves, and *conservationists* like Gifford Pinchot argued for areas where environmental protection could be combined with compatible land use or resource exploitation (see *Environmentalism: Preservation and Conservation*). On both sides of the Atlantic a number of nongovernmental organizations (NGOs) were established between 1830 and 1930 to promote conservation and wildlife protection (like the Sierra Club in California—founded in 1892); as well as continuing to promote environmental concern some of these bodies played an important role after the Second World War in establishing powerful new environmental NGOs like the International Union for the Conservation of Nature and Natural Resources (IUCN) and Friends of the Earth.

Publication of Darwin's *The Origin of Species by Means of Natural Selection* in 1859 helped established concepts like 'natural selection' and 'survival of the fittest'. These ideas and scientific advances in the nineteenth century led to some rethinking of long accepted ideas about humankind and nature. From the mid-nineteenth century the development of science, particularly concepts of the evolution of species, encouraged some to argue that the human environment–development relationship was strongly influenced or even largely controlled by physical conditions like climate. Race was also often seen as another determinant of development. These *environmental determinists* have been divided into the 'scientific' (e.g., Ellsworth Huntington 1915), who tried to objectively explore how nature might affect human fortunes, and those who promoted 'crude and subjective' arguments. The latter especially were cited to justify racial and political extremism, notably that which helped support fascism in Germany. Similar problems were caused by supporters of *social Darwinism*, who argued for development to be shaped by competition, self-interest and eugenics, rather than mutual aid, co-operation and tolerance of the less developed (Pepper 1984). Although, much discredited by the 1940s, it is probable that these concepts helped discourage social scientists from exploring environment and development issues until well into the 1970s.

Serious drought and soil degradation in the US Midwest 'Dustbowl,' especially between 1932 and 1938, displaced many farmers and darkened the air as far as Chicago and Washington DC. Novelist John Steinbeck drew on the misery caused by the disaster for his novel *The Grapes of Wrath* (1939), as did the folksinger Woody Guthrie; both were at first seen as subversives criticizing the American lifestyle before they provoked public concern (see *Desertification*). The US Government had begun to pass 'New Deal' measures to control the land degradation by the mid-1930s, notably the foundation of the US Soil Erosion Service (in 1933) and its successor, the US Soil Conservation Service (in 1935). Just as the public in North America and Europe had started to see signs that there were environmental limits to development the Second World War diverted attention and resources.

4.3 Attitudes Toward Environment and Development After the 1940s

During the immediate post-War period attention was mainly focused on economic and industrial reconstruction and improving food production. The British, struggling to raise vegetable oil production, invested heavily in the Tanganyika Groundnut Scheme in the late 1940s and early 1950s, largely by failing to consider basic environmental parameters the development efforts failed and wasted large sums of money. This was one of the first environment and development disasters, soon followed by oil-spills, nuclear waste escapes, and other problems. The Cold War diverted attention and funds from environmental studies and development programs, and continued to do so until the 1980s; but by triggering antinuclear weapons

protest movements, it also helped to establish environmental politics in Europe. A few writers explored environment and development issues in the 1940s and 1950s (e.g., the writings of Teilhard de Chardin and Aldo Leopold helped stimulate environmental interest in the 1960s and 1970s), and some NGOs and public figures began to bring conservation and pollution issues to the attention of the public in North America and Europe. In 1949 the UN held one of the first post-War meetings, the Conservation Conference at Lake Success, New York State. In 1948 the IUCN, an NGO body which has acted as a very influential network supporting conservation and promoting interest in environment and development issues was founded, now known as the Union for World Conservation, it continues to be highly important (for a history of the IUCN and conservation, see Holdgate 1999).

By the early 1960s attitudes towards environment and development had begun to change in Western nations, this is probably attributable to peoples' growing affluence and leisure time, development of the media, improved knowledge of the structure and function of nature (in part thanks to the exchange of information and research during the International Geophysical Year of 1957–1958 and the International Biological Programme of 1964–1965), and well-publicized pollution accidents and other development-related environmental problems. It has also been suggested that the US Civil Rights Movement and 'hippie' culture encouraged people to ask questions about development and to value the environment more. Another significant development was that NGOs and groups of concerned individuals began to fight environmental issues in law courts. Interest in environmental matters 'took-off' in California, spreading to the rest of North America and Europe, reaching a peak between about 1966 and 1974. During this period what is variously described as 'environmentalism,' an 'environmentalist movement,' an 'environmental movement,' or an 'ecology movement' spread (the first is probably the best term to adopt). A number of popular books helped provoke public interest in environmentalism, one of the most seminal and earliest being *Silent Spring* (Carson 1962), which voiced concern about DDT pollution.

Today *environmentalism* is generally seen as a moral code or set of mediating values to guide human conduct. Environmentalism is often confused with *ecologism* which is more a political ideology requiring its adherents to seek ethical and moral changes and to move away from giving priority to the welfare of humankind in any evaluation of development options. Environmentalism generally allows followers to put humans before nature and to seek managerial solutions rather than make far-reaching changes of development ethics and morals. Environmentalism encompasses a huge diversity of beliefs and attitudes, some pragmatic and willing to draw-upon science, others more romantic, and some keen to avoid modern science. In general mid-1960s to mid-1970s environmentalism was dogmatic, rich in advocacy rather than workable proposals, and focused on the need for conservation, and the threats of over-population, pollution, and careless technical innovation (Farvar and Milton 1972), it was also largely unpoliticized and restricted mainly to middle-classes and intellectuals. Many environmentalists, especially the *neo-Malthusians* (e.g., Ehrlich 1972), warned of a coming 'crisis.' In the UK a popular environmentalist journal *The Ecologist* was founded in 1970 and public interest was stimulated by authors like Goldsmith et al. (1972) and Ward and Dubos (1972). The feelings of 'crisis' were fanned when the USA and USSR space programs released pictures of the world from space, prompting awareness that war, pollution, and other development problems took place within a finite and vulnerable system—a realization captured at the time by the expression 'Spaceship Earth.' At about this time the Club of Rome published *The Limits to Growth* (Meadows et al. 1972), which argued that in a finite world the established patterns of development were akin to cancer. Amidst bitter debate this helped initiate a rethinking of development ethics and the nature of economics (see *Cassandra/Cornucopian Debate*).

In 1969 James Lovelock proposed the *Gaia hypothesis*, there have been several variants of this, but they all essentially argue that life on Earth has not simply adapted to physical conditions it is part of a complex inter-relationship. The hypothesis is disputed, but if accepted, the implication for development is that humans must carefully 'fit in' and ensure they do not upset any of the delicate mechanisms that maintain a stable environment, failure to do could result in catastrophic ecological change (see *Gaia*).

Warnings that the Earth faces an environment and development crisis have increasingly been issued since the 1960s. The cause is identified as one or a combination of the following: population growth; cavalier use of nature; misapplication of technology; faulty development ethics. Those concerned with environment and development face a dilemma: problems may be expensive, socially damaging, or impossible to solve once they happen, it therefore makes sense to try to monitor crucial thresholds and act to prevent a crisis (a turning-point after which action is less effective or hopeless); yet there are risks in warning of threats and acting before there is irrefutable proof unless a so-called 'win–win' approach can be found which gives benefit whatever the outcome (see *Precautionary Principle*). There are risks that accepting there is a crisis will divert attention from actually solving problems and will promote undesirable 'crisis management,' rather than careful problem avoidance. Recognition of a crisis may be a mistaken over-generalization and lead to failure to uncover causes.

In 1973 the UN Environmental Programme (UNEP) was established to promote environmental care worldwide. Based in Nairobi, rather than Paris or

Washington or some other developed country capital, to help ensure developing countries are not alienated, the UNEP often struggles to gain adequate funding. North America and Europe started to pass legislation in the late 1960s to develop more pro-active planning approaches which aim to reduce or avoid unwanted impacts. One of the most important examples of such legislation was the 1969 US National Environmental Protection Act (NEPA) (passed in 1970), among its achievements was the promotion of *environmental impact assessment* (EIA) procedures, and within ten years it had been copied in many countries around the world.

Nevertheless, in spite of continuing environmentally-damaging accidents, conflict over natural resources (e.g. the UK–Iceland 'Cod Wars' between 1952 and 1976), growing politicization of environmentalism, and the 1972 UN Conference on the Human Environment (held at Stockholm), popular interest waned after 1974. Ironically, the 1973–74 OPEC oil crisis led to fears of energy scarcity which diverted public attention and led to allocation funding to pay for more expensive fuel imports so there was less for environmental care. In many poor countries debts began to mount after 1973 prompting increased exploitation of natural resources to earn foreign exchange which accelerated environmental damage also, as funds became scarce, poverty grew and the poor often resorted to environmentally-damaging livelihood strategies. So, as environmental problems grew there was less money to spend on tackling them, added to this there were political changes in the USA which by the late 1970s saw less government enthusiasm for expenditure on environmental protection.

4.4 Attitudes Toward Environment and Development After the 1970s

At the time of what was effectively the world's first international ecology 'summit,' the 1972 UN Conference on the Human Environment at Stockholm, environmental matters were poorly reported, environmentalism was hardly politicized (outside Germany and a few other countries), few states had ministries or departments for the environment, and there was disinterest, distaste or even fear of calls for limits to growth and to protect nature. A number of representatives, especially those from developing countries, voiced the views that environmental care was a luxury their nations could not afford; that it was a ploy used by richer countries to delay further development and subjugate or exploit them (see *Ecological Imperialism*); or, at the very least, was hypocrisy coming from states which had damaged their own environments to grow rich. When the 1992 UN Conference on Environment and Development met at Rio de Janeiro virtually all countries had ministries of environment; most delegates accepted environmental concern was a vital, integral part of development and not a luxury; the prevailing view was that rich and poor countries were interdependent parts of one global environment; and that practical and possibly painful measures must be taken to solve problems and promote more development in poor countries. In twenty years there had been a 'sea change.'

Certain publications helped achieve this attitude shift, one was *Our Common Future*, the 'Brandt Report' (Independent Commission on International Development Issues 1980), which spread the idea of developed and developing country interdependence eroding the view 'aid is charity' (i.e., the rich would benefit from helping the poor develop and by protecting the world environment). Other influential publications included: the *World Conservation Strategy* (1980) and the 'Brundtland Report' (World Commission on Environment and Development 1987). These publications rekindled public interest in environment and, to a greater extent than before, in development issues; they also spread the concept of *sustainable development*. Sustainable development was more palatable than zero growth called for by supporters of the limits to growth argument; it links aid, environment and development in a concept which, although difficult to give a precise and universal definition for, argues for stewardship to minimize environmental and social damage, efforts to ensure future options are not reduced and, if need be, aid to help achieve these aims (see *Sustainable Development*) (Reid 1995).

During the early 1980s the expression *green* was increasingly applied to environmental issues, largely as a friendly media 'shorthand.' The meaning is vague, but in the main stands for environmentally-friendly and environmentally-sensitive, so 'greening' means 'improving environmental care,' and a 'green,' someone concerned for the environment. 'Greening' has marked the spread of environmental concern to a wider spectrum of Western (later other) societies, than in the 1970s. Interest has spread beyond the middle-classes to the public as a whole, and business, the legal profession, technology, the media, consumer protec tion bodies, marketing and advertising, economics and social studies, theology and philosophy have 'gone green.' This is especially important with respect to economics and commerce, given the crucial role these have in development. Economics has been seeking to develop environmentally-sensitive approaches, an early green economics publication being *Blueprint for a Green Economy* (Pearce et al. 1989). By the late 1980s many large bodies, including the World Bank and most aid agencies, had established environmental departments and green guidelines.

Many interpret this greening as indicating a new social movement: the *green movement*, certainly since the mid-1970s a new 'green' relationship has developed between the social sciences, natural sciences, policy making, and development implementation. Some see

the green movement as a 'cultural attack' on the ills of modern society and economics (Adams 1990, p. 71), and it has been argued it is a manifestation of a postmodern and postindustrial cultural shift. The green movement is very diverse, but most would accept it embraces environmental sensitivity, social responsibility, grass-roots democracy, and nonviolence.

Although many greens scorn politics, or support whatever party they feel will give the best protection for the environment, an aspect of greening has been the spread of environmental politics. Green politics first originated in New Zealand and West Germany with roots in anti-nuclear weapons protest, feminism, and the US Civil Rights Movement, early romantic environmentalists (like Henry Thoreau), and more recent writers on *social ecology*, environmental ethics and *deep ecology* (such as Arne Naess) (see *Ecology, Deep*). Starting in Hamburg during the early 1970s, green politics established a newspaper—*Die Grünen*—and candidates were elected to German State legislatures, and a few years later, to the national Parliament. Early German activists include Petra Kelly, Herbert Gruhl, and Rudolph Bahro. Only a scattering of greens have been elected to governments in Europe and other countries (virtually none in the USA), and if anything support has waned wince the mid-1980s, however they triggered a greening (somewhat cynical) of established political parties. At the close of the twentieth century there can be scarcely a single country in the world without green NGOs (increasingly networking globally), sympathetic newspaper, radio and television editors, politicians interested in cultivating an environmentally-sensitive image, and growing commercial interest in environment.

It has become increasingly apparent that various 'development pressures' are damaging, or have destroyed, established livelihood strategies, leading to environmental damage and human misery. For example, the spread of sedentary agriculture has disrupted seminomadic herders; economic policies may trigger shifting cultivation leading to land degradation; population growth or land development policies may promote settlement of unsuitable and vulnerable soils. As traditional ways breakdown new ones must be found which improve and sustain human welfare without environmental damage. Development therefore faces more challenges than ever before.

Governments, business, and NGOs increasingly adopt *environmental management* measures to try to ensure the *polluter pays* (i.e., whoever is responsible for environmental damage meets the cost of remedy) and minimize unwanted impacts, using precautionary techniques like environmental and social impact assessment, environmental accounting, and eco-auditing. Foreign aid is nowadays almost always conditional on the application of such measures, and is increasingly focused on reducing or avoiding environment and development problems. Since the late 1980s concern about *transboundary environmental problems* has increased, these include acid deposition; stratospheric ozone depletion; chemical pollution; loss of biodiversity; and global warming. There has been progress in understanding the structure and function of the environment and in techniques for measuring and analyzing data—for example, satellite remote sensing and geographical information systems (GIS) (for handling constantly updated data). At the Rio 'Earth Summit' in 1992, participating nations signed a Declaration on Environment and Development; Conventions on Biodiversity (protection) and Climate Change (control), and endorsed an environment and development action program: *Agenda 21* (Keating 1993). Nations have started to negotiate and ratify solutions for environment and development problems, but often back-off when it comes to actually spending money or foregoing possible profits (see *International and Transboundary Accords, Environmental*). Governments and individuals are becoming aware that consumption and technological advances can mean environmental damage and move toward better monitoring and enforcement of controls for environmental problems.

Environment Regulation: Legal Aspects

1. Definition of ER

ER is the guiding by law of human activities with a view to preventing them from damaging the natural environment.

'Regulation' means the setting of specific rules for specific purposes mostly involving administrative agencies in the implementation of the rule. Their form can be laws or sublegal rules. This distinguishes regulation from more fundamental constitutional norms, but also from basic rules of civil law. With the opening up of civil law for more specific political purposes such as consumer and environmental protection, and, more generally, with the growing understanding of any law as an instrument of organizing society, civil law instruments can also be regarded as regulation. Regulation is distinct from decision-making in individual cases, in that the former consists of rules addressing many cases and takes the form of an ordinance or otherwise, while the latter typically results in administrative acts and contracts. In a broad sense, however, regulation is understood to mean the whole setting of state intervention into the market by means of the introduction of goal-oriented law, the setting up of related administrative agencies, and the application of the law in individual cases.

In many states a pattern of ER has evolved consisting of (a) laws protecting specific media, such as flora and fauna, the atmosphere, water, and the soil against various kinds of dangerous activities (media-related laws); (b) laws concentrating on specific dangerous activities and directing them to respect the various media mentioned above, such as the marketing and use of toxic substances, the disposal of waste, the application of risky technologies (such as genetic engineering, nuclear power), etc. (activity-related laws); and (c) laws on instruments applicable for various activities and media, such as land-use planning, environmental impact assessment, access to environmental information, environmental liability, etc. (horizontal or instrument-related laws). Laws organizing the utilization of natural resources, such as laws on land-use planning, minerals exploitation, fishery, agriculture, and forestry, can also be regarded as ER to the extent that they are concerned with environmental issues. A recent trend in many countries is to assemble ER in comprehensive codes. France, the Netherlands, and Sweden have successfully completed such an exercise.

2. Legal Perceptions of the Environment

The type of ER a society chooses depends on how it perceives the environment (Winter 2000). The relationship between nature and the law varies both with the historical development of societies and with the current geographic situation in any given society. In subsistent economies nature is regarded as a powerful 'fate' or agent to which people must defer. The law (e.g., guild rules) impedes individual initiative and thus indirectly prevents overexploitation of the environment. In the industrializing world nature is seen as a resource which can be exploited in order to raise living standards. The law is preoccupied mainly with releasing and assisting individualistic economic energy and inventiveness. In a way it is also environmental law, but in the sense not of protecting but of utilizing nature. In wealthy societies nature is thought of as the environment of the individual, which must be protected in order to secure healthy physical conditions. ER is mainly a child of this kind of society. In today's globalized world a new common perception has not yet emerged. The developing countries still picture

nature as an exploitable resource whilst the developed countries, carrying the environment concept to the global level, would like to have the third world's nature preserved as their carbon sink, gene bank, etc.— in other words, as *their* environment. Ongoing international discourses tend to foster the vision of nature as a global *biosphere*. The interacting physical and biological processes of this biosphere have developed mechanisms of negative loops which can absorb many disturbing events. Humanity is, however, about to instigate more and more positive loops which may endanger the livability of the earth. Therefore, today's ER has, by content as well as level, increasingly become globalized itself.

3. *Difficulties and Responses*

One major difficulty ER must cope with is *uncertainty*. Often it is scientifically unresolved whether suspected environmental damage does or will exist and, if so, whether it was or will be caused by a certain human undertaking. For instance, for a long time it was unclear if acid rain damage to forests was in fact caused by sulfur dioxide emissions. Today it is uncertain whether the global warming caused by 'greenhouse gases' will persist or be reversed by counter-effects, such as cooling effects brought about by the vegetation growth promoted by increased carbon dioxide emissions. In former times when ER was a matter of police power (i.e., restraint, governmental control of society) a determined and immediate *danger* of damage was required for ER to come into effect. Often, the damage did materialize and ER could only look for repair and compensation.

Today in many countries ER follows the *precaution principle*, which requires that preventive safeguards shall be applied even in situations where there is a *risk*, but no certainty, of damage. Also, a primary concession for a risky undertaking may more easily be modified or revoked if better knowledge reveals formerly unknown risks.

Another difficulty to cope with is that ER often involves economic loss, e.g., when an emission standard requires the installation of costly technology. From a long-term perspective environmental benefit will often prove to be economically rewarding (new markets for integrated technology and products, avoidance of disasters, etc.). But individual actors facing regulation normally have to incur adaptation costs. Legal cultures differ as to how they take such costs into consideration. The Anglo-American legal culture is more prepared to balance ecological gain against economic costs. ER is then inappropriate, if the costs outweigh the benefits (cost–benefit analysis, CBA). By contrast, continental European culture somewhat one-sidedly looks at the ecological risks, thereby revealing a basic skepticism against unrestricted relativization of environmental goods. Best available techniques (BAT) are demanded notwithstanding the cost, except if they are obviously extreme. Both of these approaches meet with difficulties: CBA, by monetarizing intangible ecological goods, may distort a fair balance, whereas BAT, by suppressing cost considerations, may cause them to reenter on the political and implementation level where costs tend to be dramatized. The solution is probably to be found somewhere in between over- and underrationalization: depart from BAT, require to quantify excessive cost–benefit ratios, but allow this only to the extent that the related goods have a market value.

A third difficulty is the frequent divergence between scientific and everyday life experience. As demonstrated by the controversy over genetic engineering, the scientific community and the general public often mistrust each other's perception of risks. This tension influences ER on all levels including legislation, sublegal standard-setting, and decision-making in individual cases. Legal cultures differ as to whether they are more scientifically or politically oriented in this respect. For instance, sublegal rule-making for environmental standard-setting in the USA is wide open for public participation, whilst the EC tends to rely on committees of experts (the so-called 'comitology'). More systematic approaches suggest an iterative procedure: first an open scoping of the valuation framework and necessary research; second, the elaboration of scientifically grounded draft standards; third, exposure of the drafts to public scrutiny; fourth, possibly a loop back to the scientific body; fifth, the taking of the decision by the responsible body (SRU 1996). Individual licensing of dangerous installations, on the other hand, is open to public participation both in the USA and the EC member states. In relation to large industrial or infrastructure projects, public inquiries have often been conducted in a hostile atmosphere far from the ideal of rational deliberation some scholars propose. In North America, mediation techniques have been used frequently, and successfully, to resolve such hostilities. By contrast, in Europe mediation is much less frequent and has seldom been successful. This difference is not easy to explain. Perhaps in Europe decision-makers are less used to open discussion, and perhaps the public is also less inclined to strike deals on environmental issues.

4. *Regulatory and Economic Instruments*

ER has frequently employed what are known as 'regulatory' or 'command and control' instruments, i.e., precise standards (environmental quality goals, emission limits, product quality standards, etc.), licencing requirements, monitoring obligations both of the industry and the administration, powers to order adjustment measures, etc. Economists have criticized this kind of instrument as inefficient. Instead they propose so-called 'economic' instruments, es-

pecially pollution charges and tradable pollution rights. They say that regulatory instruments disregard the different pollution abatement costs of the parties concerned, and thus require a great deal of money to be spent on costly technology with marginal protection effect. Economic tools are more efficient as they allow the entrepreneur to decide whether to pay and pollute or to invest and not to pay. A closer look at the enforcement level in the command and control framework, however, reveals that administrative agencies proceed with some flexibility when requiring abatement investments. Also, strict and equally applicable standards provide the enforcement agency with a most valuable bargaining position (Gawel and Lübbe-Wolff 2000, p. 65). Another criticism is that regulatory tools need more administrative personnel than other instruments. Again, a closer look shows that economic instruments must also be monitored closely in order to work effectively. Inversely, economic instruments do not work when it comes to preventing serious accidents or abating 'hot spots' of pollution. The parties concerned adopt a trading approach, in which they expect something in return for any concessions. This atmosphere may cause all concerned to lose sight of the material problem. This is why many countries have been reluctant to move from command and control to economic measures when it comes to ER.

However, under specifiable conditions economic instruments may indeed be more effective, or at least more efficient, than command and control. For instance, the Californian Acid Rain Program fixed the maximally tolerated emission quantity of sulfur dioxide, allocated pollution rights, and allowed intra-firm and, later, inter-firm trading of these rights. The scheme was deemed successful (Sorrell and Skea 1999, p. 43). Whether it was more effective than a regulatory option would have been is impossible to say, but it was probably more efficient. In more abstract terms emissions trading may work when the target can be agreed upon, the polluting substances are singular, and the number of polluters limited. As to polluter charges, the German 'ecotax' on energy consumption can serve as an example. The tax must be borne by every consumer, but it is collected by the energy utilities. The aim of reducing energy consumption could hardly be reached by command and control measures. This shows in more abstract terms that the charge does work if an unlimited number of persons need to be addressed, and if there is no 'hot spot' situation.

5. *Regulatory Measures and Self-control*

Besides reacting to the heteronomy innate in ER, the actor may also protect the environment by *autonomous self-control*. Autonomy can be founded on the moral beliefs of individual actors or organizations, as well as on social norms developed out of social interaction or association. Professional organizations and standardization bodies have learned to consider environmental effects when designing product or production standards. Many large companies have introduced self-binding rules (e.g., the Responsible Care declarations of the European chemical industry) which are intended to guide their personnel and at the same time inform the public. Many have also established environmental management apparatuses and schemes. In addition, the market mechanism has shown some capacity to make an autonomous push towards environmental protection. For instance, companies may develop environmentally adapted products in anticipation of future consumer preferences. The line between the market and the political sphere is blurred when consumers participate in boycott action, such as that taken against the Shell oil company in the Brent Spar case, where Shell had planned to dump an old oil platform in the North Sea but was prevented from doing so by public action.

These various phenomena of autonomy of the individual, company, association, or market mechanism are explained in various ways. One strand of theory suggests some innate force of self-organization or autopoiesis of social systems (Teubner 1996). Another points to the fact that self-regulation which is effective and not mere paperwork is normally incited, structured, and supervised by heteronomous ER. Indeed, the internal environmental management schemes in place in many companies were instigated (but not imposed) and framed by voluntary auditing laws such as the Auditing Regulation of the EC. Voluntary commitments incurred by a company or group, or association of companies, are often triggered and guided by the threat that otherwise the government might issue a binding regulation or order. Sometimes they are framed as a contract providing for the monitoring of effects and for sanctions in case of noncompliance (for a legal framework for voluntary covenants see the draft German Environmental Code (articles 35–39) Ministry for the Environment 1998). Therefore, in a practical perspective, self-regulation as an instrumental solution must always be tuned with a binding framework of ER.

6. *Legal Protection*

Regulation normally constitutes a two-tiered relationship between the addressees and the government. In rule of law systems judicial review of this relationship is provided. Depending on the system, legal recourse may be granted against regulation in the form of individual administrative acts, as well as sublegal acts and even laws. In ER there are addressees who by implication have the right of appeal, and the situation with this kind of regulation is further complicated because it is characterized by a three-tiered relationship involving third parties (neighbors, etc.). These also ask for legal protection against environmental risk. Civil law remedies directed at the polluter, such as

injunctive reliefs and tort or strict liability, come alongside public law remedies directed at the administrative organs, such as the action for quashing an administrative act (e.g., a construction authorization for a dangerous installation), or for issuing an administrative act (e.g., an order to prohibit the marketing of a toxic substance).

These remedies are, however, confronted with the problem typical of ER that often the environmental damage reaches beyond the individual sphere of the affected third party (consider the destruction of a biotope on propertied land implicating the extinction of a species), or that the third party is only indirectly or morally affected (contamination by pesticides of groundwater which may be used for drinking water purposes, destruction of a forest resort frequented by birdwatchers) (Prieur 1996, p. 842). Legal systems differ in the extent they open their legal remedies up to those 'trans-individual' interests. This may be done by allowing other agents than the individual to defend the related collective interest, and by extending the scope of legal arguments to collective concerns. In the realm of liability Brazilian law, for instance, allows for an action called 'civil-public' which can be filed by the public prosecutor as well as by environmental associations for restoration of or compensation for ecological damage (Leme Machado 1998, p. 290). As to third party appeal against the administrative authorization of dangerous activities, French and English law, for instance, only require the plaintiff to show to be affected in a factual interest (Winter 1996, p. 129), whereas according to the narrower German concept the plaintiff must show that a subjective right or at least an interest individually protected by law was violated (Kloepfer 1998, p. 510). US law takes a middle position by requiring that (a) the plaintiff's factual interest is affected and (b) this interest lies within the zone of interests protected or regulated by the relevant law (Findley and Farber 1999, p. 78). The overall European trend points in the same direction.

Legal systems differ also with regard to the density of judicial review of administrative action. Some reduce court review to errors in law (USA, UK, France) whilst others extend it to errors in fact (Germany). Case law has, however, more and more blurred this line. The overall practice has become to reduce or extend court checking, depending on whether the previous administrative proceeding was court-like or not, if the matter involved complex technical, prognostic or evaluative questions or not, etc. (Findley and Farber 1999, p. 120, Kloepfer 1998, p. 532).

7. *Transnationalization of ER*

ER has been transnationalized step by step. There are three main ways in which this has happened. The first may be called the 'market trajectory.' It is put in force by national regulation of product quality (e.g., threshold values for exhaust from cars or for pesticide residues in food). This constitutes an import restriction for foreign products and at the same time a competitive disadvantage for the internal export industry. This again creates an incentive for both the ER and the foreign state to strive for the harmonization of product standards. As a first step a regime (i.e., rules and institutions) is created which checks whether the distortion of trade implied in the national ER can be justified by the public interest in the envisaged environmental protection measure (so-called 'negative integration'). An example for this is Articles 28–30, Treaty of the European Community (ECT) in combination with judicial review under Article 226 ECT of national ER by the European Court of Justice (ECJ). As a second step the regime issues product standards of its own ('positive integration'). The competence basis for this in the EC is Articles 95, 175 ECT (Krämer 2000).

The second development pattern may be termed a 'relocation trajectory.' It sets off with national regulation of production processes (e.g., emission standards for installations). Such regulation will already have been undermined, in its implementation or even in its design phase, because the industry concerned, envisaging cost differentials, threatens to move to low-standard countries. This leads the ER state to push for an international regime. As the avoidance of environmental investment is not regarded as 'commercial dumping,' those regimes normally practice 'positive integration.' Depending on the sophistication of the regime the joint criteria are framed only in broad language or in the form of precise standards. In the EC the pertinent competence basis is Article 175, ECT.

The third pattern, which may be termed a 'commons trajectory,' starts with situations where adequate ER is absent. This leads to an overexploitation of environmental resources (e.g., destruction of tropical forests), or overutilization of the environment as a medium for residues (e.g., destruction of the ozone layer, climate change). Not only the inactive home country but also foreign countries suffer from such environmental damage because it transcends state borders. This triggers their interest in creating international regimes for the protection of transnational environmental 'goods.' Some of these goods (the high seas outside sovereign rights, the ozone layer, the climate) are legally understood as international common heritage, others (tropical forests, genetic resources) as sovereign rights of the host states but of common concern.

As to the organizational capacity of the international environmental regimes (Young 1994, p. 140), the basic pattern is the founding agreement, a secretariat and the conference of the contracting parties (COP), whose conclusions are not directly binding but need to be ratified. Sometimes technical committees are set up

which accelerate the production of strategies, standards, and implementation measures. More advanced regimes have introduced simplified procedures of adopting binding conclusions (e.g., the opting out procedure). In the long run the international regimes, because of their diversity and number (there are about 250 international environmental protection agreements—some of which form a joint regime), need to be restructured in order to enlarge membership, remove overlapping competences, and improve decision-making and implementation effectiveness. This is even more urgent in order to build worldwide 'positive integration' capacity alongside the worldwide 'negative integration' established by international regimes such as the WTO (Esty 1994).

Environmental Adaptation and Adjustments

The nature of the relationship between people and their physical and built environments is constantly changing. The societal choices regarding natural resource use, alterations in the physical world, or responses to environmental threats vary widely. The timing and scale of these choices affect people and places differently, are time dependent (affect current and future generations), and leave a very distinct geographical imprint. Within the social science literature, these responses are categorized as human environmental adjustments and adaptation.

1. Adjustments to Environmental Threats

Humans continually make decisions in response to the physical environment. These decisions are labeled *adjustments*. Some adjustments are purposeful, but many others are incidental and undertaken unwittingly. The term adjustment is used to describe intentional actions taken by individuals or society to cope with risk or the uncertainty of environmental threats. The concept was initially used in the context of coping with extreme natural events (e.g., floods, earthquakes), but has since been expanded to include a range of nature–society interactions. Understanding human adjustments to environmental extremes has been a fruitful research path in the social sciences since the mid-twentieth century (Cutter 1994, Mileti 1999).

It is the interaction of environmental conditions and human systems that gives rise to environmental hazards. The range and choice of adjustments to hazards are influenced by elements in both the human and physical systems. Some adjustments are too costly to implement, while others may not be successful and ultimately lead to greater costs in the future. While benefits may be derived from some adjustments, they also come at a cost, or are not shared equally among all potential beneficiaries. While there could be hundreds or thousands of potential individual or collective adjustments to environmental threats, normally they are classified into three major categories: (a) modifying the causes of environmental threats, (b) reducing human vulnerability, and (c) distributing losses.

1.1 Modifying the Causes of Environmental Threats

There are many examples of successful and less successful attempts at modifying the cause of environmental threats. For example, in the 1970s, considerable research was undertaken to explore the

range of modifications that could reduce the physical impact of natural hazards (White and Haas 1975). Cloud seeding to reduce the severity of severe storms, underground explosions to relieve fault stress, and damming of rivers to prevent catastrophic flooding are notable examples. As the range of environmental hazards broadened in later decades, so did examples of modifying the causes of these new threats: pollution reduction from its source (point and nonpoint); governmental restrictions in the manufacturing and use of known cancer-causing chemicals (DDT); and federally mandated reductions in chemicals that cause human cognitive dysfunction (lead) or endocrine disruption (dioxins, furans, and PCBs) (Colborn et al. 1996). Within the global change literature, the term *abatement* has been used to describe the range of actions designed to reduce the source or cause of that environmental threat, but the meanings are similar. Greenhouse gas reductions (through fuel switching or conservation) are examples of modifying the cause of the global warming hazard.

1.2 Reducing Human Vulnerability

Broadly, vulnerability is the potential for loss, yet within the environmental hazards literature there are conflicting characterizations of the term as well as methodologies for measurement (Cutter 1996). Vulnerability variously refers to personal or individual potential for loss, societal vulnerability to hazard events and losses, or the resilience of society to environmental threats (Dow 1992). Biophysical vulnerability refers to elements in the physical world that contribute to the loss potential, such as climate perturbations (increased drought, sea-level rise), human modification of ecosystems (deforestation, desertification), or location (relocation) of industrial activity (such as toxic facilities, coal mining, or other extractive industries). Social vulnerability examines the characteristics of various social groups (wealth, gender, race/ethnicity, age) that either constrain or enhance human ability to respond adequately to or cope with environmental threats. Both social and biophysical vulnerability have explicit spatial outcomes that can be mapped and thus compared from local to global scales.

Vulnerability is increasingly used in the hazards and global change communities to describe the differential impact of environmental changes on people and the places where they live (Blaikie et al. 1994, Bohle et al. 1994, Hewitt 1997, Comfort et al. 1999, Oliver-Smith and Hoffman 1999). Vulnerability science is still in its infancy and has not progressed far enough for the development of a universal set of specific indicators as of yet.

Purposeful, short-term adjustments designed to modify vulnerability are often referred to as *mitigation*. Mitigation includes land-use planning (Burby 1998), the reduction of losses through building codes, or improved warning systems to reduce human losses. More often than not, mitigation actions are prompted by a specific hazard event. However, it is the incidental and incremental adjustments taken prior to a hazard event that often attain greater importance in reducing overall losses. The elevation of housing structures so that the ground floor is above base flood levels (flood hazard), the construction of 'safe rooms' in houses to reduce the human losses from tornadoes, fish advisories to reduce human consumption of fish caught in polluted water to decrease bioaccumulation of toxins in human fatty tissue, and carbon sequestration as a means for mitigating greenhouse gas emissions are examples of mitigation actions to reduce human vulnerability.

1.3 Sharing and Distributing Losses

Insurance, relief, and recovery operations are all examples of individual or collective loss sharing. When a disaster strikes, governmental agencies and nongovernmental organizations are mobilized to provide assistance in the form of temporary shelter, food and water, and power. The costs of such operations are normally not borne by the individual disaster victims, but rather by society at large. While the impacts are local and may outstrip the ability of a community to respond, the economic costs are more widely shared. Relief organizations (Red Cross and Red Crescent Societies), faith communities, and governmental agencies (US Federal Emergency Management Agency, UN Disaster Relief Organization) all assist in recovery and the rebuilding of devastated communities.

Insurance is another example of loss sharing, but not everyone has equal access to it. In the United States, the public looks toward insurance as the mechanism for loss compensation (Kunreuther and Roth 1998). Insurance as an adjustment will become less viable in the future as the costs of disasters increase and the realization that neither the insurance nor the reinsurance industry have sufficient resources to pay for a worst-case event. Other examples of loss sharing are financial incentives and disincentives (taxation) which encourage or discourage risky adjustments.

2. Adaptation

Adaptation describes longer-term activities that take into account the threat of environmental extremes or changes. Adaptations often take place unknowingly, simply reflecting the modification of environmental conditions (Turner et al. 1990) or the changing occupancy of threatened regions (Kasperson et al.

1995). Adaptation is rooted in social and cultural systems. Biological adjustments are also considered adaptive such as the assimilative capacity of biogeochemical cycles to absorb pollutants without immediate systems degradation. As with other aspects of culture, these adaptations, while appropriate in some circumstances, are not always the best solution to responses to environmental threats. Often, adaptation to one hazard or environmental threat prompts greater vulnerability to others.

3. Factors Influencing the Choice of Adjustments

Under ideal circumstances, individuals and society would have a full set of choices that they could select from in adjusting or adapting to environmental threats. How people choose adjustments is not always clear-cut, simple, rational, or even economic (Burton et al. 1993). There are a number of factors that constrain the set of adjustments and influence the choices that are made and these are described below.

3.1 Local Control and Local Focus

Local control and focus facilitate the adoption of adjustments as communities and individuals see a direct benefit from their hazard reduction efforts. When a homeowner decides to take action to reduce the risk of storm damage to the home, or when a city council votes to remove flood-prone land from development, both are engaging in purposeful adjustments. For mitigation efforts to become successful, individuals (and communities) must become aware of the hazards that affect them and realize they have a personal stake in avoiding, minimizing, and mitigating the costs and impacts of hazards on the local community.

Mitigation has been encouraged at the local level, because hazard control strategies implemented at the national level have been only partially successful. Flood mitigation policy in the United States provides a useful illustration. The structural era of flood control—federal construction of channels, dams, and levees—led in some instances to an increase in vulnerability from more extreme events (Platt 1996, 1999). These structures created a false sense of security and an assumption that the flood threat had been eliminated, resulting in increased human activity in floodplains, thereby increasing vulnerability to flood hazards. Given the relative lack of success in actually controlling floods (modifying the cause), it has become apparent that a less costly and more appropriate approach to flood mitigation should focus on land-use patterns within floodplains.

In the United States, for example, the National Flood Insurance Program (NFIP) requires appropriate floodplain development by communities that want to participate in this national insurance program. While spreading the loss, this program does have its drawbacks and critics (Platt 1999). The NFIP has the potential to encourage development within the floodplain precisely because low-cost insurance is provided by the federal government, thus reducing the incentive for homeowners to mitigate on their own such as floodproofing their home or moving away from the floodplain altogether.

3.2 Perception of Risks and Hazards

The perception of hazards and risks play an important role in understanding how and why individuals choose specific adjustments (Burton et al. 1993). Depending on the perception of the threat, those at risk will either seek additional information, seek actions to protect themselves, or continue with their normal activities. Hazards not considered threatening, whether due to lack of information, lack of scientific certainty, or some other factor, result in little or no preparation. Factors that influence the perception of hazards include hazard frequency and past experience, cultural/social attributes (age, wealth status, gender), and the credibility of hazard information. The perception of the environmental threat also colors the choice of adjustments people are willing to undertake to curb damaging effects. For example, the public is aware of the causes and potential impacts of global warming, although the linkages between individual human activities and global impacts are not completely understood. Because individuals do not 'see' their own contributions in greenhouse gas emissions or feel any personal responsibility for the hazard, they are unlikely to adopt any short-term adjustments such as purchasing more fuel-efficient cars or driving less.

3.3 Experience

As noted above, a belief must exist that lives and property are susceptible to harm from a particular hazard before individuals or organizations will undertake mitigation efforts (Palm 1990). Adjustments based on experience are subject to the material capabilities and personality constraints discussed next. It has been shown that individuals with little or no experience with a hazard are less likely to accept information, recognize the seriousness of the threat, or take appropriate action to protect themselves from harm. For some hazards there is little direct human experience. In these instances, the choice of adjustments will be based primarily on the perception of the threat and belief in the scientific certainty about potential impacts. In the case of global warming, the perception of the threat is low (requiring very few adjustments), whereas in the case of nuclear power

plants the public perception of risk is fairly high, resulting in very strict siting, regulatory, and safety controls.

3.4 Socioeconomic Characteristics and Personality

Socioeconomic characteristics such as gender, wealth, education, age, race, and ethnicity are not only correlated with risk and hazard perception, but also with adjustment adoption. For example, women have been shown to perceive risks differently, to be more risk-averse than men, to experience risk and hazards more often, to take a longer time to recover after disasters, and to undertake substantial preventative or mitigative actions in response to environmental hazards (Enarson and Morrow 1998).

Wealth also constrains the adoption of adjustments. Insurance, while technically feasible, is not an option for families with limited incomes. As a general rule, the poor are more susceptible to hazards owing to lack of resources, poor housing quality, and an inability to recover quickly. A host of equity literature is also supportive of race and ethnicity as contributing factors in creating vulnerability. Race and ethnicity shape the adoption of adjustments through differences in hazard perception and experiences, an understanding of and belief in the science behind the hazard information, and attitudes toward the dissemination of information.

Finally, personality influences adjustments since they are further narrowed by one's belief in their ability to control events. There is evidence that suggests that 'locus of control' influences the choice of adjustments. For example, if one feels powerless in the face of natural events (a fatalistic belief), then that individual is more likely to remain in place despite hurricane evacuation orders. Conversely, individuals who feel that they can control events around them, may take other courses of actions in response to an environmental threat such as floodproofing a home, evacuating out of harm's way, or reducing energy consumption to produce fewer greenhouse gas emissions.

4. Adaptation Versus Mitigation

Adapting to environmental threats means undertaking long-term changes in the ways we use the environment and interact with it without trying to prevent the landscape transformations from initially taking place (Kempton et al. 1995). Adaptations (sea walls and dikes, permanent relocation of populations, permanent closure of facilities) do little to reduce the source of the threat. Rather, the actions taken are in direct response to reducing human vulnerability.

Mitigation refers to the short-term actions that relieve losses (insurance, housing rehabilitation), but it is also synonymous with preventative actions that guard against future hazards and their associated losses. The implementation of either adaptation or mitigation strategies depends on the nature of the environmental threat, and will require public education and information, technology development and transfer, and economic, financial, legal, and institutional mechanisms. Further, each strategy will be distinguished by its capability for implementation at the local, regional/state, national, or international levels.

The drought hazard provides a good example of the difference between adaptive and mitigative responses. Societal dependence on the water budget for a particular area can lead to disaster when these supplies fail. While the drought 'trigger' may be found in the physical world, drought impacts should be viewed as resulting from the variability in the supply of and demand for water.

Since most droughts are local or regional occurrences, the initial policy responses tend to develop from local and/or regional concerns. In the United States, the federal government is involved in most aspects of water resource planning, but most drought policy is enacted by individual states and there is no consistency among them. In other developed countries, drought initiatives generally come from the central government, but normally in the form of aid to get the local constituents to change behavior. In Australia, for example, the national government encourages agricultural producers to adopt self-reliant procedures in managing climate variability. The government provides education in risk management, sustainable agriculture, and drought preparedness and only provides direct assistance under exceptional drought circumstances. These actions tend to be more mitigative and encourage water consumers to modify their behavior and practices to reduce the wasting of water.

In developing countries, drought response tends to be more adaptive. Since the GNP of many of these nations is much lower than those of developed countries, there is less money available for the government to spend on drought mitigation. The adjustment burden, therefore, falls on individual families who adapt by planting crops in seasonal floodplains, using drought-resistant varieties, or growing quick-ripening crops in preference to species that promise a higher average yield. These societies have managed to adapt successfully by being rich in resourcefulness despite their relative lack of financial wealth.

Geographic scale is crucial in understanding the distribution of hazards, their impact, and human responses to their reduction. While initiatives to curb losses may come from national or even global authorities, greater success is realized through the efforts at the local level. The ability to undertake significant mitigation or adaptation actions in response to environmental threats will depend on the

range of adjustment alternatives, the perception of the viability of them, their cost, and their relative impact in reducing the source of the environmental threat. These factors will vary over time and space and across social groups, economic sectors, and political jurisdictions.

Environmental and Resource Management

1. Setting the Scene

The worldwide decay in environmental quality conditions and the gradual depletion of natural resources, sometimes referred to as the 'new scarcity,' has been a dominant theme for research and public policy during the latter part of the twentieth century. The global interest in environmental matters is partly caused by the increased pressures that a mounting population and increased production exert on the earth's natural resource base. In addition, as personal incomes rise and leisure time becomes more freely available in the developed world, concern with more immediate human needs has been accompanied by an interest in preservation and conservation for the sake of future generations as well as other regions of our world. We observe an increasing interest in 'quality'—next to 'quantity'—as an important constituent of individual and collective welfare.

It seems likely that the issue of environmental degradation will stay with us until far in the next millennium. Already Plato in his Kritias was complaining about human activity which had turned the landscape of Attica into a skeleton and a wasteland. We also know about environmental regulations in medieval European cities which aimed to control the use of coal burning or the noise annoyance caused by horse-drawn carriages. And the early stage of the Industrial Revolution demonstrated an abundance of urban environmental quality degradation. But in our era, the size and the intensity of resource use and of related environmental decay have taken such massive forms that the stability and sustainability of many ecosystems—both locally and globally—is threatened. This has stimulated the launching of the concept of sustainable development in research and policy making at the end of the 1980s, as well as the international

research on biodiversity loss and climate change risks during the 1990s.

Much of the early interest of the last century centered on public health in dense agglomerations. As sociomedical knowledge on how diseases spread developed, urban authorities sought to improve the local environment by measures like sewage control and clean water supply to reduce the diffusion of germs and infection. This trend, much later, led to policies embodied in various initiatives of clear air legislation to reduce local atmospheric pollution that causes smog and other harmful effects. Wealthy societies, and the better off within poorer societies, with the time and resources to expand, became concerned with the built environment and with shaping nature in ways that they found aesthetically pleasing. Over the centuries this has led to specific patterns of landscapes in the countryside and the provision of parks and gardens in urban areas. This has created a general concern on quality of life, in addition to economic dependence on resources and environment.

The resource and environment base of our earth is a complex system that comprises an enormous diversity of forms consisting of biotic and nonbiotic components. Essentially, the resource and environment base is made up of three main interrelated classes: biotic resources emerging from soil or water (such as vegetation and animal populations); abiotic resources with productive or consumptive values (such as minerals and energy); and environmental components needed for our well-being (such as clean water or fresh air).

Traditionally, resources are subdivided into renewables (which may be replenished with or without human intervention) and nonrenewables (which cannot be reproduced within a meaningful time horizon). Both types of resources can be depleted.

The main problem in environment and resource management is the interwoven nature of the 'new scarcity' question. Resource use leads to pollution, and abatement of pollution requires additional resource use. Clearly, technological innovation (e.g., recycling) may help to alleviate some of these problems, but with a rising population, and rapidly rising consumption and mobility levels it will be extremely difficult to achieve a sustainable development over a time scale involving many human generations. Furthermore, resource and environment issues may manifest themselves at local or regional scales, but they are part of a globally interwoven ecosystem. Consequently, the 'new scarcity' has clear spatial and temporal horizons which extend far beyond the current level of thinking and acting.

Against this background, the concept of sustainable development has become 'en vogue.' Although this notion has already a longer period of existence, it became fashionable after the publication of 'Our Common Future' by the World Commission on Environment and Development (WCED) (also known as the 'Brundtland Commission'). The Commission called attention for the need to consider our planet as an integrated social, economic, ecological and political system which needs collective initiatives and actions in order to ensure continuity under changing conditions. The report suggested that economic growth and environmental protection can go together, which was subsequently tested by Duchin et al. (1994) using a multisector–multiregion model for the world. Their conclusion was negative.

2. *Back to the Roots*

The scientific analysis of the physical conditions of our earth has already a history of many centuries, as is witnessed by the body of knowledge collected in such disciplines as biology, physical geography, archaeology and chemistry. The social sciences were latecomers in studying issues of environmental quality and nature. Of course, there are early examples of social science research on environmental and resource issues, for instance, by nineteenth-century scientists like Malthus and Marx. But it lasted until the 1960s and 1970s when the urgency of environmental degradation and resource depletion had become so widely recognized that various social science disciplines started to develop a pathway for environmental research. This does not mean that in some disciplines attention had never been given to resource and environment issues. On the contrary, in economics we observe a long-standing interest in resource scarcity, in relation to agricultural land use and mineral use. The Physiocrat thinking in economics even advocated that nature—in particular, land and water—were the real sources of economic wealth. But this early interest in resource use was mainly instigated by the (positive) productive contribution of physical resources to economic activity. Only a few economists in the first part of the twentieth century recognized the 'unpriced scarcity' nature of the environment and of many resources (notably Pigou). Marshall introduced the concept of 'externalities,' which meant that the social value of various goods and services, including nature and the environment, is not or is insufficiently reflected in market prices, so that a socially undesirable use of these goods and services will follow. This may be the result of myopic behavior of selfish people, the public good nature of various resources, the lack of control by property rights or proper regulations.

The real interest in environmental issues started essentially in the 1970s when the growing recognition of a worldwide environmental decay and of severe resource depletion (in combination with a population explosion) received an unexpected but welcome support in the oil crisis. This sudden event was complemented by the First Report to the Club of Rome ('The Limits to Growth'), which was based on a scenario analysis with a systems dynamics model of the World.

Although the scientific contents of the latter study left much to be desired—as a result of conservative information on resource availability and insufficient incorporation of negative behavioral and technological feedback mechanisms—it created a shock effect among social scientists. This gave rise to an intensive debate between growth optimists and pessimists (Daly and Townsend 1993).

This also marked the beginning of the social science interest in environmental sciences. Economists constructed abstract models of economic growth and resource use (Dasgupta and Heal 1979) and developed a theory of environmental policy for correcting environmental externalities (Baumol and Oates 1988). Economists and psychologists began to investigate how people value environmental change, environmental policy and ecosystem management, using stated preference and revealed preference methods (Hanley and Spash 1993). Demographers started to investigate the relationship between resource scarcity, population growth and migration. Decision theorists tried to develop new tools for policy-making that were more tuned to the often qualitative and unpriced nature of environmental goods (such as multicriteria and multi-objective decision tools). Many disciplines worked together in integrated modeling and assessment, addressing both ecosystem and global scales (climate). Finally, statisticians became involved in the formidable task of developing new statistical data that would map out and monitor energy use, environmental deterioration and the like. So, in some 25 years time there has been an explosive interest among social scientist in environment and resource issues.

It should be noted that there are many ways for a simultaneous analytical treatment of economics and environment. Since the 1960s, a great many attempts has been made to link economics to the ecology (Costanza et al. 1997). An important contribution began simply with a reflection on the principles of the materials balance for resources (extracted or collected, transformed, consumed and emitted) and on the need to take account of an economic viewpoint of such processes (Ayres et al. 1999). Several attempts have also been made to build economic and social accounting systems that could incorporate the measurement of economic welfare and performance together with the measurement of environmental indicators and performances. The integration of economics with ecology has also been approached from the viewpoint of land-use—where economic and ecological processes have the most disruptive effects—and of urban environments. In addition, the interaction between economics and ecology has next been dealt with for situations with global risks and uncertainties.

In the past decade, one can observe an avalanche of publications on environmental issues, not only in popular journals, but also in academic publication channels (journals, books). Most of these publications demonstrate clearly the multidisciplinary nature of environmental sciences, which caused researchers from various disciplines to cooperate, with more or less success. In particular, the field of 'ecological economics' (and its journal with the same title) has shown the relevance of multidisciplinary thinking in environmental and resource economics.

3. *A Short Account of Core Topics*

In this section, we will offer a concise overview of major topics in the area of management and economics of environment and resources. These issues are covered in detail in van den Bergh (1999). A very readable introduction is Kahn (1998), while a thorough treatment is provided by Perman et al. (1999).

A major focal point with already a long tradition is—as mentioned above—natural resource management, for both renewable and nonrenewable resources (Clark 1990; Dasgupta and Heal 1979). Questions analyzed in this context concern optimal extraction of non-renewable resources under competitive conditions (such as the well-known Hotelling cake-eating choice dilemma). In the literature on these issues, much attention is given to the (as yet uncertain) options offered by technological innovations and to the statistical uncertainty in estimating the resource stock (so far all estimates appeared to be rather conservative). This relates to the problem that the correct way of measuring resource scarcity is subject to debate, and has given rise to a range of scarcity indicators. From a management perspective, much attention has also been devoted to the implications of limited competition (e.g., monopolistic and oligopolistic market forms). Also renewable resources have gained much interest, in particular in the agricultural, fishery and forestry sector. Important issues here are uncertainty, re-investment rules and multiple-use conditions. Finally, in recent years we have observed an intensified interest in two particularly important resources with a wide societal and global coverage, viz. water and energy. These two resources are important concerns in both the developed and the developing world, not only because of their immediate far reaching implications of emerging scarcity but also because of the changing markets of these goods towards more deregulation and privatization.

A recurrent theme in environmental and resource economics is the economic valuation and evaluation of environmental goods, such as clean air or water. The main problem here is the nonpriced nature of many environmental goods, so that the environment runs the risk to be forgotten in any cost–benefit analysis for plan or project evaluation. The question is then whether it is possible to restore a missing market, e.g., by introducing shadow prices via taxation schemes or an artificial market, or to edict regulations to ensure at least a minimum respect for environmental goods,

e.g., in the form of standards. Although from a market theory perspective shadow prices (including taxes and subsidies) are often regarded as superior, in practice many forms of standard stetting have emerged, as they are more unambiguous and better testable. In the literature a wide variety of valuation approaches has been proposed. These can be categorized as travel-cost methods (based on revealed preference approaches using generalized travel costs), contingent valuation methods (based on state preferences, i.e., experimental surveys or questionnaires), and hedonic pricing methods (based on revealed preferences related to property values). A prominent question in valuation theory is the reliability of the various value estimates. Various considerations are relevant in this respect: the strategic contents of responses to interviews or survey questionnaires; the distinction between use and nonuse values; the choice between 'willingness to pay' and 'willingness to accept compensation' measures; and scale and double-counting issues (Hanley and Spash 1993, Turner et al. 1999). Recently, benefits transfer and meta-analysis have been used to avoid having to undertake costly new valuation studies. For environmental policy purposes various adjusted approaches have also been developed, such as social cost–benefit analysis and multicriteria evaluation methods. These methods have been widely applied. Nevertheless, their application faces various caveats, in particular problems associated with choosing a correct social rate of discount, incorporating spatial or temporal equity issues, and addressing problems where only qualitative or fuzzy information is available.

Another topic that makes up an indispensable component of the study of the environment and natural resources is the geographical dimension. Many environmental problems may seem to be local or regional issues, but have a worldwide impact. This is caused by two factors, viz. international (or interregional) trade and the spatial diffusion of pollution (or the spatial dimension of externalities in general). For example, the high efficiency of the meat industry in Western Europe is co-determined by the importance of tapioca from Thailand, which leads to widespread environmental decay in the latter country. Phenomena like ozone-layer destruction, the rise in ocean levels and desertification are other illustrations of the geographically interwoven nature of the environmental problem. As a result, cross-boundary and global environmental problems have provoked much scientific debate, not only on the causes but also on the policy responses (e.g., international environmental agreements, trade regulations, etc.). Such issues play also a recurrent role in negotiations on trade liberalization in the context of the World Trade Organization (WTO).

In a more theoretical setting, much attention is also given to equilibrium-distorting effects of environmental externalities in international trade. Issues investigated there are the effects of imperfect competition, industrial specialization and interlinkages; the consequences of unilateral environmental regulations; trade in pollutants (e.g., toxic materials); and the position of Third World countries. Cooperative and non-cooperative game strategies are studied in the context of global warming, climate change, acid rain, stratospheric ozone and global biodiversity. And finally, from a geographical perspective, much attention has been paid to point versus nonpoint source pollution problems, land use, urban environmental issues, locational issues and transportation. In retrospect, the spatial dimension of resource and environment issues has been addressed on various occasions and from different perspectives, but there is certainly still a broad research field in the geography of the environment.

Next, we will address the problem of environmental and resource policy. The frequent absence of markets for environmental goods, i.e., market failures, leads to a distortion in the price system and hence to an inefficient allocation, which causes environmental decay, resource depletion and the acceptance of high environmental risks. There has been a formidable range of publications on environment and resource policy, in particular on the choice of policy instruments; on different taxation regimes, technical and product standards; on subsidies, tradable permits, deposit-refund systems, stimulating self-regulation via covenants; and on joint implementation. In economic theory, efficiency has been the dominant policy selection criterion. However, in practice instrument choices will also be influenced by other criteria, such as effectiveness (relating to uncertainty, monitoring and control), equity (social and political feasibility), sustainability (ecosystem stability and resource availability) and international feasibility (agreements, laws and policy coordination). Various topics have been discussed in relation to the choice of instruments of environmental policy: the impact of imperfect markets; the encouragement of technological innovation; research and development; environmental tax reforms; and the role of transaction costs. Certain proposals for environmental tax revisions, or 'ecotaxes,' in popular jargon, have been argued by some to create a double dividend, that is, a beneficial outcome for both environment and employment. In general, however, economists are very skeptical about the existence of 'win–win' (or 'no-regret' or 'low-fruit picking') policies. This is partly related to the inevitable efficiency–equity trade-offs in policy-making. Finally, in the past few years we have witnessed a large flow of scientific contributions on international agreements and negotiations regarding transboundary or global environmental and resource issues. Harmonization of international regulations appears to be still a field fraught with many conflicts and divergent policy strategies.

As a last topic, the scientific apparatus developed to come to grips with the complexity of the new scarcity

will be mentioned. Standard monodisciplinary approaches cannot always be applied in a straightforward manner, as always multiple dimensions and disciplines have to be taken into consideration. Examples range from lessons obtained from thermodynamic theory to marketing principles being applied to eco-labeling. Mass balance calculations are needed to undertake life cycle analysis, and analogies of ecosystem models may be used in the context of 'industrial metabolism.' It is therefore no surprise that a uniform analysis framework has not emerged. On the contrary, we observe a great diversity of methods and models. Some important classes are: input–output and materials balance models; optimal control and dynamic programming models; partial and general equilibrium models; policy evaluation methods such as cost–benefit and multi-criteria analysis; game theoretic models; resource extraction models; natural resource accounting methods; evolutionary and other dynamic simulation approaches; meta-analysis; and experimental methods.

The previous overview has clearly highlighted the need for proper communication in the environmental sciences. Progress—in terms of new insights and impacts on policy—will only be made if environment and resource issues are jointly analyzed within common themes in research.

4. *Towards a Sustainable Environment*

Doomsday prophets have spent much time building an image of the world where environmental deterioration would herald apocalyptic perspectives. It is surprising to note that in many parts of the world we have seen a recovery of threatened ecosystems and environmental quality conditions as a result of active policy intervention, technological progress and behavioral change. It seems as though economic growth is not necessarily at odds with environmental sustainability.

Environmental sustainability is often divided into weak and strong sustainability. 'Strong' refers to the idea that every component of the environment and nature has to be maintained, with 'Deep ecology' as its most extreme proponent. 'Weak' refers to a change that makes some environmental components worse off, provided that the overall net balance is still positive. The distinction relates to ethical positions as well as views on the possibility of substitution (as opposed to complementarity) between nature or environmental goods and services on the one hand and socio-economic artifacts on the other hand. The question of weak and strong environmental sustainability is also co-determined by the degree of disaggregation of the environmental system under consideration, by the geographic scale at which environmental problems are studied and by the time horizon.

The notion of sustainable development is related to the old debate on growth versus environmental protection (Daly and Townsend 1993). In the context of endogenous growth theory it seems plausible that economic progress may be accompanied by environmental quality improvement, provided a sufficient part of public and private expenditures is allocated for environmental protection measures, for environmental investments and for environmental research and development. This has inspired a debate on sustainable growth. Clearly, such a discussion can only lead to conclusive answers if it is supported by empirical facts. This discussion on the 'decoupling' or 'delinking' hypothesis has laid the foundation for the so-called 'environmental' or 'green Kuznets' curve, where the underlying assumption is that after a stage of environmental decay as a result of economic growth, a new stage may set in during which economic growth supports a more environmental benign development. This growth optimism, however, is thus far not supported by sufficiently reliable statistical data, although it is clear that there are many examples of environmental improvement in a growing economy. But the green Kuznets curve does certainly not hold for all environmental indicators. A related important issue is the attempts to correct the conventional measure of welfare, GDP per capita, for environmental decay. Although this would not lead to a perfect indicator of welfare or progress, it could render a much better indicator for public and private decision-making, notably by central banks, international financial institutions and financial markets.

Just as the academic interest in environmental problems has evolved, so has the institutional setting in which they are addressed. There has been a movement away from micro-policy making in the hands of city councils, regional public bodies and the like, to macro-policy making, involving global agencies such as the United Nations and World Bank. Indeed, one of the pressing issues of contemporary environmental debate is the appropriate jurisdiction for different levels of government.

It is thus clear that the concept of sustainable development has been the source of much creative environmental research in the past years. But effective implications for environment and resource management still have fully to emerge.

5. *Concluding Remarks*

Environmental analysis extends across virtually all academic disciplines. Indeed, many disciplines such as economics and engineering have specific subareas of interest specifically devoted to environmental issues. The multidisciplinary and transdisciplinary nature of environmental research makes it difficult to keep track of the key literature.

In a few decades time, an overwhelming amount of research effort and research findings on environment

and resource issues can be observed. Environmental science has become a rapidly evolving field with a strong social science component. Environmental and resource economics has generated many insights about environmental policy design, natural resource management, development and growth policies, international trade and environment, transboundary pollution issues, and international agreements and policy coordination.

A rapidly evolving field is environmental business management (sometimes referred to as 'environmental management' or 'business and the environment'). This brings together scientific insights and business experiences. Many firms, especially larger ones, have accepted the importance of environmentally sustainable action and strategy, for various reasons. It has not only led to many in-house adjustments (waste treatment, environmental accounting, internal organization), but also to strategic decisions about 'green marketing,' eco-labeling, investments and involvement of various stakeholders. So far, however, a close link with the theoretical and empirical literature in traditional environmental and resource economics is lacking. A fundamental and longstanding question that their synergy could resolve is how firms make decisions about environmental management in complex and international situations, which are dominated by multiple stakeholders, rapidly changing markets and new information and communication technologies. This could provide information on what type of environmental regulation is most effective and efficient in the long run.

In conclusion, resource and environmental economics has created a breadth and depth of scientific insights into the new scarcity. Both theoretical and empirical knowledge has been generated in a surprisingly rapid pace. A multidisciplinary orientation has offered a great strength to this relatively young discipline in attacking complex and topical policy issues.

Environmental Archaeology

1. Description

As a result of historical and cultural differences in the development of the field, what is called environmental archaeology in English, Spanish, and Italian is known in other languages as the equivalent of ecological archaeology or archaeology of the milieu. Because of the underlying differences in perspective and the absence of a coherent theoretical, methodological, or technical framework, it is a 'field of studies' rather than a 'discipline.' Its focus could be defined as: 'the study of the past of our terrestrial milieu, its relationship to humans, and the latter's relationship to their environment.'

Recent reference works omit the concept (Mignon 1993) or define it as 'a broad range of specialized studies in archaeology that pertain to prehistoric human-environment interactions' (Michaels 1996). These studies apply methods from the natural and life sciences to the study of past environments and the ways people exploited and changed them. Depending on the application or the discipline of origin, they are commonly divided into the following.

Geoarchaeology includes geomorphology, archaeopedology, and archaeometry (the application of geophysical prospection methods to archaeology) as well as (sometimes) isotopic dating and characteriz-

ation methods, and the rapidly expanding field of soil micromorphology of ancient sites and landscapes. Among the *archaeobotanical* methods one finds palynology, macroscopic and microscopic analyses of charcoal, fruits, or seeds, and the study of fossil plant crystals (phytoliths). The latter is growing in importance as it does not depend on the preservation of organic materials.

The study of ancient animal remains is the preserve of *archaeozoology* (or zooarchaeology, see *Zooarchaeology*), which identifies the animals, determines their age and sex, reconstructs their population dynamics, etc. to better understand their significance to prehistoric people. In this domain, isotope analyses have recently added a dimension.

Finally, bioarchaeology deals with humankind: human growth and growth deficiencies, activity levels, nutrition, parasites, illnesses, and much more. In the latter three of these fields, DNA studies promise to open new avenues.

In the meantime, the essential unity of environmental archaeology (as opposed to the disciplinary diversity of the approaches to it) is gradually being recognized (Reitz et al. 1996). The tardiness of that development and the difficulties it encounters are rooted in its intellectual origins.

2. *The Roots and Early Development of Environmental Archaeology*

Since the fourteenth century the natural sciences have flourished by focusing on issues concerning closed systems, in which independent, irreversible changes have played a negligible role. They successfully encroached on many areas which for centuries had been considered outside their remit, creating an opposition to the historical disciplines (Evernden 1992). By the mid-nineteenth century, they had fundamentally changed our worldview to the point that, in everyday life, 'nature' was increasingly preferred over 'tradition' or 'the past' to explain self-evident observations (Girard 1990). As the then dominant schools of thought dealing with the long term, 'natural history' and *Kulturgeschichte* illustrate the fundamental dilemma of environmental archaeology.

'Natural history' is the forerunner of evolutionary biology; in both one first explains the observed functioning of physical or biological systems in terms of rigorously derived laws or general principles, and then attempts to reconstruct their possible antecedent states (Jonas 1982). In the absence of an accepted explanatory theory, early nineteenth-century natural historians either assumed that God created things as they are, or avoided the problem altogether by focusing on systematics rather than origins. J.-B. de Lamarck (1744–1829) is an exception, accepting intragenerational changes but not their inheritance (1802, 1809). For the *Kulturgeschichte* school, past and present are part of an irreversible, complex process, and writing history involves simplifying it through a continued back and forth between the observed past and the present in which one interprets. The nonrecurrent event is considered an essential aspect of human behavior, and the historian is concerned with the impacts of chance as well as of the role of individuals. A fundamental refusal of the positivist position dominant in the natural sciences underpins these ideas. W. Dilthey (1833–1911) summarized it as follows: 'We explain nature, we understand humanity' (Dilthey 1988).

Beginning in the 1850s, new approaches emerge. Charles Darwin (1809–82) explains (1859) long-term 'natural' change by arguing that the first living beings could have been much simpler than the present ones. Distinguishing ontogenetic from phylogenetic evolution allows him to explain the past and the present of all species by invoking 'variation' and 'natural selection,' mechanisms operating at the metalevel of the long-term existence of species, rather than at that of the individual and/or the single generation. Moreover, the theory of evolution breaks the iron grip of reversibility and/or replicability on explanation, and facilitates the reintroduction of historical explanation in the realm of nature. At roughly the same time, sociologists such as E. Durkheim (1893, 1895), building on the work of G. Vico (1668–1744), C.-L. de Montesquieu (1689–1755), M.-J. de Condorcet (1743–94), and A. Comte (1798–1857), argued for the importance of the study of the social and functional dynamics of societies, while anthropologists such as E. B. Tylor (1871, 1878) and L. H. Morgan (1877) argued for a universal pattern of development of all societies. Their 'social evolution' introduced 'naturalist' elements into the study of 'culture,' breaking with the *Kulturgeschichte* school.

Emerging in this climate, between the humanities and the natural sciences, prehistoric archaeology and environmental studies constituted an ambiguous middle ground because they dealt with phenomena which change qualitatively and irreversibly during the period of observation, and with the interface between people and their natural environment. Neither fit the mechanistic approach of the natural sciences because these exclude the study of qualitative change, nor did they fit the historical approach, which focuses on the human, nonrecurrent, aspects of behavior. Like 'natural history,' prehistoric archaeology reconstructs a past that moves from the simple to the complex, and in order to write it, simplifies the complex present. It involves description of the transformation of processes (in which neither chance nor idiosyncrasies play a part). This contrasts with classical, medieval, and later archaeology in Europe, as well as the archaeology of the great civilizations, which have evolved in the historical realm. To this day, these two archaeologies operate very differently.

In 1866 E. Haeckel defined his 'new science of ecology,' as 'the science of the relationships of the organism with its environment, including all conditions of existence in the widest sense' (Haeckel 1866). He does not include humankind in it—in effect, he defines 'environment' in much the same way as 'nature' was defined a few centuries earlier, as 'non-organism.' Darwin on the other hand reconfigured Lamarck's concept of 'environment' as 'the conditions of natural selection,' and included mankind in his 'web of life.' Thus, the distant past and the environment both became objectifiable and separable, fit to be studied by rigorous, 'scientific' methods within a 'naturalist' concert of disciplines, but dealing with humanity as well as the nonhuman natural world. It is thus no surprise that environmental archaeology enters the arena of the archaeological disciplines as the handmaiden of prehistory.

The study of the natural environment of prehistoric man developed first in those parts of Europe in which traditional 'classical' or 'literary' archaeology was the least dominant: Scandinavia, the Low Countries, Northern Germany, Switzerland, and the UK. The first known formal association between prehistoric archaeology and the biological sciences is the so-called 'Danish Royal Commission for Research on Shell Middens' instituted in 1848, which included the leading people of the day, such as J. J. A. Worsaae, J. Steenstrup, and J. S. Forchhammer. This is part of a blossoming interest in past environments in the nineteenth century, in which geology played an important part, as exemplified by G. de Geer's (1858–1943) work on varve chronology in Sweden, and E. J. Lennart von Post's work on prehistoric palynology (1884–1951). In Switzerland, A. Morlot followed in these footsteps when the first lakeshore dwellings were excavated in the 1850s and 1860s (1861).

In The Netherlands, at about the same time, paleogeographers seem to have been convinced that landscapes reflect processes in which natural and human dynamics both play an important part. In 1920, a plant physiologist (A. E. van Giffen) was appointed to a chair in archaeology at the newly founded Biologisch-Archaeologisch Instituut of the University of Groningen, with the aim of doing integrated research on the origins and history of the Dutch coastal system. He notably stimulated archaeozoological and later palynological research, and instituted a university degree (at MA and Ph.D. level) in environmental archaeology just after World War II.

In the area of archaeological pollen analysis, the next steps were set by German scholars working in the moors in the northern part of their country (Bertsch, Reinerth). Their efforts eventually led to the foundation, around 1960, of the influential Institut für Küstenforschung in Wilhelmshafen (north Germany) by W. Haarnagel. But already before the war UK (H. Godwin 1933) and Scandinavian (Joh. Iversen) scientists had enlarged the temporal and spatial scope of palynological research.

In the UK, partly following in the footsteps of V. G. Childe (1928, 1929), J. G. D. Clark (1939, 1940), C. Vita Finzi (1969), E. Higgs (1972), and others gave the field an enormous impetus in the 1950s through to the 1970s under the name economic archaeology—emphasizing geology and archaeozoology. From the late 1960s, ideas of the Cambridge school of 'new geography' were introduced in UK (environmental) archaeology, initially by D. L. Clarke (1968).

In the USA the first attempts at studying environmental matters were again related to shell-middens (E. W. Gifford 1916). J. Steward (1937, 1955) and L. White (1949, 1975) are early but very influential protagonists of the idea that the environment greatly influences, if not determines, the core aspects of any culture, and proposed the combined, comparative study of culture and the environment. W. Wedel (1941) and E. Haury (1950) provided early stimuli through their fieldwork in other parts (the Great Plains and the Southwest, respectively). The expeditions organized by Braidwood in the 1950s and 1960s (Braidwood and Willey 1962) to various early prehistoric sites in the Near East constituted an important step because they brought specialists in all the necessary disciplines together in the field, disseminated the environmental approach to near eastern archaeologists all over the world, and provided training to 'stars' of the next generation (e.g., R. McC. Adams, K. V. Flannery). K. Butzer's work is an important turning point (1965, 1971) because of its breadth and interdisciplinary perspective, integrating not only the environmental disciplines but also geography, for example (1982).

3. *Oppositions Between Nature and Culture, Past and Present are at the Core of the Discipline*

As a result of the context in which it was born, and notwithstanding the exponential increase in the number of its practitioners during the last 30 years of the twentieth century, and the increasingly direct confrontation of the modern world with environmental problems, environmental archaeology has had difficulty in defining its identity by resolving the dichotomies which underpin it: 'nature–culture' and 'past–present.'

Until well into the 1970s, most environmental archaeologists viewed humans as reacting to (adapting and exploiting) the conditions set by the dynamics of nature. Then, partially under the impact of the 'green' movement, awareness grew of human impact on the environment, particularly in the area of climate, vegetation, and animal life. As the focus in environmental studies in general shifted to sustainability, a new perspective emerged. People were henceforth also

seen as proactive, albeit generally in a destructive sense. The difference can be illustrated by looking at the distinction, in French, between *le milieu*, that is, that which human groups are in the midst of, and *l'environnement*, that which surrounds human groups. Although in both cases, the focus is on what surrounds human beings, in the former the perspective is human. Nature's cohesion, its unknown aspects, its strangeness, and force are amplified, whilst the confusion and the handicaps of humanity are accentuated; change is attributed to nature, and people have no choice but to adapt to it.

In the latter case, the perspective is nonhuman: the cohesion and strength of nature are diminished, while the same properties are accentuated in humanity. The known aspects of nature seem to be more important, and it thus seems more controllable and loses its dangerous appearance. Humanity, in this perspective, is viewed as the source of change: people create their environment.

More recently, recognition is growing that both these points of view are essentially anthropocentric. Humans should be seen as 'just another unique species' (Foley 1987), and one cannot separate social dynamics from natural ones, even though different approaches are used to investigate them. McGlade (1995) thus argues: 'there is no natural (sub-)system, there is no social (sub-)system, there are only socio-natural interactions.' These interactions are driven by different kinds of dynamics within and between the two realms. Inanimate dynamics concern only energy and matter, whilst among plants and animals the role of information is limited. Within the life span of individual organisms, it is confined to stimulus-response and behavioral optimization, while over longer periods genetic transmission may induce structural changes. Only among human beings does the exchange of information regularly result in structural changes within an individual's lifetime. And although human impact on the environment is as immediate as that of other species, the human reaction to environmental change requires that a society becomes aware of environmental problems before it can respond to them (Luhman 1985). That requires a conjunction of both environmental and social dynamics, and interaction between these dynamics takes the form of resonance, rather than direct cause and effect. But bridging the gap also involves different ways of linking past and present. Ecologists have for some time been aware of this (e.g., Martinez Alier 1990), but had not really developed that angle until some adopted the complex systems approach, which offers a very tempting perspective to anyone striving to integrate the natural, life, and social sciences with the humanities:

(a) It conceptualizes problems in both natural and social dynamics in a language which is independent from any of the disciplines.

(b) It studies interaction between phenomena at different spatiotemporal scales by viewing macroscopic, apparently stable phenomena as the result of unstable interactions between microscopic entities.

(c) It reformulates natural dynamics from an irreversible temporal perspective by dealing with both process and event within the same approach, and placing each in the context of the other, thus relativizing them and facilitating description of historical processes in 'natural science' terms and vice versa

(d) Its dynamic descriptions of apparent structures introduce the notion that any structure operates in a field of tension and can be viewed as a flow, thus bridging the gap between pattern and process, and linking structures dynamically to their environment.

(e) By highlighting the metastability of many apparently stable patterns and structures, and the nonlinear character of many processes, it deals with chance and necessity, continuity and change, tradition and innovation, from one and the same perspective, thus moving away from our traditional bias in favor of stability, and our focus on investigating change.

(f) It invites us to rethink the relationship between cause and effect in all disciplines, because the effect of a change in a state variable depends to a very great extent on the state of the entire system at that moment, so that similar causes can have different results, and different causes similar results.

4. *The Challenge*

Surmounting the 'nature–culture' and 'past–present' oppositions seems to be coming within reach (and why not, as many other cultures have never created the oppositions in the first place, cf. Descola 1994?). But achieving it requires that environmental archaeology gains its own place under the sun in the 'concert of disciplines' by addressing questions which are central to the long-term relationship of people with their environment, and thus reflect the interests of ecologists, historians, geographers, and others as well. For example:

(a) Many purely ecological issues which demand a very long time frame to deal with them effectively, but for which historical or instrumental data are only available for at most a hundred years or so. Paleoclimatology operates at a global scale, for example, but the effects of climate differ between regions, and need to be investigated with techniques in which environmental archaeologists excel. Moreover, there are such issues as the long-term evolution of biodiversity (Odgaard 1999), biological successions, species interactions (Lawton 1999), etc. In such areas, ecology's origins as a natural science have often limited observation to short-term dynamics, and have confined explanation to a search for universals without consideration of individual events. And what about the long-term evolution of scalar interactions?

(b) Issues concerning human–environmental coevolution (Thompson 1999). Observing the behavior of human populations in a particular area over 10,000 years, for example, highlights the growing interdependency between the species involved and its effects on the resilience of that system (van der Leeuw 1998). Such studies therefore have an original contribution to make to present-day questions about 'sustainability.' Similarly, a long-term perspective on the relationship between changes in the natural dynamics and in human resource exploitation, technology, and spatial organization helps us to understand different landscapes (Naveh 1998). That in turn enables us to look at a much wider range of possible socionatural states of resilience than we would otherwise.

(c) At the human end of the spectrum, we will need to stand back and develop better overall ideas on such topics as (i) the dynamics responsible for long-term human evolution; (ii) the genesis of human societies; (iii) the way human biological and social evolution have slowly transformed our environment and in many cases made it dependent on its interaction with society; and (iv) the dynamics by which humans have over time, dealt with their need to subsist in that environment. Here archaeology has made considerable advances, but the coevolutionary aspects which are the particular domain of environmental archaeology have not kept pace.

(d) To create a viable future, we need to find new ways to articulate the different kinds of socionatural components in a landscape dynamic. As Di Castri (1997) has argued, the way the world is changing demands of ecologists that they move toward studying systems in which human beings dominate. This is exactly where environmental archaeologists are stronger than most 'pure' ecologists. Playing a role in such a reorientation of ecology, combining strands in ecology such as landscape ecology and restoration ecology with new movements in archaeology such as historical ecology, seems a very worthwhile challenge.

Environmental Challenges in Organizations

Environmental challenges in organizational and management studies initially referred to the restrictions that the external environment imposes onto the survival of organizations. In the last decades of the twentieth century it has come to designate the survival of both organizations and the natural (or ecological) environment. The transformation occurred simultaneously in the practice of corporate environmental management, and in the studies concerning organization and environment. This article presents both the empirical responses that have been developed by formal organizations in facing environmental challenges as well as studies on environmental management and ecological sustainability.

1. The 'Environment' in Organizational and Management Studies

The environment in organizational and management studies has historically been treated as an organizational contingency (see *Structural Contingency Theory*). The environment was synonymous with the organizational environment, something abstract and a-temporal, having little to do with the natural environment (Shrivastava 1994). The main concern of theories of organizations in the 1960s was the restriction that the external environment imposes on the survival of organizations, rather than the environmental burdens that organizations cause to the natural environment.

The pervasive assumption in both research and management practice that organizations had a capability, and indeed should, control their environments was questioned in the work of the population ecology perspective (see *Ecology: Organizations*). The title suggests that the organizational ecology (as it is also known) is an ecological theory of organizations. In fact, it represents the transplantation of concepts and calculus techniques from the discipline of ecology to the world of formal organizations. The application of biological models to the analysis of the 'ecology of organizations' has nothing to do with the natural environment. The use of the concepts of 'environment' and 'ecology' as metaphors to express the 'organizational environment' or 'the ecology of organizations' was not an intentional strategy to deny the importance of environmental issues in organization studies. The all-encompassing meaning of the terms themselves is what could mislead one to think the opposite. Nonetheless, what makes these perspectives vulnerable to criticism is the dominant epistemological position about research in organization studies that they tend to assume. The positivistic rigidity that dominated organizational studies until the late 1970s resulted in a scope of research that did not allow much space for its own reflexivity.

The emergence of new metaphors and paradigms for organizational analysis in the late 1970s undermined the historic hegemony of functionalist perspectives (see *Organizations, Metaphors and Paradigms in*). These new theoretical approaches questioned some taken for granted assumptions about research and management, transforming organization studies into a 'contested terrain' (Clegg et al. 1996). The acknowledgment that the external environment affects organizational action in the same way that organizations impact on the natural environment began to appear in early 1990s, giving rise to the development of research and theories on organization and environment.

Implicit in the studies about environmental issues in organizations is the assumption that a theoretical imperfection allows companies to externalize their environmental and social costs on to society. Market prices do not always reflect total costs of products (Hawken 1993). There is a discontinuity between empirical outcomes and theoretical representations of organizational action. Environmental and social costs that occur during the life cycle of products—the extraction of raw materials, manufacturing, use, and final disposal or recycling—are not considered in most companies' accounting systems (Grey et al. 1993). Increasingly demanding regulatory measures, public demand for environmental protection and compensation, and consumer demand for cleaner processes and products, constitute some of the current environmental challenges requiring organizations to eliminate or internalize these costs. Firms responded to these challenges by developing novel environmental strategies and management practices, described in the next section.

2. Organizational Responses to Environmental Challenges

Until the 1970s it was common for companies to avoid compliance with environmental regulations. From 1970 to 1985 the general attitude of companies was to go only as far as to comply with centralized regulatory measures that commanded them to internalize environmental costs—normally achieved by installing pollution-control equipment. Typically, firms resisted the command and control type of regulation because it did not generate incentives for them to assume higher levels of environmental responsibility (Fisher and Schot 1993).

From 1985 to the mid-1990s, dialogue between legislators and industry resulted in business accepting some responsibility for solving environmental problems, at the same time that new regulatory mechanisms were being proposed as alternatives to the command and control approach. Industry associations, in partnership with governments and other

interest groups, responded to the consumer and public demand for environmental protection, and shareholder rejection of environmental risks by instituting voluntary business codes of environmental practice. The standardization of environmental management systems such as the European Eco-Management and Audit Scheme (EMAS) and the International Organization for Standardization (ISO) 14000 environmental series constituted another type of voluntary program developed in the 1990s. Eco-labeling programs have also been put into practice, aiming to inform consumers whether manufacturers' products meet certain criteria for environmental impacts during the various stages of a product's life.

Pollution prevention was the basic principle guiding these initiatives, which focuses on minimizing or eliminating waste before it is created by production processes. As a whole, voluntary schemes have not generated significant improvements in corporate environmental practices, and regulatory approaches based on extended producer responsibility are expected to emerge in the early decades of the twenty-first century. Corporations will be required to develop product stewardship strategies to minimize pollution not only during manufacturing but also to reduce environmental costs associated with the entire life cycle of their products (Hart 1997).

Economic incentives for the incorporation of ecological issues into business practices became more evident in the environmental management literature in the second half of the 1990s. Increasing costs of pollution control, the development of new technologies for pollution prevention, and cost-savings from waste reduction, emerged as driving forces for proactive corporate environmental management (also known as beyond compliance environmental practices). Ecological requirements started to be seen as an integral part of quality management principles and potential sources of competitive advantage. Porter and van der Linde (1995) asserted that environmentally friendly regulation could act as an incentive for companies to innovate and use resources more efficiently. The result would be a gain in both corporate profits and environmental improvements—a double dividend or win–win scenario. Support for this approach, however, has not been unanimous. Empirical evidence questions the extent to which one can generalize the results of specific case studies to the entirety of commerce (Howes et al. 1997).

Finding hidden opportunities for organizations to profit from environmental strategies became an appealing theme for both business and academic communities. Nonetheless, the double dividend debate inspires a more crucial issue in the study of organization and environment: the role of business in promoting sustainable development. Are corporate environmental management practices conducive to ecological sustainability? Can incremental improvements lead modern industrial societies to sustainable patterns of production and consumption? Are radical changes imperative to ecologically sustainable societies?

3. *Research on Environmental Management and Ecological Sustainability*

Research on organizational responses to environmental challenges as well as the identification of necessary changes for the creation of ecological sustainable organizations and societies frame the focus of current use of the 'environment' in organizational and management studies. Typically, the literature adopts one or other of radical or reformist approaches (Egri and Pinfield 1996). Radical studies normally have their foundations in areas such as deep ecology, social ecology, and eco-feminism, which consider biospecies egalitarianism a prerequisite for economic advancement in harmony with nature. In this view, radical changes in the values guiding organizational actions are required. Conversely, reformist approaches stress the necessity of working within the rules that currently guide managerial action. The studies assume that organizations—and more specifically, business enterprises—are both the responsible agents, and the ones most likely to be sufficiently powerful to promote environmental reform and lead modern societies towards *Natural Capitalism*—a term proposed by Hawken et al. (1999) to simplify the arguments favoring organizations to value ecosystems services by internalizing environmental costs.

The lack of evidence that organizations will change their behavior out of altruistic motives leads reformists to assume that incrementalism is the guiding principle of organizational change. The gradual incorporation of ecological values into corporate strategies and practices would happen over time, they argue. Incrementalism is the basic principle of technical approaches from the natural sciences to environmental management, and most corporate responses to environmental challenges, described in the previous section, are exemplars of this perspective.

By the end of the 1990s the number of publications in organization and environment remained small, compared with traditional areas of research, but the natural environment gradually gained ground in the study of organizations. Environmental issues entered research through traditional areas of organizational studies such as institutional theory and resource-based theory. Together with the (technical) area of environmental management, the majority of these studies tended to be reformist in nature, urging scholars to attend to the difference between practices of environmental management and research, education, and management for ecological sustainability (Roome 1998).

Environmental management practices in corporations are expected to reduce the impact caused by

industrial and commercial activity, but whether these practices are conducive to sustainable development remains uncertain. In practical terms, the business community tended to equal the concept of 'sustainable development' with 'eco-efficiency'—an extension of environmental management techniques in corporations. Theoretically, from the reformist perspective, there is still a notable lack of understanding whether incremental innovations in systems of production and consumption are conducive to ecological sustainability. Conversely, from the radical-perspective, if a biocentric world is to be achieved, such environmentalists have yet to develop a theory to make this transition feasible.

4. *Future Directions for Theory and Research in Organization and Environment*

In the context of the social sciences, particularly in organizational and management studies, environmental challenges increasingly demand consideration of interdependencies between natural and artificial (social, economic, technological) systems. In the emerging area of organization and environment the importance of corporations as the principal agencies responsible for environmental disruptions is acknowledged. Radical theorists demand a complete revision of the values guiding business: only a cultural revolution can lead to ecologically sustainable societies, they suggest. Reformists assume that ecological modernization of systems of production and consumption is the only viable alternative in the quest for sustainable development (Spaargaren and Mol 1992).

There is already widespread acceptance that 'sustainability' cannot be confined to the realms of focal organizations but requires co-ordination of economic, social, and environmental prerequisites at the industry and societal levels. Human rights issues, such as equity in trade and empowerment of minority groups, are seen as integral elements of ecologically sustainable organizational strategies and practices (Welford 1997). Economic globalization makes boundaries between social, economic, and environmental systems more diffuse and the development of interdisciplinary studies and cross-level analysis increasingly necessary.

The expertise accumulated in organizational and management studies, used in conjunction with disciplines such as engineering, economics, and sociology, can be expected to generate knowledge about current systems of production and consumption as well as alternative models for their reorganization. The mechanisms for the integration of ecological principles into business strategies and practices that foster or inhibit organizational learning and change need further research (Roome 1998). Understanding structural and behavioral prerequisites that might increase the pace of environmental innovations and inter-firm collaboration is also crucial for the creation of more efficient industrial systems, and consequent dematerialization of the economy. In sum, research about organizational strategies and practices that can lead to ecologically sustainable systems of production and consumption, constitute the main environmental challenge for organizational and management studies in the early decades of the new millennium.

Environmental Change and State Response

Environmental change is one of a myriad of pressures or demands made upon state resources and attention. Many of the responses to environmental stress that

occur involve uncoordinated human responses greatly affected by markets. Accordingly, producers and consumers respond to changes in prices, relative incomes, and external constraints. But frequently market 'signals' do not reflect social values, as in the case of intergenerational equity, for example, or the deleterious effects of environmental degradation are not internalized in market prices and remain as 'externalities.' As a result, states often choose to intervene with collective actions aimed at managing environmental change and reducing the associated adverse social and economic effects.

Accompanying environmental changes will be events and consequences that are potential 'signals' of threat to society. Such signals occur with or without societal recognition. If no recognition occurs, there is no (or limited) social learning or stimulation of action by the state, and the lack of response may accelerate the human driving forces of change as a means of positive feedback. If the degradation is recognized, whether by individual farmers, the media, or governmental officials, and elicits recognition and concern, then the response mechanisms of the state are set into action. Once the state receives and recognizes that an environmental change poses a threat, it typically moves to interpret the threat, to assess its social meaning and significance, and to locate it on the policy agenda (see *Environmental Policy*). Responses occur at many different levels, so scale may become an important factor in state response, particularly 'scaling-up' and 'scaling-down' problems. These refer to the extent to which patterns and causes of relationships, such as how institutions affect human behavior, observed at one scale can be expected to operate at higher or lower scales (Ostrom 1990, Young 1999). Such issues are only now beginning to receive concerted attention in the social sciences.

All societies, including states, engage in processes by which those at risk, the mass media, societal groups, institutions, and the state itself, assess whether a particular change involves a risk worthy of attention and how serious the risk is (see *Environmental Risk and Hazards*). This 'social processing of risk' includes information flow; the communication channels and social networks through which individuals, groups, and institutions interact; the formation of public perceptions and concerns; and the degree to which social capital and trust exist. Modern environmental groups play an important role in state response to environmental risk by targeting particular environmental threats for action, in calling such concerns to media attention, and by shaping public values and attitudes. Meanwhile, a global shift in public values has led some analysts (e.g., Inglehart 1990) to highlight the emergence of 'green ideologies' related to the growth of 'postmodern' values and lifestyle changes with economic development, and the effects of such shifts on heightened public concerns over environmental issues.

This societal processing function has been described in a 'social amplification of risk' framework (Fig. 1), in which social structures and processes 'amplify' or 'attenuate' signals to society concerning the seriousness and the manageability of the environmental risks (Kasperson et al. 1988). Since most of society learns about the flow of environmental change and risk events through information systems rather than through direct personal experience, risk communicators, and especially the mass media, are major agents (or what are termed 'social stations') of risk amplification and attenuation. Particularly important in shaping group and individual views of risk are the extent and content of media coverage, and particularly the way the environmental problem is framed. Information about environmental change flows through multiple communication networks—the mass media represented by television and newsprint, the more specialized media of particular professions and interests (including, increasingly, the Internet or the information superhighway), and, finally, the more informal personal networks of friends and neighbors. The mass media cover risks selectively, emphasizing those that are rare and dramatic while downplaying, or attenuating, more commonplace but often more serious risks, such as soil erosion or climate change. Environmental risks and risk events, thus, compete for scarce space in the media's coverage, and the outcome of this competition is a major determinant of whether a risk will be socially amplified or attenuated.

In postindustrial states, large organizations—multinational corporations, business associations, and government agencies—mostly set the contexts and terms of society's debate about environmental problems. The President's Commission on the Accident at Three Mile Island (1979) in the USA for example, concluded that the 'mind set' that permeated the institutions charged with managing nuclear safety represented the primary problem in ensuring the safety of the nuclear technology used to produce electricity. Breakdowns in internal organizational communications can also contribute to attenuation of risk, as occurred in the space shuttle *Challenger* accident, when the risk concerns of technical experts failed to reach top decision makers within the US National Aeronautics and Space Administration. Large corporations develop markedly different kinds of organizational cultures that influence their ability to assess the environmental effects of their activities and products. The behavior and interactions of institutions and organizations are major sites of risk amplification and attenuation and require detailed attention in gauging how different countries respond to similar environmental challenges.

Apart from the array of societal processes involved in the social amplification of risk, states also use a variety of means to inform themselves of potential or emerging environmental hazards (see *Environmental Risk and Hazards*). *Monitoring* implies an active and

Figure 1
The social amplification and attenuation of risk

often systematic search by institutions or individuals for information or signals of environmental threats. *Alerting* refers to the warning function associated with the identification and assessment of risk. Both functions play key roles in identifying social problems and initiating societal responses. The perception of an environmental hazard begins with the first sense of danger but changes as increased information develops. The identification of risks is tied closely to social perceptions and occurs in a variety of arenas within the state—scientific research, the mass media, environmental groups, and the dissemination of industrial products. Global environmental risks, it should be noted, pose new challenges to traditional monitoring and alerting systems (see *Global Environmental Change: Human Dimensions*). High scientific uncertainty and political stakes are often present in such issues, and past experience is often unreliable as a guide to future risks at the global scale. And so societal alerting and assessment systems assume a larger role and burden in threat anticipation.

State alerting systems for environmental threats range over a wide diversity of institutions, roles, and contexts. Knowledge of environmental change does not always arise from purposeful monitoring of the environment but often occurs by serendipity or by chance. In many cases, the motivation for monitoring is aimed at the realization of some other societal goal, such as health promotion, economic growth and development, or policy effects. Additionally, particular institutions or social groups may experience a change that suggests a departure or discontinuity not previously experienced. Mountain dwellers of Nepal, for example, learn of environmental change through a wide array of experience—increased mudslides, declining crop yields, and growing scarcity of fuelwood, whereas the Nepali government learns about it through accounts of local crises trickling up from remote areas or through reports of failures of development or aid programs (Jodha 1995).

With the initial assessment that an environmental problem exists, it may become a policy issue (see *Environmental Policy*). How the issue is conceived and socially constructed is critical; political ideology and cultural values are major factors influencing this social construction. The power structure of society directly influences this process, of course, and particular values or ideologies may be dominant in the 'framing' of the issue. Authorities of the state, for example, have constructed deforestation in Borneo as a problem of 'shifting cultivation,' whereas deforestation and associated fires in Amazonia have been seen as the inevitable price of either frontier development or hamburgers for US markets (Kasperson et al. 1995). If the environmental problem is constructed as a concern only to those most directly involved with the natural resource utilization process (the manager closest to the environmental source), adjustments may be largely cosmetic or of the 'hidden hand' variety. If, however, a problem achieves sufficient salience as to require

concerted collective action, and comes together with other political confluences needed for policy action, interventions to ameliorate the risk may be undertaken. Whether policy actions or interventions occur will depend upon whether 'policy windows' exist, that is, where opportunities for pushing pet proposals or a favored conception of the problem are available (Kingdon 1995). These interventions may be particularly likely at 'critical junctures' where three different streams—problems, policies, and politics—which are ordinarily largely independent of one another come together (see *Environmental Policy*).

Various management strategies are available to state responses, including such options as bearing the risk, preventing or reducing the risk, initiating precautionary actions, spreading or reallocating the risk, fostering greater adaptiveness and resilience (see *Environmental Adaptation and Adjustments*), or ameliorating the consequences after they have registered their initial impacts. Among these risk-response strategies, *avoidance* refers to action to evade the problem or exposure to it (as in relocation from threatened areas); *consequence mitigation* refers to ameliorating the impacts (as through disaster aid or food relief); *bearing the risk* means deciding to absorb the stress and impacts caused by the environmental degradation; *risk spreading* refers to strategies, such as insurance, that reallocate the risk over larger populations without reducing the risk itself; and *adaptation* involves strategies by which society changes itself in order to reduce further or future impacts of the risk. Each of these approaches typically makes use of mechanisms appropriate to particular political cultures, such as taxes, regulations, marketable allowances, liability or legal resources, technology-based approaches, social and economic incentives, and dissemination of information (Rayner and Malone 1998). Structural changes—those responses that seek to address directly the basic nature of the driving forces—may also occur but such intervention is more fundamental and politically costly. Technology development, redistribution of land, wealth, and power, and fundamental reorientation of social and economic priorities are examples of such state responses. Still other far-reaching relevant state responses include enhanced status for women, family planning, debt cancellation, land reform, increased support for the traditional rural sector, and inclusion of environmental costs in national accounting systems.

Substantial differences exist among countries in the nature of responses to environmental change (see *Environmental Policy*). Vogel (1990) argues that environmental concerns in Japan have focused on public health, attention in Germany has centered more on the protection of nature, and the USA and Britain have occupied intermediate positions between Japan and Germany. Variations in national political cultures, the role of nongovernmental organizations, and the power of business in the policy process all contribute to these differences. Different countries also reveal substantial variations in regulatory styles, with the USA displaying an adversarial regulatory style, with demanding and specific quantitative standards, whereas Britain and many other European countries employ more flexible standards and greater discretion in enforcement (Stern et al. 1992).

Global environmental risks may pose distinctive challenges for the state management systems, institutions, and approaches that deal with them. The effectiveness of institutions, it has been argued (Young 1999), depends upon the match between the characteristics of the institutions and the nature of the environmental systems with which they interact. Institutional failures may arise because of mismatches between environmental processes and institutional designs and capabilities. Environmental management often strives for creating relatively high scientific certainty and anticipation, effective 'rational' choice among options, and a 'command-and-control approach to management. Increased attention is being given to 'adaptive management' approaches that may be more robust, resilient, and effective over time with many types of transboundary and global risks (Lee 1993; see also *Environmental Adaptation and Adjustments*). Such a management style proceeds from the recognition that environmental risks often cannot be comprehensively assessed, that large uncertainties typically characterize major elements of the risk problem, and that surprises are certain to occur. Another recent response that has gained favor, particularly in Europe, has been the growing invocation of the precautionary principle as an approach to managing uncertain environmental risks.

Environmental Cognition, Perceptions, and Attitudes

Individuals' primary interaction with the natural environment, as with other aspects of their experience, is through their senses. They form feelings and impressions that both shape and are shaped by their basic cognitive structures and values. At deeper levels of processing, they form more explicit beliefs and attitudes, even theories and ideologies. These cognitions, perceptions, and attitudes affect both individuals' own well being and that of their environment. People feel better in a healthy natural environment and feel better knowing that their natural environment is healthy. The health of that environment depends on the choices that they make, as consumers, workers, citizens, officials, tourists, and industrialists (Garner and Stern 1996, Kaplan and Kaplan 1989).

At the present time, environmental protection enjoys broad support. It is expressed in public opinion polls (e.g., Dunlap et al. 2000), in the popularity of nature programming on television, and in the growth of 'socially responsible' mutual funds, which control 13 percent of the US market and typically screen firms for their environmental behavior. However, the fate of the environment depends on the actual support (or opposition or indifference) emerging in specific decisions. These choices are enormously varied, in their options, consequences, and decision-makers—not to mention their national, social, cultural, institutional, and economic settings.

The diversity and complexity of these decisions poses a challenge to researchers. One response is performing case studies, fully respecting the particularities of each situation. Environmental studies scholars have produced many such accounts (Slovic and Dixon 1992). Their observations shape and constrain the theories of environmental scientists, seeking general, testable theories about environmental behavior. These scientists have typically adopted one of the two classic compromises for producing general accounts of heterogeneous phenomena. (a) *Holistic* approaches look for recurrent behavioral archetypes, groups of people who respond in predictable, but different ways (e.g., Cotgrove 1979, Douglas and Wildavsky 1982). For example, one might posit 'eco-freaks' who resolutely oppose any intrusion into pristine areas or 'technocrats' who automatically dismiss such concerns. (b) *Reductionist* approaches assume that all individuals respond to common factors, but interpret and weight them differently—sometimes leading to different actions (Stern 1992). In them, eco-freaks and technocrats (and everyone else) would attend to similar outcomes and processes. However, they might view them very differently, in terms of their attitudes and beliefs. Both kinds of account coexist in dual-process theories of attitude and cognition. In them, holistic first impressions create an orientation toward a stimulus (e.g., an environ mental cause or insult). A parallel process involves analytical thinking, elaborating that impression. The result might be interpreting it in terms of more detailed (holistic) archetypes or (reductionist) cross-cutting concerns. Such analysis can overturn first impressions. However, it can also be constrained by them. Many common cognitive processes encourage the perseveration of beliefs. For example, people tend to seek confirmatory, rather than contradictory evidence; to resolve ambiguity in favor of current beliefs; to exaggerate the definitiveness of small samples of evidence (Gilovich et al. in press). How hard people work to understand an issue should depend on how important it seems, what returns they expect from their efforts to learn, and how great is their general need for cognition. Those factors, in turn, reflect and shape the opportunities that they have to affect their environment.

1. *Holistic Accounts*

A general account of environmental behavior is only useful if researchers can unambiguously translate complex real-world situations into its necessarily abstract terms. For holistic theories, that translation process may be holistic itself, attempting to identify specific cases with theoretical archetypes. Holistic interpretation allows astute observers to use the full set of available data. Moreover, if those observers write well, the coherence of their accounts should help readers to retain and integrate the information that is presented. Archetypes are a natural way to organize evidence, even if that sometimes leads to neglecting discordant details.

Unfortunately, holistic interpretation also allows motivated observers to exploit the richness of the evidence, in order to fashion desired accounts. For

example, they might exploit the privileged position of hindsight, so as to craft interpretations that affirm their theories. Or, they might strategically identify other people with positive or negative archetypes, in order to advance a political agenda. The very act of categorizing others is an exercise of power. It can reduce those individuals to stereotypes and present the observer as possessing superior insight (and perhaps even morals). It can feed prejudices and benefit from the natural tendency to create simplistic views of other people.

These possibilities are not lost on the partisans in environmental conflicts, who value the opportunity to demean their opponents and flatter their allies. As a result, holistic characterizations are often offered and evaluated by individuals without scientific credentials. Conversely, scientists can have a political following because of the conclusions they reach, independent of the quality of their work. Pundits can drape themselves in the trappings of academia, seeking its rights, but not responsibilities, in order to achieve political ends. The narrative character of holistic accounts means that both professional and amateur ones have the same outward form. Commentators may have insights to offer. However, they are in a different business, without the scholarly constraints of sharing sources and reflecting previous research. Thus, readers need to check the scientific pedigree of environmental narratives. What training did the authors have? What peer-review screens did their work pass?

With ongoing environmental issues, more systematic measurement of holistic archetypes might be possible. If the archetypes are clearly defined, it should be possible to operationalize them in an individual difference measure (e.g., Dake 1992). If these measures pass conventional psychometric criteria (e.g., reliability, construct validity), then they allow objective tests of their theory (e.g., '"corporate greens" have the deepest commitment to consumption-related issues'; 'environmental pessimists have the greatest scientific knowledge and institutional distrust'). Of course, this strategy also requires similarly systematic characterization of the other elements of the prediction: what the environmental issues are, how those individuals perceive them, what their observable behavioral responses are, what meaning they attach to those actions, and so on.

If archetypes cannot be measured authoritatively, then individuals may be characterized by more observable categories, such as gender, race, income, or nationality. The price paid for the precision of such characterizations is losing the theoretical force of a well-crafted archetype. For example, surveys in the US have found particularly high environmental concern among African–Americans (Vaughan 1993). Speculatively, that concern could reflect greater direct exposure to environmental problems (so that they have more reasons for concern), greater awareness of their immediate surroundings, greater physiological sensitivity (e.g., because of multiple exposures or weakened immune systems), greater suspicion of societal institutions, fewer resources for self-protection, and so on. An analogous array of hypotheses follows from Slovic's (1999) finding of similar attitudes toward the environment across most US populations. The one exception was white males who, on average, were more favorable toward technology and less concerned about the environment. Characterizing the subset of white males responsible for this overall group difference is a starting point for a theory of archetypes, sorting out the experiences or circumstances creating these distinctive views.

1.1 Reductionist Approaches

Comparable measurement issues confront reductionist approaches, looking at how people respond to a common set of concerns, as expressed in different environmental issues. In these models, individuals evaluate an action in terms of its expected effects on the probability of occurrence for each of a set of consequences. Those consequences might be experienced personally (e.g., changes in taxes, wilderness opportunities, social standing), socially (e.g., changes in health, justice, property rights), or environmentally (e.g., changes in biodiversity, the introduction of novel life forms). An action is attractive to the extent that it increases the chances of good things happening and decreases the chances of bad ones. These models belong to the general class of rational-actor models. They preserve the basic logic of orderly decision-making found in neoclassical economics, but vary in how strongly they endorse its normative and optimality assumptions.

The theoretical challenge for researchers is identifying a concise set of consequences, with important impacts in multiple situations. If that set exists, then general statements are possible, regarding 'what matters to people, when it comes to the environment.' Although an appealing aspiration, such sweeping summaries are limited by the actual relevance of the issues. For example, social norms may loom very large for curbside recycling, where all one's neighbors can see what one does. Those norms may have little effect on roadside littering when no one is looking—unless the norms have been internalized as a personal value or the action (not littering) has become a matter of habit.

Thus, differences in the importance of issues can reflect (earnestly considered) differences in situations, and not just (hypocritical) situational ethics. As a result, some of the most successful attempts to predict behavior from beliefs and attitudes have focused on specific domains, such as home energy conservation (Stern 1992). These studies find that conservation increases when people see greater benefits and fewer barriers. These patterns can be sought in everyday

circumstances or in the context of interventions intended to encourage such behaviors (e.g., recycling or political campaigns). Good communication should improve citizens' understanding of the issues, making their actions more consistent with their values (and more predictable).

Like holistic approaches, these models face the challenge of assessing beliefs and values, for the people whose behavior they hope to predict. Even a valid model can fail empirical tests, if its terms are measured poorly. One form of protection for reductionist models is provided by their additive structure: they sum the impacts of favorable and unfavorable factors, allowing good and bad expectations to cancel one another. Such models are relatively insensitive to errors in measurement and specification (Dawes 1988). As a result, they will have some predictive validity as long as they include rough approximations of the relevant factors—or factors correlated with them. Unfortunately, such robustness inhibits theoretical development. It is hard to interpret the weights estimated for the factors in the model or to know whether they are actual drivers of behavior or just surrogates. An important exception to this rule arises when one consideration overrides all others, as something that must or must not be done. Such a decision model is noncompensatory, in the sense that there is no way to overcome the stigma associated with an action—or to diminish the moral high ground that it confers (Flynn et al. 2001).

2. *Perceived Risks and Benefits of Environmental Changes*

Assessing beliefs and values is a central activity for cognitive and social psychology. Assessing them for environmental issues has posed significant challenges to the state of those sciences. Environmental changes can involve novel, unintuitive processes, surrounded by uncertainty and couched in unfamiliar terminology. They may extend over time, individuals, and species, in ways that are hard to grasp, much less evaluate. They pose choices as esoteric and fateful as those arising from modern medicine (e.g., advanced directives regarding life support, genetic screening, rationing scarce resources among competing needs). The environment suffers directly when people make poor choices. It suffers indirectly when investigators mismeasure what people want regarding the environment—hence send inaccurate signals to policy makers and citizens. These practical concerns have encouraged environmental social scientists to break new ground in these traditional assessment activities.

The difficulties that face investigators, in posing these questions, echo the difficulties that face individuals, when life poses them. As a result, the research agenda has combined descriptive and prescriptive goals, trying to understand current behavior in order to facilitate better informed behavior in the future. Those improvements are sought both in beliefs and values. People need to understand how the environment works and how changes can affect their lives (health, emotions, children, etc.). They need to understand themselves well enough to know what values to assign to these impacts.

As a result of these applied concerns, studies of beliefs often have an evaluative framing. They ask, not just what do people know, but whether people know enough to make effective decisions. When people face specific decisions, the adequacy of their knowledge can be evaluated relatively precisely—especially compared to general tests of environmental knowledge, which generally have no analytical foundation for selecting items. A decision-making perspective allows specifying what people need to know, and not just what it would be nice to know.

In the context of values, the evaluative framing asks whether people have succeeded in constructing stable opinions about specific environmental choices, consistent their relevant basic values. It recognizes that, even when a topic is familiar (e.g., declining fish populations, invasive species, suburban sprawl, vector-borne disease), the specific choice may not be. As a result, individuals cannot just 'read off' a response, from a universal utility or value function. In effect, they may not know what they want. In such cases, researchers need to decide whether to take people as they are, with fragmentary positions, or help them to derive more reflective ones. The former strategy risks a sin of omission if respondents are swept along by the incomplete set of issues evoked by a particular question. The latter strategy risks a sin of commission, if interacting with respondents distorts, rather than deepens, their understanding.

These questions of competence can be asked regarding both citizens and technical specialists. The answers have implications for the roles that these individuals should play in environmental decision making. When citizens lack the desired competence, a case can be made for rule by experts (or for intensive education). When even the experts don't know very much, a case can be made for moving slowly (unless that allows even more poorly understood processes to go on unchecked). The current debate over genetically modified organisms revolves on whether anyone understands them well enough to make sound choices. Those who doubt that even the experts know enough to proceed often invoke the 'precautionary principle.' At times, it is just a (holistic) slogan of distrust. At times, it is a request (or demand) for incorporating deeper forms of uncertainty into cost, risk, and benefit analyses. These concerns pose significant challenges to the measurement and characterization of expert knowledge (Funtowicz and Ravetz 1990, Kammen and Hassendzahl 1999).

The emerging science of belief and value assessment draws on two converging research traditions. One

leads from psychophysics to attitude research. The second leads from decision theory to behavioral decision theory.

2.1 Psychophysical Measurement

Emerging from the natural sciences, many early psychologists focused on what came to be called psychophysics, determining the psychological equivalent of physical stimuli. The conceptualization underlying these studies holds that a combination of physiological and psychological mechanisms translates those stimuli into an internal state of arousal. If asked, individuals can report on that state, either verbally (by word or number) or by some other action (e.g., pressing on a handgrip, adjusting a rheostat to show the light intensity equivalent to the loudness of a tone).

The most straightforward environmental applications of the psychophysical approach ask people how they feel about a specific environment (e.g., how natural, attractive, rich…is it?). They might be asked to use direct ratings (Daniel and Vining 1983) or to make similarity judgments, which are then subjected to multi-dimensional scaling (Gärling 1976). Alternatively, they might be asked to sort pictures that vary in the roles played by natural and built objects (Cantor 1977). Using pictures frees respondents from having to encode verbally what they see and like. As a result, it may capture attitudes that people have difficulty expressing, because they lack the words or hesitate to use them (e.g., because of social unacceptability or uncertainty about terminology). One set of properties, identified in such studies, is coherence, complexity, legibility, and mystery (Kaplan and Kaplan 1989).

Psychophysical studies create a significant interpretative burden for investigators, who must decode the meaning for respondents of both stimulus and response (Fischhoff and Furby 1988). Just what features did respondents notice? What did they overlook? What did respondents believe about the services that the focal environment provides and the peril it faces? Did they detect hints (intended or inadvertent), regarding what to say? Would they respond similarly in less hypothetical circumstances? It takes a suite of converging studies, with suitable manipulation checks, to establish what people think they are evaluating and how deep their understanding is. Such interpretative issues have been at the center of the continuing controversy regarding contingent valuation, a method advanced by some resource economists for monetizing goods not traded in any conventional marketplace (e.g., the survival of an endangered species, the improvement of atmospheric visibility) (Mitchell and Carson 1989). In the attitude measurement tradition, interviewers ask respondents how much they are willing to pay in order to prevent an adverse environmental change or to accept as compensation for it. If valid, the responses to these questions could be used in cost-benefit analyses. In that role, they would represent environmental changes that would otherwise be neglected in policy making dominated by economic analyses. However, these are intellectually demanding questions. By definition, they require explicit, quantitative evaluations of complex, novel stimuli with many potentially relevant details.

Attitudes have both strengths and weaknesses as anchors for evaluating environmental goods. The ease with which they are evoked means that individuals typically have some feelings to draw upon, whatever question they face. On the other hand, such initial feelings can be hard to overcome when more analytical responses are required (e.g., willingness to pay for a specific good) (Kahneman et al. 1999). Strong feelings can blur the details of serious environmental questions. Debates over the validity of contingent valuation have focused on whether respondents are properly sensitive to the amount (or 'scope') of the environmental change being evaluated (Arrow et al. 1993). The death of migratory birds saddens many people. Envisioning many dead birds creates more sadness than the death of few. The challenge is to translate degrees of sadness into appropriate monetary equivalents. Doing so may require intensive, interactive processes, which depart from the nonreactive norm of attitude research.

Even if such elicitation processes are successful, questions can be asked about the appropriateness of their goal. At the extreme, monetization assumes that everything of value has an economic equivalent. A more modest aspiration is to assign economic values wherever that is possible, but without assuming that they are everything. However, one might still worry that the focus on economics 'anaesthetizes moral feeling' (Tribe 1972). Furthermore, it would take a very disciplined process not to let monetized effects swamp diverse other ones.

Despite the residual ambiguity of their results, these studies place important constraints on studies using other procedures. Methodologically, features that demonstrate a robust influence in attitude studies should be explicitly represented in the stimuli used with other methods. Otherwise, respondents need to guess about the features that are missing, based on those that are present. Substantively, the basic preferences reflected in attitude studies should be observed in studies using in other methods. If not, then doubts must be raised about the robustness of the preferences (or the methods).

In the attitude research tradition, evaluation focuses on a single option. Formally speaking, those evaluations could reflect the alternatives as well, in terms of the opportunity costs of forgoing those other options. However, in cognitive terms, the nature and consequences of those alternative actions will inevitably be less clear than those of the focal one. With many options, the alternatives may not even be fully

enumerated. However, even when there are but two complementary options (e.g., develop/don't develop), thinking about one need not call the other to mind. As a result, each option might evoke different concerns. Asking about it alone does not allow individuals to express their full suite of relevant values.

2.2 Decision Theoretic Measurement

The early days of the modern environmental movement presented many technology managers with opposition that they could not, or would not, understand. One natural response was that their opponents were misinformed. The initial research response was to determine how well people understood the magnitude of different risks, conceptualized as annual fatality rates. The research found (a) a strong correlation between lay and statistical estimates; (b) systematic deviations from the best-fit curve, partially attributable to the relative *availability* (in memory) of examples of the different causes of death; (c) considerable ordinal (and even ratio–scale) consistency in judgments across response mode (e.g., fatalities vs. relative death rates); and (d) considerable inconsistency in absolute estimates, across response modes. Thus, respondents seemed to have a fairly robust intuitive feeling for relative risk levels, which emerged however these (unusual) questions were asked (Lichtenstein et al. 1978).

However, rather different judgments emerged when respondents judged 'risk,' rather 'average year fatalities.' Moreover, the risk judgments were better predictors of their attitudes toward technologies (Slovic et al. 1979). Many studies have sought the determinants of subjective definitions of 'risk.' One early candidate was 'catastrophic potential,' in the sense that people see greater risk in technologies capable of claiming many lives at a single time. Anecdotal support for this hypothesis can be found in the attention drawn to plane crashes and public concern over nuclear power (despite citizens' recognition that, in an average year, the death rate from nuclear power is negligible). Subsequent research suggested, however, that catastrophic potential was not as significant as the uncertainty associated with technologies that can produce large accidents (Slovic et al. 1984). Avoiding uncertain technologies reflects risk aversion, rather than an attitude toward how deaths are distributed over time. These are different ethical stances, with different policy implications. Concern over catastrophic potential means providing incentives for locating technologies remotely and disincentives for creating technologies that could, conceivably, affect large numbers of people. Concern over uncertainty means providing incentives for research that sharpens risk estimates and disincentives for highly innovative technologies (which can't be known that well).

The search for defining attributes of 'risk' can be traced to Starr's seminal (1969) claim that, for a given level of benefit, the public tolerates higher levels of risk when they are incurred voluntarily (e.g., skiing), rather than imposed involuntarily. As evidence, he presented aggregate estimates of annual deaths and economic benefits from eight sources. In his plot, he sketched in two parallel 'acceptable risk' lines, an order of magnitude apart, for the voluntary and involuntary risks. This sort of *revealed preference* analysis assumes that society manages to achieve acceptable risk-benefit tradeoffs from technologies. If so, then that tradeoff should be seen in lay perceptions of risks and benefits (which drive political processes).

A study testing this hypothesis asked citizens to judge 30 technologies in terms of current risks and benefits, acceptable risks (given the benefits), voluntariness, and eight other features (e.g., catastrophic potential, dread, controllability, known to science, known to the public) (Fischhoff et al. 1978). It found:

(a) discrepancies between lay and statistical estimates of risk and benefit;

(b) a weak correlation between estimates of current risks and benefits (so society was not seen as exacting greater benefit from riskier technologies);

(c) no increase in the risk-benefit correlation, when mean judgments of the risk attributes were partialed out (indicating that respondents did not see society as having set a double standard for, say, voluntary and involuntary technologies);

(d) a belief that the acceptable level of risk for most (but not all) technologies was lower than respondents' current estimate (rejecting the hypothesis of effective societal risk management);

(e) a significant correlation between judgments of current benefits and acceptable risk levels (indicating a willingness to have more risk with greater benefit); and

(f) a large increase in predicting acceptable risk levels from perceived benefits, when many of the risk attributes were partialed out (suggesting the desire for a double standard, accepting greater risk when, say, it is incurred voluntarily).

3. Prescriptive Applications of Cognitive Research

3.1 Setting Public Policy

If robust, such results provide guidance to public policies affecting the environment. At the simplest level, they show a willingness to accept risk-benefit tradeoffs (possibly surprising some critics of lay rationality). They also show attributes of risk that might be considered when designing technologies or regulatory mechanisms. Different definitions of risk can lead to different social priorities. That is true even for different ways of measuring a single attribute. For example, mortality risk can be summarized as prob-

ability of premature death or as lost days of life expectancy. The latter measure puts a special premium on deaths of young people (where many days are lost with each life). With the former measure, a death is a death (Crouch and Wilson 1981, Fischhoff et al. 1981). Either could consider the distribution of risk across the population (e.g., among those who do and do not benefit from a technology), or leave equity considerations to others. Technical specialists often follow professional conventions when computing their estimates. Nonetheless, those definitions still incorporate ethical considerations. Whether citizens (or their representatives) are consulted is a reflection on accepted political processes.

In cognitive and administrative terms, dealing with a large set of attributes is unwieldy (and, at some point, intractable). As a result, many studies have looked for redundancy among risk attributes. Using various data-reduction techniques, typically they have found that much of the variance in ratings of the attributes can be accounted for by two factors. One seems to reflect how well risks were known, by science and by those exposed to it. The second seems to reflect how much risk is dreaded, inequitable, involuntary, and personally threatening.

If such issues are on citizens' minds, democratic societies need ways to incorporate them in public policies, lest trust be eroded. Institutionalizing analytical procedures that incorporate public values (e.g., definitions of risk) is one possibility. Processes that directly involve citizens have increasingly been advocated, with environmental issues both driving and reflecting societal pressure for more consultative government and industry (e.g., Canadian Standards Association 1997, UK Royal Commission on Environmental Pollution 1998). The US Environmental Protection Agency (1993) fostered some 50 state and regional efforts to set priorities among risks. These panels' ability to structure their work as they saw fit, and to receive clear explanation of technical matters, seemed critical to their success (Davies 1996). Nonetheless, it was unclear what features any particular panel had considered, nor what weight it gave to each feature. Without such transparency, the credibility of its conclusions could lack credibility, for individuals who were not party to the deliberations. Furthermore, skeptics might wonder whether participants really understood the environmental risks that they were judging.

3.2 Ensuring Citizen Competence

Thus, cognitive approaches to preference elicitation draw upon two of the major streams in psychology, as it has developed over the past century-plus. The psychophysical stream envisions values as emerging from direct perceptual processes; these visceral responses, then, require intellectual effort, in order to translate them into terms that address specific policy questions. The decision theory stream envisions specific values as being derived intellectually from basic values; these, then, must be connected with individuals' life experiences, lest they be but transient artifacts of the elicitation procedure.

Both streams recognize the following steps that individuals must traverse, if they are to formulate meaningful positions—with either researchers or policy makers as their audience:

(a) Encode the task—in order to understand the choices being offered.

(b) Access relevant personal values—in order to structure the evaluation process.

(c) Integrate the relevant values, as interpreted in the specific context—in order to construct a preference.

(d) Translate that preference into terms recognizable by the investigator or policy maker.

The first step to ensuring such shared understanding is creating a full task specification, characterizing all features that matter to investigators or respondents (e.g., Fischhoff and Furby 1988). How hard investigators have to work to convey these task definitions depends on how far they share a common frame of reference with respondents. For example, as the vote approaches on a widely debated referendum, many citizens know what commitment it implies and can respond reliably to a poll eliciting their values. When that occurs, many details 'go without saying.' Omitting them both saves time for less obvious details and respects conversational norms.

Communicating the remaining details has been approached from both a bottom-up and a top-down perspective. The former involves creating a supply curve for facts, focusing presentations on the facts that respondents most need to know, but currently do not. If successful, it allows using recipients' attention most wisely, as well as evaluating the adequacy of the understanding that they achieve. Sometimes, only a few things really matter. Sometimes, many do. Top-down communication takes advantage of people's well-known ability to absorb information more quickly, when they can organize it into *chunks*, clusters of facts cognitively processed as units. Mnemonists have mastered integrating diverse facts into highly flexible templates. Ordinary people tend to organize information spontaneously into less coherent, domain-specific *mental models* (Johnson-Laird 1983). Invoking one takes advantage of existing beliefs, allowing some task features to go without saying, while making others easier to absorb. However, mental models can also encourage unintended inferences, while hindering the processing of unexpected features. Like other metaphors, they require some interpretation, and may evoke varying images. Thus, here as elsewhere, empirical research is needed to design the best communications, then to evaluate their success (Fischhoff 1999).

4. Conclusion

Environmental decisions are enormously diverse. Individuals can have a hard time grasping the issues involved and deciding how they feel about them. These difficulties are part of the task of researchers, hoping to characterize or facilitate environmental decision making. Driven by the importance of these problems, environmental social scientists have cast a wide net, for potentially relevant methods and theories—extending and integrating them along the way. They make it possible to go beyond speculation and anecdote, regarding what people believe and want about specific environmental issues. Most people report caring about the environment. Its fate and theirs depend on how well they understand what is happening with it and convey their desires for its future.

Environmental Conservation: Ethical Concerns

1. Major Debates on Ethical Systems

Should our environmental responsibility emerge from the concern for consequences of our action or from the

criteria that we chose to take those actions? There are several frameworks that have been used such as: Libertarianism, Contractualism, Relativism, Deontology, and Teleology, for analyzing ethical dilemmas.

Bentham (1748–1832) developed a simple universal principle for deciding what is good, calling it the principle of utility. According to this theory, the doer of any good act tries to maximize the amount of happiness to the doer and to others affected by it. Critics have argued that hedonic calculus could not be the basis of estimating moral worth of an action, arguing

> that because some pleasures are inherently better than others (getting an education, say, is better than getting drunk), they have inherent worth that makes them desirable, it throws in question that the very possibility of hedonic calculus follows; it would mean that pleasure and pain are no longer considered the basic unit in terms of which the worth of all acts and goals are to be measured (Goldberg, 1995, p. 117).

The boundary of feelings of those sentient beings whose pain affects us becomes part of our moral boundary.

What are the different ways in which ethical concerns are manifested when describing the environmental problems or prospects? One of the persistent issues, which emerges in the dialogue on ethics, is the distinction among facts and values. Goldberg states: 'facts concern the way things actually are, the evaluations are the judgments about things ideally as they ought to be' (1995, p.5). Amartya Sen, in a very significant contribution (1981), observed that what we choose to describe involves value judgments and how we choose to describe it also involved a value judgment. The descriptive 'is' becomes the normative 'ought'.

2. *Determinants of Domain of Responsibility*

2.1 *Boundary of Pain*

Does the degree of pain suffered by other species determine the boundary of our responsibility? Some have argued that predation is a rule in nature and thus why should an anthropomorphic view of nature be decried so much. But survival of the fittest is also a feature of a natural system. Will that be acceptable as a basis of human social evolution? Darwin is believed to have remarked that humans were not necessarily on the top of the ecological chain as some higher form than others. Each organism may have adapted to its niche and thus may have advantages over other species in that niche: no single species is higher or lower than another. Our responsibility for another species may emerge from the pain we cause to it. The other view, as we shall see later, is that not every species may experience pain. Jeremy Bentham (1748–1832) held that

> any being capable of suffering should have his or her experiences taken into account by utilitarian calculations. However, according to right theorists, any version of utilitarianism, no matter how carefully conceived it is, fails to provide sufficient protection for innocent life, human or non-human (Pluhar, 1998, p. 165).

Pluhar asks,

> Do animals have a *prima facie* right to life or a *prima facie* right not to be tortured? One might hold that some animals have no serious right but do have a right not to be tortured or one might hold that that they have a *prima facie* right to humane treatment that could be overridden by the need to preserve allegedly more morally significant lives. (Pluhar, 1998, p. 162).

But then this argument raises another dilemma, which is about hierarchy of moral responsibility. René Descartes (1596–1650) proposed 'beings that are not rational are incapable of suffering.' According to him, non-human animals are merely organic machines without consciousness, unlike humans, who allegedly are amalgams of material bodies and immaterial minds (souls). Though he claims that he does not deny that non-human animals are capable of sensation, he is denying that they can suffer.

2.2 *Responsibility for Conservation Arising out of Greater Human Purpose*

Dower asks,

> Should we care for the environment because other life forms in nature, or nature itself, have a value, moral status independent of our interests, or because it is in our own collective interests to protect it? (1998, p. 769)

The scope of moral responsibility needs to be defined and different cultures experiencing tremendous loss of environment are defining it implicitly by making false compromises between development and environment. It appears as if one could have the former without the latter (unless we genuinely believe that Western societies are indeed more developed than the rest, as they certainly offer more consumer choices to their citizens). Human purpose could be to prosper, without impoverishing other human and non-human sentient beings, but it could also be defined by various cultures in negation of certain rights of others. Can ethics be determined by voting on it? We do not think so. A great degree of consumerist culture survives in most democratic European societies and yet its sustainability is questionable. The democratic way of arriving at the human purpose does not make it more legitimate and moral.

Human purpose can be defined in minimalist terms. One cannot solve all environmental problems but one can certainly solve some. Should one not try to solve a few because others remain? At the same time, our concern extends not just to those we know, see, or recognize. Our responsibility is to society and the biosphere at large, hence the international agreements such as the Convention on Biological Diversity (1992).

2.2.1 Agricultural ethics. The responsibility towards long-term sustainability of land, biodiversity, and well-being of animals, has been contrasted with a desire to intensify agriculture by crossing the natural barriers among species by using biotechnology or other technologies. For some, biotechnological tools can lead to better environment, if these help in reducing or eliminating chemical pesticides. However, these tools can do the opposite by unleashing environmental risks. The biotechnological revolution involving incorporation of genes from one species into another has raised a great many ethical issues. The invocation of the precautionary principle itself has become contentious. If in doubt, this principle advises that we err on the side of conservation. Some have interpreted this to mean that no research need be done to explore biotechnological alternatives, even if these were to have the potential for solving some nutritional and food needs. Others argue that the issue of hunger is not one of production, but of distribution. Ethical dilemmas arise when we enable the hungry to obtain sufficient food (through the public distribution system) through environmentally destructive land use practices (such as cultivation on marginal lands). Whether biotechnology can help solve this problem is as much an issue of ethics as one of policy and institutions. For instance, it can reduce pressure to bring more land under cultivation by increasing productivity of existing land. Ethical dilemmas also emerge when:

(a) intellectual property rights are granted over life forms (such as the Harvard onco-mouse) or other organisms violating the sanctity of life, as well as granting monopoly to those who did not and can not create life (except for modifying it into the laboratory),

(b) risks are taken in releasing in the environment genes which, in their natural conditions, did not have the possibility of diffusing among species (e.g., through transgenics tolerant to herbicides),

(c) animals are treated with hormones or other reagents which increase their productivity, yet affect their well-being or shorten their life cycle, and

(d) solutions are not developed to grow crops in problem soils, such as alkaline or salt-affected soils, through biotechnological means.

2.2.2 Asymmetry of rights and responsibilities. Risks are involved not just when things are changed but also when they are left unchanged. It is this position justifying inertia that populist arguments have made their mainstay. While exploring biodiversity or associated knowledge systems, ethics of extraction assumes asymmetrical rights and responsibilities (Gupta, 1994, 1995, 1999). We never acknowledge the creativity and innovations as well as traditional knowledge systems of local communities and individuals conserving resources in our writings (the whole discipline of ethnobiology has been a testimony to this). We do not share benefits with them fairly, never share what we have learned from them and others in their language. The Honey Bee network set up in 1989 to document and disseminate grassroots creativity and green innovations is an exception (http://www.sristi.org/honeybee.html). We complain when the same communities and individuals are at times forced to follow environmentally unfriendly actions. Studies have shown that the regions of high biodiversity in the tropics are also inhabited by the poorest people, who have the lowest educational levels (despite exceptions), who have high emigration of males and consequently a high proportion of households headed or managed by women. Yet discourse on environmental ethics has seldom reflected on these systematic relationships.

2.3 Ecocentrism/Biocentrism/Deep Ecological Ethics

The rights of not just the animate but also the inanimate, of not just the human but equally other species, and of not just the born but also the unborn are articulated in a combination of biocentric, ecocentric, and deep ecological ethical perspectives. Ecocentric theorists include Kenneth Goodpaster, Lawrence Johnson, Holmes Rolston, Baird Callicott, Arnold Leopold, John Rodman, etc., who essentially argue for moral rights of all beings and ecosystems. A lake has a personality if endowed with values, in the same way as mountains and species. Munshi (1952), a famous writer, in his lecture entitled 'A Gospel of Dirty Hand' tried to link the soil with soul. He did not see any way we could understand the relationship between nature and human beings if we did not see the linkage between nutrient cycle, hydrological cycle, and local institutions. Of course, he contrasted the ethic in which nature was held supreme, with the local tribes who, overawed by nature, remained what some may call 'primitive.' Other tribes or social groups, which overpowered nature, vanished into oblivion because they crossed the limits of nature. He argued for moderation. Some ecologists argue, however, not just for moderation but for a hands-off policy. The

> recognition of moral status of non-sentient living things can thus be depicted as the next step in the history of moral development (Rawles, 1998, p. 276).

Pedersen (1993) distinguishes two strands of modernity drawing from Giddens' work (1990) which may have a bearing on the evolution of ecocentric ethics. He refers to separation of space from place and of time from ecological space. Such a conception of ecological space does not require cultural association with a locality. Callicott (1994) hopes that such an international environmental ethic can evolve which can be compatible with local vernacular cultural traditions linked to space and time in a very different manner. The evolution of global time and of global space may also lead to the emergence of a global social group without a particular living space or habitat to qualify for specific environmental value.

Biegart (1999) recalls the contrast of perspectives between Native Americans and European settlers about water (surface flow). He gave the example of the late Philip Deere of Oklahoma, medicine man of the Muskogee Nation, who termed rivers and streams as the veins of the world. Clogging them, one could say would clog not just the life in them but the life of humans as well. The sacredness of water in all such cultures indicates that by polluting waters we are also polluting the spirits that sustain these waters.

2.3.1 Accountability towards perfect strangers and other non-persons. Human needs cannot always take priority over the needs of nature and other living beings. How do we determine our accountability towards the future generation, which is unknown to us? The future generation is made up of 'perfect strangers'—i.e., who are not known and are unknowable. We do not hear the voice of the unborn. What should be the responsibility of the present generation to discern the needs and preferences of such sentient and non-sentient beings with whom we are unable to communicate? There needs to be some response using contemporary as well as traditional value systems (Gupta 1991).

The cultures of the world have evolved means of generating and monitoring responsibility towards other living beings. But this responsibility need not emanate only from human value systems. Goodpaster observes,

> to be worthy of moral respect, a unified system need not be composed of cells and body tissue: it might be composed of humans and non-human animals, plants and bacteria. (Rawles, 1998, p. 279).

Johnson argues that 'various beings other than individual organisms can meaningfully be said to have interests, and that these interests are morally significant.' The beings in question include species and ecosystems. Brennan critiques this position and suggests that the claim of Goodpaster

> rests upon a naïve and scientifically outmoded view of ecosystems and species, neither of which have the characteristics that Johnson has attributed to them.

Brennan disagrees with the claim that

> ecosystems have interests, because he takes this claim to presuppose a view of ecosystems as goal-directed that the scientific community has largely rejected. (Brennan, in Rawles 1998, p. 279).

2.4 Socio-psychological Roots of Ethical Consciousness: The Internal Values

Hill (1978) brings in a personal psychological aspect while identifying roots of ecological ethics. He adds,

> my psychological argument is that truly ethical behavior originates wholly from the healthy, unhurt, undistressed parts of individuals; and unethical behavior originates from the hurt part. If we want people to behave ethically, then we must provide environments that are supportive of the healthy part of individuals (Hill 1992, p. 11).

Stone (1987) argues that monist (one best way to resolve ethical dilemmas) arguments have to be tempered by moral pluralism. The latter implies that one looks at the ethical basis of not just the action choice, but also the motivations of the actors and the institutional context of both the actors and the actions. There could be other planes as well. Can we not use a universalistic ethical principle in one part of our life space and use pluralistic values in other parts? Innovations from the Honey Bee data base on grassroots innovations managed by the Society for Research and Initiatives for Sustainable Technologies and Institutions (SRISTI) seem to indicate segmentation of life space.

The institutional behavior is the one where internal commands replace external demands. One does a thing not because one is being supervised but because that is the right thing to do. Environmental ethics is at a crossroads. We are looking for new indicators that will generate internal responsibility for caring for nature across different cultural contexts and worldviews. But what constitutes nature and what determines whether responsibility for its care globally, regionally, and locally will invoke equally strong internal commands: these questions remain open. Legal and public policy instruments are evolving and seem to indicate increasing concern for environmental care. But calls for such concern in the current geopolitical context from Western countries immediately invites criticism from developing countries. They see this call from the West as the sign of new emerging environmental protectionism. They argue that Western societies accumulated wealth by destroying their environment, which gives rise to a

precipitous argument: that therefore developing societies also need to have the right to accumulate wealth by destroying their own environment. Moral discourse will have to take a center stage in each of these polarized polities.

2.4.1 Environmental perception and cognition. Dunlap et al. (1993) have provided some of the most striking evidence against the notion that concern for the environment stems from 'postmaterialist values' (Muller-Rommel 1989). In a worldwide survey of citizen concern for the health of the planet, a high level of environmental concern was found in developing as well as developed countries. Such a concern is a necessary condition, though is insufficient for taking effective action. Stern et al. (1995) looked into the factors that may influence these environmental concerns of the citizens. One of the important findings of the authors is that activation of personal stable values is possible through organized efforts which try to influence the values in the direction of conservation ethic or otherwise. A study done by Gupta looked at the profile of the green consumers (Gupta et al. 1997). It revealed four types of consumers: (a) active mobilisers, (b) populist mobilisers, (c) passive practitioners, and finally, (d) those who were indolent and indifferent. The fact that there was not much difference in the proportions for each category indicated the possibility that social values could gravitate to either side depending on the nature of effect, available information, and action of organized interest, would have on internal values.

Austin and Schill (1991) and Boyce (1995) have argued for taking into account the need for environmental justice while looking at the issues of environmental care. SRISTI (1993) has argued for the need to combine ethics, equity, excellence, efficiency, environment, and education.

Gandhi provided a thoughtful summary of environmental ethics when he said that the world had enough for everyone's need but not enough for everyone's greed. The concepts of *aparigrah* (not accumulating more than one needs), *ahimsa* (non-violence) and frugality developed by him provided a practical guide to responsible living.

In the emerging modern consciousness in which a human being is no more responsible for his or her individual moral space but for the whole world, Amato (1982) argues that claims of guilt and gratitude will ultimately make us humble and bring us into harmony with our collective destiny. The exploration of environmental ethics is thus a journey into an abyss of responsibility for self and society, for present and future generations, and for the human and the non-human sentient and non-sentient beings, things, places, and also for time. We need to extract a slice of our time from the womb of ever-forgiving nature, which is learning to forget forgiving. That is the real tragedy and also the challenge.

A. K. Gupta and R. Sinha

Environmental Determinism

Environmental (or geographical) determinism views the natural environment as the basic factor controlling human achievement, an environment incorporating location and the geophysical and biophysical features native to the earth, including climate, structure, minerals, soil, flora, and fauna—all that is intrinsically 'earthy' rather than formed or shaped by human action. Some blur this issue by incorporating human-modified features, others reduce the rigidities of 'determinism' to 'influences,' strong or slight. Some trace environmental influences deep within the human psyche. Environments vary with the objects 'environed.' 'Environmentalism' can also refer to the search for environmental relationships and efforts to salvage the ecological system. Contextual awareness is therefore needed to pluck one theme from a varied setting, interpreting 'environment' and 'determinism,' separately and together.

Frequently dismissed as passé, environmental determinism nevertheless touches sensitive and perhaps unresolved issues—the remote and continuing impact of nature on humans, human and racial genesis, ethnic and national origins, conditions that favor or frustrate economic and intellectual achievement, the global constraints and opportunities that define all hopes of present or future accomplishment—perhaps the whole panorama of human studies, now extending into biogenetic and biosociological realms.

1. *Prehistory from Hippocrates to Montesquieu*

Frequently entangled with astrological or 'cosmic determinism,' environmental determinism permeated Chinese, Indian, Babylonian, and Greek philosophy before the dawn of Western Civilization. By the fourth century BC, Hippocrates had combined the 'elements' of earth, air, fire, and water with geographic location to promote economic and communal health, evaluating swampy hollows and windy uplands accordingly. Greeks generally perceived their Mediterranean shores as a 'golden mean' remote from northern winters and southern heat, a zone favoring moderation, intellectual pursuits, and civil discourse. Open steppes were fine for savage Scythians, and sun-burned Africans and Asians were deemed to lack the spirit essential for

liberty and war. As Glacken (1967) remarked, 'the familiar assertions of modern times … are found in a cruder form in antiquity: warm climates, produce passionate natures; cold, bodily strength and endurance; temperate climates intellectual superiority; … and a fertile soil produces soft people, a barren one makes them brave.'

Greek thought cast long shadows across Medieval Europe, with variant determinisms facing the unforeseen. P. Sorokin found few who failed to mention 'geographic influences,' and Renaissance sage Jean Bodin (1530?–1596 AD) scanned 2000 years of earth and sky for principles to guide the French monarchy through religious and ethnic strife. Two centuries of Enlightenment later, Montesquieu (1689–1755) might ignore the stars, but still insisted that 'climate is the first, the most powerful, of all empires.' Such epigrams evoked challenge from Church and philosopher alike. Theologians could scarcely accept 'revealed religion' as a matter of climate, Voltaire found bad weather no excuse for bad government; and skeptic Hume could not correlate national characteristics with atmosphere. In rejoinder, Montesquieu affirmed he had never thought that blind fatality could generate intelligent beings, that physical and moral causes were always intertwined, thereby provoking later determinist-possibilist debate, but his 'determinism' lingered beyond the Encyclopedic era as the particularizing sciences, geography included, took shape.

2. *Cosmos, Teleology, and Environment*

Montesquieu's 'environmentalistic' instances were echoed by Immanuel Kant (1724–1804) as he lectured on the roles of space and time in organizing geographical and historical phenomena, and shortly thereafter Alexander von Humboldt (1769–1859) and Karl Ritter (1779–1859), founding fathers of modern geography, generated similar interests, although not necessarily in deterministic fashion. Humboldt, seeking law in the natural Cosmos, repeatedly warned that presuppositions regarding environmental impact on human character involved 'wanton trespass' beyond the limits of knowledge, pointedly observing that New World grasslands lacked the pastoral nomadism of the Old World, even as American desert skies generated no parallels to Arabian astronomy (Tatham, in Taylor 1957). Yet environmental awareness informed his views of esthetic life, and (however secular) he sought always to manifest 'the perpetual influence of physical nature on the moral system and on the very fate of mankind' (Anuchin 1977).

Such thoughts were central for Ritter, confident (with J. Herder) that Divine teleology joined earth and humans as body and soul, relating historical progression to geographical form. The continents, framed by landform and climate, presented natural regions which fostered cultural education and differentiation. Localizing human–historical data in 'Erdkunde,' Ritter thought that once the 'general laws' of nature and humans became clear, humans could glance 'backwards and forwards, to determine from the whole of a nation's surroundings, what the course of its development is to be and to indicate, in advance of history, what ways it must take to retain the welfare which Providence has appointed for every nation whose direction is right and whose conformity to law is constant' (Dickinson and Howarth 1933). Much already seemed apparent, for civilization, dawning in the Orient, reached its contemporary zenith over the fretted coastlines and narrow European seas, and could brighten to an American sunset. Such qualified determinism, stripped of its teleology, could harden into the 'scientific' determinism that was to follow.

3. *The Anthropogeographical Tradition*

Deterministic thought flowed strongly through the late-1900s, with Darwin, Marx, and Freud becoming household names, and sociologist Comte and historian Buckle articulating 'social laws.' It would have been surprising had some not invoked 'geographical environment' as determinative. As memories of Ritter and Humboldt faded, and Departments took shape in Germany, influxes from the natural sciences reinforced physical geography, while human geography paused uncertainly. Darwinism seemed a welcome barrier against academic Balkanization, bonding all life forms to an ancient earth, rather than presuming the adaptation of earth to humans (Freeman 1962). 'Survival of the fittest' was linked with race and culture, natural law plausibly extended through 'Social Darwinism' to society, and 'Evolution' accounted as excluding teleology. Re-evaluation of such interpretations now seems essential, given neo-Lamarckian thoughts, and P. Kropotkin's cooperative evolution. Yet a 'superficial gilding of Darwinian rhetoric' entered geographical discourse (Livingstone 1992). Certainly biological Darwinism was initially appropriated by Friedrich Ratzel (1844–1904) as he sought application of natural-scientific law, with his trilogy of space, location, and social dynamics situated in environmental settings. Critics found his first volume on 'Anthropogeographie' presenting 'man as essentially passive, [responding] with Euclidian precision [to] the laws of the physical environment which determine human activities, distributions, and organization, in both space and time' (Dickinson and Howarth 1933).

But subsequent readings have softened early criticism, for Ratzel followed analyses of the historical impact of geographical features with attention to cultural migration and growth, measuring and mapping the 'co-variants of human distributions' (Dickinson 1969). In 'Politische Geographie,' evolving societies and states filled their respective

lebensraum, expanding toward natural or ethnically shaped boundaries—an idea conceptually fertile and generally devoid of the nationalistic provocation some discern among later geopoliticians.

Ratzel's American disciple, Ellen Churchill Semple (1863–1932), excised organic metaphor and extended illustrative examples in 'translating' anthropogeography for the 'Anglo-Saxon world.' 'Influences of Geographic Environment' were traced through the history of America, the World, and the Classical Mediterranean. Particular attention was given to mountain passes, rivers, sea routes, cultural migrations, contact zones, and the subsequent emergence of political entities. To critics her examples seemed tendentious, furthering a dubious mono-causal approach to historical and cultural complexities. Darwinian concepts obtruded in statements that 'Man is a product of the earth's surface,' molding every thought and act, strengthening body and wits together. Yet, she warned, 'geographic determinant' was shunned and 'geographic control' mentioned only with caution (Semple 1911).

4. *Physiography and Climatic Change*

Attempts to find 'anthropogeographical laws' variously appropriate for inhabitants of mountains, plains, coastlands, peninsulas, and scattered islands aroused skepticism, but were compatible with the views of W. M. Davis (1850–1934), founding father among American geographers. Discarding Ritter's and Guyot's teleology for evolutionary 'cause-and-consequence,' he postulated that it was only the relationship of earth to inhabitants that gave geography its distinctive and unifying character, a theme encapsulated as 'physiography' and 'ontography,' all life-forms included—a formulation which 'set the pattern for the pursuit of man–land relationships on a deterministic basis' for the first decades of the twentieth century (Dickinson 1976).

Other American universities, pioneered by Chicago, followed this Davisian concept (Blouet 1981), even as Ellsworth Huntington (1876–1947), moving from physiography to ontography, became intrigued with the potential linkages of climate and civilization, a theme pursued from the dune-fringed lakeshores of Central Asia to tree-rings in the American Southwest, from Yucatan to Palestine, and beyond. Typed as a climatic arch-determinist by the 'Pulse of Asia,' he revised his ideas with criticism and experience, replacing progressive desiccation with climatic oscillation, and searching for climatic optima within the cyclonic Westerlies, where sequences of fine and stormy weather seemed to stimulate. Field observations revealed abandoned villages, evidence of bygone agriculture, alluvial deposition, and glacial retreat. Combing historical records and voluminous correspondence (selective fact gathering, some said), he sought to match, measure, and correlate historical and geographical patterns. Using maps, graphics, and sometimes vivid prose, he personified geography (and climatic determinism) to the American public. Not unaware of challenge, he accounted climate a largely overlooked factor in the selective triad, a process blending natural environment, eugenics, and cultural impetus—dying, however, with his magnum opus unfinished (Martin 1973).

5. *Stop-and-go Determinism*

Huntington exchanged similar views with Griffith Taylor (1880–1963), British born and Commonwealth oriented, who, migrating to Australia, moved through geology and climate to geography, seeing environment as suturing his physical and human concerns. As weather-person and physiographer, he accompanied Scott's last Polar expedition, and thereafter Antarctica's icy wastes and Australia's desert Outback were engrained on his environmental consciousness. He found his own assessment of the economic margins curtailing development and population growth at odds with those of 'boosters' advocating 'Australia Unlimited.' Somewhat pugnaciously, he relinquished his Geography Department at Sydney for the hopefully more congenial University of Chicago, whence he moved to found the Department at Toronto, incidentally close to the margins of the vast Canadian Shield, where settlement was restricted by geology and climate.

Taylor's outspoken 'geocratic' determinism had its limitations. Conceding Western Europe and Eastern America to the Possibilism advocated by 'We-ocratic' microgeographers, he scanned the earth as a whole, affirming that, facing expanses of barren rock, frigid cold, and harsh aridity, habitation was reduced toward the vanishing point (Taylor 1957). Correlating the racial distributions of anthropology with 'evolution on the map,' he viewed geography's task as environmental analysis. As a 'stop-and-go-determinist,' he sought 'Nature's plan,' believing that 'humans are like the traffic controller' in a city, accelerating, slowing, or stopping the flow of traffic, but ever alert to the economic cost of disregarding Nature's directions, including those of 'geopacifics,' focused on the benefits of international cooperation.

6. *Russian Environment and Marxist Thought*

Beyond the bounds of the West extended vast steppes, forests, and waterways, and Tsarist historians 'attributed many peculiarities in the historical development of Russia to the direct influence of the natural environment,' K. M. Ber affirming 'the fate of peoples is determined in advance and seemingly

inevitably by the nature of the locality they occupy' (Anuchin 1977). Such theses breed their antitheses, especially when urgent priority is given to industrialization. Wrestling with the determinism of dialectical materialism, geographers such as N. N. Baranskiy sought to link productivity with environment, but were overruled when the Communist Party accepted Stalin's 1938 edict, precluding consideration of 'the geographical environment' as 'a determining influence,' and affirming modes of material production as crucial (Matley 1966). With 'geographical deviationists' silenced and environmental determinism shunned as 'Western,' Soviet geography separated into 'physical' and 'economic–cultural' branches, reflecting 'incompatible' natural and social laws.

Following Stalin's death in 1953, some geographers ventured public challenge. V. A. Anuchin, finding 'inhuman' physical geography and 'unnatural' economic geography objectionable, urged a synthesis expressive of dialectical–materialistic 'determinism' rather than the 'indeterminism' of those who, denying causation, separated humans from Nature. Invoking Marxist phraseology, he presented the human race, emergent through labor and tool-making, as qualitatively distinct, if thoroughly 'natural.' Not all geographical exegesis was considered relevant to humans, for earth's 'landscape envelope' included untouched components (such as sea-floors and Himalayan peaks) remote from nature–human relationships, and excluded from 'the effective environment.' There, the spread of human population and its products reshaped 'the natural environment' into 'the geographic environment,' complexly uniting inorganic, organic and societal components into one humanized world, roughly equivalent to Western concepts of 'cultural landscapes.' Within this ultimate and seamless 'geographic environment,' natural elements continued, so Western-style environmental determinists—although likely to mistake conditions for causes, and be mechanically direct rather than dialectical when mediating natural laws into human settings—could thus appear valid, given occasional and accidental circumstance. Consequently, 'certain occurrences and phenomena in the geography of population and economy … may be determined, admittedly in an indirect but yet decisive manner, by the geographic environment and even [by] its natural complex alone.'

Anuchin's appeal for a merger of nature and humanity into one 'geographic environment' seemingly failed, but his impact appeared in 1963 when the Communist Party, prompted by geographers including N. N. Baranskiy and Y. G. Saushkin, rescinded Stalinist definition of geographic environment as 'a purely natural category,' even as dusty Virgin Lands, shrinking Aral Sea, and planning complications reinforced contentions that a unified geography could indeed assist in rehabilitating nature and humanity in Soviet 'territorial complexes.'

7. *'Possibilities' in Western Geography*

Given Soviet insistence that social laws reflected dialectical materialism, such changes were not viewed as concessions to Western-style 'possibilism,' and Russian geographers were becoming aware that few Western colleagues appreciated description as 'environmental determinists.' After 1900, European opinion had moved as 'determinism' and 'organism' became suspect, and society, not environment, was scanned for essential causes of social change. (Martin and James 1993). Alerted by sociological critiques of Ratzel, French geographers followed Vidal de la Blache and Brunhes into 'possibilism.' Environment was conceded its essential role, but *genres de vie* (or lifestyles) were followed into 'regional personality.' British geographers, also regionally inclined, were perhaps less precise, casually invoking Darwinian 'response to environment' (Freeman 1962), and indulging in 'frankly boring' debates about determinism (Livingstone 1992).

In the seminal 1920–40 era, pragmatic American geography was redefined by European—especially Germanic—influences. Anthropologist Franz Boas promoted anti-environmentalism, W. M. Davis moved from physiographic environmentalism toward regionalism (Blouet 1981), and others, H. H. Barrows in particular, urged geographers to move to undeterministic 'human ecology.' More decisively, C. O. Sauer, alluding to O. Schluter and S. Passarge, challenged all definitions presupposing environmental relations as parasitic and biased, moved tangible 'landscape' to the fore, and left environmental ties to be proved. Agreeing with A. Hettner, R. Hartshorne defined 'the nature of geography' in 'chorological' or 'areal differentiation' terms, thus deflecting attention to regionalism rather than environmentalism—a 'deviation' from geography's *raison d'être*.

With environmentalism excluded from definitions, some sensed a 'death blow to the doctrine of environmental determinism' (Dickinson 1976), but subsequent statements suggest otherwise. Questioning views that the valid search for environmental relationships necessarily presupposes 'determinism,' some note shifts to influences—'probabilistic,' 'possibilistic,' or simply 'permissive' (Lewthwaite 1966). Many, broadening their concept of geography to encompass historically formulated 'traditions,' followed 'the man–land tradition,' with mutual interaction sometimes progressing from land to humans deterministically. Others, following 'spatial traditions,' abstract geometrical 'deterministic systems' from the overall environment. Some have traced analogies, with cultural variations, between Western environmentalism and Oriental geomancy. Others have seen 'eurocentricity' at the core, and some, inspired by Marxism, view environmentalism as a class-derived phenomenon.

8. Environment Remains

Doubtless many a component—eurocentricity, imperialism, nationalism, racism, class, and other interests—have been involved in origin and expression. However, if ideas be judged on their own merits, not pronounced 'guilty by association' but evaluated for potential insights, then 'environmental determinism' cannot be dismissed out of hand. Buttimer (1993) affirms that 'the most demanding challenge for the geographer today is how to incorporate nature and the biophysical environment in descriptions of context while avoiding the resuscitation of environmental determinism.' Of course, with mind as well as matter involved in all human thought and action, a robotic response to environment is automatically excluded, but nevertheless 'physical causation' is an unavoidable fact, evident when an earthquake or hurricane strikes. In such situations 'geographical controls' are real enough, and at the abstract conceptual level (presumably in conjunction with other and alternative concepts) environmental determinism has its analytical value.

Whatever our views, the environment is always with us: driven out the door, it comes back through the window. 'Environmentalism' covers many things, not least recurrent crusades to avert the spoliation of natural or cultural treasures (Manners and Mikesell 1974). However, environment surrounds and touches all things, whereas 'environmental determinism' suggests ultimate limits to human aspirations. Willy-nilly, 'environment' seems likely to evoke abiding interest.

Environmental Economics

It may seem strange to someone unfamiliar with economics to assume people's behavior can be described independently from the environmental systems that sustain their very existence. Nonetheless, this is exactly what conventional economic analysis does. Production, exchange, and consumption decisions are usually modeled in ways completely separate from the natural environment. Over the last 30 years of the twentieth century there has been a growing realization among ecologists, and to a lesser degree in the economics profession as a whole, that this approach can lead to serious mistakes. Environmental economists study the effects that environmental systems have on the positive predictions and normative recommendations of economic models (see Solow 1991).

Early in the history of economic modeling, Hotelling (1931) and more recently Dasgupta and

Heal (1979) as well as numerous other economists recognized the importance of intertemporal issues for economic choices involving renewable and nonrenewable natural resources. These types of economic analyses are treated separately in the *Encyclopedia*.

Environmental economics assumes there are things people care about, either directly because they enhance individual well-being or indirectly because they influence the production of other commodities, that are: (a) scarce; (b) available outside markets; and (c) influenced by the activities of others. These objects of environmental choice (OECs) have diverse characteristics and result from a variety of activities. Six topic areas organize this overview: the allocation problems they pose, the design of policy, measures for the amounts of environmental amenities and their economic values, OECs as risks, the distributional implications, and interactions between growth and environmental resources.

1. Problems—Public Goods, Externalities, and Congestion

The definitions for public goods and externalities are closely linked to the conditions required to sustain private property rights. As a result, the allocation problems they create are sometimes reduced to descriptions of causes and remedies for market failures.

Pure public goods are nonrival and nonexcludable in consumption (Cornes and Sandler 1996). Each person's consumption of a public good does not reduce the amount available to others. Moreover access to these goods cannot be limited. While it is hard to provide examples satisfying these ideal conditions, it is easy to cite examples of goods and services with attributes close to a pure public good's features. Local air quality, measured in terms of the concentration of airborne pollutants, varies with location but within large areas is approximately the same for all individuals living there. The global concentrations of greenhouse gases (e.g., CO_2, methane, etc.) can be described as examples of pure public 'bads' because emissions of them at any location have equivalent effects on their atmospheric stocks. However, the consequences of those accumulations for climate change and local weather conditions will depend on where people live. Perfect adherence to the ideal definition of a public good is not essential to consider the implications of 'publicness' for the efficiency of different resource allocation mechanisms.

Externalities describe a class of interactions between two or more economic agents. One group's (or individual's) consumption, production, or exchange activities have unintended effects on the production or consumption of others. These external effects resemble public goods (or bads) in that they can have the same nonrival and nonexcludable attributes.

Congestion describes a phenomenon whose externality effects reduce the nonrival attributes of a public good. For example, over some levels of recreational use of a beach or a wilderness area (and the levels will be different in each case) further users can be supported without extra cost or diminution in the satisfaction each person realizes from his or her use. However, at some point, this simultaneous use diminishes each person's experience. The phenomena linking those losses to the added users of a resource at the same time is described as congestion.

While all three of these concepts are relevant outside environmental applications, they have found special meaning when environmental resources provide the services treated as OECs or as the assets whose services provide the conduits for the negative or positive interactions between economic agents.

These concepts are important for at least two reasons. First, the incentives created by private markets do not assure that resources will be allocated to their highest valued uses when one or more of these problems is involved. Second, the information available from markets cannot be assured to signal and evaluate the performance of economic institutions. Much of environmental economics can be interpreted as responses to these issues.

2. Policies—Context, Design, and Performance

Economic analysis seeks to abstract from the 'details' of a problem, focusing instead on the incentive properties of each decision context. In the case of environmental problems these details can matter to the insights offered by economic analysis. For example, economic descriptions of production and consumption activities must be consistent with materials and energy balances (Kneese and Bower 1968). When they are not, it is easy to overlook the residuals and the problems that must be faced in disposing of them. This insight is important because most externalities arise from using the services of an environmental asset (i.e., the ambient atmosphere or a free flowing river) for residual disposal. The form and severity of environmental externalities depend on both the types of residuals involved and the functions of the ecosystem receiving them. As a rule, the ecosystems are open access resources whose services in some uses are rival applications. They may well also be subject to depletion over time.

Economic prescriptions for these externalities (as well as for congestion) tend to focus on creating the 'right' incentives. Private choices should reflect their full or social incremental cost (i.e., the private marginal cost of producing any commodity plus the marginal external costs due to any damages associated with a commodity's production, consumption, and ultimate disposal). When the marginal damages associated with the production or consumption of a good are

measured per unit of each residual emitted, it is sometimes described as the price that should be charged for that emission. Pigouvian taxes or effluent charges set equal to these marginal damages are one type of policy response to externalities.

Under simplified conditions, efficient resource allocation in the presence of environmental externalities (or congestion) requires that, at the margin, agents face the full cost (or benefit) of their actions including the damages caused directly or indirectly from each choice. Those experiencing damages are assumed to take defensive actions and costs computed recognizing these choices, but the injured parties do not need to be compensated (Baumol and Oates 1988).

With full information, policy can take a variety of forms. These can be charges per equivalent unit of impact (taking account of the ecosystem) to the agents causing externalities; permits to emit pollution that can be traded; and even subsidies to abate emissions. Each of these policy measures can be made to appear equivalent in terms of the incentives for incremental choices. Each approach requires different implementation rules and a different set of adjustments to reflect their effects at the extensive margin of choice (e.g. the entry and exit decisions of firms). Charges vs. subsidies will affect incentives to enter an industry (Carlton and Loury 1980). Tradable emission permits must be denominated in units reflecting the effects of emissions on the services associated with ambient environmental quality that defines the OECs. They must also consider both the initial distributions of permits among firms, the rules for trading, and their ability to be saved (if temporal patterns of emissions are important).

Unfortunately, in the setting where actual decisions must take place, information is scarce and uncertainty abounds. If uncertainty affects the marginal control costs, then it can affect the preferred policy instrument. Comparing charges vs. marketable permits (denominated in units of the OEC) Weitzman (1974) has shown the choice depends on the relative steepness of the marginal benefit and cost schedules. Tradable quotas are favored if the marginal damage function is steeper than marginal abatement cost and effluent charges for the reverse. His results depend on the approximate linearity of these schedules. Moreover, the conclusion is a relative statement not an absolute judgment. Composite strategies using price and quantity instruments together can be shown to be better in the sense that they enhance overall welfare (Roberts and Spence 1976).

This summary implies that with perfect information either instrument can lead to an efficient resource allocation. Charging for emissions or distributing permits to pollute seems to convey 'rights' to different economic agents to use ecosystems' services. The conclusion that they can be equivalent may seem counterintuitive. While surprising it is one reflection of the general implications of the Coase (1960) theorem. That is, in a world of perfect information, no transaction costs, and no income effects (from assigning rights to ecosystem services) the theorem demonstrates the assignment of rights will not affect the efficient outcome. It is often used in arguments that externalities can be resolved without public sector intervention by assigning property rights to ecosystem services. In most cases the practical relevance of this conclusion is an empirical question. Nonetheless, the economic logic underlying the theorem also explains why the available policy instruments can be equivalent.

Until recently, most environmental policy was driven by the broad goals of the existing legislation. In the USA the rulemaking process, implementing this legislation, has favored command-and-control (CAC) regulations. Specific technologies were prescribed to meet objectives such as using the best available control technology to establish the lowest emission rate. These types of engineering standards specified, at the unit process level, emission rates for the same types of pollutants that sometimes were quite different for separate equipment within the same plant. The result was very different incremental costs for controlling the same pollutants. Abatement costs were also increasing over time as more stringent controls were imposed. Areas found to be in nonattainment with environmental standards faced restrictions on further economic activity. The result was a policy environment seeking some ways of increasing the flexibility in how firms could respond. Some regions in the USA had started the process of 'regulatory reform' and introduced some movement toward the use of economic incentives when the 1990 Clean Air Act dramatically changed the US regulatory climate. It offered the first large-scale emission permit trading system as a way of realizing more stringent controls for sulfur dioxide. Ellerman et al. (2000) estimate that emission trading yielded cost savings by 33 to 67 percent of the most reasonable CAC alternative. Permit trading schemes are being considered or used in small regional markets for an array of environmental resources—including air and water pollutants, wetlands, habitat for endangered species, and carbon dioxide (see Tietenberg 1990).

Most economic choices about market goods and services cannot be analyzed realistically without recognition of their environmental consequences. This requirement is symmetrical. Environmental policy analysis cannot ignore the market and regulatory context for the products produced along with the environmental externalities. Two sets of insights have been especially important to reaching this conclusion. The earliest, associated with Buchanan (1969), argued that a monopolistic product market may, by restricting output, serve environmental goals. In this context, imposing effluent charges or restricting emissions with tradable quotas could actually lead to welfare losses.

The logic underlying this result is more general. Judgments about the preferred incentives to realize an

efficient resource allocation in an economy with externalities and multiple distortions are extremely difficult. An emerging issue indicating how such distortions can affect the design of environmental policy began with the promise of 'double dividends' from effluent charges on CO_2 emissions (Bovenberg and de Mooij 1994). Subsequent research rediscovered the issues associated with designing optimal product taxes in the presence of multiple taxes—an important theme of the optimal taxation literature (Auerbach 1985). The double dividend argument relies on using the revenues from environmental fees (or authorized permits) to reduce the marginal rates of one or more large, pre-existing taxes. It is suggested that the result of the tax substitution may be zero or negative gross cost. Subsequent research has extended arguments about the potential importance of pre-existing tax distortion to evaluations of the effects of new environmental regulations, suggesting in the case of SO_2, costs over 70 percent higher than they would be in the absence of the taxes (Goulder et al. 1997). Nonetheless it is important to recognize how specific this conclusion is to the circumstances described in each model. Changing the assumptions about how private goods relate to the externality in consumers' preferences will affect the size of the excess burden attributed to existing taxes and therefore the gains from reducing them. What is less likely to change is the attention the argument implies should be given to the political economy of how and why environmental legislation takes specific forms.

3. *Amounts: The Role of Nonmarket Valuation and Benefit-cost Analysis*

Nearly all analysis of policy instruments assumes we know how much environmental quality to provide. Answering this question involves more than deciding the amount of pollution permitted. It requires consideration of a wide range of natural assets whose amenity services are important to people. Everything from endangered species and their habitat to land and water resources that provide essential capacity for a wide range of outdoor recreation must be considered. Some choices must be made more carefully than others must because some allocations of a natural environment will irreversibly alter its ability to provide amenity services (Krutilla 1967, Krutilla and Fisher 1975).

The extent of 'publicness' of the OECs compounds the difficulties in making these choices. Free-riding incentives arising from nonexclusion assure that private action alone cannot be relied upon to realize the efficient level of these types of resources (Cornes and Sandler 1996). Recovering information equivalent to what is provided when market exchanges correctly signal scarcity requires economic 'detective work.'

Two strategies have been developed since Hicks (1943) first defined rigorously the monetary representations for the tradeoffs defined by economic choices (Freeman 1993). The first relies on the logic of revealed preference and uses choices of private goods to recover the tradeoff information. For example, it recognizes that a consumer's decision to purchase (or rent) a home in an area free of air pollution reflects, in part, a payment for that ambient quality in comparison to the next best alternative (Palmquist 2000). With a wide array of alternative conditions, the price gradients arising from different air quality conditions, with other housing attributes held constant, would reveal the incremental willingness to pay for improving air quality (Freeman 1993). Similar logic implies one could use the trips taken to recreation sites at locations with different travel costs to reveal the demand for the recreation these sites provide (Freeman 1993). Given a set of recreation sites, varying in quality conditions, consumers' visitation decisions offer the potential to measure the incremental value of those quality dimensions. Decisions to avert or mitigate the negative consequences of pollution offer the same potential to reveal underlying tradeoffs (Freeman 1993).

The logic underlying each strategy relies on reconstructing the unobserved elements required to define the economic tradeoff revealed with each choice. In the case of nonmarketed goods this process implies that a connection is also defined between the decision and the OEC of interest. For the tradeoff to be informative about an individual's preferences for the nonmarketed good these connections must convey a degree of exclusively (i.e., economic value of the amenity requires consumption of the linked private good). They must also specify how enhancements in an individual's ability to pay would change them. One way this control over the substitution and income effects of choice is implemented comes from the joint imposition of restrictions on the properties assumed in describing an individual's utility function. Weak complementarity (Mäler 1974) and the Willig (1978) condition are among the most commonly used. Weak complementarity maintains that the environmental amenity is of value when it is used with the private good. Without some positive consumption of that good and improvement in the amenity has no value to each person. The Willig condition adds to this restriction a requirement that the incremental value of increases in the amenity, per unit of the private good consumed, do not change with income.

Stated preference approaches to recovering economic tradeoffs offer the second nonmarket valuation strategy. They rely on presenting people believable (but hypothetical) choices with proposed financial consequences and interpreting their stated decisions as bounding economic tradeoffs (Mitchell and Carson 1989). An important motivation for proposing choices arises from the inability to link all the ways amenities enhance people's well being to observable choices of

private goods. Such unlinked reasons are sometimes referred to as nonuse or existence values (Krutilla 1967). Stated preference methods are controversial because they require that survey responses be treated as economically consequential (Diamond and Hausman 1994, Hanemann 1994).

The primary use for nonmarket valuation estimates has been in benefit-cost analyses of projects involving environmental resources and regulations intended to improve environmental quality. Benefit-cost analyses (BCA) assume there are reasons why an existing resource allocation is not efficient. The analysis seeks to evaluate whether an aggregate choice improves the efficiency (Arrow et al. 1996). Four aspects of applying BCA are especially important. First, the net benefits from an aggregate choice are summarized as a present value and are influenced by the time horizon and discount rate used. Both are potentially influential and controversial judgments (see Portney and Weyant 1999 for a summary of the issues in making a choice). Second, large changes in relation to the overall economy have general equilibrium effects that may require evaluating the effect at the household level and aggregating (i.e., computing net benefits at the household level rather than aggregating benefits and costs separately, see Hazilla and Kopp 1990). Third, BCA analyses will always face incomplete information about the changes being evaluated from a baseline to a new outcome. When an irreversible choice is being made and there is the possibility for resolving some of the uncertainty over time, the analysis should include the conditional value of any new information that would be consequential to the decision (Arrow and Fisher 1974). Finally, monetization of all factors creating benefits or costs is not essential for BCA to be informative. Observed choices (at the individual level) define bounds for the tradeoffs implied by a decision. This same logic can be used to delineate bounds for the missing elements in a BCA. That is, we define what the missing elements in a measured value for net benefits would need to be to support a specific choice (Krutilla and Fisher 1975).

4. *Risk: Perceptions and Values*

One of the most important classes of OECs involves environmental sources for changes in the probabilities of undesirable outcomes. For example, air pollutants have been associated with premature death and increased episodes of serious illness. These decisions are highlighted for two reasons. First, the framework for evaluating private and public choice must consider attitudes toward risk and the opportunities available to adjust to it. Within a framework that evaluates decisions made before the uncertain events are resolved, there has been considerable discussion of how these risks should affect monetary measures of policy outcomes and discounting. There seems to be broad consensus that attitudes toward risk and opportunities for private and public adjustment should be built into the monetary measures of *ex ante* net benefits and not to the discount rates (Portney and Weyant 1999). Second, studies of laypersons' risk perceptions and behavior in both experimental and survey contexts suggest marked discrepancies between subjective beliefs and experts' recommendations. Equally important this behavior contrasts with the predictions of an expected utility model for individual choice. These differences are especially important for small probability and long latency outcomes (Slovic 1987). Such findings raise questions with what constitutes an informed choice and potential limits to consumer sovereignty (Machina 1990). They also highlight the role of information and risk communication as policy instruments.

5. *Distribution*

The term distribution in most economic analyses of policies would lead to a discussion of equity effects, interpreted as evaluating the consequences of actions for different income groups. For environmental policy, distributional considerations are inherently more complex. At least four perspectives have been considered. First, the use of an aggregate net benefits criterion for evaluating policy itself is a distributional judgment. It implies departures from a strict efficiency standard and a willingness to admit policies where there exists the potential for improvements. Positive aggregate net benefits means those gaining could compensate those losing. It does not require the compensation to take place.

The second distributional perspective follows from the identification of long lived, potentially irreversible externalities—with greenhouse gases and nuclear waste being two widely recognized examples. In these cases the distribution of costs and benefits extends across generations and the equity issues are often framed in ethical terms. One important implication of this line of reasoning is that policies should treat all generations alike. As a result, this line of reasoning would seem to imply a zero discount rate should be used. However, there is an equally strong intuition from a different perspective suggesting it is not morally acceptable. It implies a decision criterion (i.e., the zero discount rate) that would demand excessively high savings rates of any one generation. This countervailing influence is important because Koopmans' (1960) classic analysis of choice rules over infinite dimensional consumption streams concluded that these rules must display impatience or some amount of positive discounting. Otherwise, it would require the first generation to sacrifice everything. With preference separability over time, Arrow concluded irreversibility does not change conclusions in favor of intertemporal discounting (see Portney and Weyant 1999). Of course

to the extent preferences or production display important substitutions or complementarities with irreplaceable environmental resources, then the guidance will depend on the details of those linkages (Portney and Weyant 1999).

Economic and environmental feedback effects can have significant distributional consequences within short time horizons. Several cases illustrate how this third perspective can arise. Deciding between command and control vs. incentive based policies can seem clear-cut, considering the total costs of meeting a uniform standard (Tietenberg 1990). However, the environmental transfer system, linking emissions to ambient concentrations, can imply the cost savings are realized by allowing the cleanest areas to become more dirty while those exceeding the standard become cleaner. These properties can impact political acceptability as well as different income and demographic groups.

Much less is known about the economic feedback loops connecting environmental policy in one sector to its impacts on others. The economic models used to compute general equilibrium responses usually describe activities as if they all took place at the same 'point-in-space' (Hazilla and Kopp 1990). Recent adaptations to these models (Espinosa and Smith 1995) and to household equilibrium location models (Sieg et al. 2000) confirm the importance of relaxing these assumptions. Indeed, the results from the equilibrium location model suggests that spatially differentiated, but consistent, air quality improvements can induce housing price adjustments (within a closed system) that imply some households would actually be worse off after an improvement in their air quality. This result arises because the housing price increases induced by some households' relocations can offset the air quality gains for those households with a small taste for environmental public goods.

The last distributional perspective, paradoxically, receives the greatest attention in agencies' design of policies (in the US some legislation specifically identifies concern for the impacts of regulations on small businesses) and often the least in academic discussions. It concerns the impact of regulations on industries and different sized firms within a sector. Empirical evidence confirms that environmental regulations can have effects on the timing, location, and scale of plant investments. Considering only air quality regulations in the US, they find that activity shifts to areas that meet ambient standards, not subject to stringent area-wide regulations. Less activity takes place in areas that are not in attainment with national ambient air quality standards. When new plant investments do take place they seem to involve larger up-front investments in comparison to what takes in the attainment areas. In one of the sectors, these authors studied (industrial organic chemicals) their results suggest plants grew to smaller sizes with regulation than in the preregulation era (Morgenstern et al. 1998).

6. *Growth and the Environment*

One of the most durable questions posed in considering interactions between the economy and the environment concerns whether the environmental system poses some 'ultimate limit' on the scale of economic activity (see Barnett and Morse 1963). Sometimes expressed in terms of raw materials (or natural resources) and other times in terms of ability to provide a sustainable food supply and waste absorptive services to a growing world population, the issue most recently has been expressed in terms of whether growth in income has a self-regulating property. That is, as household income grows, the taste for environmental amenities increases. Providing these services requires reducing pollution, protecting natural environments that provide habitat for endangered species, and enhancing absorptive capacity of ecosystems for some types of pollution.

At one scale, this issue has been posed using what is termed an 'environmental Kuznets curve' (Grossman and Krueger 1995). Pollution is hypothesized to have an inverted U-shape with household income. It increases until income growth creates demand for amenities that ultimately reduces pollution and leads to policies that restore environmental quality. To date, the questions raised in this line of research have been based on empirical analyses, relying on the contemporaneous performance of economies varying in pollution and household income, as if they could be treated as descriptions of a single economy moving through a dynamic process.

This new formulation of the old question is potentially important. It casts the issue in its most relevant form. Economists are concerned about the services provided by environmental resources because market institutions cannot be assured to signal the scarcity of these resources. Understanding both the static distortions to patterns of use and the dynamic nonmarket incentives to bring about changes in the utilization of these natural assets is important for designing new institutions that recognize the role of environmental resources in assuring that it is possible to continue to enhance economic well being.

V. K. Smith

Environmental Health and Safety: Social Aspects

Environmental health, especially related to toxic substances, is a highly politicized area. As the use of chemicals in industry, agriculture, and the household has become central to the whole economy, many problems have been detected. The physical and mental health impacts of toxic substances have generated significant social movement activity, have led to major government regulation, and have demonstrated the capacities of laypeople to make important advances in scientific knowledge.

1. The Scope and Significance of Environmental Factors on Health

Much disease is caused by substances and conditions in people's surrounding environment, including chemicals and air particles in factories, pesticides in agriculture, toxic wastes in residential neighborhoods, and radiation in the atmosphere. The 'environment' is so broad a term that we could virtually subsume all disease processes under the umbrella of unhealthy living and working conditions. But when experts speak of social aspects of environmental health, they generally focus on the health effects caused by toxic substances in people's immediate surroundings. These chemical-related, air-pollution-related, and radiation-related diseases and symptoms are the phenomena that have generated much conflict, policy making, legislation, public awareness, media attention, and social movement activity.

These social outcomes were prefigured by prior developments in occupational health. Many harmful effects of chemicals and substances are first found in the work setting, and then generalized to the community level. There was much corporate, governmental, and scientific opposition to detecting and remediating occupational causes of disease, setting a tone for responses to environmental conditions. Even a clearly work-related condition such as black lung disease was the source of great contention, with coal miners pitted against corporations and the federal government (Smith 1981). Mesothelioma (a form of lung cancer) and asbestosis (a pulmonary disease) are now generally understood to be caused by asbestos, although there was great conflict until quite recently (Brodeur 1985).

Rachel Carson's *Silent Spring* (1962) sparked the first mass public attention to environmental health effects. Carson demonstrated how pesticides, especially DDT (dichlorodiphenyl-trichloroethane), caused morbidity and mortality in animals and humans. Her work led to significant pesticide regulation in the USA, the National Environmental Protection Act, the Environmental Protection Agency (EPA), and the new wave of the environmental movement.

The 1978 Love Canal situation was the first occasion on which human health was central in an environmental crisis, prompting the creation of the Superfund Program by the US EPA. Residents were warned by state health officials that toxic chemicals permeated their neighborhood in Niagara Falls, New York, where a chemical company had donated a dump site to the city to build a school. The revelation meshed with residents's awareness of a history of experiencing health effects. Residents and their scientist allies discovered elevated rates of miscarriage, birth defects, cancer, and chromosome damage (Levine 1982). The residents organizing to get action by state and federal governments led many other communities around the country to act similarly.

2. Types of Environmental Health Effect

2.1 Lay Discovery of Environmental Health Effects

Much of the knowledge about environmental health effects has come from actually or potentially affected people. Some situations involved immediate health effects, such as the dioxin-laced waste oil in Times Beach, Missouri (USA). Others involved episodes without immediate effects, but where effects were expected to follow, as at the Three Mile Island (TMI) nuclear plant. Sometimes there was the discovery of prior contamination episodes, such as in the case of radiation releases from the Hanford, Washington (USA) nuclear facility. Sometimes there are unexplained clusters of disease, of which people are seeking the cause, but do not yet have a specific emission to trace it to, as with Gulf War illnesses.

Environmental justice activism expanded these concerns as Blacks, Latinos, and Native Americans in the USA discovered excess lead poisoning and disproportionate placement of landfills, incinerators, and toxic waste sites in poor and minority areas (Bullard 1993, Bryant and Mohai 1992). Women's growing involvement in toxic waste activist groups has heightened the importance of gender issues (Blocker and Eckberg 1989).

Laypeople's success in identifying environmentally induced diseases and their likely causes is striking. A valuable example is the lay discovery of the health effects of the Hanford nuclear reservation. Citizens began with initial questioning, followed by extensive self-education through reading, talking with neighbors, querying officials, and analyzing primary sources. Ultimately, they compelled the release of massive numbers of documents, documented many accidental and planned radioactivity releases, identified thyroid disease among 'downwinders,' and were instrumental in US Energy Secretary Hazel O'Leary's 'openness' policy that brought to light many releases and accidents, as well as many unethical radioactivity experiments on captive populations (Kaplan 1997).

2.2 Physical Health Effects

People are exposed through many routes: water supply, contamination of foodstuffs and animal feed, chemical factory and transportation leakages and explosions, trash incineration, contamination from toxic waste sites, and exposure to household chemicals, fertilizers, and pesticides (see *Environmental Stress and Health*).

Toxic substances have been implicated in diseases of all organ systems. The physical health effects of toxins are not a separate category of symptoms and diseases, but are best understood as forms of poisoning. The

disputes over environmental health effects are therefore usually not about the symptoms *per se*, but about their etiology. Although a few toxins have 'signature' diseases (e.g., asbestosis and mesothelioma), most do not. Hence, neither sufferers nor clinicians are likely to attribute individual cases to a toxic exposure. There has also been intense debate on the presence of abnormalities that are not specific diseases, such as chromosome damage, eye blink reflexes, and reproductive abnormalities (Brown and Mikkelsen 1997, Colborne et al. 1996).

2.3 Mental Health Effects

Toxic contamination episodes often leave a residue of fear and anxiety, and case studies show that depression is common. In contrast with natural disaster situations, people have to fight to gain public recognition of the pollution in human-caused disasters. Litigation contributes to the ongoing depression by forcing people to relive their illness experience through the seemingly endless process of depositions, testimony, and consultations with independent experts. During the year after the TMI accident, mothers experienced new episodes of affective disorder at a rate three times higher than a nonexposed control group in another location (Bromet et al. 1982).

Post-traumatic stress disorder (PTSD) has been found in many toxic waste sites. People retained a 'death imprint' of memories of the disaster, and felt a strong 'death anxiety.' Many experienced 'death guilt' concerning what they thought they should have done to prevent a loved one's death (Lifton and Olson 1976).

Bruce Dohrenwend (1981) compared demoralization (the emotional state of the nonmentally ill general population) of TMI-area residents with the clientele of a community mental health center. With a higher score indicating more disorder, the overall mean score of the mental health center clients was 28.3, for TMI-area women 30, and for TMI-area men 25. Of those interviewed directly after the accident 26 percent showed severe demoralization. Even two years later, TMI residents had more symptoms, poorer task performance, and higher levels of serum catecholamines (a biochemical marker of stress) than did controls who lived near an undamaged nuclear facility (Baum et al. 1983).

People in contaminated communities often reassess the environment, seeing it as a malevolent force. Even the home may become threatening. Residents lose faith that the world is just, and may even think that they deserve their fate (Edelstein 1988). Victims lose trust in government and in the ordinary operations of the economy and polity, since the established institutions do not help them. This failure precipitates further emotional distress.

2.4 Community-wide effects

Contamination episodes harm communities, disrupting ordinary social relations as well as damaging health. Victims suffer loss of community bonds (Erikson 1976), have conflict with local government officials (Levine 1982), develop anxiety about their surroundings (Edelstein 1988), and may argue with other residents over what to do (Couch and Kroll-Smith 1992). Communities facing contamination episodes are often in the midst of 'chronic technological disasters' (Couch and Kroll-Smith 1985), long-term, unfolding problems that often haveno visible starting point, but which eat at the social fabric. These 'invisible environmental contaminants' are felt by residents as 'occult,' mysterious factors (Vyner 1988).

2.5 Social Responsibility

Disease sufferers and their allies target the corporations they hold responsible for contamination episodes. Residents have often expected local, state, and federal government support for their claims. Government failure to support victims's claims has led to increased mistrust of government. Residents in many contaminated communities have become radicalized in response to the combination of corporate pollution and government inaction (Szasz 1994). Toxic contamination episodes at a local level can have dramatic national effects. The dioxin release at Seveso in Italy led to major conflict in parliament over many issues, from remediation to abortion access for exposed women. In Japan, PCB (polychlorinated biphenyl) contamination of cooking oil resulted in national-level wrangling, as political parties took up the issue (Reich 1991). In the case of the Chernobyl meltdown in the USSR, there were many international repercussions as radiation passed over borders. Citizen response to toxic contamination has been a major element of popular social movements in the USA, at a time when social movements have otherwise been in decline. This has been less the case in other countries, perhaps because many of them already have powerful Green parties and other similar movements.

3. Issues and Conflicts in the Definition and Measurement of Environmental Health

3.1 Standards of Proof

Environmental health effects pose difficult research issues, such as inadequate history of the site, lack of clarity of the route of contaminants, determining appropriate sampling locations, small numbers of

cases, getting appropriate control groups, migration in and out of exposed areas, lack of knowledge about the characteristics and effects of certain chemicals, and unknown or varying latency periods for toxins. Epidemiology studies usually have such small numbers of exposed persons that observed rates must often be 20 times that of expected rates in order to attain statistical significance (Neutra 1990). New approaches argue that small effect sizes should not be viewed as obstacles, since even low relative risks are very powerful if large numbers of people are affected. Similarly, consistency across many studies should be acceptable as evidence of etiological linkages, even if not all of those studies meet statistical significance (National Research Council 1991). Ozonoff and Boden (1987) distinguish statistical significance from public health significance, since an increased disease rate may be of great public health significance even if statistical probabilities are not met. They believe that epidemiology should mirror clinical medicine more than laboratory science, by erring on the safe side of false positives. Although it is not always easy to evaluate the effects of removal of a hazard, researchers have produced such findings. In the well-known childhood leukemia cluster in Woburn, Massachusetts (USA), no new cases of leukemia developed after contaminated wells were shut, and birth weights returned to normal at the Love Canal and the Lipari, New Jersey (USA) landfill sites after exposure declined (National Research Council 1991).

Despite the many shortcomings in environmental epidemiology data, reviews of the research show that most controlled studies find associations between hazardous waste sites and human health (National Research Council 1991).

3.2 Other Obstacles to Knowledge on Environmental Health

In medical training, environmental medicine is relegated to a minor position (Institute of Medicine 1988). In one survey of all Massachusetts physicians, those whose practices are located in communities with Superfund sites were no more knowledgeable about environmental health hazards than other physicians (Brown and Kelley 1996). Medical centers and research institutions are not necessarily interested, since environmental health has low prestige and little funding, and can put medical facilities in conflict with local centers of power.

Corporations have fought against recognition of environmental health effects because of the financial cost involved in settlements, fines, production restructuring, and alternative forms of disposal. Government agencies have been reluctant to affirm most relationships between contaminants and disease. One reason is the fear that business will be harmed. Another is that governmental failures to regulate chemicals and other toxic substances are a source of public anger, and governments do not want to be criticized for their shortcomings.

3.3 Lay Involvement

Environmental health has become a major public concern due to dramatic environmental catastrophes such as the contamination at Love Canal, the dioxin exposure at Times Beach the dioxin explosion at Seveso, and the Union Carbide explosion of methyl isocyanate in Bhopal, India. Citizens were often the first to point out problems, and even when they were not, they typically took the lead in studying the situation. Lay-initiated health studies have been central to the development of environmental epidemiology.

However, many epidemiologists and government officials have criticized lay involvement, assuming that it must be biased. An example can be seen in the Woburn toxic waste crisis, where a major health survey was conducted by an alliance of Harvard biostatisticians and Woburn residents. They examined childhood leukemia, pregnancy outcomes, and childhood disorders from 5,010 interviews, covering 57 percent of residences with telephones. The researchers trained 235 volunteers to conduct the survey, taking precautions to avoid bias. Childhood leukemia was found to be significantly associated with exposure to water from two municipal wells. Use of that well water had been associated with perinatal deaths since 1970, eye/ear anomalies, and CNS/chromosomal/oral cleft anomalies. Water exposure was associated with kidney/urinary tract and lung/respiratory disease. This study would not have been possible without community involvement, yet government agencies and the American Cancer Society charged that the study was biased (Brown and Mikkelsen 1997).

4. New Methods and Measures Needed for Improved Knowledge and Action

Much environmental epidemiology is carried out in crisis situations, using very small samples. More routine monitoring is necessary, such as through regular national health surveys and toxic disease registries. Scholars need to decide what size of geographical area is most useful and must make clear connections between community contexts, environmental variables, and health outcomes. They need to decide what are the best health outcomes, both in terms of data access and in terms of plausible connections to environmental quality. Better environmental measures are needed to avoid the problem of existing data sources that give a wide array of units

of measurement for such items as toxic releases, type of releasing facilities, water quality, and air quality. Extracting data from the US EPA is cumbersome, requiring tedious Freedom of Information Act requests and lengthy waits. In the USA it is also important to link cross-state data, since researchers are unable to match exposure in one state with morbidity and mortality in another. Cancer incidence and mortality is not sufficient. Other less serious illness must also be studied.

Scholars need to come up with creative models that study health outcomes in relation to a variety of inputs, including political structure, public participation, access to health services, economic factors, population density, racial/ethnic proportions, environmental quality, and access to the natural environment.

Environmental History

1. The Term Environmental History

Environmental History deals with the history of human impacts on nature and the interactions between humans and nature. It asks how nature influences humans, how humans intervene in nature and how nature and humans interact. To be able to understand these processes, it also investigates changes in nature not caused by human action. The terms nature and environment are largely seen as being synonymous. In traditional, preindustrial societies generally they describe the natural environment, comprising elements such as the landscape, rivers, climate and weather, animals, plants, etc. These natural factors are also of importance for industrial societies. At the same time, their environments are shaped more and more by human action citing, for example, the environment of modern towns, in which today more than half of the

world's population lives. In addition, nature itself increasingly is shaped by human action. In Europe, there are hardly any and world-wide relatively few regions where humans did not interfere, so that in today's world we can speak of a man-made or even an artificial nature.

To understand such diverse developments the term environment as well as environmental history has to be defined very broadly. In practice, however, mostly it signifies the natural environment, being aware that in modern societies a pristine nature hardly exists any more. But this terminological ambiguity is acceptable since environmental history above all is interested in the interactions between humans and nature and the transitions between these two. In doing this kind of research, the contribution of other disciplines such as geography, geology, biology, and many others is important, and it is sometimes argued that environmental history as a matter of principle should adopt an interdisciplinary approach. In practice, however, interdisciplinary approaches have proved to be demanding so that most of the contributions to environmental history still come within from single disciplines, not just from historians, but also from geographers, biologists, social scientists, and others (Worster 1988).

2. *The Emergence of Environmental History*

The relationship between the natural environment and humans has been a topic in Western and other civilizations from ancient times (Glacken 1967). Considering the great importance of nature for preindustrial societies, it was understandably seen as a powerful agent, bringing about abundance, beauty, and health as well as need, disasters, and suffering. In this context, deterministic arguments developed, which were especially prominent in the nineteenth and early twentieth centuries explaining, for example, differences in societies, behavior, or racial characteristics as caused by the natural environment. Also prominent were traditions which placed humans into a wider cosmos of nature and propagated a harmony between these two. It is, however, difficult to tell whether these were idealistic concepts of a mainly religious or philosophical nature or to which degree they actually shaped the daily practice.

These long established approaches have not disappeared, but towards the end of the nineteenth century in industrial societies the role of nature became less important, especially in the academic debate. It was not until very recently that a new understanding developed, this time stressing the importance of human action in shaping the environment. An understanding of these influences had developed in the nineteenth century, but it was mainly after the 1950s that this approach became prominent and helped to establish the new field of environmental history as we know it today. At that time, it had become all too obvious how far reaching and often disastrous the effects of human intervention in the environment could be.

In the 1950s and 1960s environmental history was taken up as a subject particularly in the United States. It spread to Europe in the 1970s and 1980s and has expanded world-wide since the 1990s. Among the more interesting recent publications are studies on the environmental history of Asia (Elvin and Ts'ui-jung 1998, Grove et al. 1998), Africa (Beinhart and Coates 1995), and Latin America (Martínez and Jácome 1999). Now (at least) two journals in English exist which are specifically devoted to this topic: *Environmental History*, with an emphasis on the US, and *Environment and History*, whose outlook is more global, paying special attention to the non-Western world. In addition, more and more conferences are taking place; the number of publications is increasing rapidly, and environmental history is entering the curriculum at school and university level. This applies above all to the US where environmental history is most firmly established and where the American Society for Environmental History was founded in 1974 (Miller and Rothman 1997). Furthermore, the European Society for Environmental History is well established, while others are being formed. The field, therefore, is marked by rapid expansion, and the best way to get information about it is to consult the H-environment web page (www2.h-net.msu.edu/~environ/).

Given the debates of impending ecological crises, early environmental history developed a strong interest in its causes, which were often seen as a peculiar feature of the Western world. Among the explanations put forward were 'Christian roots of our current ecological crisis'; the rise of modern 'mechanistic' science; the repudiation of traditional customs and of a softer, female understanding of nature; and, of course, modern industrialization. Coming with these explanations was the notion that historically a balance between humans and nature had existed which was then destroyed by one or several of these factors (Merchant 1989, Cronon 1995).

For the existence respectively destruction of this balance different periods are named. A radical position blames the first appearance of humans; others emphasize the transition to agricultural societies, while mostly the development of the modern world, especially industrialization is held responsible, since it did not just destroy the existing balance and small-scale structures, but also initiated developments which brought about today's environmental problems: a rapid increase in population; the move to and the rise of big cities; the intensification of agriculture; the use of fossil fuels; a massive consumption of resources; the production of new, artificial materials; and new forms, and disastrously high levels of pollution. Numerous studies were undertaken showing in great detail how

human interference had altered the landscape; how the discharge and waste of industry, household, and cities had destroyed many forms of life; had endangered human health and had slowly but seemingly unavoidably contributed to the increasing ecological crisis (Turner and Clark 1990, Miller and Rothman 1997).

The results of these developments were felt globally and even began to affect the biosphere, putting at risk not just humans but all forms of existence. Against this background, conventional, that is, anthropocentric approaches were criticized and it was demanded they be replaced by biocentric notions which did more justice to animals and nature. Most radical amongst them is the Gaia-hypothesis. It sees the earth and the biosphere as a living organism which needs to be protected, but can also defend itself against human interference. Global warming is interpreted in this way. This thesis, however, was and still is a minority view. Much more widely shared is the argument that ecology has become so important that it has established a new scientific (and political) paradigm.

3. *Recent Developments and Debates*

Among the many developments in the recent debate within environmental history the following merit special attention. The concept of ideal, constant ecological balances is today seen an oversimplification. Rather, it is a feature of such balances that they are not stable and that none of them is more 'natural' than the other. Second, it has been shown that nature in Europe, North-America, China, and many other parts of the world has been altered by humans for several centuries, if not millennia, while the controversy of whether preindustrial societies existed in harmony or in conflict with their environment is often shaped by presentism. In this context, it is debated whether the concepts of nature and environment are also socially constructed. And finally, there are numerous indications that modern science, modern institutions, and modern form of productions are not solely harmful for the environment, but can also contribute to a better, more complex understanding of it.

3.1 *The Concept of a Stable Past*

For a time, environmentalists subscribed to the concept that natural processes culminated in stable balances and that these balances represented and ideal state. For some this ideal had existed some time in the past while others saw it as an objective to be realized in the future. Today, it is commonly accepted that the concept of ideal balances and of an ideal nature is misleading (Cronon 1995). Ecological balances are inherently instable, and there are no clear-cut ecological criteria except for human preferences to favor one or other. We may prefer the current climate to the ice-age, but ecologically speaking the ice-age may have been more stable. As a result we cannot avoid anthropocentric perspectives, since no ideal-state independent of our knowledge and preferences exists, and also since we cannot look at nature through the eyes of an animal, a plant, or the biosphere. Consequently, there have to be debates and value judgments about such preferences. Scientific knowledge or historical findings on their own cannot provide answers, but they offer valuable information.

In these debates, it has to be taken into consideration that humans have altered their environment for centuries. Even early societies such as hunters and gatherers effected great changes, for example, by using fire to clear trees or to hunt animals. Also, preindustrial societies could exploit their resources to such a degree that these ran out, thereby causing grave crises. A much debated example is the case of wood forests. For many societies, wood was the most important resource and was needed not only as fuel but also to build houses and ships, to produce tools, and numerous objects for everyday use. In many parts of Europe in the late eighteenth century, there were dramatic warnings that a shortage of wood was imminent. We now know that many of these warnings were grossly exaggerated, but behind the rhetoric, elements of a real crisis existed (Radkau 2000).

The probably best known example for far-reaching human interference in nature can be found in China, where it has taken place for almost 3,000 years (Elvin and Ts'ui-jung 1998). Other examples are the disappearance of forests in the Mediterranean (McNeill 1992) or in Scotland, where today a great deal of opposition exists to reforestation schemes in the barren Scottish Highlands—preferring the present state of nature. Similarly, the first nature reserve in Germany, the Lüneburg heath is the result of massive interference through deforestation and grazing by large numbers of sheep. Today, it requires constant management to keep it as it is.

3.2 *Ecological Imperialism and Traditional Structures*

The global dimension of ecological developments has been emphasized by the concept of ecological imperialism, most prominently put forward by Crosby (1986). He argues that Western imperialism succeeded not so much because of superior technology or arms, but because of the deadly viruses and bacteria the white conquerors brought with them. He describes an ecological clash of cultures which left the indigenous population largely helpless and brought about the death of millions of them. In the meantime, numerous other studies on the environmental consequences of the European expansion have appeared on, for ex-

ample, the consequences of British forest policy in India, the adaptation of European agrarian techniques, the environmental effects of the plantation-system, or of monocultures, etc. (Griffiths and Robben 1997, Grove et al. 1998).

Before these studies were published, the traditional methods of agriculture or pasture in Africa or Asia were often described as being harmful for the environment. The indigenous population, it was argued, had too little, if any knowledge and tended to overexploit the resources, for example, through overgrazing by keeping too many cattle or by destroying the remaining wild animals. As a consequence, nature reserves were established and local people often forced to settle elsewhere; new, Western technologies in agriculture were introduced, and the traditional methods widely discredited. It is interesting to note that similar arguments had been put forward in the eighteenth and nineteenth centuries in Europe and North America. Here, too, traditional methods and customs were first attacked as being inefficient and harmful to nature, and later almost completely abolished (Hughes 2000, Radkau 2000).

In the 1980s and 1990s these assumptions about traditional methods were increasingly challenged. At that time, many of the new, large-scale projects had failed; monocultures and the vast agricultural agglomerates had caused enormous ecological problems; and despite newly introduced plants and fruits crop failure as well as famines had continued to occur. In this context, environmental historians, too, (re)discovered the advantages of traditional methods and argued that these had been particularly well adapted to the differing local conditions; that they had not been based upon ignorance, but on knowledge accumulated over generations, and that they had been better suited to their environment than many of the modern techniques, which furthermore often went together with processes of centralization, thereby further alienating farmers from their roots. The new, centralized projects were heavily criticized and it was argued that they should be replaced by traditional, local practices. These were seen as having been part of a balance with the environment, destroyed by the white colonialists. Given the widespread disappointment with Western approaches, this point of view gained prominence, as it emphasized the negative, destructive consequences of modern science, bureaucratic centralization, the capitalist profit-motive, and market-oriented production. Similar arguments had been developed by environmental historians working on earlier periods of European and North American history. But in the former colonies these arguments had an important political edge and in addition corresponded to developments in the debate on imperialism, which also emphasized its destructive effects (Grove et al. 1998, Crosby 1986).

These debates have yielded important results. They have shown that traditional methods—far from damaging the environment—often were particularly well suited to the local and regional situation; or that small units often provide more scope to protect nature and the environment. At the same time, there was a tendency to portray too simplistic a picture. The mingling of species is not necessarily negative. Rather, it is inevitable, and in most cases nature and culture benefit from new biological combinations (Diamond 1997; Griffiths and Robben 1997). In addition, traditional methods, too, interfered with nature and were not always as environmentally-friendly as is often assumed. The same can be said about traditional institutions, for which the commons are a much debated example.

3.3 The Debate on the Commons

Until recently, this debate was dominated by the notion of the 'tragedy of the commons,' according to which the communal ownership of resources almost unavoidably leads to their exhaustion. For each individual it makes sense to use as much of the communal resources as possible. Even if they use less, there still is a tendency to exhaust the resources since everybody else would continue to maximize their own advantage. Therefore, so the argument goes, no inbuilt mechanism to preserve the commons exists, especially not in time of crisis. A similar argument was put forward in the eighteenth and nineteenth centuries, when agrarian reformers and (mainly big) landowners tried to abolish the still existing commons. In the recent environmental debate this notion has gained renewed prominence. The depletion of fish stocks in the oceans or the pollution of water, soil, and air are seen as proof that communal, that is, free goods tend to be exploited. As a result, property rights are advocated, arguing that private owners of goods have an inherent interest to guarantee their existence over a longer period of time.

Recent research by environmental and other historians has led to a reappraisal of the commons. Their findings show that different mechanisms of control and regulation to curtail individual excesses did in fact exist. Many commons survived for decades, others for centuries, indicating that efficient mechanisms to keep a stable balance must have existed. In addition, the establishment of private property rights could and did lead to rapid exhaustion if the new owners were interested primarily in a quick and high return and/or adopted methods such as monocultures not suited to the local conditions (Radkau 2000).

Not all commons existed for long periods of time. There were also cases of resources being exploited and the land becoming exhausted. Such cases seem to have increased in Europe towards the end of the eighteenth and especially during the nineteenth centuries, mainly due to the rapid increase in population. There are many indications that the traditional methods did not

offer enough scope to deal with this increase. This is not surprising, since historically speaking such a rapid increase is an exceptional phenomenon and exhaustions of resources did not usually occur. Preindustrial societies had a much less sophisticated and efficient technology, a lower level of science, or a less developed infrastructure, which limited the growth of the population, the economy and the exploitation of resources. As a result, interference with the environment was less widespread and far less damaging than after industrialization (Merchant 1989, Hughes 2000).

Considering today's environmental problems and the enormous population pressure the debate on the merits of commons respectively private property has lost some of its importance. There are historical examples both of exhaustion and of prudent care, so that an ideal-type juxtaposition of these two concepts is not helpful. The same can be said for the relationship between modern and traditional forms of the economy or of dealing with nature. Here, too, a juxtapositon is problematic not the least since historically the boundaries between the different spheres and approaches have been anything but clear cut. Practitioners of traditional methods were often influenced by new findings while the development of modern science was shaped by traditional assumptions and knowledge. This is also true for the colonies, even though here the confrontation between the two worlds was particularly intense. Very often, however, the existing structures, for example, in agriculture remained intact. And it has even been argued that the science of ecology originated in the colonial context where the indigenous plants and animals posed a challenge to colonial officials inducing them to have a closer look at the exotic environment in their postings (Grove 1995).

These and other examples show that since the 1980s more complex approaches and arguments have come to the forefront in environmental history. Here, as in other branches of historical studies, the identification of culprits and victims or the juxtaposition of traditional and modern has proved not to be very productive, not the least since the representatives of traditional methods largely were portrayed as victims, not as agents and historical subjects. The insistence on the complexity of historical processes, is, of course, not specific to environmental history, but here it has an added dimension. Given the enormous diversity of environments which in turn are shaped from place to place by very different natural factors, it is very difficult to come to general conclusions or to transfer findings from one place to another.

3.4 *Deforestation and* 'Waldsterben'

The advance of more complex arguments has also contributed to widely accepted assumptions being questioned, for example, the deforestation paradigm. It is a widely-held assumption that increased forest removal in mountainous areas enhances the frequency and severity of floods in the adjacent lowlands. Recurrent flooding in Switzerland in the nineteenth century established this paradigm in the scientific community as well as in public perception. In Germany, the flooding of the Rhine and the Oder in recent years are seen as further proof of this assumption. And in the Ganges delta the inhabitants blamed the clearing of forests in the Himalaya area for the recurrent floods in recent years. However, new research carried out in the floodplains of Bangladesh and in Switzerland has cast doubts upon these widely-held views. In Bangladesh, the deforestation paradigm disagrees with empirical facts, and Switzerland similar results exist, which show that the floods there corresponded to significantly higher rainfall.

In the case of the *Waldsterben*, too, recent findings have fundamentally challenged previous knowledge. In the 1980s the fear of dying forests was one of the major topics in the environmental debate, above all in Germany. It was agreed generally that as a result of air pollution, caused by industry, households, and traffic, most—some even argued all—of the forests would disappear. Now recent research has come to the conclusion that there probably never was such a thing as widespread *Waldsterben*. On the contrary, over the last decades trees in most parts of Europe have—apart from some very small areas—grown faster than before. It seems, that the thesis of the dying forest was based on a misleading research method (Brüggemeier 1998).

These and other findings show, that in environmental history, too, the concepts and terms used are socially constructed. Nature may be a powerful agent, guided by its own laws and often being beyond human influence, but it cannot speak for itself, so that to talk about nature or the environment, constructions are inevitable. At the same time, nature itself exists, of course, independent of such constructions so that environmental history can make a unique contribution to the current methodological debate on construction and reality.

3.5 *Recent Developments in Industrial Societies*

These examples should not give a wrong impression. There can be no doubt that we still face very serious environmental problems. But it seems that our knowledge of the historical processes and causes leading to them is vaguer than has long been realized, that these processes were often more complex, and that some of our assumptions have to be questioned, including the developments within industrial societies. Here, the period after the Second World War seems to be of special importance. On the one hand we have—beginning with the USA—the rise of the consumer societies, which use a greatly increased amount of

resources, above all energy, and produce markedly more emissions and waste (Pfister 1995). There are many indicators that the current environmental problems originated in this period and that their negative effects for the environment are still accumulating. On the other hand, it was also in this period that the environmental movement and environmental policies established themselves. It is still too early to judge their achievements but it can at least be debated whether these have been greater than is commonly perceived (Brüggemeier 1998, Simmons 1993).

When dealing with industrial societies a problem facing all environmental history becomes even more evident: how to judge human interference in the environment. In industrial societies, this interference is, of course, especially widespread and has destroyed much of the pre-existing nature. But will it do to see it only as having been destructive, or would it be more appropriate to emphasize the aspect of change? Are the terms man-made or artificial nature merely descriptive or do they stand for new concepts and new criteria? And what could these criteria be?

Undoubtedly, a lot of research still has to be done in environmental history. We know how some of today's major ecological problems developed, but the knowledge very often is incomplete and above all differs greatly from country to country. The same can be said about the environmental movements; changes in technology, law, and politics; the attitudes of political parties and institutions, of different groups in society; of the changing perception of environmental problems or of the many facetted attempts—and failures—to do something about them. If environmental history takes up these issues it will have to pay particular attention to international aspects on the level of causes as well as policy, taking account, for example, of the different international conferences and treaties of recent years McCormick 1989, Bailey 1995).

4. *Sustainability and Prospects*

For these topics and for environmental history in general the concept of sustainability could prove to be useful. It is true that this concept is very vague and that a great number of different, often conflicting definitions exist. However, many of them share three aspects which are interesting for environmental history: societies are sustainable, if they do not consume more renewable resources than grow every year; if they do not produce more emissions than the environment can absorb; and if of other resources they only consume as much as can be replaced by alternatives.

It is obvious that modern industrial societies do not fulfill any of these criteria. In fact, they are so far off the mark that one can doubt whether it makes sense to apply them. The same cannot be said of preindustrial societies. Almost by definition they depended practically completely on organic, that is, renewable resources; they produced very little emissions, and it could be argued—according to the three criteria mentioned above—that they were sustainable. At the same time, politically, economically, and socially, they were often in a precarious situation, given the recurrent crises such as famines or plagues. The enormous importance of environmental factors for these societies has been stressed in recent publications. These take up the long established debate on the influence of nature on human societies, but avoid its deterministic shortcomings and have again opened up a very important area of research (Diamond 1997).

Are ecological sustainability and social stability difficult to reconcile? This is an oversimplification, but the concept of sustainability could lead to new insights for environmental (and other) historians. At the same time environmental history could make important contributions to the current debate about the sustainability of industrial societies, which—in theory—is not limited to ecological concerns but also integrates political, economic, and social ones.

The development of environmental history over the last decades has not established a new paradigm nor has it closed the gap between science and the humanities. But, environmental history has raised important new questions; it has (re)introduced the topic of nature and the environment into historical studies, not only through specialist research, but especially by adding new perspectives to established areas and problems; and while it has not closed the gap to science, it has built many bridges. In short, environmental history has grown up. It will continue to flourish and make important contributions.

Environmental Justice

Despite significant improvements in environmental protection over the last quarter of the twentieth century, millions of Americans continue to live in unsafe and unhealthy physical environments. Hardly a day passes without the media discovering some community or neighborhood fighting a landfill, incinerator, chemical plant, or some other polluting industry. This was not always the case. In the 1970s, the concept of environmental justice had not registered on the radar screens of environmental, civil rights, or social justice groups. Nevertheless, it should not be forgotten that Dr. Martin Luther King, Jr. went to Memphis in 1968 on an environmental and economic justice mission for the striking black garbage workers. The strikers were demanding equal pay and better working condition. Of course, Dr. King was assassinated before he could complete his mission.

1. *Birth of a New Movement*

The national environmental justice movement emerged around the issues of fairness, social equity, and environmental protection. This new movement embraces the principle that all communities are entitled to equal protection and enforcement of environmental, health, employment, housing, transportation, and civil rights laws and regulations that impact quality of life. The environmental justice framework rests on developing tools and strategies to eliminate unfair, unjust, and inequitable conditions and decisions. The framework also attempts to uncover the underlying assumptions that may contribute to and produce differential exposure and unequal protection. It brings to the surface the *ethical* and *political* questions of 'who gets what, when, why, and how much' (Bullard 1996). The national environmental justice movement/framework has its origins in the United States of America.

1.1 *Definition of Environmental Justice*

Environmental justice is defined as the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment means that no group of people, including racial, ethnic, or socioeconomic groups should bear a disproportionate share of the negative environmental consequences resulting from industrial, municipal, and commercial operations or the execution of federal, state, local, and tribal programs and policies (US Environmental Protection Agency (EPA) 1998).

1.2 *Early Struggles*

Another landmark garbage dispute took place in Houston, Texas, a decade after the Memphis garbage strike. African–American homeowners in Houston began a bitter fight to keep the Whispering Pines sanitary landfill out of their suburban middle-income neighborhood. The residents formed the Northeast Community Action Group or NECAG. In 1979, NECAG and their attorney, Linda McKeever Bullard,

Figure 1
Summit delegates hold a rally on the steps of the nation's capital, Washington, DC, 1991 (Photo by R D Bullard)

filed a class action lawsuit to block the garbage facility from being built. The 1979 lawsuit, *Bean vs. Southwestern Waste Management, Inc.*, was the first of its kind to challenge the siting of a waste facility under civil rights law.

The landmark Houston case occurred three years before the environmental justice movement was catapulted into the national limelight in the rural and mostly African–American Warren County, North Carolina. The environmental justice movement has come a long ways since its humble beginning in Warren County where a hazardous-waste landfill ignited protests and over 500 arrests. This marked the first time Americans had been arrested protesting the siting of a waste facility.

The Warren County protests provided the impetus for US General Accounting Office to conduct an independent investigation. That study revealed that three out of four of the off-site, commercial hazardous waste landfills in Region 4 (which comprises eight states in the South) were located in predominantly African–American communities, although African–Americans made up only 20 percent of the region's population (US General Accounting Office 1983). Nearly 15 years later, the state of North Carolina committed over $25 million to cleanup and detoxify the controversial Warren County landfill.

The protests also led the Commission for Racial Justice (1987) to produce *Toxic Waste and Race*, the first national study to correlate waste facility sites with demographic characteristics. Race was found to be the most potent variable in predicting where these facilities were located—more powerful than poverty, land values, and home ownership or occupancy status.

1.3 The People of Color Summit

The 1991 First National People of Color Environmental Leadership Summit was probably the most important single event in the young movement's history. Held in Washington, DC, the 4-day Summit was attended by over 650 grassroots and national leaders from around the world. Delegates came from all 50 states including Alaska and Hawaii, Puerto Rico, Chile, Mexico, and as far away as the Marshall Islands (Fig. 1).

The Summit broadened the environmental justice movement beyond its antitoxics focus and demonstrated that it is possible to build a multiracial

grassroots movement around environmental and economic justice. On September 27, 1991, Summit delegates adopted 17 'Principles of Environmental Justice.' By June 1992, Spanish and Portuguese translations of the Principles were being used and circulated by NGOs and environmental justice groups at the Earth Summit and Global Forum in Rio de Janeiro.

2. Government Response

The federal EPA manages, regulates, and distributes risks. During its 30-year history, the EPA has not always recognized that many government and industry practices (whether intended or unintended) have adverse impact on poor people and people of color. In 1992, after meeting with community leaders, academicians, and civil rights leaders, the EPA (under the Bush Administration) admitted there was a problem, and established the Office of Environmental Equity. The name was changed to the Office of Environmental Justice under the Clinton Administration.

The agency produced *Environmental Equity: Reducing Risks for All Communities*, *a* comprehensive report that examines environmental justice concerns in low-income and people of color communities (US Environmental Protection Agency 1992). The EPA also established a 25-member National Environmental Justice Advisory Council or NEJAC under the Federal Advisory Committee Act. The NEJAC is comprised of stakeholders representing grassroots community groups, environmental groups, nongovernmental organizations, state, local, and tribal governments, academia, and industry.

2.1 Environmental Justice Health Symposium

In February, 1994, seven federal agencies, including the Agency for Toxic Substances and Disease Registry (ATSDR), National Institute for Environmental Health Sciences (NIEHS), Environmental Protection Agency (EPA), National Institute of Occupational Safety and Health (NIOSH), National Institutes of Health (NIH), Department of Energy (DOE), and Centers for Disease Control and Prevention (CDC) sponsored a national health symposium, 'Health and Research Needs to Ensure Environmental Justice.' The February conference was attended by more than

Figure 2
President Clinton signs Executive Order 12898, Washington, DC, 1994 (Photo by White House Press Office)

1,000 scientists, researchers, health professionals, educators, government officials, and community stakeholders.

Environmental justice leaders offered their own environmental protection framework. This framework adopts a public health model of prevention (i.e., elimination of the threat before harm occurs) as the preferred strategy, shifts the burden of proof to polluters/dischargers who do harm, who discriminate, or who do not give equal protection to people of color, low-income persons, and other 'protected' classes, allows disparate impact and statistical weight or an 'effect' test, as opposed to 'intent,' to infer discrimination, and redresses disproportionate impact through 'targeted' action and resources (Fig. 2).

2.2 Executive Order 12898

In response to growing public concern and mounting scientific evidence, President Clinton on February 11, 1994 issued Executive Order 12898, 'Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations.' The Order attempts to address environmental injustice within existing federal laws and regulations. It reinforces the Civil Rights Act of 1964, Title VI, which prohibits discriminatory practices in programs receiving federal funds. The Order also focuses the spotlight back on the 1969 National Environmental Policy Act (NEPA), a law to ensure for all Americans a safe, healthful, productive, and aesthetically and culturally pleasing environment (Council on Environmental Quality 1997).

3. Communities under Siege

A growing body of evidence reveals that people of color and low-income persons have borne greater environmental and health risks than the society at large in their neighborhoods, workplace, and playgrounds (Bryant 1995, Bullard 1999a, 1999b, 1999c, 2000, Stretesky and Hogan 1998). A recent study from the Institute of Medicine (1999) concluded that government, public health officials, and the medical and scientific communities need to place a higher value on the problems and concerns of environmental justice communities. The IOM study confirmed what most impacted communities have known for decades. People of color and low-income communities are (a) exposed to higher levels of pollution than the rest of the nation, and (b) experience certain diseases in greater numbers than the more affluent, white communities (Institute of Medicine 1999).

3.1 Unequal Protection

The *National Law Journal* uncovered glaring inequities in the way the federal EPA enforces its giant Superfund laws. White communities see faster action, better results, and stiffer penalties than communities where blacks, Hispanics, and other people of color live (Lavelle and Coyle 1992). Clearly, communities that are located on the 'wrong side of the tracks' are at special risk from exposure to environmental hazards. Race has been found to be independent of class in the distribution of air pollution, contaminated fish consumption, location of municipal landfills and incinerators, abandoned toxic waste dumps, polluting industries, and lead poisoning in children (Commission for Racial Justice 1987, Agency for Toxic Substances and Disease Registry 1988, Pirkle et al. 1994).

3.2 Childhood Lead Poisoning

Lead poisoning is the number one environmental health threat to children of color. Figures reported in the July 1994 *Journal of the American Medical Association* on the Third National Health and Nutrition Examination Survey (NHANES III) revealed that 1.7 million children (8.9 percent of children aged 1 to 5) are lead poisoned, defined as blood lead levels equal to or above 10 micrograms/deciliter. The NHANES III data found African–American children to be lead poisoned at more than twice the rate of white children at every income level (Pirkle et al. 1994). Over 28.4 percent of all low-income African–American children were lead poisoned compared to 9.8 percent of low-income white children. During 1976–1991, the decrease in blood lead levels for African–American and Mexican–American children lagged far behind that of white children.

In California, a coalition of environmental, social justice, and civil libertarian groups joined forces to challenge the way the state carried out its lead screening of poor children. The Natural Resources Defense Council, the National Association for the Advancement of Colored People Legal Defense and Education Fund (NAACP LDF), the American Civil Liberties Union, and the Legal Aid Society of Alameda County, California won an out-of-court settlement worth $15 million to $20 million for a blood lead-testing program. The lawsuit, *Matthews vs. Coye*, involved the failure of the state of California to conduct federally mandated testing for lead of some 557,000 poor children who receive Medicaid. This historic agreement triggered similar lawsuits in several other states that failed to live up to the federal mandates.

4. The Path of Least Resistance

The southern US has become a 'sacrifice zone' for the rest of the nation's toxic waste. Lax enforcement of environmental regulations has left the region's air, water, and land the most industry-befouled in the US. Louisiana typifies this pattern. Nearly three-fourths of Louisiana's population, more than 3 million people,

Figure 3
St. James Citizens for Jobs and the Environment and allies hold a press conference in opposition to Shintech's proposed polyvinyl chloride plant, Convent, LA., 1997 (Photo by Environmental Justice Resource Center)

get their drinking water from underground aquifers. Dozens of aquifers are threatened by contamination from polluting industries. The Lower Mississippi River Industrial Corridor has over 125 companies that manufacture a range of products including fertilizers, gasoline, paints, and plastics. Environmentalists and local residents have dubbed this corridor 'Cancer Alley' (Motavalli 1998, Bullard 2000).

4.1 Corporate Welfare

Louisiana is also a leader in doling out corporate welfare to polluters. Industries routinely pollute the air, ground, and drinking water while being subsidized by tax breaks from the state. In the 1990s, the state wiped off the books $3.1 billion in property taxes to polluting companies. The state's top five worse polluters received $111 million dollars over the past decade (Barlett and Steele 1998) (Fig. 3).

Subsidizing polluters is not only bad business, but it does not make environmental sense. A growing body of evidence reveals that 'states with lower pollution levels and better environmental policies generally have more jobs, better socioeconomic conditions and are more attractive to new businesses' (Templet 1995). Louisiana and other states could actually improve their general welfare by enacting and enforcing regulations to protect the environment.

4.2 Dumping on Native Americans

It should not be a surprise to anyone to discover that Native Americans have to contend with some of the worst pollution in the US (Tomsho 1990, Taliman 1992). Native American nations are prime targets for waste trading. More than three dozen Indian reservations were targeted for landfills, incinerators, and other waste facilities in the early 1990s. Native American groups and their allies defeated most of these waste proposals.

Racism operates in energy production (mining of uranium) and disposal of wastes on Indian lands (Churchill and LaDuke 1983). The practice has left many sovereign Indian nations without an economic

infrastructure to address poverty, unemployment, inadequate education and health care, and a host of other social problems. In 1999, residents of the Eastern Navajo reservation filed suit with the Nuclear Regulatory Commission to block a permit for uranium mining in Church Rock and Crown Point, New Mexico.

4.3 Transboundary Waste Trade

Hazardous waste generation and international movement of hazardous waste pose some important health, environmental, legal, and ethical dilemmas. Shipping hazardous wastes from rich communities to poor communities is a global problem. In the real world, all people, communities, and nations are not created equal. Unequal interests and power arrangements have allowed poisons of the rich to be offered as short-term remedies for poverty of the poor. This scenario plays out domestically (as in the US where low-income and people of color communities are disproportionately impacted by waste facilities and 'dirty' industries) and internationally (where hazardous wastes move from OECD states to non-OECD states).

The conditions surrounding the more than 2,000 maquiladoras, assembly plants operated by American, Japanese, and other foreign countries, located along the 2,000-mile US–Mexico border may further exacerbate the waste trade. The industrial plants use cheap Mexican labor to assemble imported components and raw material and then ship finished products back to the US. Nearly a half million Mexican workers are employed in the maquiladoras.

All along the Lower Rio Grande River Valley maquiladoras dump their toxic wastes into the river, from which 95 percent of the region's residents get their drinking water (Hernandez 1993). In the border cities of Brownsville, Texas and Matamoras, Mexico, the rate of anencephaly—babies born without brains—is four times the national average. Affected families have filed lawsuits against 88 of the area's 100 maquiladoras for exposing the community to xylene, a cleaning solvent that can cause brain hemorrhages, and lung and kidney damage.

The Mexican environmental regulatory agency is understaffed and not equipped adequately to address the problem (Barry and Simms 1994). Only time will tell if the North American Free Trade Agreement (NAFTA) will 'fix' or exacerbate the economic, public health, and the environmental problems along the US–Mexico border.

5. Conclusion

The environmental justice movement emerged in response to environmental and social inequities, threats to public health, unequal protection, differential enforcement, and disparate treatment received by the poor and people of color. The movement redefined environmental protection as a basic right. It also emphasized pollution prevention, waste minimization, and cleaner production techniques as strategies to achieve environmental justice for all Americans without regard to race, color, national origin, or income.

The poisoning of African–Americans in Louisiana's 'Cancer Alley,' Native Americans on reservations, and Mexicans in the border towns all have their roots in a system characterized by economic exploitation, racial oppression, and devaluation of human life and the natural environment. Unequal political power arrangements have allowed poisons of the rich to be offered as short term economic remedies for poverty and unemployment. Having industrial facilities in one's community does not automatically translate into jobs for nearby residents. Similarly, tax breaks and corporate welfare programs have produced few new jobs by polluting firms.

The environmental justice movement has established clear goals of eliminating unequal protection. This call for environmental and economic justice does not stop at the US borders but extends to communities and nations that are threatened by the export of hazardous wastes, toxic products, and 'dirty' industries. Environmental justice leaders are demanding that no community or nation, rich or poor, urban or suburban, black or white, should be allowed to become a 'sacrifice zone' or dumping grounds. They are also pressing governments to live up to their mandate of protecting public health and the environment.

Environmental Planning

For millennia, humans have realized the importance of conserving important natural resources and minimizing the damage that their activities cause to the natural environment in which they live. They have followed two broad strategies to protect environmental resources and reduce or eliminate these impacts. The first is to shape land use patterns so as to protect people against natural hazards such as floods, to prevent inappropriate consumption of natural resources, and to segregate or locate appropriately activities that pollute the environment. The second is to control emissions or discharges directly.

Environmental planning embraces those activities of government agencies and private organizations whose primary purpose is to manage the impacts of the human use of land on the natural environment, by taking thought for the future and choosing courses of action that promote appropriate goals. In parallel with environmental planning, environmental pollution control, usually in the form of media-specific laws such as the United States' Clean Air and Clean Water Acts, seeks to control discharges, emissions, and environmental pollution in general by a variety of means, the most important of which will be summarized below. While obviously important, cultural, social, psychological, and economic considerations are not the focus of environmental planning.

Because of the scope and complexity of the activities it addresses and their far-reaching and variable impacts, the field of environmental planning defies easy definition. Furthermore, conceptions of the relationships between humanity and the environment change over time, so that the character, goals, methods, and, indeed, the ethical foundations of environmental planning, are continuously evolving. At the beginning of the twenty-first century environmental planners carry out such varied responsibilities as analysis of the natural environment as a component for comprehensive plans; the preparation of environmental impact statements for governmental programs; the drafting of plans for recreational areas, parks, and other types of open space; and the development policies for the protection of prime farmland, wetlands, flood plains, and other natural resource areas.

1. *Brief History of Environmental Planning*

Although the term 'environmental planning' is of relatively recent origin, humankind has undertaken the activities it now embraces for millennia. At least five thousand years ago, the earliest urban civilizations—the 'hydraulic' societies of Sumer, Egypt, and the Indus Valley—undertook major programs to harness natural forces. Large-scale irrigation projects provided the water needed to supply the broad agricultural foundation on which the urban civilizations were built. Certainly, the Romans engaged in a substantial amount of what we would today include in environmental planning as they built extensive public works, such as the dams, reservoirs, aqueducts, and sewerage systems that served their far-flung cities.

In Islamic cities from Morocco to Iran, abattoirs, tanneries, and textile dyeing operations were relegated to the outer, downstream, edges of the medina (the old city), far from the Grand Mosque, the central souk (market), and the principal residential areas. Across the Islamic world after the seventh century, gardens were associated with paradise, and many palaces contained elaborate gardens that gave their owners respite from the harshness of the climate. Superb examples such as the fourteenth century Alhambra palace of the Nasrid caliph, Yusuf I, in Grenada, Spain, (Hoag 1977), are creations that fall within the broad definition of environmental planning.

In eleventh- and twelth-century Europe, after a long hiatus following the collapse of the Roman Empire in the fifth century, Italian cities adopted municipal codes that regulated both the disposal of wastes (forbidding, for example, their discharge within the town) and the number and location of pollution-generating activities (Zupko and Laures 1996). A growing interest in nature found expression in the Renaissance gardens of Florence, Rome, and Tivoli (McHarg 1992). Here, in the sixteenth century, artists such as Bramante, Raphael, and Palladio imposed a simple geometry on the forms of nature. A century later, landscape gardeners such as André Le Nôtre developed formal Baroque gardens at Versailles and Vaux-le-Vicomte, that 'testified to the divinity of man and his supremacy over a base and subject nature' (McHarg 1992). A strongly divergent tradition developed in England in the eighteenth century. Landscape gardeners such as Lancelot 'Capability' Brown and William Kent created the famed English landscape for their aristocratic clients, a setting for their manor houses that appeared natural but was as much an artifice of the human mind as the formal gardens of Paris and Rome (McHarg 1992). Nature and its forms became something to be respected and idealized.

In the nineteenth century, interest in public health mounted, especially in the link between sewage discharges from rapidly growing cities, pollution of their water supplies, and outbreaks of typhoid and dysentery. Many major cities undertook the construction of public water supply and sewerage systems. In 1872, responding to a growing interest in the conservation of critically important natural areas, during the administration of President Grant, the United States created Yellowstone National Park, the first in what was to become an impressive system of parks. Frederick Law Olmsted designed a number of parks, the best known of which is Central Park in New York City.

The American city planning movement, which began in the early twentieth century, drew inspiration from the public health, housing, and City Beautiful movements, and from early German efforts to zone land according to its most appropriate land use. But it was concerned more with the management of new development than it was with the moderation of human impacts on the natural environment and the conservation of natural areas. Environmental concerns took a back seat during World War I, the Roaring Twenties, the Depression, World War II, and the reconstruction and normalization years immediately thereafter. After World War II, Aldo Leopold called for a new kind of ethic that called on humankind to serve as the steward of nature, not its sovereign (Leopold 1949), and in 1962 Rachel Carson's *Silent Spring* fired the American imagination with her chronicle of the devastation that country's profligate waste disposal, pesticide use, and weak environmental policies were wreaking on its environment (Carson 1962). Ian McHarg, winner of the prestigious 1999 Japan Prize for City Planning, argued eloquently and persuasively that plans for the development and redevelopment of rural and urban areas must be based on a comprehensive inventory of ecological data that presents a complete picture of the geological, hydrological, pedological, limnological, physiographic, climatological, and biological systems in the area that is the subject of the plan (McHarg 1992).

It was not until the 1960s and the early 1970s that a newly felt concern for the environment, and a deepening awareness of the damage that humankind was inflicting on it, resonated with something deep in people's souls. This found expression in the United States and across the world, in the enactment of a substantial body of environmental protection laws. More than in any preceding era, public and private decision-makers have been called upon to take into account the environmental impacts of the various policies and infrastructural systems they propose.

2. *The Intellectual Context of Environmental Planning*

At the beginning of the twenty-first century, environmental planning lies at the juncture of two major fields of policy formulation and implementation: comprehensive growth management and environmental pollution control.

Comprehensive growth management seeks to advance a broad spectrum of goals and objectives. It addresses the location, density, use, height and bulk, and phasing or timing of urban development and redevelopment, and the provision of various infrastructural systems. At the same time, it seeks to protect critically important natural resources, such as farmland, flood plains, marshes, and other areas of critical ecological concern. Since 1970, nation after nation and governmental jurisdiction after governmental jurisdiction have come to recognize that any effort to manage urban and regional development and redevelopment must be grounded in an understanding of the natural environment within which they are occurring. Comprehensive planning takes into account the underlying geology of the area, the impact of proposed development on ground water, rivers, lakes, wetlands,

and coastal waters, the impact of manufacturing and transportation activities on air quality, the effects of urbanization on the natural biota, the impacts of suburban development on the supply of prime agricultural land, and the effects of solid and liquid waste disposal on the natural environment. Environmental planning is a key component of comprehensive growth management.

Environmental pollution control policies are broadly concerned with air, water, and earth pollution, and such global problems as loss of biodiversity, global warming, and depletion of the stratospheric ozone level. Decades of contemporary efforts to protect the environment and reduce environmental pollution have confirmed that humanity and the natural environment are interdependent. Changes in the natural environment can cycle back and cause serious harm to mankind. Transportation, land development, and land use affect environmental quality, whether it be by covering over wetlands, changing the hydrological characteristics of watersheds so as to increase flooding and aggravate drought conditions, converting farm land to residential developments and shopping centers, or creating automobile-dominated transportation systems that generate a major proportion of dangerous environmental pollutants. Environmental pollution controls often include the management of land development and the design of transportation systems so as to reduce pollution. Environmental planning, the management of land development, and the design of transportation systems are key components of environmental pollution control.

3. *Emphasis in Current Theory and Research*

In the field of environmental planning, there are a number of areas of research that are attracting interest from academics and practitioners.

3.1 *Research on the Scientific Basis of Environmental Planning*

Considerable work is being done in the natural sciences and ecology to strengthen the scientific underpinnings of an effective environmental planning effort. Some subjects are fairly specific, such as determining a river's flood plains for differing flood recurrence intervals, or developing more cost-effective ways to clean polluted industrial sites. Others are much broader, such as determining whether the global warming that the world is currently experiencing is the cause of the rise in atmospheric carbon dioxide concentrations, or vice versa, and determining the nature and probability of the effect of various hazardous materials on the human body.

3.2 *Implementing Environmental Planning*

Environmental planning embraces more than the various studies that environmental planners perform in the process of preparing a comprehensive plan. It includes a careful assessment and selection of the most appropriate strategies of implementing the various goals of environmental planning and protection. Among the most important, with examples from the American experience, are:

3.2.1 Strategies based on disclosure. Environment assessment and impact statements such as those mandated by the United States' National Environmental Policy Act of 1969 (NEPA), and numerous state counterparts, with respect to major governmental programs have a significant effect on the environment. This enables affected governmental agencies and citizen groups to find out about proposed actions and to assert their influence to modify their outcome.

3.2.2 Strategies based on increased intergovernmental coordination, often accompanied by greater public participation in the decision-making process. For instance, the American Intergovernmental Coordination Act and NEPA call for collaboration among the various governmental agencies with responsibilities in a particular region.

3.2.3 Command and control strategies. These approaches have long been the workhorse of environmental planning and protection. A government establishes a regulation that restricts private activity, such as a flood plain zoning ordinance or a statute seeking to reduce air pollution by setting permissible emission levels. This regulation sets a standard with which the private actor must comply, and then applies sanctions to those who violate the standard. Command and control strategies may take a number of forms, from simply specifying certain environmental standards, to controlling market access, to prohibiting certain kinds of actions, to requiring that firms internalize formerly externalized environmental costs.

3.2.4 Strategies based on market-based incentives. Many American jurisdictions have experimented with techniques that seek to influence private actors' behavior by providing economic incentives or disincentives that induce citizens to change their behavior simply because it is more profitable. 'Transferable

development rights' (TDR) systems allow landowners whose land has been severely regulated to sell to other landowners the right to build at somewhat higher density than they would be permitted to without the TDRs (see Sect. 3.4). Also, the 1990 amendments to the United States' Clean Air Act established a system for trading emissions allowance for oxides of sulfur (SO_x) and nitrogen (NO_x) that permits electric utilities to meet statutory requirements either by reducing their emissions by installing more effective air pollution control devices or by buying emission rights from other producers, whose emissions are well below their assigned level (see Sect. 3.4). Finally, many nations have created tax incentives that seek to increase after-tax income of individuals and companies that engage in conduct that is either environmentally protective or environmentally enhancing.

3.3 Sustainability

The 1989 Report of the World Commission on Environment and Development (The Brundtland Commission) proposed a summary definition of sustainable development: 'development that meets the needs of the present without compromising the ability of future generations to meet their own needs.' This oft-quoted exemplary statement articulates the basic principle that we should live off the income of our natural capital and not consume non-renewable resources in a profligate manner. As such, it focused heavily on the natural environment and called for a policy of wise stewardship of the world's natural resources and a reduction in the amount of pollution that humankind was discharging into the environment. The concept of sustainability has since been expanded to include profound social, political, and equitable considerations, such as (Newman and Kenworthy 1999; see also, Beatley and Manning 1997):

(a) 'The elimination of poverty, especially in the Third World, is necessary not just on human grounds, but also for environmental reasons.' Third World economic and social development, with the attendant reduction in rates of population increase and a reduction in international strife, is a necessary prerequisite for achieving a just and balanced steady world state.

(b) 'The First World must reduce its consumption of resources and the production of wastes.' First World citizens consume many times as many natural resources and discharge much greater amounts of pollutants into the environment than do their Third World counterparts. If Third World standards of living are raised without a corresponding lowering of the material consumption of the First World, the effects on the environment will be devastating.

(c) 'Global cooperation on environmental issues is no longer a soft option.' We have already recorded potentially irreversible changes in the environment, such as the loss of a number of species and a decrease in biodiversity, and the reduction in the stratospheric ozone layer. One respected scientist has predicted that, unless we drastically change our policies toward tropical rain forests, as many as one-quarter of the world's species will have become extinct by the year 2020 (Wilson 1992). Humanity must make difficult decisions or risk devastating systemic changes in the environment that could well lead to the extinction of the human race.

(d) 'Change toward sustainability can occur only with community-based approaches that take local cultures seriously.' Many of the activities that have adverse impacts on the environment are managed locally, so that local environmental planning strategies comprise a critical and fundamental element of a policy that moves toward sustainability.

The growing recognition of the central importance of achieving a policy of sustainable development so that human activities do not irretrievably disrupt basic ecological systems is reflected in the creation of governmental institutions such as the United States' President's Commission on Sustainable Development and in numerous United Nations and international conferences, such as the Rio Declaration, coming out of the United Nations Conference on Environment and Development in Rio de Janeiro in 1992.

More and more, environmental planning will be premised on principles of sustainable development at all scales. For instance, the automobile-based urban sprawl that characterized late twentieth-century urban development in many countries is profligate in that it consumes much more prime farmland and areas of critical environmental concern than a more compact, mass-transit-oriented pattern of development would. It requires the use of resources to construct new infrastructure systems, at the periphery of our metropolitan areas, while under-utilizing the installed capacity that already exists in our inner cities. Here environmental plans are critical components of comprehensive growth management systems for designing and creating new urban communities.

3.4. Market-based Incentives: Economic Dimensions of Environmental Planning

Another area that is the subject of considerable research and experimentation is the realignment of economic incentives to encourage actions that conserve the environment and discourage actions that damage it. At the national and international scale, analysts such as Daly and Cobb (1989) and Repetto and McGrath (1989) advocate the revision of the system of national accounts that is used to determine gross domestic product. Late twentieth-century practices do not create national capital asset accounts that

include natural resources, such as forests, minerals, and prime agricultural land. Nor do they depreciate these assets when timber is harvested, minerals extracted, or rich soil lost to erosion. Instead, the wood, coal, iron ore, and other raw materials are registered as income when they are sold, with no corresponding entry for the draw down in the capital asset. This is in stark contrast to buildings and other man-made capital assets, which are depreciated each year because their cost is an important input into production. Other proposals include the imposition of 'green taxes' on activities that pollute the atmosphere. The idea is to shift the incidence of major taxes from 'goods,' such as income and real property, to 'bads,' such as environmental pollution and energy derived from nonrenewable natural resources (Hawken 1993). Along the same lines is the successful American program for reducing emission of oxides of sulfur and nitrogen by large electric power generating plants by setting up a market on which emissions allowances for these pollutants may be traded. In an effort to introduce more decisional flexibility than has been possible under traditional 'command and control' methods of regulation air emissions, the US Environmental Protection Agency assigned each of some 111 utilities in the Midwest and East regions of the country a maximum emission level of tons of SO_x and NO_x per million BTUs of energy produced. If a company was able to reduce its emissions below the prescribed level, it could sell the balance of its permissible emissions to a company that was producing more than its allotment, permitting the latter to exceed that level by the amount of the emissions purchased. The program introduces decisional flexibility because plant managers are enabled to calculate the most efficient way to meet tightening environmental standards. This program has been widely credited with making it possible for electric utilities to reduce their emissions of these two pollutants by more than 50 percent in the ten years since the program was set up. The 1997 United Nations Framework Convention on Climate Change at Kyoto produced a Protocol that proposed to apply these ideas to emissions of carbon dioxide and other so-called 'greenhouse gases,' in an effort to address the build-up of these gases in the atmosphere.

In the field of environmental planning, TDR programs, which exhibit certain similarities to the trading of emission allowances of SO_x and NO_x, have been used in a number of jurisdictions to protect prime farmland and areas of special environmental significance, such as flood plains, beaches, and marshes. The local government imposes zoning limitations on key land such as farmland or flood plains that reduce the density at which they may be developed and then assigns the owner a certain number of development rights, usually calculated on a per acre basis. The owner may sell these rights to a developer who owns property in an area where the government wishes to encourage more dense development. The developer will be able to develop at a higher density than would have been possible, had he not purchased the TDRs.

The general objective of these market-based incentives is to shift from primary reliance on the command and control system of managing urban growth and protecting environmental resource lands to an approach that uses economic incentives and disincentives to encourage environmentally beneficial activities, and discourage activities that despoil the natural ecosystem.

3.5 Environmental Justice

Another dimension of environmental planning that has long been of concern but has become more central in the last decade or so—and also adumbrated in the *Brundtland Report*—is that of equity: Are the environmental benefits and burdens of particular projects distributed evenly throughout the various segments of society? Or do the benefits tend to accrue to the more prosperous and powerful, and the burdens to the poor and those citizens who are members of disadvantaged minority groups? At the local level, this may involve the decision to locate a trash-to-steam plant near a poor African–American community. At the international level, it may concern the construction of a major waste tire disposal facility or of a 'ship-breaking' operation in a developing country that is in desperate need of international exchange.

Considerations of environmental justice lead to determining the range of the detrimental impacts from a proposed project, and then defining the various communities that exist within that range. If all or most of the people within the range are poor or members of minority groups, the actor should seek alternatives.

Environmental Policy

1. *History and General Characteristics of Environmental Policy*

1.1 *History*

For as long as people have been altering their environment, they also have been polluting and depleting their natural resources. A striking historical illustration of the links between population growth, economic needs, and environmental change concerns the immense degradation of forests since the twelfth century in Europe to meet the timber supply for an increasing population. Only in the eighteenth century, in response to the devastating effects of the overexploitation of forests, was the concept of sustainable development formulated, with a view to the future need for a regular supply of timber and the preservation of the other functions of the forest.

In the twentieth century, international environmental policy evolved over several periods, reflecting the state of the environment, changes in political consciousness of the environment, the development of scientific knowledge, the application of technologies, and the changing structure of the international legal order. From the 1930s through the 1960s, a science-based literature gradually evolved which laid the foundation for political action in the field of environmental protection. In 1962, Rachel Carson published *Silent Spring*, an attack on the indiscriminate use of pesticides and a call for a change in the way humankind viewed the natural world. The book attracted immediate attention and contributed to a heightened public awareness of an endangered environment. Carson's research focused on the indiscriminate spraying of pesticides like DDT. As a result of her writing, DDT was banned as an insecticide in the USA and in most countries of the world. Today, the book is rightly considered a milestone in the history of environmentalism which has influenced modern thinking far beyond DDT. In 1970, a new awareness of the place of humankind in nature, of the sensitivity of nature, and of human responsibility, culminated in what may be considered the first systematic modern legislative and institutional response to the growing environmental challenge, being the National Environmental Policy Act (NEPA) by the US Congress and the establishment of the Environmental Protection Agency (EPA). Key initiatives of environmental policy date from the late 1960s and early 1970s when public demonstrations and riots were on the agenda in industrialized countries and when environmental pollution had become a major public health concern, initially because of the new phenomenon of acid rain in North Europe. These years of public unrest and distrust witnessed a slow erosion in 'business as usual,' and the rising call for 'the conservation of nature' soon led to the chaotic birth of the first green parties in Europe and, at the global level, led to the UN Conference on the Human Environment (so called Stockholm Conference) of 1972—the beginning of the active period of international environmental policy with new insights into the relationship between human society and the earth's natural capital. The Stockholm Conference set the scene for novel international activities at the global and regional level and also influenced legal and institutional development. In 1973, the United Nations Environmental Programme (UNEP) was created as the central environmental focal point in the United Nations, and other international organizations slowly followed suit and presented environmental protection concepts of their own, as did for example the Food and Agriculture Organization of the United States (FAO), World Health Organization (WHO), World Meteorological Organization (WMO), United Nations Educational, Scientific and Cultural Organization (UNESCO), and the World Bank.

1.2 *Characteristics of Modern Environmental Policy*

Knowledge of the impact of humankind on the natural world has grown rapidly since the emergence of the term 'environment' in the early 1960s. The emission and impact of sources of pollution became more understood, and new sources of pollution were discovered slowly. Ecology as a science was now regarded seriously by most scientists and the public. During the 1970s, the volume and influence of ecological studies increased, and new technologies to investigate the environment were developed, such as radar to observe the earth's surface. In the 1980s, purely scientific matters began to acquire a political dimension. Regional and global environmental threats became part

of the international community agenda as scientific evidence identified the potential consequences of climate change, ozone depletion, and loss of biodiversity. Local issues, like the forest destruction in the tropics or desertification, were recognized to have transboundary or even global consequences for mankind.

While the substance of environmental policy formulation is largely dominated by science, political essence is often characterized by the delay between cause and effect.

Environmental issues, like the ongoing dramatic forests losses, the increasing emission of greenhouse gases, and the loss of biological diversity call for *long-term strategies* in the field of environmental policy. The dimension of time is relevant for both international and national environmental policy. The experiences of the last few decades of the twentieth century demonstrate that democratic governments are better equipped to deal with long-term issues than authoritarian or totalitarian regimes. But political democracies as well as market economies may themselves be guided by parameters and values that make only limited allowance for long-term aspects for the sake of short-term concern for voting results or shareholder value. In practice, party leaders need to determine exactly what balance should be struck between quick successes and effective long-term policies. Environmental consequences of economic or social policies do not necessarily affect those persons or generations who enjoy its immediate benefits, and the momentary intangibility has given rise to the call for intergenerational equity and sustainable development. Political action to address these concerns has, moreover, to deal with the fact that science is not always clear on cause and effect of environmental degradation.

Originally conceived by German forest managers in the eighteenth century, the notion of *sustainable development* was highlighted in the final report by the World Commission on Environment and Development ('Brundtland Report' 1987) as 'development that meets the needs of the present without compromising the ability of future generations to meet their own needs.' The concept of sustainable development evades precise definition; in essence, it highlights two primary policy concerns of environmental policy: the integrated consideration of environmental, economic, and social issues and the expectation that policymakers will strike a fair balance between the interests of present and future generations (intergenerational equity). Having made numerous appearances in international treaties and other instruments, sustainable development is today firmly accepted as the key concept of international environmental and development policy. A single operational-oriented definition of the concept is impossible in view of the diversity of social, economic, and cultural conditions prevailing in each individual state. On the international level, the key challenge of environmental policy today lies in the ongoing search for a workable and effective consensus on the meaning of sustainable development which reflects the realities of both industrialized and developing states.

2. *Areas of Environmental Policy*

In terms of their origin and their effect, environmental problems may be divided into local and regional, international, and global issues. Such distinctions neglect that all sources of pollution and degradation originate form one local point, but they are useful in considering and formulating appropriate policy responses on local, regional, and global levels.

The thematic issues and areas of environmental policy are diverse and faceted.

(a) Global climate change is one of the greatest environmental challenges. For the most part, the increase of the concentration of greenhouse gases in the troposphere and the artificial warming of the earth's atmosphere seems to be due to human activities, including particularly fossil fuel use, land use change, and agriculture. The overwhelming weight of scientific authority predicts an alarming increase in temperature of about 1.4 °C to 5.8 °C by 2100 relative to 1990 and a rise of the average sea level of between 9 cm and 88 cm by the year 2100. Such changes would entail grave consequences for economies, the environment, matters of health, and food production.

(b) The accelerating decline of many of the world's forests represents another great problem facing the global community. The increasing human needs of a growing population in the developing countries, agricultural expansion, overharvesting of industrial wood and fuelwood, unsustainable commercial logging, forest fires, air pollution, overgrazing, pests, and diseases cause the ongoing massive forest destruction today, mainly in the tropics.

(c) The extinction and ecosystem destruction goes along with a relatively unknown loss of biodiversity. It is recognized that between 50 percent and 90 percent of all species currently in existence dwell in tropical forests. The global loss of species and natural habitat is proceeding at an alarmingly fast rate, with unknown but potentially disastrous future consequences.

(d) Another major issue concerns soil degradation which has affected about one-third of the world's agricultural soils and which often leads to desertification. Deserts account for about 7 percent of the earth's total land surface; the livelihoods of over 1 billion people in more than 100 countries are jeopardized by desertification, as farming and grazing land becomes less productive.

(e) Local and regional problems of the pollution of air and water have in part been addressed with success in industrialized states in the past decades, but continue to grow in most parts of the developing

world, in particular in the still growing number of megacities.

(f) The main pressure on land use is caused by an expanding economy and the demand for food by a growing population. Global food demand is expected to increase by 50 percent by 2015 and by more than 110 percent by 2050, with further pressure on the remaining nondomesticated areas worldwide.

(g) High population growth, the ongoing industrialization, and improving standards of living contribute to a higher demand for fossil energy. In the developed countries, energy use per capita is already extremely high and continues to increase slowly, and the much smaller developing nations' share of commercial energy consumption is expected to increase to nearly 40 percent by 2010. Energy consumption in the transportation sector is also expected to grow in both the developed and the developing countries as higher incomes will lead to a rising number of private cars in use. Energy consumption leads both to local and global problems of air pollution.

(h) Not only the earth's land surface, but also the oceans are threatened by ecological damage. The main environmental concerns to international waters stem from water quality degradation and overexploitation of marine resources. Land-based human activities cause 70–80 percent of the marine pollution and constitute a serious problem especially in coastal zones which provide 90 percent of the world's fishing catch and where 75 percent of the world's population live.

(i) The disposal and transport of industrial and domestic hazardous waste is another main problem on the national and international environmental agenda; many industrial products and chemical wastes are either nondegradable or difficult to dispose of.

(j) The development of modern tourism is characterized by a notable diversification in the location of new tourism destinations, particularly in Asia, North Africa, Latin America, and the Caribbean, with the result not only of economic growth, but also of an increasing environmental degradation in these regions.

3. *Instruments of Environmental Policy*

The aim of environmental policy interventions through different kinds of instruments is to correct failures or to control specific behavior in achieving society's environmental goals.

3.1 *Constitutional Provisions*

Constitutional provisions to protect the environment are an instrument of national environmental law, like Art. 20a of the Basic Law of the Federal Republic of Germany, introduced in 1994. Art. 20a provides that 'pursuant to its responsibility for this and future generations, the State shall protect the natural basis of human existence by legislation within the framework of the Constitution, and by the exercise of its executive and judiciary powers.' This rule establishes the protection of the environment as one of the goals of the State, although is does not accord any rights directly to the citizen.

3.2 *Command-and-control Approaches*

Two major kinds of tools are available for environmental policy: on the one side the more reactive command-and-control approaches (CAC) and on the other side preventive market-based instruments that create economic incentives not only for industries but also for private persons to reduce harm to the environment. Governments have traditionally employed CAC regulations in the 1970s and 1980s. This approach was subsequently reconsidered when economic studies pointed out that CAC regulations are often cost-ineffective, inflexible, and of limited efficacy. In particular, the private sector lacks an incentive to invest in developing a new and better control technology or strategy when the government dictates flat CAC rules.

3.3 *Market-based Instruments*

Limited inefficiency of CAC-regulations and the need to stimulate polluter's self-interest in the search for environmentally useful innovations have resulted in the development of alternative instruments achieving a better integration of economic and environmental decision making on a political and/or legal basis. The so-called market-based policies allow private industry and markets to remain relatively free in choosing the most efficient means of achieving environmental goals, and market incentives provide for increased flexibility and cooperation between government and industry; nevertheless, market-based-instruments require at least government supervision. Various types of market-based policies exist today.

Emissions trading was introduced in 1968 in the USA, and the attitude and perception towards tradable allowances among policymakers have since evolved; this concept allows a polluter to benefit from the results of a more effective actor in the same branch by way of paying for his additional effort. The interest in emissions trading especially for controlling greenhouse gases has grown during the 1990s, greatly influenced by the successful establishing of a tradable permit system to control sulfur dioxide and ozone-depleting substances in the USA. A special trading system for greenhouse gases is now envisaged in Art. 17 of the Kyoto Protocol (1997) to the UN Convention on Climate Change. The basic idea of emissions trading is simple. Each participant is subject to an allowed level of emission, and he is allowed to exchange parts of his emission allowances with another entity. Economically, emitters with low abatement costs will reduce emissions and sell their excess allowance, whereas polluters with high abatement

costs will prefer to buy them. The allowable emission total can be reduced over successive time periods. The Kyoto Protocol allows for two other types of flexible market-based innovations, namely Joint Implementation among industrialized countries and projects in developing states governed by the the so-called Clean Development Mechanism.

Another approach to promoting pollution prevention relies on *voluntary self-commitments* by industry, such as the voluntary self-commitment of European car manufacturers to achieve reductions in fuel consumption. Such voluntary programs are faster to implement than regulations and may produce faster reductions. The quantitative assessment of voluntary programs is still difficult partly due to the fact that these programs are still new.

Market incentives can also come from *positive subsidies* for environmental purposes, in forms of grants, soft loans, tax allowances, or special environmental taxes (so-called 'eco-taxes') levied on products that are harmful to the environment when they are used in the production process, consumed, or disposed of. At the same time, subsidies granted for other than environmental reasons often result in the degradation of the environment. Below-market financing costs for some electricity infrastructure, tax preferences for oil and mineral extraction, agricultural commodity price programs or tax preferences for private vehicle transport will in effect harm the environment if they support measures which encourage the emission of environmentally harmful pollutants, the generation of waste, and the excessive use of natural resources. In consequence a debate to reduce or to eliminate such subsidies has begun, so far without major effect on state practice. The financial consequence of environmental policies for the public budget rightly often dominate public debates about environmental reform, and the reduction of subsidies provides an important response to such budgetary concerns.

The *environmental impact assessment* may today be called a classical instrument. It provides for a systematic check procedure for relevant public or private projects, e.g., for the construction of power stations, airports, motorways, but also for some agricultural or infrastructural projects. Such assessments are intended to provide the governmental authorities and the private entrepreneurs with better environmental information about the consequences of a project in the planning stages.

3.4 Neoliberalism and Environmental Policy

The paradigm of economic neoliberalism raises hopes for more prosperity, but it also raises questions concerning the protection of the environment. The call for a lean state allows for and fosters a liberal economy which has dominated national and international debates in the 1990s and has been reinforced by the globalization of the economy. Inasmuch as free markets by themselves do not price negative environmental effects, economic neoliberalism will have to be combined with governmental or intergovernmental structures equipped and authorized to gather sufficient information and to exercise sufficient authority to protect the environment as a public good. This holds true, in principle, for the national and for the international level.

4. Principles of International Environmental Relations

In addition to substantive legislation describing in concrete terms the rights and obligations of the subjects of national or international environmental law, the international implications of environmental issues are reflected in a large number of principles, rules, or purely political goals which are still under development.

4.1 Sovereignty Over Natural Resources

Environmental issues do not respect national boundaries. Thus, environmental issues pose new challenges for state sovereignty, which is traditionally defined as affirming the independence of states in deciding about their own affairs, including their choices to define policies on the natural environment within their territory. Therefore, sovereignty over natural resources implies the right of a state to protect, but also to pollute or even to destroy the environment on its own territory. However, this right ends where environmental degradation is no longer restricted to the national territory and activities within one state's jurisdiction adversely affects conditions in another state. The obligation to protect the rights of other states within their own territory is generally accepted as a maxim of international law and frequently quoted in international environmental protection conventions and declarations, for instance as principle 21 of the Stockholm Declaration.

With regard to contemporary environmental problems with no single identifiable source like ozone depletion, global warming, polluted waters, eroding soils, loss of forests, and biodiversity, states have to assume responsibility not only for the ecological well-being of their own territory, but also of the earth's ecosystem. Thus, sector-specific regimes are developed among states which recognize that it is in the national interest to address jointly issues of global and regional environmental management.

4.2 Common but Differentiated Responsibility

Without disregarding the fact that efficiency in environmental protection can be achieved only by joint effort and obligation, the principle of common but

differentiated responsibility reflects the fact that industrialized nations and developing countries differ both in their responsibilities and capabilities. Many problems now existing in the field of environmental protection have arisen solely as a consequence of industrial production of the developed countries. Because developing countries are at an earlier state in the development process, they now insist on pursuing their own economic and social development, which includes polluting the environment in a manner formerly practiced by those states which today count among the industrialized nations. Thus, integration of developing states into global environmental regimes remains one of the key issues in designing international environmental policies.

In view of a potential conflict between economic necessity and ecological responsibility, a number of provisions in international treaties concerning environmental issues take into account the special situation and particular requirements of developing countries; in concrete, the relevant rules typically address issues of technology transfer and funding. For the time being, the principle of common but differentiated responsibility is a purely political concept, reflecting practical conditions and options without being legally binding.

4.3 Scientific Uncertainty and the Precautionary Principle

Decisions on international environmental issues have to be taken in the face of scientific uncertainty: new scientific information can either confirm the assessment of risks or determine a less serious risk than estimated. The precautionary principle requires that a nation shall take measures to prevent environmental degradation even while there is a lack of full scientific knowledge. While originating in the context of the marine environment, the precautionary principle is now being applied to nonmarine issues such as the ozone depletion and climate change. One of the first texts to mention the precautionary principle was the preamble to the Convention for the Protection of the Ozone Layer; in the Rio Declaration it is embodied in principle 15. Although the precautionary principle appears in a number of international declarations, its basis and scope remain controversial. The growing practical acceptance of the concept was reflected in the successful negotiation of the Biosafety Protocol to the Biodiversity Convention in 2000.

4.4 Preventive Principle

The principle of preventive action states that it is much more effective to prevent pollution than to remedy its effects or to assign liability for environmental damage. Therefore, states are obligated to take measures designed to protect the environment early enough to keep environmental harm from occurring. The preventive approach has been endorsed *inter alia* by the 1972 Stockholm Declaration, the 1982 World Charter for Nature, and in a large number of international treaties. Principle 11 of the 1992 Rio Declaration calls on states to enact 'effective environmental legislation.' Not only incorporated into specific environmental treaties, but also into treaties of more general application, such as the European Community Treaty (ECT), the preventive principle involves the obligation constantly to take into account environmental concerns in all area of governmental activity and control. Instruments like early-warning systems, risk assessments and stronger monitoring provisions reflect the anticipatory approach. Despite differences in national legal systems, it will be of elementary importance to ensure that these principles are implemented in every state in a manner sufficiently efficient to benefit the environment.

5. International Environmental Law

5.1 Global Issues

International environmental issues have increasingly burdened national governments and the factual degradation of the environment poses serious problems for the maintenance of national sovereignty. International policies to respond to such degradation reflect this factual situation, and in the long run the deliberate acceptance of the restriction of national sovereignty by way of acceptance of international agreements may be more advantageous from the vantage point of national freedom than insistence on national legal sovereignty and the absence of binding agreements. This paradox of environmental policy, however, remains to be universally understood and accepted.

A period of international environmental law began with bilateral fisheries treaties in the nineteenth century to halt overexploitation; yet practical effects were narrowed by emphasis only on border-related environmental problems. Early attempts to develop international environmental rules focused on the conservation of rivers and seas and the conservation of wildlife; the first whaling convention was adopted in 1931. The second phase in the development of international environmental policy was marked by the creation of the UN and the specialized agencies in 1945. Subsequently, international organizations on the regional and global level slowly began to address environmental issues, and the new range of environmental concerns included a focus on the causes of pollution resulting from certain ultrahazardous activities. However, recognition of the relationship between economic development and environmental

protection hardly existed. Nevertheless, growing policy concern over environmental protection prompted not only new actions on the local and national level, but also led to international efforts. The first culminating point was the Stockholm Conference in 1972. The goal set by governments at this conference was to 'protect and enhance the quality of the human environment for present and future generations' (Principle 1 of the Stockholm Declaration on the Human Environment). In the mid-1980s, a renewed internationalization began to take place: the increasing interdependence among states called for new foundations for international environmental cooperation. New regional and global conventions concerning environmental issues were adopted, and the first treaty to protect the ozone layer was concluded in 1985.

The next fundamental breakthrough in the international negotiations of universal environmental issues was embodied and articulated by the United Nations Conference on Environment and Development in Rio de Janeiro in 1992 (UNCED), attended by 176 states and several thousand nongovernmental organizations. UNCED was concerned with a new paradigm of environmental politics, namely the new search for the balance between environmental protection and economic development. The conference adopted two legally binding treaties, the Convention on Biological Diversity and the Framework Convention on Climate Change, and three nonbinding instruments, the Rio Declaration, the Principles on Forests, and the AGENDA 21. UNCED has reaffirmed the need to integrate the concept of sustainable development and its environmental dimensions into economic policies. The World Bank, in particular, has since insisted more than other international organizations on the need for a holistic response to economic social and environmental issues and has started to work on so-called comprehensive development frameworks with its client states. In principle, a consensus has also emerged on the importance of technology cooperation as a strategy of sustainable development; while developing states have called for the transfer of machinery and technical equipment, developed states prefer to discuss the transfer of knowledge of science and technology and support for the institutional capacity to address environmental issues.

In the follow-up to UNCED, various institutional innovations have been introduced, like the Commission of Sustainable Development (CSD) within the United Nations. Also, funds have been set up for the purpose of transferring financial resources and technology for special sectors, e.g. the Multilateral Ozone Fund. The Global Environment Facility (GEF), initiated in 1990, and substantially reformed in 1994, is responsible for the financing of projects in the field of global environmental protection, particularly for measures in four focal areas (protection of the ozone layer, climate, international waters, and biological diversity). The GEF stands out today as an institutional recognition for the requirement of environmental cooperation between North and South, with a novel voting structure which prevents North or South dominating. While in the GEF industrialized states have recognized in a binding way that effective global environmental policy presupposes support of the developing states by the developed world, developing states in turn have accepted that efforts within their economies and societies are required in the effort to address the global issues. It is true that the funds for the GEF are currently limited, less than US$1 billion per year.

In 1997, the nineteenth UN General Assembly Special Session (UNGASS) took place to review progress in the field of sustainable development as set out in the Rio Declaration and Agenda 21 ('Earth Summit +5'). Five years after Rio, some positive results had been achieved, reflected in the increasing willingness of states to accept international treaties to protect the world's climate, the ozone layer, biodiversity, and to combat the spread of deserts and soil degradation. Influential segments of civil society have been formed to address the long list of issues on the environmental agenda. Nevertheless, significant environmental problems remain in all regions of the world, and *communiqués* formulated by professional speech-writers cannot do away with the fact that the state of the global environment continues to deteriorate. Generally speaking, international environmental policy making is today seriously hindered by the absence of an effective body with a voice and authority comparable to the influence of other international organizations such as the World Trade Organization (WTO) or the International Monetary Fund (IMF). This institutional deficiency will become more and more noticeable as national governments will remain inclined to focus on their national agendas and on short-term issues. Thus, institutional improvement will remain on the agenda on the international level as a prerequisite for more effective policy making.

5.2 Regional Issues

The environmental rules of regional organizations must be considered in the context of their overall legal and political structure. Thus, the environmental law and policy of the EC is highly influenced by the Treaty of Amsterdam, adopted on October 2, 1997, which has introduced important changes to the environmental provisions of the EC treaty (ECT). Sustainable development has now been formally introduced as one of the goals of the European community (Article 2, ECT). Furthermore, the principle of integration, requiring the integration of environmental policy demands into other areas of community policy, is now embodied in a single provision in the very first part of the ECT (Article 6, ECT).

As the USA, Mexico, and Canada moved to liberalize regional trade through negotiations of the North American Free Trade Agreement (NAFTA), environmental concern played a significant role in the discussions. Despite many environmental provisions in the Agreement, i.e., environmental, health, and safety standards as well as sanitary and phytosanitary measures, the provisions were seen by the US environmental community as inadequate in response to the environmental risks posed by the liberalized trade among the three nations. In consequence of this criticism, the parties have negotiated a Side Agreement, the North American Agreement on Environmental Cooperation (NAAEC), which went into force on January 1, 1994 together with NAFTA.

With an increasing importance of regional economic associations, it will be important to formulate environmental policies which are not in practice subordinated and evaded in the application of the rules on economic progress.

6. *Prospects*

In the developing world, about 2 billion people live on less than US$2 per day, and it is estimated that only half of them have access to clean and safe water. Development experts point out that these numbers may grow rapidly in the coming decades, and it has been rightly said, from an environmental viewpoint, that poverty acts as the most 'toxic substance.'

At the same time, the developed world relies on patterns of production and consumption which are often wasteful and which are not sustainable in the long run if adopted by people in the developing states. In these facts lies the basic cause and primary challenge of growing environmental problems. Ultimately, environmental policies will succeed or fail to the extent that they effectively address the underlying causes of these facts. If formulated against the forces of the market and without incentives for more environmentally benign technologies, such policies would fail. Also, the support of such policies by strong sectors of civil society is necessary. In the end, however, governments and international organizations are needed to formulate, accept, and implement effective environmental policy.

Environmental Policy: Protection and Regulation

Environmental policy is a commonly used term that eludes a simple, all encompassing definition. Essentially it is concerned with how best to govern the relationship between humans and the natural environment for the benefit of both. This broad definition has the merit of successfully capturing the unbounded character of the environment as a field of policy, touching as it does upon virtually *every* aspect

of social and economic life. However, it lacks specificity: most if not all policy areas are concerned with changing the world 'out there.' One way to proceed towards a more precise definition is to break the term down into its component parts—environment and policy. Albert Einstein famously defined the *environment* as 'everything that isn't me.' Environmentalists would argue that this fundamentally depersonalises 'the environment' which is inherently a subjective, spiritual experience specific to each and every one of us. However, they would agree that his notion of 'everythingness' is useful insofar as it confirms powerfully the complex and essentially unbounded nature of environmental policy, underlining the need for policy responses which are integrated with the main sectors of society. On this line of reasoning, which is now beginning to attract much greater political purchase, *every* policy area has environmental implications and should be conceived of as 'environmental.' In other words, the broad and holistic definition is actually more useful than it first appears. All this may seem like a fairly minor definitional problem but environmentalists argue that the 'everythingness' of the environment is why they find it so difficult to get politicians to take the matter seriously. The very interconnectedness of environmental problems render them unamenable to simple, soundbite politics and *ad hoc* policy interventions. Consequently, they tend to be marginalized.

Environmental policy commonly is defined in terms of the problems it addresses. So if we look at the traditional content of environmental policies, most are associated with controlling pollution, limiting the loss of natural habitats, managing waste such as sewage and litter, and reducing the impact of natural hazards such as flooding (McCormick 1991). These policies normally are put into effect using regulatory tools although recently there has been a pronounced trend towards using nonregulatory tools such as subsidies, eco-taxes, voluntary agreements, and information campaigns. However, environmental policy in the broader sense described above touches upon many more issues than this functional list of issues implies. Indirectly it is related to food and energy production, the transport of goods and services, human health and safety, consumer choices, the survival of biological species, and national and international security in the broadest sense. In short, environmental policy addresses nothing less than the complex, reciprocal links between modern society, the economy, and the environment. In that sense it is probably unique among policy areas in its breadth and complexity (Ingram and Mann 1983). Achieving a harmonious balance between societal, economic, and environmental systems is the main aim of sustainable development, the main organizing concept of contemporary environmental policy.

If 'the environment' is amorphous then the term 'policy' is equally slippery. A dictionary definition is 'a course of action or principle adopted or proposed by a government.' However, some policies comprise a whole series of decisions, layered on top of one another. Policy-making is recursive: policies are put into place to address problems then immediately retuned to fit new political demands. Moreover, policies may be adopted formally by national governments but the detailed aspects of implementation are often left to lower levels of government to determine. Therefore, when a local pollution control officer negotiates with the owner of a polluting factory over the details of site license or emissions permit, they are arguably making policy. Finally, policies also serve a symbolic purpose. Some are only ever statements of intent which governments have no real intention of enacting. Policy, therefore, should be thought of in terms of courses of action and inaction. To summarize, policy is as much an ongoing *process* of interaction as a discrete product or output of the political system, written down in legal texts.

1. *The Characteristics of Environmental Policy*

We can therefore summarize environmental policy as an evolving societal process of addressing the quality of the natural world: hardly a crisp and clear-cut definition! Perhaps the best way to illuminate the concept is to compare the environment with other policy areas such as health, the economy, and crime. According to Weale and Williams (1992), the objective characteristics of a policy area have an important bearing upon the form of politics and policies that develop around it.

1.1 *Public 'Goods' and 'Bads'*

Environmental quality is a classic example of what economists term a nonexcludable or 'public' good. By that they mean that the benefits of environmental quality accrue to most if not all citizens (or, to put it another way, the costs of degradation are borne by society rather than just the polluter). This seemingly self-evident observation has a number of important implications for the scope of environmental policy. First, large parts of the environment—the atmosphere and large areas of the ocean—are common property and nobody can be excluded from using them. This means that while benefits of resource use tend to be concentrated spatially, the costs or 'externalities' typically are dispersed across myriad individuals in the form of pollution (or economic 'bads'). Think of a smoking factory chimney pouring black soot on to the houses surrounding it, for example. In this example the polluter has an economic incentive to carry on consuming clean air in the knowledge that the bads will be born by the whole neighborhood. Second, while the financial cost of improving the environment often falls on one small section of society (e.g., the

owner of the factory), the benefits normally are spread widely among myriad of users. This is partly why polluters, who have a strong incentive to unite and fight to protect their right to pollute, have an immediate advantage over those who suffer the disbenefit. The latter are often too widely dispersed or individually suffer too little to mobilize into a coherent group. Third, those fighting for the 'public' interest or the welfare of natural entities do not necessarily act automatically to achieve their individual or group self-interests—an observation first made by the political scientist Mancur Olson. He argued that individuals have an incentive to 'free ride' by consuming environmental quality in the hope the cost will be born by some other party or society as a whole. For example, polluters of a stream will continue to pollute in the hope that a sufficient number of other users desist from polluting it. However, the public good aspect of environmental problems also conditions attempts made to abate environmental damage. Then, recreational users of our hypothetical river may well calculate that it is easier to free-ride (i.e., wait for someone else to tackle the polluter and share in the benefits of clean water) than do something about it themselves. One of the reasons why motorists continue to drive is that they cannot be excluded easily from the benefits (i.e., less air pollution and congestion) which are generated when some of their number give up their vehicles and turn to public transport.

1.2 The Need for Regulation

Because environmental damage has its origins in otherwise socially legitimate activities like energy and food production, the role of the state is often to police the consumption of public goods by limiting the level of damage that one section of society can impose upon others. Environmental policy is, therefore, inherently *regulatory* in nature, although regulation inevitably has distributive and redistributive consequences (Lowi 1972). Lowi argued that whereas distributive policies (e.g., welfare programs) produce close, dependent relationships between the state and interest groups, regulatory policies produce more conflictual forms of politics. However, not all interest groups enjoy the same level of influence or political power. Some routinely have more of 'a say' than others in determining the content of policy by 'capturing' the regulatory process. The precise manner and extent to which the state is captured by sectional groups is disputed hotly among political scientists (Dunleavy and O'Leary 1987). It is abundantly clear, however, that business groups do enjoy a structural advantage over other groups—one that exacerbates the collective action problems suffered by environmental groups. According to Lindblom (1977), the basic fact that *all* governments, whether Left or Right, need a healthy economy to provide jobs and welfare support, forces them to adopt measures that are in the interests of business without business having to take any observable action. Scientists too have their own independent policy objectives, and can be thought of as an interest group. In some situations 'epistemic communities' (Haas 1992) of scientific experts have had a decisive influence on the course of policy by steering decision-makers to their preferred solutions.

1.3 Complexity and Uncertainty

Once human development exceeds the planetary capacity for self-repair, environmental assets can collapse and disappear, never to reappear. Admittedly, some environmental assets and functions are repairable or substitutable (individual trees can be replanted; water can be transported), but many others (a delicate wetland habitat, for example) are not. Irreversibility complicates environmental policy making, differentiating it from other areas such as tax or social affairs where problems can be more easily revisited. Irreversibility implies that piecemeal policy responses should be substituted for ones that foresee problems and address them systematically. In practice, the environment often responds slowly and subtly to human interventions, and 'local' problems are sometimes only the observable tip of much more complicated and spatially dispersed set of processes. For instance, the pressure to pollute a local river with pesticides and fertilisers may stem from a national policy to intensify agricultural production in order to compete in world markets. The 'international' agricultural policy and the 'local' pollution policy are interconnected and should be developed as such. However, in practice it is often extremely difficult to trace the connections between and within particular spatial levels and sectors, leading to compartmentalized policy making. This raises the question of how decisions should be made at one level when the entire sequence of consequences for other levels or sectors cannot be predicted. Should decision-makers err on the side of caution or proceed in the hope that unfavorable consequences will not arise? This is one of the reasons why the precautionary principle—the idea that policy makers should go 'beyond science' to address potential problems when the threat of harm is significant and potentially irreversible—has become such an important issue of policy debate in areas such as genetically modified food and endocrine-disrupting chemicals (Jordan and O'Riordan 1999). But, whenever the state of the environment cannot be determined precisely before or after a decision is made, the scene is set for those with vested interests to twist scientific ignorance to suit their own cause. Political systems find it difficult to cope with genuine uncertainty in policy making. This is why difficult environmental

policy decisions routinely are handed to committees of experts to deliberate upon, delaying still further the adoption of protective measures.

1.4 Time and Space

We have noted that environmental quality is a classic example of a public good, but the costs and benefits of policy do not necessarily accrue to the same citizens. Consequently issues of equity and justice are central to most, if not all, environmental decisions. More often than not, those who suffer most from environmental damage are the poorest who lack the means to protect themselves, while those who benefit have a vested interest in maintaining the status quo. The precise spatial and temporal distribution of costs and benefits produces alliances of self-interest which battle to determine the scope and content of environmental policy. The construction of a bypass road around a congested village, for example, will greatly improve the welfare of its residents but at the cost of disruption to those living in the path of the alternative route. Balancing these different needs becomes a central question of *politics* (or decision-making) which is pervasive in all forms of environmental policy making. Another problem facing policy makers is how to account for the well being interests of future generations whose needs can only be guessed at. According to the most widely adopted interpretation of sustainable development, policy makers should address the needs of current generations of humans without compromising the ability of future generations to meet theirs. Clearly, this raises very thorny questions of justice and morality, to say nothing of due democratic process.

1.5 Political Borders

Unfortunately for policy makers, environmental problems show scant regard for political borders. Essentially, there are three types of international problem. The first arises when the legitimate activities of one state have international implications (e.g., acid rain and global warming). Then there are global processes such as trade and international debt that have environmental implications. Finally, there is the problem of how to preserve resources such as rainforests and regional seas that reside in one part of the world but are valued by all. Olson's theory of collective action illuminates the difficulties in achieving cooperation between otherwise sovereign states, especially when action is required from those who can legitimately say they are not to blame. Regional arrangements, such as those pioneered by the European Union, provide the best evidence of successful international diplomacy.

However, many of the disputes about who is responsible for causing and remedying global environmental problems such as global warming change hinge on a North vs. South axis, though not exclusively so. In these circumstances, environmental policy relies upon regimes—international conventions and protocols—to develop the necessary amount of trust between participants. In some circumstances institutional arrangements are put in place to deliver 'selective incentives' (Olson 1965) (i.e., technical and financial assistance) to bring reluctant countries on board whose participation is considered vital to the success of the regime (Jordan 1994).

1.6 Environmental Policy Integration

While the environment functions as an integrated whole, the bureaucracies set up to manage it typically are fragmented into different sections in order to avoid administrative overlap and inefficiency (Weale et al. 1991). The mismatch between institutions and environmental problems has been an enduring problem for policy makers since time immemorial. The environment is probably unique in the extent to which it cuts across traditional sectors of government. It is why environmental policy making often produces furious conflicts betwn environmental ministries and the older and often more powerful parts of government representing finance, agriculture, transport, and so on. Thus, one of the great unmet challenges of the 1990s has been to find mechanisms to *integrate* environmental concerns into all areas of decision-making (Jordan 2000, Weale and Williams 1992). According to the UN ('Brundtland') report that did so much in the late 1980s to set the terms of the international debate about sustainable development:

> Those responsible for managing natural resources and protecting the environment are institutionally separated from those responsible for managing the economy. The real world of interlocked economic and ecological systems will not change; the policies and institutions concerned must (World Commission on Environment and Development 1987).

In the 'real world' of bureaucratic politics described by Brundtland, each department defends its own position while resisting a line that, while potentially beneficial to society as a whole, clashes with its 'own' interests. So, even if the environment department wishes to push a greener line, it is likely to come up against fierce opposition from departments representing the interests of farmers, industrialists, or road builders.

1.7 Nonhuman Entities

Environmental policy is probably the only domain of policy that has as its main goal the protection of nonhuman entities. Just about everybody supports some form of environmental protection. But the crucial question is to what extent should moral

significance be ascribed to plants and animals, especially if it involves self-sacrifice and higher economic costs? There are essentially two ethical positions in this debate: technocentric and ecocentric. The clash between these value positions, which have remained remarkably resilient in spite of the widespread greening of party politics, policy making, and government throughout since the 1970s, is clearly identifiable in most contemporary environmental disputes. Those who adopt a *technocentric* view regard nature as a source of resources to be exploited, whereas *ecocentrists* feel that the nonhuman world has interests and moral significance independent of humans valuation—what economists term 'existence value.'

While the technocentric view is hierarchical, manipulative, and managerial, the ecocentric view, by contrast, embraces community scale, natural rhythms, and a morality based on ecological principles. Business tends to adopt a more technocentric line, which conditions the general direction of policy via the structural commitments outlined above. The 'green' case put by environmentalists is much more ecocentric. If anything, 30 years of environmental debate has led to a convergence of interests towards the center of this continuum of worldviews. To a greater or lesser extent environmentalism has made all industrialized societies much greener. This is reflected in and nourished by the discourse surrounding the term sustainable development which presents environment and development as two sides of the same coin, one being the necessary precondition of the other. Sustainability as defined by the Brundtland report is politically palatable precisely because it carries the comforting message that the world *can* grow its way out of ecological and geopolitical crisis.

Despite this convergence, contemporary environmental conflicts are still driven by the clash between worldviews. We see this in the current debate about genetically modified organisms (GMOs) and foods. The large chemical companies are technocentric in their outlook, stressing the benefits of manipulating natural processes for human benefit. Their faith in the power of science to achieve a transition to modified crops in a predictable and controlled manner sets them apart from environmental groups who stress the fundamental uncertainties involved—uncertainties which, if not respected, may result in disastrous and irreparable damage to natural biodiversity. At the root of the unfolding debate about GMOs is the question of whether humans have the moral *right* to 'play God' with nature. The technocentric has few moral qualms about this, whereas the committed ecocentric does. We miss a great deal if we try interpret environmental policy making solely in terms of the exercise of political power, the clash of institutions, and the development of the law. Beliefs, morals, and ethics make up the 'glue' that cements individuals together into interest groups, informing their political positions and policy preferences.

2. *The Main Elements of Environmental Policy*

2.1 *A Brief History*

As policy areas go, environmental policy is relatively youthful, the main planks dating back only as far as the early 1970s. This is not to say that there were no environmental provisions before that time, only that they were relatively fragmented, aimed mainly at securing human health, and developed in a reactive and *ad hoc* manner. Environmental policy gained its impetus from the great upsurge of public interest in environmental matters that occurred in the late 1960s. Landmark books such as Rachel Carson's *Silent Spring* and *Blueprint For Survival* by the *Ecologist* magazine suggested a global crisis was imminent—a message which found a keen and receptive audience in the USA and Western Europe. It is often said that the first evocative images transmitted from space of Earth floating precariously in the inky blackness of deep space, catalyzed and intensified public concern. They emphasized much more clearly than words the finiteness of the planet and did much to encourage a *global* perspective. It is also undeniably true that the unprecedented magnitude of human induced environmental change throughout the twentieth century had also produced an objective reduction in environmental quality. The European Union's (EU) environmental division, DG XI, the UK Department of the Environment (DoE), and the United Nations Environment Program (UNEP) all date from this period, as do the Norwegian and Danish environment ministries (Hanf and Jansen 1998). The policies adopted were mainly regulatory in nature, specifying process and emission standards that had to be met. In those countries with administrative systems that were less well developed, this early period saw the development of basic standards for the main environmental media—air and water—and for waste and noise pollution.

In the 1980s and 1990s, the focus shifted from dealing with the symptoms of environmental damage—pollution, waste, habitat loss—to addressing the underlying causes. The trend towards redesigning institutions and organisations to tackle problems at root is often labeled 'ecological modernisation' (Weale 1992). This involves moving from setting end of pipe standards to tackle the social processes that generate the emissions in the place. The shift towards more diffuse and less interventionist policy tools in part reflects political pressure from business for more flexible and economically efficient alternatives to regulation. The 'new' tools in the armoury of environmental policy now include:

(a) *Ecolabels*: these signal the environmental impact of products and processes to purchasers and investors. Eco-auditing and lifecycle assessments help to rate the ecofriendliness of products and processes by measuring their overall environmental impact.

(b) *Ecotax reform*: working with the grain of markets, taxes are designed to penalize economic 'bads' and, through hypothecation mechanisms, reward 'goods' such as labour. For example, in 1997 the UK adopted a tax on the waste deposited in landfills, the revenues from which are diverted to environmental projects and employee taxes.

(c) *Environmental assessment*: the aim here is to implement the principle of environmental policy integration. The US National Environmental Policy Act (1969) formally required an environmental assessment of individual projects such as a new road. The EU is developing plans to introduce similar provisions much earlier in the decision-making process, via the assessment of overarching policies and programs (strategic environmental assessment).

(d) *Integrated product policies*: using various devices to 'green' the production of goods from their design and production, through to final disposal. A good example is the EU's packaging waste directive that aims to reduce the overall quantity of waste material.

(e) *Strict liability regimes*: by making developers legally responsible for remedying the damage they cause, such regimes are seen as a means of encouraging a more consistently preventative approach to environmental issues. The European Commission has been trying to develop such a regime since 1993.

2.2 National Policy Styles

When we study the political response to environmentalism, we see that states and supranational organizations have followed slightly different paths reflecting their history and political mandate. By and large, the current allocation of responsibilities respects the principle of subsidiarity, which holds that problems should be addressed at the lowest appropriate administrative level. Thus, global problems are addressed at the global level (i.e., the United Nations), regional problems at the regional level (e.g., the EU), and the rest at the national or subnational level. Environmental pressure groups and scientists have learned to work at all levels, removing environmental policy from the domain of purely state-guided action and placing it in the context of a multilevel system of governance.

In spite of the internationalization of environmental policy making, individual states continue to pursue different approaches, reflecting their individual geographical circumstances, political and constitutional make-up, cultural orientation, and economic conditions (Skou Andersen and Liefferink 1997, Jänicke and Weidner 1997). The interaction of these circumstances gives each country a distinct national 'policy style' (Richardson 1982) which pre-exists its response to new political issues. The concept of national policy style would seem to contradict Lowi's basic thesis that the functional characteristics of a problem determine the main aspect of policy. Policy analysts continue to debate which is more important. It is clear, though, that Britain and Germany, two of the largest and most important actors in the EU, have a long history of approaching problems in very different ways (Weale 1992). The British style is highly consensual and reactive, and decisions are made by bargaining between actors in the context of informal rules. Since the 1980s Germany has adopted a more anticipatory approach based on explicit standards and programs which are designed to 'force' the development of clean technologies. Different again is the American 'style.' It is much more open, conflictual, and rule-bound, reflecting the adversarial nature of the US political system. The importance of the free market in American society partly explains why the USA has gone furthest in experimenting with economic instruments, such as tradable permits (Golub 1998).

Significantly, these national differences also explain why countries perceive the same environmental problem in very different ways. Significantly, the environment 'out there' and the policies adopted to protect it are:

> themselves … products of the political process. Countries will vary among themselves and over time as to what is considered to be an 'environmental problem' as well as with respect to what should be done, and by whom, about it (Hanf and Jansen 1998).

2.3 The Policy Process

The policy process normally is seen as having a series of sequential parts or stages. These are (a) problem emergence, (b) agenda setting, (c) consideration of policy options, (d) decision making, (e) implementation, and (f) evaluation. According to this 'textbook' view of policy, the first task facing environmental groups is to get a particular problem on the agenda for discussion and, if possible, consideration by policy makers. Policy makers then select the best course of action based on specialist advice, make the policy, then hand it on to administrators to be implemented. This stage-based view emphasises that policy is a process involving many different parts of the Government. It is also simple and intuitively appealing. But in practice, policy issues are interconnected, policy makers fumble around for solutions in the context of great uncertainty and many internal and external constraints. Often what was done in the past has a determining effect on how new issues are processed.

There is a multitude of different models and theories which try to explain how the machinery of government makes policy (Ham and Hill 1993, Parsons 1995, John 1998), each presenting a slightly different account of how the constituent elements interrelate. *Pluralists* believe that political power is widely, although by no means evenly, spread throughout society. Although

there are very powerful groups in particular policy sectors, no single group is successful continuously or capable of distorting the entire policy process to its advantage. In policy terms, pluralists assume that the agenda-setting process is open and competitive, with the government acting as an honest broker. Once adopted, though, policies must still be steered through the reefs and shoals of the implementation process. Because of the competitiveness of the policy process policy outcomes tend to be unpredictable.

Neopluralists on the other hand argue that business is in a 'privileged' position compared to other groups. Instruments like the mass media help to structure environmental politics by removing 'grand majority' issues concerning the fundamentals of the political order from the agenda, leaving citizens to debate an endless range of 'secondary' concerns (Lindblom 1977). Whereas pluralists assume that grievances are brought fully into the open, neopluralists argue that they are organized out of politics by institutional rules and routines. Policy is made and implemented within fairly small and stable groups of actors (or networks) clustered around particular government departments. According to neopluralists, policy outcomes generally reflect business preferences rather than those of environmental groups, who find it difficult to gain access to decision makers or conclude that the chance of bringing about change is so slim as to be not worth fighting for.

Finally, structuralists (e.g., *Marxists*) believe that the state is under powerful structural pressure to nurture economic growth regardless of the environmental implications (Benton 1996, Pepper 1996). On this view, the welfare state and most environmental controls are nothing more than a sham, put in place to pacify critics and keep the conflict between economic classes to manageable levels. For Marxists, environmental problems are rooted in the unequal distribution of resources within society. There can be no lasting solution to such problems until the social system is structured more equally. Although longer-term outcomes inevitably reflect the needs of business, there may, however, be limited, short-run concessions to environmental demands.

2.4 What Drives Environmental Policy?

Having defined the policy process and the main tools used, the obvious question is what actually drives it forward? Where do the inputs, or political issues, come from which create the agenda for environmental policy making? The answer partly is conditioned by which of the three models described above is used. These differences notwithstanding, ultimately the source of all green ideas is environmentalism, a broad social movement which emerged in the late 1960s reflecting a growing public demand for a better environment (Doyle and McEachern 1998). Environmentalism, the roots of which stretch far back into the past (Pepper 1996), is reflected in a long-term shift in public opinion towards 'quality of life' issues such as peace and tranquillity, and an increasingly active and diverse range of 'green' pressure groups. Environmental concern has exhibited a broadly cyclical pattern over time, with particularly pronounced peaks in the late 1960s and late 1980s. Closer scrutiny reveals that these short-term pulses coincided with periods of economic growth and social introspection.

The political scientist, Downs (1972), has produced a simple model that captures these dynamics. He argues that environmental issues evolve slowly in a culture of scientific enquiry and suppression. This is usually a fairly secretive phase during which gloomy prognoses are carefully explored away from the glare of media concern. The second phase in his 'issue attention cycle' was one of media attention and anxiety triggered by crises. Since the 1960s, the environmental movement has benefited enormously from a series of symbolic environmental crises from Amoco Cadiz, Seveso, Three Mile Island, to Chernobyl and GMOs.

The third phase is the reactive process in which political institutions rush to cope and adapt. The early 1970s and the period 1989–92 were both marked by important institutional innovations. The respective focal points were the international conferences at Stockholm in 1972 and Rio in 1992 which spawned a suite of international regulatory protocols. In turn these triggered a higher order of public and private awareness, much greater financial investment, and corporate planning. During the fourth phase the costs of protection sink in, and demands grow for regulation to be rolled back to allow enterprise and economic growth. So-called contrarians begin to question the accuracy of the more gloomy environmental claims (North 1995). However, downgrading the importance of environmental protection succeeds only in sowing the seeds of the next crisis, and so the cycle begins again. Significantly, however, political concern has not settled back to the original level, but has oscillated upwards around a steadily rising curve. The radical environmentalist critique has been blunted greatly as governments have adopted tougher and tougher environmental policies. But ratchet-like, the laws and public institutions put in place to protect the environment during each upsurge, have helped to fix environmental values in place, providing a platform for the next burst of policy making.

3. Conclusion

Environmental policy has reached a critical stage in its relatively short life. In the 1970s governments across the world responded to environmentalism by establishing agencies and laws to address specific issues such as oil pollution, acid rain and ozone depletion, as and

when they arose. The primary aim of these early innovations was to safeguard human health rather than protect the environment for its own intrinsic value. Policy makers regarded environmental problems as being essentially technical in nature and politically uncontentious; policies were overwhelmingly reactive rather than proactive, and sectoral rather than integrated across policy domains.

But the discourse surrounding environmental issues has begun steadily to metamorphose into one centered on sustainable development. Significantly, sustainable development is not simply development as conventionally understood, 'greened' by bolting on cleaner technologies and reducing waste, but a *process* of human development which simultaneously satisfies social, economic, and environmental goals, within and between different generations across the world. The emerging orthodoxy is that environmental thinking must now be integrated permanently into areas of policy that have traditionally been regarded as 'nonenvironmental' such as agriculture, transport, and energy. One of the most important lessons learnt since the 1970s is that the fundamental driving forces of pollution and habitat loss reside in these sectors. Unless and until these forces are addressed at their roots, environmental protection will always be a reactive, piecemeal, and *ad hoc* activity. Politically speaking, environmental policy integration represents a new and potentially difficult stage in the continuing development of environmental policy, although the idea behind it has been canvassed by environmentalists for decades (Dobson 1990). However, the political stakes are high because by greening other policy areas environmental policy is in effect progressively undermining its own, hard-won independent existence. The irony is that if and when the environment is reflected fully in every aspect of policy making there will be no need for an identifiable 'environmental' policy.

Environmental Psychology: Overview

Environmental psychology is the study of the impact of the physical environment on people and the impact of people on the physical environment. This broad definition will be qualified in several respects

to distinguish environmental psychology from psychology in general and from other subfields with similar aims, in disciplines such as human geography, physiology, and sociology. Environmental psychology is also known as an area of applied psychology, although as in many other such areas a substantial proportion of the research is devoted to theoretical and methodological development. Today environmental psychology provides a theoretical and methodological foundation for environmental planning, design, and management.

The first section will briefly outline how environmental psychology developed historically. A problem conceptualization follows which is used to define focuses of the environmental psychology research. Finally, some of the major research focuses are described.

1. Historical Development

Transformation of the earth's surfaces by human beings has a long history. A primary aim is to create protection against threats to survival. In the 1960s the scientific study of the psychological effects of the humanmade environment began, largely motivated by a concern for the deterioration of human environments (e.g., Proshansky et al. 1970). A sensible early approach was to compare psychological effects of the humanmade environment with those of the natural environment in which the human species evolved (see *Natural Environmental Psychology*).

Research strategies in environmental psychology were first outlined by Craik (1968), based on the dominant strategy in personality assessment. Measurement issues were naturally at the forefront in the early research in environmental psychology. In particular, it was necessary for progress that methods were developed to assess physical settings outside the psychological laboratory as well as to assess how people react to such settings.

Important substantive research problems were originally defined by design professionals whose training made them sensitive to many subtle effects of the designed environment on human behavior. They used this knowledge in designing environments. However, in the face of criticism they became concerned about the scientific basis of their work. Social scientists observed a decline in the quality of urban life. To physiological psychologists this opened new meaningful research problems of how health and well-being are related to the physical environment. Cognitive psychologists concerned about the ecological validity of their research discovered in environmental psychology the possibility for investigating the acquisition, representation, and use of everyday knowledge (of the physical environment). Social psychologists saw in environmental psychology a way out of the laboratory to do meaningful research in the real world. Since the new focus on the physical environment did not stop them from analyzing the social environment, they offered influential conceptualizations in which the physical environment is presupposed to interact with the social environment in shaping human behavior.

The history of environmental psychology as well as its current status is documented in a series of comprehensive reviews published in *Annual Review of Psychology*, see, for example, Sundstrom et al. (1996). In 1987 the *Handbook of Environmental Psychology* was published under the editorship of Daniel Stokols and Irwin Altman. Following this benchmark publication several edited series of books have appeared with reviews of research in different subfields (e.g., Zube et al. 1987–97). Current research is primarily disseminated in three journals with slightly different emphases: *Journal of Environmental Psychology*, edited by David Canter, represents the psychological perspective; *Environment and Behavior*, edited by Robert Bechtel, covers the broader interdisciplinary field of environment–behavior research; and *Journal of Architectural and Planning Research*, edited by Andrew Seidel, is primarily an outlet for architectural and environmental design research. Several textbooks have also been written. The most comprehensive of these (Gifford 1997) cites approximately 5,000 studies.

2. Problem Conceptualization

A research problem in environmental psychology has three facets: the environment, the person or group, and the activity the person or group is engaged in. Any of these facets may be analyzed at different depths, ranging from what may be termed a molar to a molecular level.

So, for instance, the environment may be conceived of as consisting of different molar types (e.g., home, workplace). They are partly defined by their spatial extension, partly by their function. Any such type of environment may furthermore be analyzed at the level of stimuli (e.g., noise, temperature) impinging on people. These two levels are the primary concern to environmental psychology. At a still lower level the physical characteristics of stimuli may be analyzed. This level is sometimes the focus when changes of the other levels are the goal, for instance, in constructing new environments.

Sociodemographic characteristics of people occupying environments are seldom a primary concern to environmental psychology whereas psychological characteristics are. Such characteristics include more stable ones referred to as abilities, attitudes, and personality traits. More transient characteristics such as knowledge, skill, and motivation are also of interest to environmental psychology.

Activities are clearly important as people's means for achieving goals. They are sometimes analyzed at

Figure 1
Facets of research problems in environmental psychology

the level of general function (e.g., work, leisure). However valuable this is, the main focus of environmental psychology is psychologically deeper. Here invariant components of all activities (e.g., perception, evaluation) are emphasized. Sometimes the focus is even on subcomponents of these component processes such as information processing stages or component emotional reactions.

At the psychologically most shallow level a study might focus, for example, on how sociodemographic factors are related to choice of leisure activities in the home. An in-depth study might instead focus on how noise levels affect information processing and mood in the workplace. Environmental psychology differs from psychology in general by its primary focus on molar environments (the filled boxes in Fig. 1), frequently also allowing longer exposures to the environment than is usual in most psychological research. Its focus on intraperson psychological processes distinguishes environmental psychology from other subfields in the disciplines of human geography, physiology, and sociology which study the effects of molar environments. It also differs from these subfields in going beyond sociodemographic factors with the aim of disentangling the ways ability, attitude, personality, knowledge, skill, and motivation modify how individuals react to the molar environment and how differences in intraperson psychological processes mediate such moderator effects.

3. *Research Focuses*

In this section three general areas of past and current environmental psychology research are described, highlighting in each a few major research focuses.

3.1 *Choice of the Environment*

Individuals either choose or are forced to choose where to be. This choice of environment may have profound future consequences for themselves and others. One research focus in environmental psychology is the choice itself. What characteristics of an environment make a person with certain characteristics choose this environment? What characterizes the choice process? Is it deliberate, habitual, or forced?

Research on environmental choice emphasizes different time scales. Some environmental psychology research targets residential choice and migration with possibly lifelong consequences (Aragonés et al. 2001; see also *Residential Environmental Psychology*). This is also a traditional area of research in social sciences such as economics, human geography, and sociology. A more frequent research focus with a shorter time scale is the study of people's daily choices of activity areas in the environment where they live, such as shopping locations, recreational facilities, and others. The demand for travel that such choices generate is being studied (see *Transportation, Psychology of*). In

Figure 2
General areas of research in environmental psychology

addition, field and laboratory studies investigate acquisition, representation, and use of both spatial and nonspatial knowledge of environments. This research on cognitive maps has expanded in different directions. As evidenced by a recent major publication (Golledge 1999), it now attracts research interests also from cognitive and computer scientists, human geographers, neuroscientists, and zoologists. Another marker is the interdisciplinary journal *Spatial Cognition and Computation* under the editorship of Patrick Olivier and Stephen Hirtle. Primarily from the perspective that people are cost minimizers, Gärling and Golledge (2000) review and analyze research on how location choices depend on the degree and quality of spatial and nonspatial knowledge of the environment. A general conclusion is that this knowledge is always incomplete, is hierarchically organized, and therefore differentially accessible in the choice process. A complementary conceptualization of how knowledge and preferences may be integrated in environmental choices is offered by Canter (1991) who sees action goals as primarily driving preferences.

3.2 Impacts of the Environment

A large number of psychological and other effects of physical environments on human beings are assumed or expected and have been empirically demonstrated. Some of these effects are relatively direct, whereas others are modified by person characteristics and mediated by intraperson psychological processes. The social environment is another mediator of effects of the physical environment.

In large part because of its potential health outcomes, a dominating research focus in environmental psychology concerns the detrimental effects of environmental stressors such as noise, crowding, and extreme temperatures (Evans 1982) as well as threats of natural disasters, technological catastrophes, or accidents (Baum et al. 1983). Such effects are extensively documented in self-report, physiological, and performance measures. A complementary research focus which more recently has attracted attention is the study of beneficial effects of environments, for instance, the restorative (Kaplan and Kaplan 1989) and stress-reducing potentials of the natural environment (Ulrich 1983). The recurrent finding that sensory deprivation may have positive effects (Suedfeld 1980) bears theoretically on this current research with important practical implications.

Another research focus is the study of groups of people acting and interacting in physical settings (see *Community Environmental Psychology*). The impact of the physical environment is sometimes mediated by the social environment (e.g., Wicker 1979), for instance, when scarcity of space leads to excessive social interaction with adverse consequences. In other cases the physical environment facilitates social contact with positive effects on, for instance, residential satisfaction.

3.3 Impacts on the Environment

Since the early 1990s the scope of environmental psychology has broadened to include the study of methods to promote proenvironmental behaviors so that the detrimental impacts of people on the physical environment may be significantly reduced (Stern 1992). Extending a conceptual framework proposed by Russell and Ward (1982), a possible integration of this new research focus in environmental psychology with the traditional ones may be achieved as shown in Fig. 2. Forced or unforced choice of the environment has psychological consequences for the person. At the same time these choices have impacts on the environment, frequently negative when they are aggregated across many people. Sometimes there are regulatory feedback loops, such as when, for instance, crowding in an environment reaches intolerable levels. In other cases, however, the harmful effects only materialize in the future. Feed-forward loops (the broken arrow) should be provided so that people take these future consequences into account when making their choices. Yet, changing behavioral antecedents and consequences has not in general been a successful method. Current research therefore focuses on different sets of determinants of proenvironmental behaviors such as habits, attitudes, moral concerns,

and value orientations. This is likely to lead eventually to both a deeper understanding of behavioral change mechanisms and more effective methods of changing behavior.

4. Forecasting the Future

There are few reasons to believe that the current environmental problems of pollution and resource overuse will soon be solved. It is more likely that demand will increase on environmental psychology to contribute to solutions. Acceptance of new sustainable technologies such as zero-emission vehicles is one salient research focus in the future. One may also see more collaboration with economists, political scientists, and sociologists in developing effective methods for promoting proenvironmental behaviors (e.g., Foddy et al. 1999).

The development of telecommunication technology may have profound influences on how the physical environment will be organized in the future. Transformations of homes into workplaces are already taking place. Electronic shopping is increasing in frequency. To forecast the effects on people is a challenging future task.

The design of intelligent buildings with many automatically performed functions poses new research tasks in the immediate future. Although these new features are basically of benefit to users, people may still react negatively because of loss of perceived control. Also, automatic control may not always work—so users must know how to take over.

Environmental Risk and Hazards

Environmental risks and hazards are a major focus of research, general concern, and public policy; and they provide an important arena for interdisciplinary collaboration between social scientists, natural scientists, and engineering. The terms encompass a wide range of definitions and practices, with considerable evolution of their meaning and use over time. This article reviews the definitions and intellectual history of each term, and considers several important developments and debates in current theory, methods, and research from the perspective of the social sciences. One of the distinctive characteristics of social science research on environmental risks and hazards is the strong influence on policy making and environmental management.

The overall cost of natural hazards, expressed either in monetary terms or through property loss or damage, is extremely high, estimated at more than $40 billion per year worldwide. Most of this is accounted for by floods (40 percent), tropical cyclones (20 percent), and drought (15 percent). Roughly two-thirds of the total cost stems from loss of life and property, and the rest is spent on attempts to reduce risk. On average, more

than 250,000 people die from hazards in a typical year, most of them in developing countries in Latin American, Africa, and Asia.

1. Definitions

Everyday use generally defines risk as the chance of loss or injury, and hazard as a source of danger. The research literature uses the terms in more complex and sometimes contradictory ways, although precise interpretations are provided in some regulatory frameworks.

Environmental hazards are defined as extreme events or substances in the Earth and its ecological system that may cause adverse effects to humans and things they value (NRC 1996). The idea of hazard includes both the event and its consequences. Environmental hazards include geophysical and meteorological phenomena such as earthquakes, droughts, and hurricanes, often called 'natural' hazards, as well as pollution problems and other 'technological' hazards. Most scholars argue that an event does not become a hazard until humans are exposed to it, and thus that hazards result from the interaction of humans and extreme events.

Environmental risks are often defined as the product of a hazard and the likelihood of its occurring, using a simple formula that defines a risk as the product of the probability of an event and its severity measured in terms of the population exposed, and the nature of the consequences. For example, the risks of a nuclear accident have been expressed in terms of the chance (e.g., one in one million) per exposure unit (e.g., a person exposed to a certain level of radiation) getting cancer (consequences).

2. Research Traditions

Although people have long been concerned with the documentation of disasters and other environmental dangers, formal social science approaches to natural hazards are often associated with a group of scholars based at the University of Chicago and led by geographer Gilbert White. White set out to understand the processes by which humans become exposed to natural hazards, such as floods, and the role that human adjustments may make in reducing hazard losses. Prior research had focused on engineering approaches to reducing hazard losses, such as constructing levees and dams, but White's work showed how such structures may actually increase losses by encouraging humans to occupy flood plains, and channeling water to create greater damage downstream (White 1958). A framework from 'human ecology' was employed to examine interactions between humans and extreme events in terms of human behavior and perceptions. White's students were able to demonstrate how views and adjustments to hazards such as drought (Saarinen 1966) and flood (Kates 1962) were influenced by the socioeconomic and personality characteristics of individuals, and by their knowledge and experience of previous events. The major categories of adjustment included modifying the environment (e.g., cloud seeding during drought), modifying human behavior (planting different seeds), or redistributing losses (crop insurance). The concept of adjustment and response was important because these human actions could reduce the physical and social impact of an extreme event.

This framework drew on behavioral theories of decisions based on bounded rationality, where individuals made decisions based on limited knowledge within the constraints of a social system. The research results influenced education and warning programs and legislation, such as hazard zoning, that attempted to reduce occupancy of hazardous locations, and improve understanding and response to hazard warnings. For example, the US National Flood Insurance Program attempts to regulate land use in flood plains as a way of reducing social and economic damage from flooding. After White moved to the University of Colorado he started the Natural Hazards Research and Applications Information Center which coordinated several national and international assessments of various hazards, and met regularly with stakeholders to discuss research results (White 1974).

Although geography provided the main disciplinary home for hazards research, sociology and anthropology were also very active (see *Disasters, Sociology of*). Sociologists, led by Enrique Quarentelli, developed a different approach to understanding natural hazards that used theories of collective behavior and social organization to understand response to disasters (Quarantelli 1978). Anthropology contributed ideas about culture and development, including research that showed the significance of indigenous knowledge and cultural traditions in attitudes and responses to hazards and risks in several regions of the world (Douglas and Wildavsky 1982).

In response to devastating droughts in Africa and earthquakes in Latin America as well as the influence of Marxist thinking in the social sciences in the 1970s, hazard losses began to be blamed less on individual decisions and more on larger scale political and economic structures (O'Keefe et al. 1977, Hewitt 1984). This critical, structural, or political economy perspective focused on processes that forced people to live in hazardous environments, limited their access to information and resources, and impoverished people to levels where they could not adjust or recover from extreme events. For example, studies of earthquake impact and recovery in Nicaragua and Guatemala showed that working class and poor households were living in fragile housing, often on steep slopes, as a result of poverty and unequal land tenure systems, and were unable to gain access to disaster relief that was

directed to the more powerful members of society (Cuny 1983).

An enduring concept to emerge from this work was that of 'vulnerability,' defined simply as the potential for loss in different places or among different social groups. Broader definitions encompass the characteristics of a person or group in terms of their capacity to anticipate, cope with, resist, and recover from the impacts of natural hazard (Blaikie et al. 1994). Vulnerability is conditioned by both biophysical and social conditions, including topography, poverty, access to information and insurance, gender, and ethnicity, and involves both external structural factors and individual capacity to cope with extreme events (see *Environmental Vulnerability*). It can be seen as the opposite of security, and as influenced by underlying dynamics of power relationships in society and access to resource entitlements (Watts and Bohle 1993).

Vulnerability studies often involved the detailed analysis and mapping of the distribution of sensitivity and resilience to hazards across geographic space, and between social sectors. Thus, they provided a deeper understanding of the distributive effects of hazards and responses to them. Women, children, and the elderly were found to be more vulnerable than the general population to many hazards.

For example, vulnerability to drought in Africa was associated with differential access to resources or entitlements to land, food, or assistance at a variety of scales ranging from the household to the global food system refracted through markets, environmental stresses, and multilateral trade and aid agreements. Influenced by Sen's analysis of famine and entitlements (Sen 1981) vulnerability emerges from the interaction between drought and individuals' abilities to produce food themselves, participate in the reciprocal or market exchange of labor and food, or gain effective access to relief and development assistance. The more frequently vulnerable groups include rural smallholders on marginal land, pastoralists, rural wage laborers, the urban poor, refugees, and displaced people, as well as women, children, the infirm, and the elderly (Downing 1996). Insights from such analyses have been used to develop vulnerability maps and famine early warning systems to assist in mitigation and relief efforts.

Other important concepts include that of 'hazardousness of place,' whereby the totality of hazards in a particular geographic location is analyzed (Hewitt and Burton 1971), and of hazards as part of everyday life in contrast to isolating them as departures from normal or accidents (Hewitt 1984). Both concepts point to the importance of viewing hazards within the larger context of social, political, and economic structures at scales ranging from the household to the community to the state. A growing interest in the hazards of the world's major urban areas has shown how the combination of population growth and migration, poor infrastructure, economic growth, inadequate institutions, and poverty is creating vulnerability to disasters (Mitchell 1999). Half the world's largest cities are located on earthquake belts or tropical cyclone tracks. The 1995 earthquake in Kobe, Japan, caused more than 6,000 fatalities and over $120 billion in economic loss. The Izmit, Turkey, earthquake in 1999 caused 20,000 fatalities and an estimated $20 billion in economic loss.

3. *Technological Hazards and Environmental Risk Assessment*

With the growth of the environmental movement and awareness about pollution problems, some researchers developed an interest in technological hazards, stimulated partly by the need for studies that would support the decisions of US regulatory agencies such as the Environmental Protection Agency or the Nuclear Regulatory Commission, and by a series of accidents and serious pollution incidents. Regulation of carcinogenic pollutants required careful assessments of the risks of environmental chemicals for human health. A 1974 study of nuclear reactor safety provided one of the first major examples of probabilistic environmental risk assessment, and prompted a vigorous debate about the appropriate methods for measuring and regulating pollution and accident risks (USAEC 1974).

Initial research on environmental risks focused on techniques for quantitative risk assessment that attempted to estimate the expected incidence of illness or death in human populations exposed to chemicals and other substances. The two major approaches were statistical or actuarial analyses based on past experiences, and laboratory experiments using animals or cell cultures. For example, risk assessment was used to estimate the expected rate of illness or death in a human population exposed to a hazardous chemical based on the number of experimental animals affected by various doses of the chemical as measured in laboratory experiments. Limitations of these environmental risk assessments included inadequate data or controls on past empirical occurrences, problems in extrapolating from high short-term experimental doses to longer-term exposure, and from animals to humans, and the likelihood of real-world multiple and interacting stresses. Risk estimates were often used to compare risks in order to allocate resources for risk management using techniques that compared a particular risk (such as coal-fired electricity generation) to risks of alternative technologies (e.g., hydroelectricity), everyday life (e.g., driving), or to the economic costs and benefits of the technology (e.g., health costs and low-cost electricity). Quantitative risk analysis has at its core the belief that decisions about technology can be made according to a monetary calculus in which costs, determined by quantifying loss of life and productivity, are balanced against total 'social

benefits.' Risk–benefit analysis became controversial because it involved calculations that included placing often inconsistent values on human lives, injuries, or ecosystem damage. Scientific rankings of risk also differed with the views of the public, as shown in the keynote article by Starr (1969) that showed the public to be 1000 times more willing, on average, to accept voluntary risks (e.g., driving) than those imposed upon them (e.g., pollution), and that the acceptability of risk was acceptability of a risk relative to the third power of the perceived benefits.

Scholars from the environmental hazards tradition such as Kates and Kasperson raised questions about public perception of risk, together with an important body of work by psychologists such as Slovic and Fischhoff (Fischhoff et al. 1981, Kates and Clark 1977, Slovic 1987). Research demonstrated that people rank risks not only on scientific studies of the probability of harm, but also on how well the process is understood, its visibility and association with cancer, the degree of catastrophe, how equitably the danger is distributed, how well individuals can control their exposure, and whether risk is voluntary or imposed. These studies helped to explain why the public was so concerned about the risks of nuclear power or toxins in the environment in comparison to more frequent or serious risks from driving or smoking. Kasperson, one of the pioneers of research into technological hazard, proposed the concept of the 'social amplification of risk' and which suggested that the actions of the media, government, and nongovernmental organizations, as well as disputes among scientists, can significantly increase or decrease public risk concerns (Kasperson et al. 1988).

As a result of the relation to decision making, the processes of risk assessment have become a continuing and frequent preoccupation of advisory councils and committees in many countries and jurisdictions, such as the US National Research Council and the European Community.

4. *Emerging Issues*

Another set of social science research activities focused on the distribution of risks among social groups and across landscapes. This work showed the unequal distribution of the benefits and risks from technologies, and demonstrated the disproportionate exposure of poor and minority populations to environmental risks and hazards. This 'environmental justice' literature has continued to influence research on environmental risks and hazards (see *Environmental Justice*).

Mapping the distribution of risks and vulnerability was facilitated by the development of computer-aided geographic information systems (GIS), which allowed for detailed spatial information on both physical and social variables to be integrated into databases and maps. These allowed the identification of hazard zones, and enabled a more rapid response to natural and technological disasters (Dangermond 1991). For example, GIS have been used to map earthquake hazards, droughts, and exposure to pollutants, and to facilitate more rapid response to emergencies by highlighting the spatial patterns of vulnerability and transport routes, as well as the location of key technical and human response and relief resources.

Social scientists also raised important issues about power and communication in risk assessment, analyzing the process by which certain groups were legitimized as experts, and the roles of scientists, government authorities, and the media in defining and managing risks (Beck 1992, Jasanoff 1993, Lash et al. 1996). The social constructionist perspective drew on discourse analysis to examine events such as the Bhopal chemical accident in India, and responses to the risks of bioengineering and climate change in terms of the framing of the debate, the use of language and imagery, and the use of science by different interest groups.

Growing demands for public participation in decisions about environmental risk fostered research on the role of nongovernmental organizations, and on models for involving stakeholders in both risk estimation techniques and management decisions. For example, research into the design and effectiveness of deliberative processes for formal and informal participation in decision making about risks provides a critical examination of different models of hearings and other forms of public input into decisions about location of hazardous facilities or development of pollution regulations.

Awareness of the potential of new global-scale environmental changes to alter the severity and pattern of environmental risks led some scholars to situate their research in the context of global climate and land use changes. Projections remain uncertain about how global warming might alter the frequency and intensity of meteorological hazards, or change the incidence of pollution at the local level. Nevertheless, researchers employed scenarios to estimate changes in hurricane risks associated with sea-level rise, or drought and epidemics associated with climate changes and their results contributed to international assessments of global change, such as those of the Intergovernmental Panel on Climate Change (IPCC 1991). The concept of vulnerability was another important contribution of risk and hazard research to global change studies, because it suggested the importance of socioeconomic context and conditions in determining the impacts of climate change or the causes of deforestation, and highlighted issues of distribution of impacts and the ability to adjust to changes (Liverman 1994).

Hazards and risks are created, responded to, and studied in a highly international context, whether it be the role of trade or climate change in transferring risks

from one region to another, the complex patterns of governmental and nongovernmental flows of disaster relief and development assistance, or the collaborations of scientists from different countries in research. International organizations such as the UN Disaster Relief Organization, the International Council of Scientific Unions, and various multinational environmental and charitable groups such as Oxfam, coordinate research and response to environmental risks and hazards. For example, the 1990s were declared the International Decade for Natural Disaster Reduction (IDNDR), with the aim of reducing hazard losses worldwide through improved prediction and reduction of vulnerability.

Environmental Sciences

The term 'environmental sciences' groups a number of disciplines which, in academia, are not usually found together. Ecology is a biological science, meteorology a physical science, and geology and physical geography also have their separate departments. Urban and regional planning is a social science. Yet all these sciences have important commonalties.

First, they have shared historical roots. All entered the modern phase of their development around 1800. The term 'Humboldtian sciences' has been given to sciences which seek, as all of these fields do, to integrate

large numbers of facts and measurements in a holistic image of their subject matter. There is a strong link with Romanticism, which, in the sciences, aimed at conceiving large wholes and finding their underlying patterns of organization. Yet, during a century or more, the various Humboldtian sciences increasingly developed within their own disciplinary boundaries.

However, from 1960 onward, the environmental sciences have again moved closer toward each other. Societal pressure played a large part therein, and the very word 'environmental' developed its momentum in the public realm before it entered scientific discourse to the extent that it has now (Jamison et al. 1990). Ecology was first science to receive its status as 'the' environmental science, not long after the publication of Rachel Carson's *Silent Spring* in 1962 and more visibly after Earth Day in 1970. Governmental science policy in many western countries has been willing to recognize ecology's centrality.

Meteorology much later than ecology rose to the status of an encompassing environmental science. It acquired this status around 1985. The 'greenhouse effect' occasioned primarily by human societies' burning of fossil fuel, and the resulting 'global warming,' have inspired governmental policies on a number of levels. These policies in turn have exercised profound impacts on priorities in science policy. Many other sciences have oriented their agenda to issues related to global warming, and are now also identified as 'environmental sciences.'

1. Ecology

1.1 Alexander von Humboldt

Alexander von Humboldt (1769–1857) had received a university education in geology. An Inspector of Mines, he was embarking on a career in the service of the Prussian government, when the inheritance of his family fortune enabled him to give up his position. By then, he had been in contact with the naturalists on board of Captain James Cook's scientific expeditions in the Pacific. In 1798, Humboldt began his own journey to Latin America. Upon his return in 1804, he became the most famous man in Europe after Napoleon. Travel and naturalistic research in the tropics were given an enormous boost through the accounts of his voyage. Among Humboldt's many admirers may be counted the Dutch King and government, who sent a scientific expedition on a journey through Java in 1820, a first in Dutch colonial history.

1.2 Humboldtian Ecology

An important conceptual innovation of Alexander von Humboldt's was the transformation of 'landscape' into a subject matter for science. Previously, the word landscape referred to a particular genre in painting, and Humboldt made good use of the painterly gaze, which confers unity on what it sees. Humboldt thus grasped the landscape in effect as an individual being. Every region of the globe had its own visual characteristics and beauty. Foremost in the appearance of a landscape was its 'vegetation,' another new concept, since it grouped plants according to the place where they lived rather than following their taxonomical order. Humboldt discovered that very different species not only occurred together, but that there were social relations among them, and he called these groupings of plants 'associations' (Nicolson 1987).

The first modern textbook of ecology by the Danish botanist Eugenius Warming appeared in 1895, with the English translation appearing in 1909. Warming retained Humboldt's original precepts on plants in social associations. He worked them out in a precise manner, exposing the diversity of degrees and styles of interdependence, which exist in nature. Josias Braun-Blanquet in Montpellier pursued this line of thought, and he and others in the so-called Zürich–Montpellier school produced a comprehensive system of Europe's plant associations. This vegetation science would play a major role in the ecological underpinning of nature conservation practices in many countries of continental Europe (Nicolson 1989). Workers in the Zürich–Montpellier school could identify which rare species belong to a certain association—hence they knew when their nonoccurrence should cause concern. In the UK, a vegetation ecology of a different style has been equally useful for nature conservation, and its practitioners were consulted by the government to designate nature reserves since the late 1940s (Bowler 1992).

1.3 Darwin and Evolutionary Ecology

Charles Darwin's famous *Origin of Species* of 1859 is as much an ecological book as it is about evolutionary theory. Darwin owed much to Humboldt's holistic ecology, as Darwin saw the various species of animals and plants forming an 'entangled' whole. But whereas Humboldt stressed harmony in nature, Darwin regarded nature much more as a creative force. Nature continually disturbs settled equilibrium through the struggle of species scrambling for a place (Worster 1985). Evolutionary ecologists stress interactions between species (populations). They do not regard the climate as the deterministic factor in the make-up of animal communities, as ecosystem ecologists tend to do.

Population dynamics has strong ties with applied ecology: economic entomology (the study of pest insects in agriculture), and fishery ecology. Already by 1900, ecologists were working on biological pest control, that is, the method of holding one insect species in check by another. The publication of *Silent Spring* gave this research an important political boost (Perkins 1982, Palladino 1993).

Several approaches in population dynamics, in particular those of Robert May and C. S. Holling, have enlarged its theoretical basis in diverse ways. Both developed new mathematical techniques, which tackled the occurrence of more or less dramatic changes in ecological systems. Though interesting leads exist with regard to nature conservation, notably in the work of Daniel Botkin, evolutionary ecology has been so far less influential in this domain than systems ecology.

1.4 Ecosystems and Systems Ecology

Systems ecology is the mathematical, computer-implemented form of ecosystem ecology. The latter assumes that large entities such as landscapes are functionally integrated wholes and it attempts to uncover their structure and functioning.

The word 'ecosystem' was coined in 1935 by Arthur Tansley, a British ecologist. Tansley wanted to place the older association or community oriented ecology on a mechanistic footing. This idea remained largely programmatic until the 1950s, when Eugene Odum pulled together some theoretical approaches and physical methodologies. Odum's synthesis launched ecosystem ecology. It incorporated an emphasis on 'productivity,' which was added to the analysis of food web relations first pioneered by Charles Elton in the UK. Odum made use of newly available physical methodologies, most importantly the use of radioactive tracers. His approach was based on a recent discovery that several species accumulate radioactive isotopes, as they get picked up in minute quantities from the environment. Radioactive tracers permitted the elucidation of food webs both qualitatively (who eats what) and quantitatively (Kwa 1993).

The next step was to turn these quantified systems of food web relations into a more formal model that could be implemented on a computer. Through computer simulation of ecosystem models Odum's fellow ecosystem ecologists hoped to find the key to the rational exploitation and control of natural resources. They hoped to use the models to help them establish the conditions under which ecosystems preserve their stability and to identify the natural mechanisms that enable them to do so.

The first model of a complete ecosystem was built in 1959, an electric model, a material analog of an ecosystem. The electrical current was the equivalent of the carbon cycle; resistors were the equivalents of various categories of groups of plants and animals, etc. The first whole ecosystem model, implemented on a digital computer, followed in 1965. These models were then gradually expanded in order to achieve closer similarity with real ecosystems. Their mathematical complexity in terms of the number of variables reached a temporary zenith in 1973. It was hoped that the models would mimic the behavior of real ecosystems at the scale of a good part of a continent. This expectation may now seem naive, but we may note that during the period 1959–1973 mainframe computers gradually became accessible to larger segments of the academic community. Many expected to use this expanded computing capacity to find the solutions to hitherto unsolvable complex problems. The prime example here is the 'Limits to Growth' model developed by Dennis Meadows for the Club of Rome in 1972 (Ashley 1983).

One important assumption built into the models was that ecosystems would be steered by climatic factors such as precipitation, temperature, and hours of sunshine. The models thus represented ecosystems as automatically steered machines, which would return to equilibrium after not too big a disturbance. However, if the functioning of the ecosystem was threatened, the ecosystem manager should make sure that equilibrium was safely reached again.

Around 1967, the US Congress became convinced that systems ecologists would be able to develop an early warning system, so that natural catastrophes could be avoided. The environmental movement also placed much trust in ecology as the science that could save humanity from its own excesses. Everywhere in the western world, measures to promote environmental hygiene were framed in a systems ecological vocabulary. As early as 1971, ecologists began to feel the pressure of popularity and increasingly voiced disclaimers about their ability 'to save the planet.'

But by then professional ecologists were no longer needed for this purpose. Systems ecology had placed an emphasis on the circulation of matter and energy in the ecosystem, and other sciences could now push ahead with charting the various cycles of chemical substances to frame problems of pollution abatement and energy conservation. Another case in point is the carbon cycle, which at one point was understood as an ecological concept and which now has become a subject matter of meteorology.

2. Meteorology

Humboldt had invented the isotherms, lines on a map, which connect points with equal mean temperature. Together with isobars and a number of other graphic representations, such as of storm tracks, isotherms formed the basis of weather forecasting well into the twentieth century. Progress in meteorology was based on an ever-expanding system of atmospheric measurements. But the skillful combination of those involved many rules of thumb.

2.1 Vilhelm Bjerknes and the Bergen School of Meteorology

Modern meteorology was founded by Vilhelm Bjerknes and his 'Bergen school' in Norway. He visualized the atmosphere as consisting of three-

dimensional air masses moving around the globe, different in temperature, density, and humidity. An important step was achieved by Bjerknes' son Jacob, who developed a model of the extra-tropical cyclone and how it moves. Bjerknes was able to exploit an existing military observational network for weather forecasting in western Norway, as it enabled him to follow the movement of the cyclones. It brought him considerable popular support in the area. The major breakthrough occurred in 1919, when the concept of the 'polar front' was born. It would take several decades before the world's meteorologists were persuaded to 'see' a battle line, separating cold air masses from the north and warm air masses from the south. Bjerknes thought that this line stretched along the entire Atlantic, or indeed around the entire globe. Along the polar front the cyclones, or low-pressure areas, were formed, which would hit the coasts of Europe with rain and storm. Bjerknes put weather forecasting on a new footing. The analysis of polar fronts for the purpose of forecasting relied on large networks for atmospheric data gathering. Bjerknes pushed for it internationally, thereby also promoting the Bergen school ideas (Friedman 1989).

2.2 The Adoption of the Bergen School Ideas in the US

The Bergen school ideas received a decisive boost when Carl-Gustav Rossby (b. 1898), a Swede who had worked with Bjerknes in Bergen, came to work at the US Weather Bureau during 1926–1927. He encountered stiff resistance to the Bergen school ideas, but he was able to recruit some followers.

In the late 1930s Rossby, by then at MIT, developed a method of calculating the large-scale motion of the atmosphere, based on the movement of long waves (later to be called Rossby waves). He put the westward movement of the extra-tropical cyclones more rigorously into the context of the general circulation of the Earth's atmosphere, thus explaining semiquantitatively how the cyclones moved. On the basis of Rossby's work, precision in forecasting methods was greatly enhanced in succeeding years.

2.3 Numerical Prediction of the Weather on the Computer

John von Neumann, a mathematician, is one of the main architects of the modern computer. During World War II he had been working on the atom bomb at Los Alamos. After the war he initiated a project to build an 'all-purpose, automatic, high speed electronic computing machine.' Von Neumann also formulated the problems that computers were to solve among them the modeling of the atmosphere. The reason why von Neumann chose meteorology may have been the military importance of weather forecasts. Jule Charney became von Neumann's collaborator in 1948. In early April 1950, the first successful numerical weather prediction was completed on the basis of Charney's simple two-dimensional model of the atmosphere. Routine numerical weather prediction began by 1955.

The early models by Charney were intellectually derived from the Bergen school. However, in the mid-1960s these models were replaced in daily forecasting by models based on the so-called primitive equations which were basic physical equations describing the atmosphere. As a result, the original Bergen 'fronts' moved to the background in numerical meteorology.

2.4 The Attempt to Modify the Weather and the Climate

Between 1946 and 1973, there was a brief flourishing of the field of weather and climate modification. In 1946, Vincent Schaeffer and Irving Langmuir, working for General Electric in the US, discovered by chance that small quantities of frozen carbon dioxide could induce a cloud to release its contents. The many experiments that followed had a simple experimental format: clouds were sprayed with a reagent (most often silver iodide), usually from an airplane (Byers 1974). By 1965, just enough progress had been achieved in the eyes of the larger scientific community to endorse the idea of weather modification. Also, mergers took place between experimental cloud seeding and theoretical modeling of clouds and the atmosphere. One of these projects had been initiated at the National Hurricane Research Laboratory in Miami, which in 1963 had seeded two hurricanes. Results were evaluated as 'encouraging if not conclusive.' Around the same time, the US and the UK began to worry about Soviet plans to divert Siberian rivers away from their flow into the Northern Ice Sea. The West's need for its own expertise on this matter provided an important impetus for the development of General Circulation Models of the whole Earth's atmosphere.

Ten years later, funding for weather and climate modification was considerably reduced, despite the meteorologists continuing best efforts. But opposition had grown. There was increasing pressure by environmental activists against cloud seeding. Also, projected figures of jet exhausts of supersonic aircraft induced worries about anthropogenic damage to the ozone layer. In general, the long prevalent optimism about human interference in the environment was giving way to fears of irreparable damage.

3. Global Warming and Climate Change

Fear of unintended catastrophe is at the heart of the current concern about global warming. Never before has science revealed a risk, which is at once of such tremendous proportions and is surrounded by so many uncertainties (Jasanoff and Wynne 1998).

The General Circulation Models of the Earth's atmosphere provide the primary evidence for the existence of a tendency toward global warming, later reconceptualized as climate change, and also that it is primarily caused by the human use of fossil fuels. The evidence is assessed by the Intergovernmental Panel on Climate Change (IPCC), an international body of scientific experts appointed by national governments to provide policy-relevant advice. The IPCC's aim to seek broad consensus around scientific matters is contested by some scientists. To others, it is justified because the stakes are so high.

General Circulation Models are now becoming linked to models of the oceans, and the influence on the atmosphere by the vegetation masses of the earth is under investigation. If research on the causes of global warming exceed the disciplinary limits of meteorology, research on the possible effects of global climate change has drawn in a still larger cross-section of the sciences. Physical geography, regional planning, ecology, and environmental economics assess the impact of global warming on land-use and the landscape. A new science of integrated assessment has sprung up, which researches ways to combine all the available knowledge into so-called 'Integrated Assessment Models.' Models of this kind were used to advise the European Commission in proposing targets for energy-use reduction at the international negotiations in Kyoto, 1998.

Models appear to be the instrument of choice to master the complexity of the environment. Their range is wide, with scopes extending from the General Circulation Models to changes in the Delta of the Rhine as the expected result of increased rainfall caused by global warming. Over the past decades, the mathematical sophistication of models has been greatly improved, as have been the computers on which they are run. Yet, expectations with regard to precision in forecasting and the extent of possible human control over the environment have diminished in important respects as awareness of complexity and uncertainty has grown. Models of the environment have become highly ambiguous things, and it is easiest to say what they are not: truthful pictures of the world as it is and how it will evolve (Shackley 1997). Scientists usually take models as tools for further research, while policy makers need them to base their decisions on. Contested as they may be, models increasingly function as mediators between the environmental sciences and society.

Environmental Security

Environmental security is concerned with the linkages between environment and security. There is no one definition as the topic is a fast-evolving one, but it is generally accepted to be a broadening of the traditional concept of national security to include environmental factors. Sometimes 'environmental' refers to the origin of a direct threat to security; for example, natural disasters or water scarcity, which can threaten the stability of a state or region. In other cases, the environment is seen as an indirect cause of violent conflict, as one of the factors (together with demographic, economic, political and social causes) in social impoverishment and inequity. Although a case can be made that political instability and conflict are them-

selves causes of environmental problems, most of the current work on environmental security examines the causal relationship in the other direction: from environmental causes to their effects on security, at national, regional and global levels. Thus, the key context is to look at the effects of environmental factors on security and not the other way round.

1. Evolution of the Concept

The concept of environmental security is diffuse because it has its origins in several different evolutionary strands and research traditions. One origin is in an expansion of the concept of military security. Another is the development of a welfare concept known as 'human security'. A third is an extension of the work in natural hazards, environmental risk assessment and the notion of ecological and geopolitical 'vulnerabilities', which has led to the concept of critical zones for environmental security. The report of the World Commission on Environment and Development (WCED 1987), which is best known for elaborating the concept of 'sustainable development,' highlighted environmental stress as a potential cause of military conflict. The 1986 nuclear accident at Chernobyl was a clear message to many people that human health and ecosystem integrity were interdependent. In 1987, President Gorbachev of the USSR proposed that 'ecological security' should be a top priority for international relations. The concept had entered the mainstream of academic and political discourse.

1.1 Military Security

The concept of national security to include nonmilitary aspects has evolved over the past few decades, as it has been accepted that issues such as ethnic and religious differences and environmental degradation affect national stability and the likelihood of conflict. Ullman (1983) argued for an expanded definition of security in which any action or sequence of events was a threat to national security if it had major and relatively sudden impacts on quality of life or significantly narrowed the range of choices available to a government or its people. Clearly, most environmental issues would not be security issues under this definition as they occur relatively slowly and do not, by themselves, significantly restrict people's ability to respond to them. However, some regional issues, such as water in the Middle East and the drying of the Aral Sea in central Asia (which has lost 70 percent of its volume since 1960), are significant enough to be considered a threat to national security, and an underlying cause in regional conflict. The assessment of threat is highly contextual and it is difficult to establish any direct cause and effect relationships.

The North Atlantic Treaty, under which the NATO alliance operates, was one of the first to recognize that security is not only based on military strength but also depends on economic and social security. This dimension has been increasingly important within NATO since the end of the Cold War, when environmental aspects of security were also integrated into NATO strategy (Lietzmann and Vest 1999).

1.2 Human Security

Human security was first defined as threats to physical security; in particular, freedom from fear and freedom from want. The Universal Declaration of Human Rights adopted by the United Nations in 1948 states that 'everyone has the right to life, liberty and the security of person.' By 1994, the concept of human security had evolved to encompass seven aspects of security: economic security, food security, health security, environmental security, personal security, community security and political security (UNDP 1994). At the same time, a distinction was made between human security and human development. 'Human development is a broader concept, defined as a process of widening the range of people's choices. Human security means that people can exercise these choices safely and freely' (UNDP 1994, p. 23).

Environmental security is highlighted as an individual component of human security and as a contributing factor to other aspects of human security, such as food, employment and health, because these depend on people's access to natural resources, like land, water and forests. Very often, these environmental security issues are played out at a regional level between national sharing borders and environmental resources.

1.3 Critical Zones and Vulnerabilities

A related concept is that of environmental criticality, when human activity has so radically altered the natural environment that it no longer can support human populations or their economic livelihoods, and it is beyond restoration by normal ecosystem processes or human efforts at remediation (Kasperson et al. 1996). This same idea lies behind the 'red zone' maps of Russian geographers and the concept of 'hot spots' of biodiversity at risk (Myers 1993).

Whether an area becomes a critical zone depends on the rate and extent of environmental degradation, but it appears that some areas are more vulnerable to reaching a critical state than are others. This has led to an interest in why certain combinations of geographic

area and human society seem to be more vulnerable than others to environmental risk, and what the thresholds and possible indicators of vulnerability and adaptation might be (Lonergan 1997).

2. Global Change and Environmental Security

More recently, the relationship between global environmental change and environmental security has been examined. Global change is manifested in many environmental effects. These stem from the warming and other changes in the atmosphere brought about through the increase of levels of carbon dioxide and other gases, and of contaminants produced through human economic activity. These environmental effects extend to changes in ocean currents, precipitation patterns on land and sea, a rising sea level, and stratospheric ozone depletion. In turn, global change impacts many aspects of ecosystem functioning and human economic activity such as loss of biodiversity, global biogeochemical cycles, agricultural and forestry production. Some of these changes are gradual and long term, while other changes relate to the frequency and severity of peak events, like hurricanes, droughts and other natural hazards. It is argued that both types of changes can significantly affect people's ability to cope with environmental risks and thus are likely to affect environmental security and conflict.

Global change has also led to a series of global environmental negotiations and agreements, as well as bargaining about trading rights to pollute. While these efforts at environmental diplomacy might seem to reduce the potential for environment insecurity and conflict, it is clear that in the short run, there are potential winners and losers among nation states as well as possible 'free-riders.' Thus the global environmental negotiations can exacerbate the potential for environmental disputes. These are revealed as ideological differences between industrialized and nonindustrialized (or developing) countries, whose interests are usually clearly different, but more importantly, they tend to emphasize regional disparities and potential for conflict.

Formal international scientific programs which seek to bridge the gap between science and policy (or research and action) are beginning to examine risk, vulnerability and security. For example, the Global Environmental Change and Human Security Project (GECHS) of the International Human Dimensions Programme on Global Environmental Change (IHDP) is studying the relationship between global change and environmental security (GECHS 1999). It is addressing some key questions: what types of environmental change threaten security? Which regions and groups of people are the most insecure and why? Can we predict future insecurities? What strategies are available to governments and communities to cope with environmental insecurity caused by global change? Another international science program, LUCC (Land-Use and Land-Cover Change) is focusing on critical regions and vulnerable places, especially what happens to the resiliency of people, agricultural production systems and biodiversity in the face of global changes like sea-level rise and increased frequency of extreme storm events (LUCC 1999)

3. Critical Zones

It has been argued that some environments, such as rainforest and tundra, are more sensitive to human exploitation and that some forms of human development, such as rapidly growing populations or 'frontier' economies (where exploitation has room to move and can therefore be more destructive) exacerbate environmental vulnerabilities. Amazonia is a tropical rainforest which has been damaged by frontier development and rapidly increasing in-migration.

Kasperson et al. (1996) examined nine regions of the world which were considered potentially critical zones according to three criteria: (a) the environmental changes must threaten the basic structure and function of the ecosystem; (b) the changes must endanger human well-being or sustained human use of the area; and (c) the threat must be great enough to overwhelm the capacity of the local people or government to deal with the degradation. They concluded that only the Aral Sea is presently a critical zone because the lake is essentially dead and surrounded by evaporated salts and highly contaminated soils. However, five of the areas studied are highly endangered and are in a pre-critical condition. These are: Eastern Sundaland (which includes the tropical forests of Borneo and the eastern Malay Peninsula); the semi-arid Ukambani region of southeastern Kenya; the deforested and highly eroded Nepal middle mountains; the arid plains in western Texas and New Mexico; and the Basin of Mexico in which Mexico City stands.

A different approach to critical zones is that being developed in the GECHS (Global Environmental Change and Human Security) project which is to identify indicators of environmental degradation and human insecurity to develop early warning of 'hot spots' for potential conflict (GECHS 1999). Data quality and reliability are major problems in this approach but some initial maps have been prepared based on an Index of Human Insecurity. The indicators include water scarcity, food import dependency ratio, energy imports as a percentage of consumption, access to safe water, expenditures on defense vs. health and education, indicator of human freedoms, urban population growth, child mortality, maternal mortality, income per capita, degree of democratization, and fertility rates (Lonergan et al. 1999). The results

show that the areas with the highest insecurity are most of Africa, the Middle East, and south and southeast Asia. Within these areas are so-called pivotal states which are balanced precariously between security and insecurity: between development and political and social chaos; and where what happens in that country can have far-reaching, even global effects. Algeria, Brazil, Egypt, Mexico, India, Indonesia, Pakistan, and South Africa have been identified as pivotal states.

4. *Environmental Security and Conflict*

A number of major research projects have focussed on the nature of the linkages between environmental security and conflict including the Peace and Conflicts Studies Programme at the University of Toronto (Homer-Dixon 1994, Homer-Dixon and Percival 1996); the Environment and Conflicts Project (ENCOP) in Switzerland (Bachler and Spillman 1996) and the International Peace Research Institute in Oslo (Gleditsch 1998, Hauge and Ellingsen 1998).

The relationship between environmental stress and conflict is a complex one and may not necessarily result in violent conflict; it can also lead to negotiation and peaceful resolution. Environmental stress almost always interacts with other social, economic and political factors before leading to conflict, and any resulting conflict can lead to further environmental stress. Usually environmental stress produces human insecurity problems like food insecurity, population movements and the breakdown of social and political institutions, and it is these secondary effects which can contribute directly to conflict. Thus, environmental stress is seen as sometimes a source of conflict, a catalyst or a trigger for conflict, depending on the circumstances. The social, economic and political context has always to be considered when assessing the potential effects of environmental insecurity.

The University of Toronto study identified three conditions of resource scarcity which could lead to conflict: (a) decreased quality and quantity of renewable resources (supply induced scarcity); (b) increased population growth or per capita consumption (demand-induced scarcity); and (c) unequal access to resources (structural scarcity). These types of scarcity can act singly but often combine to produce two common phenomena: resource capture and ecological marginalization. Resource capture occurs when a decrease in resources quantity or quality coincides with population increase, and the most powerful groups in society ensure that the resources are redistributed in their favor, leading to severe environmental scarcity for the poorer and weaker. Ecological marginalization occurs when population increase and inequitable access to natural resources combine to cause population migration, usually to more marginal and less inhabited environments like steeper mountain slopes and more-arid areas. The resulting higher population densities and lack of local environmental knowledge can lead to severe environmental damage by the migrants (Homer-Dixon 1994).

The ENCOP (Environment and Conflicts) Project sponsored by the Swiss Government and the Swiss Peace Foundation considers all conflicts to be social and political events even when environmentally induced. It found that the main contextual factors for environmental insecurity are: perceptions, especially when one group sees their interests as being threatened; economic vulnerability and resource dependency; institutional and technological capacity; cultural and ethno-political factors, especially where there are differences in wealth and power; the existence of democratic institutions and political stability; participation in decision making; and what mechanisms of conflict resolution are available. Based on a series of case studies, the ENCOP project found that environmentally induced conflicts were of three main types: (a) between different groups within a country; (b) through processes such as population displacement which leads to conflicts crossing national borders; and (c) when internationally shared resources like rivers, regional environments or global commons become degraded and lead to inter-state conflict.

5. *Environmental Migrants*

Environmental degradation has been cited as one of four root causes of refugee flows, together with political instability economic tensions and ethnic conflict (UNHCR 1993). The number of environmental refugees is estimated to be 10 million out of the 17 million official refugees and more than half of these are believed to be in sub-Saharan Africa (Westing 1992). But the numbers may be far greater and appear to be rapidly increasing. The greatest effects of climate change may be to displace millions of people through shoreline erosion, coastal flooding and agricultural failures.

Although the World Commission on Environment and Development identified environmentally induced population movements as a recent phenomenon (WCED 1987), there is much evidence that people have had to move from land affected by natural disasters, warfare and mismanagement throughout—and before—history. Despite the size of the problem, there has been relatively little empirical research on the role of environmental change in population movements. Some of this movement is across national borders, but it is estimated that for every individual who moves across an international border, there are two or three persons who have to move within their country. These are internally displaced persons (Myers 1995).

There are a number of difficulties in understanding the role of the environment in causing people to move.

Migration research has long shown that the decision to migrate is a combination of 'push–pull' factors, as people weigh the advantages and disadvantages of where they are presently located compared to where they plan to move. It is difficult to isolate the role of environment in this decision unless there is a specific environmental stress such as an earthquake or flood from which people are fleeing and after which they are likely to return. Other environmental 'push' factors include slower environmental degradation such as deforestation; soil deterioration through erosion, salinization or waterlogging; and desertification and falling water tables, which make agriculture less viable. Development projects such as dams and irrigation schemes have often involved enforced resettlement. In India, it is estimated that over 20 million people have been displaced by development projects since the 1960s (Fornos 1992).

6. *Critical Perspectives*

Although work on environmental security has gained momentum in the 1990s in both academic and policy circles, there are strong critics from both the security and environmental sides of the debate. Security critics point out that broadening the definition of security to include aspects like environment, food security, and economics, renders it useless as an analytical tool as it means different things to different people. Furthermore, it encourages the military to undertake 'environmental' missions which takes time and resources away from their real task of military preparedness. Environmental critics claim that the research in environmental security is methodologically weak and cannot find causal links between environment and security. They also see that security institutions are looking for new missions ('greening of security') to maintain their funding after the end of the Cold War. Developing country scientists see the concept of environmental security as a northern industrialized paradigm. There is also concern that the concept of environmental security encourages a military 'us versus them' approach to problem solving, where complex relationships between environmental change and human development require less simplistic and more collaborative solutions (Lipschutz 1992, Gleditsch 1997, GECHS 1999). Despite these criticisms, environmental security is rapidly developing as a focus at the nexus of research and policy.

Environmental Stress and Health

1. *Introduction*

This article examines how the concept of stress has been used to specify environmental characteristics that may lead to disturbances of intended behavior, psy-

chological and physiological discomfort, and health aspects of residents living in the vicinity of noisy or toxical sources. The physical environments considered here have enduring characteristics and are not directly under the control of the residents. This fact constitutes one of the main characteristics of psychological stress: people may consider the environmental load to be harmful, but they usually cannot stop the emissions of the source directly. In addition, they often learn from authorities that the emissions are harmless, and yet they have to rely on authorities in order to reduce the environmental load. The focus of this article is on dose-response relationships between environmental characteristics and psychological reactions of the residents. The observed reaction-variance between residents is due partly to measurement errors both on the physical and the response side, and due partly to factors intervening between the physical characteristics and the responses. Nevertheless, in some cases there are clear dose-response relationships that can be used in order to predict the average main effects at given physical loads.

2. *Definitions of Environmental Stress*

Although there are many different concepts of stress in the respective fields of medicine, psychology, and sociology, it is generally understood that stress is aversive in some sense. Psychologists often favor the stress concept proposed by Lazarus (1966), and Lazarus and Launier (1978), which defines stress as a transaction between stimulus and response, i.e., the process that reflects the individual appraisal of a stimulus by persons who see an imbalance between environmental demands and their own response capabilities to cope adequately with the demands. It should be noted that this concept relies heavily on individual self-reports, but sometimes even the individuals concerned do not notice the dangers that a certain situation provides for health, e.g., the potential hearing loss implied by loud music.

2.1 *Characteristics of Environmental Stressors*

Environmental stressors are usually considered to fall into one of four distinct classes: cataclysmic events, stressful life events, daily hassles, and ambient stressors (Evans and Cohen 1987). Cataclysmic events comprise sudden catastrophes that affect many individuals at the same time. For instance, floods, major storms, earthquakes, volcanic eruptions, nuclear power plant accidents, chemical plant accidents, and the discovery of toxic waste dumps belong to this category. Cataclysmic events are seldom predictable, neither with respect to their beginning, nor with respect to their course, but they are usually expected to be rather short.

Stressful life events are major incidents in the course of life that require major individual adaptive responses. Such events include major changes in work, or residential environment, e.g., beginning a new job, moving to a new residential area, major construction work in the present residential area, or a major perceptible change in the operating conditions of a nearby stressor. The event as such is usually short, but the behavioral consequences may be long, or permanent.

Daily hassles are repeatedly occurring aversive events of ordinary life, such as arguments with colleagues, crowded classrooms, and traffic congestions on the daily route to work. Although they typically are more or less predictable, the individual has little means to avoid such hassles, and the duration is rather short.

Ambient stressors is a term proposed by Campbell (1983), denoting more continuous and intractable background characteristics of the physical environment. They often go unnoticed, like the continuous hum of the air conditioning, the permanent dust in an industrial area, and the faint hiss of the central heating system. Most people believe that they can adapt to ambient stressors, and they consider the costs of coping with such stressors to be higher than simply enduring them.

In addition, each type of environmental stressor can be categorized along several dimensions, of which we mention only three.

(a) The major dimension is the degree of controllability over the environmental stressor. Control may be either direct (e.g., switching off the neighbor's noisy lawn mover), indirect (e.g., closing the windows in order to reduce the noise penetration), social (e.g., calling authorities to stop the noise), or cognitive (e.g., knowing that the noise will stop in about an hour). It has often turned out that stress effects decrease with increased control, but sometimes control has secondary stress effects (e.g., closing the windows will increase the temperature inside the house).

(b) Related to cognitive control is the predictability of the stressor. High predictability of the occurrence and time course of an aversive agent may help people to cope with it. For instance, residents in the vicinity of city rail systems usually know exactly the time schedule of the trains and seldom complain about noise and vibration, but they feel irritated when a train is missing. Alternatively, knowing beforehand that a new airport will open in the neighborhood does cause greater stress effects than knowing that the old airport will close in the neighborhood (Hatfield et al. 1998).

(c) Stressors may be more or less perceptually salient or identifiable. Some environmental agents are of rather low intensity and may either be not detected at all (e.g., low radioactive radiation), others are only detected when intensity changes (e.g., the faint current of air conditioners). If an environmental agent is not perceptually salient, stress reactions may occur be-

cause people get informed about potential hazards, and the type and degree of stress reaction depends very much on the content of information and the credibility of its source.

2.2 Variables Intervening Between Stressors and Their Effects

Although it is true that varying degrees of environmental load cause varying degrees of stress reactions in the average, it is also well known that the same degree of environmental load does not cause the same degree of reaction in every person or in every situation. It depends on situational, personal, and social variables whether an environmental agent becomes a severe problem for a person or not. For instance, a faint burning smell or a sudden noise may cause greater alarm reactions at night than the same events occurring during daytime—this is an example of situational moderation. Individual differences in susceptibility are well known with respect to noise and smoke, i.e., persons who judge themselves to be rather susceptible to noise generally show greater noise reactions than persons who judge themselves less susceptible. A similar relation holds for smoke, and recent evidence (Winneke and Neuf 1992) fosters the belief that environmental susceptibility is a general individual trait, comprising susceptibilities for different environmental agents.

While individual differences are thought to be the result of the individual development of a person, social intervening factors are thought to be the result of social developments, shared by larger groups of the society. For instance, a plant that emits fumes and noise may cause less stress effects when a group evaluates the source positively in some other respect (e.g., as providing jobs). Of course, there is no clear-cut distinction between personal and social factors, because the individual development usually takes place within a certain society, and there is also a considerable individual variation with respect to sharing the views and evaluations of society in general. For an extensive discussion of moderating variables for noise, see Guski (1999).

3. Effects of Environmental Stressors

3.1 Effects of Noise

Noise is defined generally as unwanted sound, i.e., a sound that is already evaluated by somebody or some group as being aversive. Since the degree of aversiveness usually increases with the level of sound, the scientific study of noise effects is restricted to the middle and upper levels of environmental sound. Sound levels are usually given in decibels (e.g., dB),

Figure 1
Percentage of residents disturbed by aircraft noise at Oslo Airport (after Gjestland et al. 1990)

but care should be given to the exact meaning of the term used for describing the sound level. For instance, a temporary maximum value of $L_{max} = 65$ dB is easily reached by every speaker at 1m distance—it may be a nuisance, but will cause no harm—while the sound energy of $L_{Aeq} = 65$ dB calculated for 16 hours of daytime is considered to be a risk for health. The main source of environmental noise-effect studies is transportation noise (road, rail, and air), because it affects almost everybody in the industrialized world. Lambert and Vallet (1994) estimated 20 percent of citizens of the European Community to be exposed to transportation noise with daytime levels of $L_{Aeq} = 65$ dB or higher.

The studies considered in this article are interdisciplinary field studies, using residents in the vicinity of traffic routes as subjects. The noise level is usually given as daytime and/or night-time sound energy, calculated from data about traffic volumes, together with a few supporting measurements at the outside of the subjects' lodgings. The questionnaires usually cover noise-effect questions (e.g., with respect to annoyance, disturbance of communication, disturbance of recreation, and sleep quality) in a closed response format, general questions about living conditions, demographic characteristics, and potential intervening variables, such as the individual noise sensitivity, health status, coping capacity, and trust/distrust in authorities of the sound source. Daytime environmental traffic noise has large statistical effects on the degree of annoyance, and the degree of reported disturbances of daily activities. Nighttime environmental traffic noise has somewhat smaller statistical

effects on the degree of general annoyance and reported sleep quality. A very typical result is the linear relationship between physical parameters of sound and the mean response of residents, at least as far as raw scores are used. Sometimes, the responses are given as percent 'highly annoyed' (percent HA), selecting only those residents who chose the upper 27 percent of the original scale. Because of the selection process, the dose–response curve is nonlinear in that case. A typical dose–response relationship is given in Fig. 1, showing the nonlinear relationship between the level of daytime aircraft noise in the residential area, and the average percentage of residents who say that they are disturbed while engaged in different activities during the day.

In comparing the effects of different sources of transportation noise, it is generally found that the mean general annoyance response is somewhat higher for aircraft noise than for road traffic and railroad noise at the same overall noise levels, if the noise levels are converted to day/night levels (L_{dn}), where night levels are weighted 10 dB stronger than day levels (Miedema and Vos 1998). The same authors (1999) conclude from a comparison of original data from several studies that personal attitudes to noise (e.g., fear or other negative evaluations of the source, and noise sensitivity) are very effective variables intervening between the physical impact and the annoyance response to noise.

With respect to somatic effects of noise, data are less clear, but there are several studies showing the prevalence of ischemic heart diseases to increase somewhat in middle-aged males with high levels of daytime road traffic noise (Babisch et al. 1999). Under nighttime transportation noise a fragmentation of the sleep structure is to be observed and can be classified as stress (Griefahn 1986, Griefahn and Muzet 1978). The effects can be observed by means of individual EEG recordings during the night, as well as by means of increased fallout of the stress hormones adrenaline, noradrenaline, and cortisol. Maschke et al. (1998) claim that an increased secretion of adrenaline and noradrenaline belongs to a defense situation, an increased secretion of cortisol marks a defeat situation. The results of an experimental longitudinal field study at Hamburg Airport show no uniform cortisol excretion reaction to persistent aircraft noise, but about half of 16 subjects display an increased cortisol excretion after a phase of adaptation during the disturbed night, and the increased cortisol levels are classified as exceeding the normal range.

3.2 Living on Polluted Soil

Residential areas are sometimes built in the vicinity of former industrial areas, and this can cause severe problems for health, if the soil is polluted. One of the best known examples is Love Canal (see Bell et al. 1995), where toxic agents had been disposed of over years into a creek, and several years after the closure of the chemical plant, residential buildings were erected in the area. When toxic evaporations were detected, health authorities alarmed the residents and offered financial help for those who wanted to move. The monetary compensations were judged to be insufficient by many residents, and a long-lasting public debate reflected the severe helplessness of many residents (Levine 1982).

Another example is a residential area in Dortmund (Germany), where toxic evaporations from a former chemical plant were detected and caused severe psychosomatic complaints (Matthies et al. 2000). The debate about possible health hazards, in combination with insensitive communication policy of the health authorities, led to ongoing psychosomatic effects even after the beginning of a complete soil exchange in the whole residential area. The amount and degree of complaints was not related to any chemical variable measured, but differed significantly from a control group in an unpolluted area.

3.3 Living With Nuclear Power Plants

Although the nuclear industry spends billions of dollars for public relations in the hope of changing public attitudes to nuclear power plants and nuclear waste, the general attitudes in Western societies seem rather skeptic. The skeptic attitudes are caused by the public experience of technological catastrophes like Three Mile Island (TMI) (1979) and Chernobyl (1986). The psychological effects of technological catastrophes on residents differ from those of natural hazards in many ways, e.g., they are more long lasting, and residents lose faith in public communications of authorities with respect to safety and control of health risks. Even seven years after the catastrophe at TMI, residents living near the damaged reactor reported more chronic stress symptoms and sleep disturbances than did control subjects (Davidson et al. 1987).

The catastrophe at Chernobyl caused severe psychological changes in the European population, especially with respect to the evaluation of nuclear power, the probability of a nuclear accident, and the health risks for children (Drottz-Sjöberg and Sjöberg 1990, Hüppe and Janke 1994). Many social scientists believe that the inconsistent and reluctant communication policy of public authorities has contributed to the stress symptoms of residents who were only slightly exposed to direct nuclear radiation.

4. Conclusions

Environmental characteristics of residential areas (such as noise, polluted soil, and nuclear power plants) may lead to disturbances of intended behavior, psy-

chological and physiological discomfort, and health aspects of residents. The relation between physical characteristics of the source and the aversive reactions can be described as a stress situation, because the reactions covary with the degree of emission, and residents usually cannot stop the emissions of the source directly. In addition, situational, personal, and social variables moderate the dose-response relationship.

Environmental Surprise

Decision makers at all scales (individuals, firms, and local, national, and international governmental organizations) are concerned about reducing their vulnerability to (or the likelihood of) unexpected events or 'surprises.' After briefly and selectively reviewing the literature on uncertainty and surprise, a definition of 'surprise' is introduced that does not include the strict requirement that it apply to a wholly unexpected outcome, but rather recognizes that many events are often anticipated by some, even if not most observers. Thus, an 'imaginable surprise' is defined as an event or process that departs from the expectations of some definable community, yet is a concept related to, but distinct from risk and uncertainty. Therefore, what gets labeled as 'surprise' depends on the extent to which what happens departs from community expectations and on the salience of the problem (for elaboration see Schneider et al. 1998). Impediments to overcoming ignorance range from the need for more 'normal science' to phenomenological impediments (e.g., inherent unpredictability in some chaotic systems) to epistemological ignorance (e.g., ideological blocks to reducing ignorance). The substantive focus will concentrate on the theme of global change. Examples of 'imaginable surprises' in the global change context are presented. Improving the anticipation of surprises is an interdisciplinary enterprise

that should offer a skeptical welcoming of outlier ideas and methods, tempered by broadbased assessments that attempt to estimate the subjective probabilities of all imaginable outcomes (e.g., Schneider 2001).

Strictly speaking, a surprise cannot be anticipated; by definition it is an unexpected event. Potential climate change, and more broadly global environmental change, is replete with the truly unexpected because of the enormous complexities of processes and interrelationships involved and our insufficient understanding of them (such as coupling ocean, atmosphere, and terrestrial systems). However risk, hazard, and related research demonstrate repeatedly that the event, process, or outcome registered as a surprise by the community in question was frequently known or forecast by others or the same event was knowable within the competing frameworks of understanding (Darmstadter and Toman 1993).

Much of the current work on surprise has grown out of an extensive body of research on uncertainty. Yet, although widely acknowledged and studied, uncertainty remains a difficult concept to define or codify. Different conceptualizations and approaches to uncertainty abound in the literature, cross numerous fields of study and touch a wide range of problem types. Two basic options are invariably followed in the face of uncertainty. The first is to reduce the uncertainties through data collection, research, modeling, simulation techniques, and so forth. Following this option, the objective is to overcome uncertainty, to make the unknown known. But the daunting nature of uncertainties surrounding global environmental change (what some have labeled 'deep uncertainty'), as well as the need to make decisions before the 'normal' science option can provide resolution, force a second option—that of managing or integrating uncertainty directly into the decision-making or policy-making process. Before uncertainty can be so integrated, however, the nature and extent of the uncertainty must be clarified.

The fields of mathematics, statistics, and more recently physics, provide the 'science of uncertainty' with many powerful means and techniques to conceptualize, quantify, and manage uncertainty, ranging from the frequency distributions of probability theory, to the possibility and belief statements of Bayesian statistics. Addressing other aspects of uncertainty, fuzzy set logic offers an alternative to classical set theory for situations where the definitions of set membership are vague, ambiguous, or non-exclusive. More recently, researchers have proposed chaos theory and complexification theory to focus on expecting the unexpected in models and theory (e.g., Casti 1994).

The practical application of many of these techniques was originally pioneered by researchers in decision analysis (see Raiffa 1968). In the fields of economics and decision theory, researchers continue to study rational decision making under uncertainty and how to assess the value of collecting additional information (e.g., Clemen 1991). Methods for modeling risk attitudes, leading to the terms risk-prone and risk-averse, attempt to capture how different people faced with making a decision react to the uncertainty surrounding the expected outcomes. Uncertainty and its related context, surprise, are treated largely as the realization that events, currently unknown, will occur affecting the final outcome of a process or decision.

This acknowledgment of uncertainty has found a prominent place in many other fields of study, each one speaking its own language of uncertainty. Research on uncertainty cross-cuts a number of different disciplines. For example, researchers making risk assessments and setting safety standards find it most useful to distinguish between risk (the probability of a certain negative effect resulting from a hazard occurrence, given the specified level of exposure), variability (inter-individual differences in vulnerability and susceptibility), and uncertainty (model parameter variability and any unexplained residual). In work related to hazards and risk, sociologists, anthropologists, psychologists, and geographers have made important contributions to the discussions on risk perception, risk communication, and the social amplification of risk (Kahneman et al. 1982, Kasperson et al. 1988, see Gigerenzer 1996 for a criticism). Similarly, work on visualizing or graphically conveying uncertainty also crosses a diverse set of disciplines including psychology, computer science, and Geographic Information Systems (e.g., MacEachren 1992).

Wynne (1992) emphasizes that the modeling of environmental risk systems requires examination of not only the scientific evidence and competing interpretations, but also investigation of the nature, assumptions, and inherent limitations of the scientific knowledge behind the data and the model. He specifies four types of uncertainty—risk, uncertainty, ignorance, and indeterminacy—each overlaying dimensions of uncertainty. *Risk* refers to a situation when the system behavior is well known and the chances of different outcomes can be quantified by probability distributions. If, however, the important system parameters are known but not the associated probabilities, then in Wynne's definitions, *uncertainty* exists. *Ignorance* is that which is not known (or even that we are aware that we do not know it) and, for Wynne, is endemic because scientific knowledge must set the bounds of uncertainty in order to function. *Indeterminacy* captures the unbounded complexity of causal chains and open networks. *Uncertainty*, in part, stems not only from an incomplete understanding of determinate relationships, but also from the interaction of these relationships with contingent and unpredictable actors and processes. However, the extent to which situations are truly 'indeterminate', as opposed to simply containing a very broad distribution of subjective probability estimates, is not a straightforward classification, for often very ill understood phenomena can still be bounded to some extent by

existing knowledge, and thus not truly indeterminate. In the areas of environmental policy and resource management, policy makers struggle with the need to make decisions utilizing vague and ambiguous concepts (such as sustainability), with sparse and imprecise information, in decisions that have far-reaching, and often irreversible, impacts on both environment and society. Not surprisingly, efforts to incorporate uncertainty into the decision-making process quickly move to the forefront with the advent of decision-making paradigms, such as the precautionary principle, adaptive environmental management, the preventative paradigm or stewardship. Ravetz (1986) takes the concept of 'usable knowledge in the context of incomplete science' one step further by introducing the idea of usable ignorance. To Ravetz, acknowledging the 'ignorance factor' means becoming aware of the limits of our knowledge. Ravetz argues that ignorance cannot be overcome with any amount of sophisticated calculations. Rather, coping with ignorance demands a better articulation of the policy process and a greater awareness of how that process operates. He recognizes that one can only replace ignorance by gaining more knowledge, but stresses that by 'being aware of our ignorance we do not encounter disastrous pitfalls in our supposedly secure knowledge or supposedly effective technique' (p. 429).

The emphasis on managing uncertainty rather than mastering it can be traced to work on resilience in ecology (e.g., Holling 1986). Whereas resistance implies an ability to withstand change or impact within some measure of performance, resilience captures the ability to give with the forcing function, without disrupting the overall health of the system. In this framework, adaptation is an ecological mechanism whose aim is not to overcome or control environmental uncertainty, but to live with, and in some case, thrive upon, it.

To recap, risk typically is defined as the condition in which the event, process, or outcome, and the probability that each will occur, is known. In reality, of course, complete or perfect knowledge of complex systems, which would permit the credible calculation of objective or frequentist probabilities rarely exists. Likewise, the full range of potential outcomes is usually not known. Thus, risk almost always is accompanied by varying degrees of uncertainty. Uncertainty is usually defined as the condition in which the event, process or outcome is known (factually or hypothetically), but the probabilities that it will occur are not known, or are highly subjective estimates (see, e.g., Moss and Schneider 2000).

Strictly speaking, surprise is the condition in which the event, process or outcome is not known or expected. In this 'strict' meaning, the attribution of surprise shifts toward the event, process or outcome itself. We may expect surprises to occur, but we are surprised by the specific event, process, or outcome involved. This meaning, as noted, begs the issue of anticipation, because the very act of anticipation implies some level of knowledge or foresight. However, it may be possible to identify 'imaginable conditions for surprise' where the conditions that might induce surprises are known even though the actual surprise events are not, for example, rapid forcing of non-linear systems (e.g., Moss and Schneider 2000).

Because of the impracticality of the strict definition of surprise for policy making, various studies advocate the use of another meaning for surprise, one in which the attribution of 'surprise' shifts more toward the expectations of the observer. Holling (1986, p. 294) recognized this meaning of surprise as a condition in which perceived reality departs qualitatively from expectations. It is this more interpretive or relational meaning of surprise—which has been labeled 'imaginable surprise'—that portends to be most useful for global change studies (Schneider et al. 1998).

Almost every event may constitute an imaginable surprise to someone. But since global change phenomena and their environmental and societal impacts are a community-scale set of issues, little can be gained for our purposes by focusing on whether someone, somewhere, may or may not have once predicted or hinted at some surprise event. More fruitful is the recognition that groups, communities, and cultures may share expectations such that a particular event is likely to qualify as a surprise for most within them. In these cases, what gets labeled as a surprise depends upon the extent to which reality departs from community expectations, and on the salience of the problems imposed.

Imaginable surprise applies to communities of experts, policy makers, managers, and educators who share common ranges of expectation that are generated by group dynamics, leaders, and signal processors, including the dominant educational and research paradigms (Kasperson et al. 1988). For these communities, shared expectations follow from dominant interpretations among the expert community (e.g., global warming is likely), from their fit with broader policy agendas (e.g., environmentally benign economic development is possible), and from vested interest, conscious or unconscious, of an agency or group to maintain a particular view (e.g., global population growth is environmentally damaging, or, alternatively, good for the economy). Since policy making often reflects a blend of public and interest group perceptions of reality, the imaginable surprise formulation is much more relevant to global change policy issues than a strict definition of surprise as an unimaginable outcome.

Since natural and social global change science remains in a range of developmental stages, the unknowns are sufficiently large to warrant attention to divergent themes about similar processes and outcomes. To facilitate this range of research, (a) measures should be taken to ensure a more open

discourse and evaluation of alternatives, such as by a more open airing and professional evaluation as opposed to uncritical, 'equal time' and equal credibility often afforded to polarized viewpoints in the popular media of less dominant or unconventional views, including those by advocacy science and scientist; and (b) by reducing the redundancy of research focused on the dominant views and theses while still preserving a diversity of approaches within dominant paradigms, that is, create research 'overlap-without-cloning.'

The assumptions associated with the standard paradigm of global climate change impact assessment, for example, although recognizing the wide range of uncertainty, are essentially surprise free. One approach is to postulate low, or uncertain, probability cases in which little climate change, on the one hand, or catastrophic surprises, on the other hand, might occur and multiply the lower probability times the much larger potential costs or benefits. Analysts, however, customarily use a few standard general circulation model CO_2-doubling scenarios to 'bracket the uncertainty' rather than to postulate extremely serious or relatively negligible climatic change outcomes. A strategic approach, that is, one that considers a wide range of probabilities and outcomes, may be more appropriate for global climate change impact assessments given the high plausibility of surprises, even if we have but limited capacity to anticipate specific details right now (Moss and Schneider 2000).

An assumption in cost-benefit calculations within the standard assessment paradigm is that 'nature' is either constant or irrelevant. For example, ecological services such as pest control or waste recycling are assumed as constants, or of no economic value in most assessment calculations. Yet should climatic change occur in the middle to upper range of that typically projected, it is highly likely that communities of species will be disassembled, and the probability of significant alterations to existing patterns of pests and weeds seem virtually certain. Some argue that pests, should their patterns be altered, can simply be controlled by pesticides and herbicides. The side effects of many such controls are well-known. What is not considered in the standard paradigm is the consideration of a 'surprise' scenario such as a change in public consciousness regarding the value of nature that would reject pesticide or herbicide application as a 'tech-fix' response to global changes.

Finally, global change portends alterations to the basic processes that govern the state of the biosphere. Global change research, therefore, might do well to anticipate these alterations, an effort that will require more than the study of extant processes and conditions alone. Various modes of analysis and approaches appropriate for such explorations, but typically underutilized in the research community, should be encouraged. Among these are: (a) backcasting scenarios from posited future states and/or reconstructing past scenarios in alternative ways to identify events or processes that might happen (recognizing, of course, that diffusion processes usually are not reversible and diffusion-dominated systems cannot be meaningfully backcast); (b) increasing attention to and support for the study of 'outlier' outcomes, searching for the reasons they appear deviant and the lessons that might be drawn from them (e.g., Hassol et al. 1997); and (c) exploring the 'resilience' paradigm (e.g., precautionary principle) alongside the 'optimization' paradigm (e.g., aggregated cost-benefit analyses) to inform policy making and diagnose alternative outcomes and risk management strategies. Other means of improving the anticipation of surprise in global change science would emerge from convening additional expert groups and asking them for more exhaustive assessments of the issues. Balanced assessments will likely lead to recommendations that 'research as usual' be tempered with more alternative or even unusual research.

In summary, global change science and policy making will have to deal with uncertainty and surprise for the foreseeable future. Thus, more systematic analysis of surprise issues and more formal and consistent methods of incorporation of uncertainty into global change assessments will become increasingly necessary. Improvements in dealing with scientific surprise in climate change in particular and global change in general, therefore, require the research and funding communities to seek a better balance among traditional and experimental research alternatives (also Kates and Clark 1996, p. 31). This aim, in turn, requires strategies that will facilitate this balance, including the difficult problem of assessing 'quality' in an interdisciplinary context.

Environmental Vulnerability

Global changes are accelerating at an ever increasing pace with varying impacts. While some societies are becoming more globalized and equipped with modern technology, others live in poverty, they struggle to survive amidst the challenges of fluctuating daily provisions, inadequate shelter, and poor provision of essential services including health and water. Both societal groups may confront environmentally vulnerable situations. People living in industrialized cities may, for example, have to encounter technological hazards (e.g., toxic chemical accidents) and those living in less-developed locations may be at risk of poorly constructed homes and inadequate basic services provision such as water (White 1974, Kates et al. 1985).

A host of practitioners (nongovernment organizations, relief workers, disaster managers), scientists, academics, and policy makers are endeavoring to understand the processes that shape the welfare and daily conditions of people and how their lives are influenced by environmental change. One way of trying to understand what enables some to better manage changing events is through a careful probing and examination of 'environmental vulnerability.' In this article environmental vulnerability will be examined particularly from the perspective of human vulnerability. Environmental vulnerability will be defined followed by examples of how the concept has changed and been used over time.

1. *Defining Environmental Vulnerability*

There have been several attempts to define and capture what is meant by environmental vulnerability ranging from geophysical, engineering, and technological aspects of environmental vulnerability through to the social, political, economic, and political dimensions. In the 1970s and 1980s, the importance of integrating these dimensions as a means to understand how such factors shape people's lives and their exposure and vulnerability to changing environments was recognized. This thinking influenced the generation of theories and concepts that were subsequently adopted in the lexicons of development, disaster management, and in global change science. One key concept which reflects this holistic view is environmental vulnerability.

Environmental vulnerability is the product of a combination of circumstances related to a host of issues which include living with risks and hazards (sudden events such as floods, earthquakes, and slow-onset events such as droughts, e.g., see *Environmental Risk and Hazards*). Other factors such as health, poverty, and gender also exacerbate existing risks/hazards, thereby heightening vulnerability and weakening positive responses to such phenomena. Environmental vulnerability is thus described with reference to the physical and social environment or the milieu in which a group may find themselves (Fig. 1).

Having briefly described what is meant by environmental vulnerability, the focus now shifts to examine how it is used in a variety of contexts. In some fields, environmental vulnerability is associated with geophysical aspects of risk and 'hazard science.' In many cases, however, particularly those characterized by poverty, certain risks, hazards, and potential disasters are not only linked to natural events but also related to slow, continuous processes that are advanced by environmental and socioeconomic vulnerability. In these regions, 'traditional' hazard/risk analyses are often compounded by other mitigating factors such as lack of access to resources, lack of accessible information, reduced response to shocks because of poverty or other factors. Recognizing this complexity, a strong emphasis on the human dimensions of vulnerability has emerged which describes both *internal dimensions* (inability or ability to cope and respond) and *external dimensions* (such as ex-

Figure 1
Configuration of vulnerability: an interaction between a household's capacity, flows of social and human assets, factors making up a 'living' in the face of a sudden/creeping shock or stress (adapted from Swift 1989, Chambers and Conway 1992, Mullins 1999)

posure to risk, shocks, and stress) (e.g., Chambers 1989, Swift 1989, Liverman 1990, Chambers and Conway 1992, Blaikie et al. 1994, Cutter 1996, Downing et al. 1996, Hewitt 1997). From this perspective, 'vulnerability' is not an absolute term but is a relational or social term. Vulnerable groups or regions are therefore those most exposed to a disturbance but who also possess a limited array of 'response mechanisms' or coping capabilities to respond to the event, crisis, or disturbance. Vulnerability also includes a 'sense of powerlessness' and has been described as a 'measure' of defenselessness and insecurity in the face of a crisis. Poor refugees, for example, dislocated from their families and family networks, lacking adequate shelter and forced to inhabit environmentally risky areas, would be most vulnerable to a sudden shock event such as an outbreak of cholera, a flood, or an earthquake.

These examples illustrate the complex nature of vulnerability and they also show how difficult it is to untangle the causes of vulnerability from a complex set of social and physical factors. They also illustrate the importance of rigorous analysis in unbundling the complex interplay between those components which shape and contribute to vulnerability (e.g., economic restructuring measures, violence and intimidation, health issues, loss of livelihoods, environmental degradation, and rapid technological development). For instance, several vulnerability assessments in poor regions examine a household's assets, 'bundles of goods,' capacities and abilities to respond to events, plus how these change or evolve over time.

Assessments of environmental vulnerability have also expanded to include the investigation of elements of both time and space. A group may, for example, become increasingly more vulnerable to an event as their coping responses become eroded over time. In several countries, HIV/AIDS, conflict, and violence are insidious, everyday factors that heighten vulnerability during times of shock or stress such as drought. Inter- and intraregional variations in environmental vulnerability also exist (see Kasperson et al. 1995). Some have therefore called for a multilayered approach when examining environmental vulnerability which involves various measurements to produce assessments of environmental vulnerability.

2. *Measuring Vulnerability in an Environmental Context*

Different organizations, scientists, and others have experimented and used an array of approaches and techniques to try and measure or target 'vulnerable groups.' Some of these include identifying indicators of vulnerability including vegetation change, flood and drought risk, food access and availability, and/or malnutrition. Methods and frameworks from which one can identify vulnerability have often been the product of a borrowing and a 'stitching' together of related approaches attempting to identify 'vulnerable environments' or 'regions of risk.' By using a variety of methods, maps of vulnerability highlighting those areas and groups that may be at social, physical, and or economic risk have been compiled (see Davies 1996, Kasperson et al. 1995). The dynamic nature of vulnerability, however, dictates that measurements of vulnerability have to be flexible and often include qualitative as well as quantitative techniques. The sustainable livelihoods approach has been used extensively in several parts of the world as a means to identify areas and groups that are vulnerable. In this approach the environment is seen to include both physical and social dimensions.

2.1 Sustainable Livelihoods Approach—Accessing a Measure of Vulnerability

A complex array of capabilities, resilience, and vulnerabilities are viewed collectively in the concept of sustainable livelihoods (see Chambers and Conway 1992, Carney 1998). This approach has become a very popular way of trying to gain a sense of the vulnerability and resilience of a community and its environment, particularly among those working in third world rural and urban contexts. The focus in such an approach is to try and determine how people live and make a living and from there try and capture those factors that may be undermining peoples' ability to produce a livelihood. In this approach people and their livelihoods are viewed together with their stores and resources (tangible assets e.g., land, water, trees and livestock, farm equipment, tools, etc.) and their claims and resources (intangible assets e.g., local networks such as relatives) within a specified environment.

In such ways livelihood analysis examines the resilience of an array of household strategies in the face of environmental change. This approach has been used in several country and household studies by, for example, organizations such as Care International, USAID, Oxfam, Save the Children Fund (UK), and others. A central element of such investigations has been to examine the interplay between the environment (e.g., such factors as land use management) and households at risk and explores how environmental factors complement or detract from flows of goods, services, and assets into a household, making such households more vulnerable or resilient to change. Environmental degradation, associated with deforestation, desertification, poor water, and land use management may, for example, prevent a household from being able to farm and or derive some benefit from the environment. A degraded environment may also heighten the risk of landslides, flooding, and other disasters.

3. Themes in Environmental Vulnerability

The last few paragraphs have been used to illustrate what is meant by the concept environmental vulnerability and how it can be used. This discussion is now extended to illustrate how environmental vulnerability has been used in various fields. Assessments of environmental vulnerability have collectively framed wider dialogue and discussion and provided a focal point in the fields of food security, climate and global change, environmental resource management, and disaster management. The focus over time for those using environmental vulnerability to inform food security has evolved to include a more holistic understanding of vulnerability. In this field, the locus of attention has moved beyond the examination of the numbers of people affected, their daily food caloric requirements, and tons of food available. Today, such efforts converge on the 'real people' including attempts to capture the daily suite of activities that people use to live and often to survive together with those factors that may undermine or encroach on these capacities. Vulnerability and chronic food insecurity, therefore, could potentially be driven by policy failures (e.g., war, economic strategies); resource poverty/bad luck, disaster (e.g., environmental hazards, asset distribution); as well as 'population transition' (e.g., demographic growth) (see Watts and Bohle 1993, Ribot et al. 1996).

As groups are compelled to exert greater pressures on resources in order to adjust, manage and, in some cases, survive, they may negatively shape and impact on their physical environment. Recognizing this relationship, development practitioners, scientists, and others have begun to adapt the concept to improve our understanding of these interactions. Sustainable resource utilization is being understood through the lens of environmental vulnerability (see *Environmental and Resource Management*). Some are using various interpretations of vulnerability to understand and unravel how institutions and issues of access and entitlement to resources shape and configure various environments (e.g., Leach et al. 1997). Access to natural resources such as trees, plants, grasses, which are exchanged for currencies and enable people to make a living, may be controlled by institutions at various levels (e.g., governments, state policies, relations within households). The strength of this institutional control may preclude individuals or groups gaining access to the resources they use and which in turn may heighten their vulnerability during times of need, shock, stress, or in changing environmental conditions (e.g., see *Global Environmental Change: Human Dimensions*).

Other practitioners including nongovernmental organizations (NGOs), governments, humanitarian, and relief agencies have also begun articulating their understanding of vulnerability as an integral component of disaster risk. Here vulnerability is used to inform mitigatory and risk-reduction measures to offset disasters. Organizations including The International Federation of the Red Cross and Red Crescent Societies, Catholic Relief Services, Save the Children Fund, and several disaster management and risk reduction networks, including those established in South America (e.g., LA RED), in southern Africa (PeriPeri), and in South Asia (e.g., Duryog Nivaran), are asking 'Why are some people and groups more vulnerable to disasters than others?' (e.g., Ariyabandu 1999, Holloway 1999). This focus on vulnerability and risk reduction to disasters has been underscored at the international level as one of the tenets underpinning the United Nations General Assembly Resolution (44/236) adopted in 1989 when the decade 1990–2000 was declared the International Decade for Natural Disaster Reduction (IDNDR).

The growing interest in vulnerability in recent years can be largely attributable to the variety of entry points that 'environmental vulnerability' gives those in fields influenced by the social and biophysical context of environmental change. When a sensitive understanding of vulnerability has been obtained then, it is argued, this knowledge can be used to inform a variety of interventions including development policy which incorporates disaster-related strategies. Several notions of vulnerability are therefore being crafted together into discourses on poverty (in both rural and urban settings), food security, disasters, rural and urban livelihoods, and assessments of local and global environments that are at risk. Despite this broad range of interest, environmental vulnerability remains a complex issue, demanding complicated methods to identify environmentally vulnerable groups or regions.

4. *Current and Future Potential Usage of Environmental Vulnerability*

Several examples of how environmental vulnerability can be used to inform planning, science, and development work can be found in a number of countries including those in Africa, South America, and South Asia. For example, in Mozambique, government, NGOs, and various other organizations (e.g., United Nations World Food Program) have used a vulnerability analysis and mapping (VAM) approach to demarcate and identify those areas and groups that are vulnerable. By using geographical information systems and other mapping techniques, areas that are prone to flood risk, rainfall shortage, suffer from poor vegetation and where food availability and food access are problems have been identified. This information is not only useful to define vulnerable areas but can also be used to inform and help target efforts by policy makers and other organizations that may be involved in development work.

In South Asia, disaster and risk-reduction networks such as Duryog Nivaran have been using environmental vulnerability as a concept and the basis for their disaster mitigation work in the region (Ariyabandu 1999). This network has illustrated that environmental vulnerability and mitigation is linked not only to understanding technological factors but also to increased sensitivity of how grass-root communities have used their experience to increase their resilience to risky environmental situations. Close examination of how gender plays a role in either heightening or reducing vulnerability has, for example, highlighted the role that women play in preparing and mitigating disasters such as droughts and cyclones. Through the sharing of their knowledge and experience women have enabled each other to face the challenges of both daily living as well as being strengthened for times of shock associated with extreme weather events.

5. *Environmental Vulnerability and the Future*

Much has been done, and still remains to be done, to advance and adapt the use of environmental vulnerability assessments to other contexts. Identification of critical thresholds of environmental vulnerability; improved indicators of environmental vulnerability in developed, technological, and developing worlds; and the identification of ways to capture issues of scale and space are current and future areas of interest. How these feed into and are in turn impacted by global change are central priority research areas of several local and international initiatives.

Vulnerability reduction, some have argued, has not been a priority in development and environmental policy and has often been a response to discrete events, linked only to disaster management. A critical area, therefore, is to better integrate environmental vulnerability and vulnerability assessments into development and environmental planning. These efforts will also hopefully assist in mitigating the consequences associated with possible changes in global environment which may accompany a warmer, more crowded, poorer, disaster-prone world.

Notwithstanding the difficulties of trying to understand, profile, and articulate notions of environmental vulnerability, it remains useful for a range of users including hazard/risk scientists, policymakers, donors, relief agents, and development practitioners. The complexity embedded in environmental vulnerability is perhaps its greatest strength because it opens ways for greater interaction, discussion, and discourse in an age of greater globalization and information exchange and one which may bring with it a variety of 'millennium bugs,' 'surprises,' and 'new vulnerabilities.'

Environmentalism: Philosophical Aspects

Environmentalism is an intellectual, moral, and political movement that arose in response to global environmental crises. Although it had its precursors in forestry preservation and national parks campaigns of the twentieth century, the contemporary movement is distinguished by a perception that there is a global, complex, interrelated web of environmental problems that pose a threat to the health, well-being, and perhaps the very existence of humanity. Even local problems—the pollution of a lake, the disappearance of a species—are perceived by environmentalists to be symptomatic of a general malaise.

Developments in the 1950s and 1960s—concerns about population growth, nuclear war and nuclear technology, the appearance of Carson's book on the effect of pesticides (1965), and the development of the science of ecology—helped to create the environmentalist outlook (McCormick 1989, pp. 47–68). The Club of Rome's influential study *Limits to Growth* (Meadows 1972) used computer models to argue that exponential growth in population, use of resources, pollution, and industrial growth, as well as interaction between these factors are leading the world rapidly toward environmental catastrophe. Although the assumptions made by the Club of Rome have been subjected to extensive criticism, environmentalists have found no reason to doubt that serious problems exist, are becoming more severe, and cannot be solved without far-reaching moral and political changes.

Environmentalism can be understood as a theoretical position (a view about the nature and causes of environmental crises), as a moral position that poses the question of what our relation to nature ought to be, and as a social and political movement aiming to bring about a society capable of living within environmental limits. These aspects of environmentalism are interdependent but will be dealt with separately in the following sections.

1. *Explanations of Environmental Crises*

Imagine a commons, says Hardin, where a community of herdsmen graze their cattle. As time goes by, the demands they make on the pasture increase, and they are aware that it will be destroyed in the not so distant future unless they impose limitations on their activities. Nevertheless, each herdsman reasons that it is in his best interests to continue to add more cattle to the commons. Since the cost of adding an extra cow will be borne by the community as a whole, he will gain more than he loses from the addition to his herd. If, for the sake of future benefits, he puts limits on the size of his herd, then he is likely to lose future as well as present gains, since the other herdsmen cannot be trusted to do the same (Hardin 1972, p. 117). 'Ruin is the destination toward which all men rush each pursuing his own best interests in a society that believes in the freedom of the commons' (Hardin 1968, p. 1244).

Hardin applies this lesson primarily to the problem of population growth, but it can easily, and more plausibly, be adapted to account for other kinds of environmental problems—pollution, overuse of resources, and destruction of environments and species. Factory owners who spill wastes into the air or the water are exploiting the freedom of the commons.

Fisherfolk whose activities wipe out the fish populations on which they depend and farmers whose irrigation practices cause rivers to become saline can be understood to be operating according to the logic Hardin describes. In fact, the dilemma he identifies, or something like it, can be used to account for destruction of environments that are not commons (contrary to what he supposes). Farmers who recognize that a farming practice will eventually ruin their own land may continue to use it because this is the only way in which they can remain competitive and avoid losing out in the short term.

Hardin regards the 'tragedy of the commons' as the consequence of human nature coming up against environmental limitations. Others, noting that some societies have managed to live within these limitations, think that the underlying causes of environmental destruction are cultural and historical. White (1967) blamed Christianity, particularly puritanical Protestantism, for encouraging a disdain for nature. Leiss (1972) claimed that domination of nature is the rationale behind Western science and technology. Other environmentalists prefer to think that the problem is due to certain kinds of technological development (Commoner 1971) or a particular scientific worldview (Matthews 1991). Marxists blame capitalism for the exploitation of nature, although they have had to acknowledge that socialism is not necessarily a remedy. Anarchists regard environmental destruction as one of the consequences of political centralization and social hierarchy (Bookchin 1980), and ecofeminists have argued that domination of nature and domination of women have the same social-cultural roots (Plumwood 1993).

The interest in finding the cause of environment crisis has waned. Most contemporary environmentalists suspect that the problems they are concerned with have many causes, and that it is a mistake to try to reduce this complexity to a single explanation or to assume that all have the same cause. Although Hardin's 'tragedy of the commons' analysis does not provide an explanation of all environmental problems or a complete explanation of any, it has the virtue of explaining how environmental destruction can persist when almost everyone acknowledges the need to do something about it. Any proposal for social and political change must come to grips with this problem.

2. *Environmentalist Ethics*

Environmentalism was motivated from the beginning by a concern about human survival and well-being. This is a moral as well as a prudential worry. Those living now—at least those who are older—may escape the worst, but environmental damage is left as a legacy for their successors. A concern for future people and the future of humanity—so obvious as a motivation to most people that it hardly needs to be stated—continues to be the moral reason for the protests and actions of most environmentalists. However, environmental problems raise issues that require theoretical reflection on moral and social values. They pose questions about how human beings ought to live and what they should regard as conducive to their well-being. They create a need to think about requirements of justice in respect to both relations between existing people and our relations to future generations. Even more fundamentally, they bring into question attitudes toward nature, and give rise to reflections about how nature should be valued.

2.1 *Environmental Humanism*

The moral point of view that most environmentalists have adopted could be called 'humanism.' Humanism demands that every human individual be treated with equal respect. An action or policy can be judged morally right only if the interests of all affected individuals have been equally considered and taken into account—and these individuals, environmentalists insist, have to include not only everyone in the world but members of future generations.

Humanism takes many forms and humanist environmentalists often disagree with each other in their moral theories and the conclusions they reach about what should be done. Proponents of 'lifeboat ethics'—those who think that the wealthy should refuse aid to poor countries that do not make efforts to become environmentally sustainable—are consequentialist humanists who think that the greatest good, taking into account the interests of present and future individuals, is best served by this policy (Hardin 1974). Marxists who respond to environmental crises by favoring a democratic socialism that eliminates waste and exploitation are humanists who think that respect for individuals requires the promotion of egalitarian and cooperative social relations. Environmental humanists with a liberal concern for social justice emphasize the need for an equitable distribution of resources and risks among existing and future individuals.

The issue of what we should do for future generations is a central concern of environmental ethics which requires not only that we think about what we ought to preserve for our descendants. It also brings into question common ideas about the scope of our duties to future people. It is commonly accepted that we have duties of justice only to our immediate successors. However, environmentalists point out that some of our activities—for example, our use of nuclear technology—leave behind waste products that can harm people thousands of years from now.

2.2 *Ecocentric Ethics*

The main debate in environmental ethics is about how nature should be valued. Humanism—indeed the

whole Western ethical tradition—has been persistently challenged by those who object to its anthropocentrism—its assumption that only human beings and their interests are ethically considerable. Ecocentered environmental ethics—the view that value in nature cannot be reduced to what promotes human well-being—has always been a minority position among environmentalists. Nevertheless, ecocentered environmentalists have had considerable influence in the environmental movement and an even larger impact on ethical theory. More radically than the animal liberation movement, ecocentrism has challenged traditional ways of thinking about value and morality.

Leopold, commonly thought to be one of the first to put forward an ecocentered position, notes that Odysseus, returned home from his travels, had no moral qualms about killing the slave girls who had consorted with his enemies. 'The girls were property. The disposal of property was then, as now, a matter of expediency, not of right and wrong' (Leopold 1949, p. 217). We no longer think that any human being should be treated as the property of another, he continues. But our relation to the land, soil, plants and other creatures that are part of our biotic community remains an economic one. He calls for a land ethic that 'enlarges the boundaries of the community to include soils, waters, plants, animals, or collectively: the land' (Leopold 1949, p. 224).

Leopold claims that a land ethic is the natural result of a process of ethical evolution. Some philosophers make a case for ecocentrism by attempting to show that the scope of humanitarian ethics can and should be widened to include as objects of moral concern all living organisms—and perhaps other things in nature. Most morally sensitive people, says Taylor, are already convinced that many of the qualities that make human beings morally considerable are possessed by sentient animals. They too have interests and feelings, and can be hurt or benefited by what we do. These similarities are a good reason for saying that animals as individuals are deserving of moral respect. A plant or a nonsentient animal is like a sentient creature in that it has a good of its own—the full development of its biological powers. If we acknowledge that this is so, and acknowledge human dependence on the complex web of life, we will be predisposed to recognize each organism as having inherent worth—a value that compels our moral respect (Taylor 1986, pp. 59–98). Johnson argues that species, wilderness areas, and other natural systems have interests in their own right and thus are valuable for the same reasons that human beings and other sentient animals are valuable (Johnson 1991, pp. 97–183).

Taylor and Johnson differ on whether parts—individual organisms—or wholes—species and environmental systems—have inherent worth. However, the difference between individualism and holism in environmental ethics is less important than it seems. The fact that human beings and sentient creatures are conscious, and thus have a point of view, gives us a natural means of distinguishing individuals from each other and individuals from the wholes of which they are part. Where consciousness is not present, individuation and the distinction between part and whole are not likely to be ethically crucial. In fact, many ecocentered environmentalists are prepared to assign inherent value to both individual organisms and the systems that contain them. A more serious disagreement among ecocentered environmentalists exists between those who value creatures or environments because they have qualities similar to human qualities, and those who think that this reason for valuing nature is fundamentally human-centered and should be rejected.

Those who reject analogical arguments for valuing nature have to find another basis for their ecocentric ethics. Some find this in a worldview that sees the cosmos or the Earth as a self (Matthews 1991, pp. 142–7). Others think that a sympathetic engagement with sciences such as ecology will lead us to an ecocentric position (Callicott 1989, p. 125), or that we will be pushed in that direction by reflection on our intuitions. Richard and Val Routley (Routley and Routley 1980, pp. 121–3) ask us to imagine that we are the last people on the planet. Would we regard it as morally permissible to destroy its ecosystems if we did not have to worry about the well-being of future generations? They expect us to answer 'no,' and as a result to recognize that we are already inclined to value nature for its own sake. We are then required to identify the characteristics that give natural systems value—they suggest diversity, naturalness, integrity, stability, and harmony—and to give these valuable systems their due when we engage in moral reasoning.

Its critics regard ecocentered environmentalism as implausible or even potentially dangerous. Why should we extend the scope of our moral concern beyond creatures who are capable of suffering? How can we accept an ethics that might prescribe policies contrary to the human good? Moreover, ecocentric ethics faces conceptual problems. If it asks us to value anything that can be perceived to have a good of its own or every system that is balanced, ordered, and integrated, then how can we avoid a requirement to value for their own sake machines, bodily organs, or social systems? Why should such an ethics have a special regard for creatures now living and systems now existing rather than equally (or more) complex, integrated environmental systems that have existed or might exist?

However, even if ecocentered ethics turns out to be implausible or unacceptable, its objective of persuading us that nature should be valued for what it is—and not simply as a resource—is reasonable and can be achieved within the confines of a human-centered ethics. If, for example, things in nature are valuable because of their aesthetic qualities then we have reason to make an effort to appreciate and preserve them. In

doing so we are valuing them for what they are. Wilderness, landscapes, species, the land itself can also be appreciated as heritage or simply loved and cherished because these environments or creatures are part of our world. Regarding ourselves as part of a community that includes our natural environment (as Leopold recommended) can enhance our sense of belonging to a place and thus enrich our lives. Such valuing retains its human center—but it may give us sufficient reason for thinking that the last people should not destroy their world.

2.3 Deep Ecology

There is another approach to valuing the environment that is sometimes regarded as an ecocentric ethics. Instead of recommending that we widen the scope of our ethical concern, deep ecology asks us to broaden and deepen our sense of self. Influenced by Buddhism and Gandhi's philosophy, Arne Naess (1973) argues that self-realization requires an identification with others. Having this identification means that self-love becomes love for others, and individuals seek not only their own ends but also the good of those with whom they identify. Naess believes that recognition of the equality of living things makes it natural and desirable for the self to identify with all creatures. By doing so we realize ourselves in a more complete and satisfactory way.

Deep ecology has been criticized, particularly by ecofeminists, for trying to master the world by incorporating it into the self (Cheney 1987). They insist that beings in nature have an independent existence and should be appreciated for what they are. It is true that some of the feats of identity that deep ecologists claim to perform are pretentious if not silly ('I am the black bear'). But there is probably no great distance between deep ecologists and feminist critics. It seems undeniable that people can learn to care about natural creatures and environments to the point where they feel diminished if these things are destroyed, and that this kind of caring can be a motivation for environmental preservation.

3. Environmentalist Politics

Environmentalists believe that by promoting an environmental ethics they are making it more likely that environmental problems will be solved. However, few deny that there is a need for an environmental politics: not merely campaigns to save the environment or to educate citizens but an environmental political theory and a long-term strategy for achieving an environmentally sound society. There are two major questions for environmentalist political theory. The first is what it means for a society to live within environmental limits. The second is how this goal is related to important political values such as liberty, democracy, justice, equality, solidarity, or liberation of women.

3.1 From 'No Growth' to 'Sustainability'

The Club of Rome report and other warnings of imminent environmental disaster encouraged environmentalists to believe that an environmentally sound society had to be a 'no-growth society,' and that achieving it had to become a priority everywhere in the world. The goal of 'sustainable development' popularized by the World Commission on Environment and Development (1987) allows that development and growth can occur within the carrying capacity of the planet. Sustainable development is supposed to leave room for development within poorer countries and encourage those in wealthier countries to look for more environmentally sound ways of maintaining their living standards.

There is a lot of room for disagreement, not only about what the environment can sustain but also about the relation between environmental preservation and sustainability. Sustainable development does not necessarily mean that wilderness areas or threatened species will be preserved, or that the values that ecocentered environmentalists find in nature will be respected. 'Sustainable development' also raises normative questions about how much environmental risk it is legitimate to impose upon present and future people for the sake of development.

3.2 Environmentalism and Political Values

There are three basic ways in which environmentalists have answered the question of how environmental objectives should affect or be affected by political values. They can be called 'pessimist,' 'compatibilist,' and 'utopian.' Pessimists think that political values such as freedom and democracy have to be abandoned or severely limited, at least temporarily, for the sake of avoiding environmental disaster. Saving ourselves and the environment has to take priority over all other objectives. Compatibilists think that necessary environmental reforms are compatible with the preservation or achievement of political values—although some restrictions on the realization of these values have to be accepted. Utopians think that in the right sort of society people would not only live in harmony with nature but enjoy more freedom, democracy, justice, equality, and communal solidarity than we do at present.

3.2.1 The pessimist approach. Ophuls regarded environmental crises as calling for a new social contract. We need a Leviathan, a Hobbesian state that is not impeded from taking the steps necessary for

protecting the environment (Ophuls 1977, pp. 222–48). Heilbroner concluded from an assessment of human behavior and existing social systems that democracy cannot be expected to survive the transformation to an environmentally sound society (Heilbroner 1974, p. 90).

Ophuls and Heilbroner feared the imminent collapse of environmental systems. Those who do not regard the danger as so great or so immediate are not inclined to accept their assessment of our social possibilities. Ophul's advocacy of a Hobbesian solution to the political problems posed by environmental crisis has been widely condemned as unnecessarily authoritarian. It is also open to the criticism that an authoritarian solution is naive. There is no guarantee that a 'green dictatorship,' once installed, would be willing or able to save the environment.

3.2.2 The compatibilist approach. Liberal compatibilists argue that an environmentally sound society can be achieved within the framework of a free, just, and democratic society, although doing so is likely to require adjustments and restrictions. Most compatibilists agree that more restrictions will have to be placed on individual freedom. Polluting activities will have to be curbed, use of resources restricted, and, in some countries at least, population growth checked. The debate centers on what kinds of restriction would be effective and morally acceptable. Let us assume, for example, that restrictions on family size are an effective way of limiting population growth. The question remains whether the measures required constitute an unacceptable abuse of freedom. Would a scheme of incentives or disincentives be more acceptable from a moral point of view—even though they are likely to affect the poor more than the rich?

Many compatibilists also accept the necessity of restrictions on the scope of democratic decision making. Recognizing environmental rights of individuals, it has been suggested, would define the limits within which democratic decision making should operate. Christopher Stone (1974) argues that natural objects, such as rivers or wilderness areas, would be better protected if they were accorded legal rights.

Liberals who aim for an environmentally sound society cannot ignore questions of justice. Although environmental problems are global, they affect some people more than others. The burden of solutions to environmental problems can also be unfairly distributed. A pollution control measure that has the effect of raising consumer prices will disadvantage those who are in the least well-off sections of the population unless the costs are offset by other factors. A scheme of incentives or disincentives for limiting family size or the use of private cars and other environmentally harmful activities is likely to be experienced by the poor as a form of coercion. Revising or adapting theories of distributive justice to deal with environmental problems and devising measures for achieving an environmentally sound society compatible with justice is one of the biggest challenges for environmentalist political theory.

3.2.3 The utopian approach. One of the first responses to predictions of environmental disaster was *Blueprint for Survival* (Goldsmith 1972) which urged not only the reduction of waste and the stabilization of population but the creation of a decentralized social system. It recommended the relocation of the population of existing states into self-sufficient communities of about 500 people who would use small-scale, low-impact technology to provide for their own needs. The communalist vision of an environmentally sound society has been popular particularly among left-wing environmentalists who rejected both the capitalist state and centralized socialist bureaucracies, and turned to anarchist ideas about social organization and community. Many Green parties, for example *Die Grünen* of Germany, regard the achievement of decentralized, egalitarian, and democratic political and economic institutions as their ultimate political goal. The US bioregionalist movement advocates self-sufficient, 'human-scale' communities dedicated to preserving and enhancing the diversity of native ecosystems. Many ecofeminists think that only in a nonhierarchical society where qualities associated with the feminine are valued will nature and women be truly liberated.

The reasoning that motivates these visions of environmental utopia is that people who relate to each other in a face-to-face nonhierarchical community, exercise control over the conditions of their lives through participatory democracy, and have a close relation to their environment will live in harmony with each other and nature without the imposition of coercive political rule. They will not experience restrictions imposed on their activities for the sake of the environment as a sacrifice of their self-interest, because they value and identify with their community and its caring relation to the environment.

Some critics think that ecoanarchism depends on an implausible view of human nature. Be that as it may, traditional societies and small communities have often been nondemocratic, restrictive, hierarchical, and patriarchal, and they have not always lived in peace with their neighbors. Ecoanarchists tend to assume, without sufficient discussion, that decentralization will produce the best results as far as communal life is concerned rather than one of the worst. Ecoanarchists also fail to provide sufficient detail about how communities will coordinate their affairs in order to deal with environmental and other intercommunity problems. The tragedy of the commons, even if avoided at a local level, could reappear as a problem concerning the relation between communities.

Ecosocialists claim with some justification that Marx's criticisms of capitalism can be used to account for the existence of many environmental problems. Driven by the necessity for making profit, owners and managers of industry cannot afford to be too concerned about causing environmental damage. A socialist society, say ecosocialists, would be able to establish social relations on a more cooperative, democratic basis. To avoid the pitfalls, moral and environmental, of bureaucratic socialism, ecosocialists borrow heavily from ecoanarchists. They too want decentralization, close relations with nature, and participatory democracy. However, they are less prepared than ecoanarchists to do away with the state and its ability to coordinate economic activity and ensure that wealth is fairly distributed among individuals and communities (Pepper 1993, pp. 226–7).

Although it is not well known or popular among environmentalists, libertarians have also presented a utopian vision of a society that protects the environment and upholds individual rights of life, liberty, and property (the only values that libertarians think a state should protect). Right to property includes the right to enjoy it without having to suffer from the polluting activities of others. A state that rigorously protects individual rights would not allow anyone to pollute without permission of those whose lives and properties are affected (Machan 1984).

3.3 Environmentalism and Global Politics

A common failing of all approaches to political theory of the environment, whether pessimist, compatibilist, or utopian, is that they concentrate mostly on the problem of transforming national societies into environmentally sound societies. There has been comparatively little reflection on practical and normative issues in relation to global society: for example, how environmental policies should affect or be affected by ideas about global justice; how utopian visions of the good life in an environmentally sound society can be translated into a blueprint for the world as a whole; whether the creation of more effective and powerful cosmopolitan institutions should be an environmentalist objective; whether global democracy, redistribution of the world's resources, and/or the recognition and protection of environmental rights as universal rights are feasible and desirable objectives; whether individuals should come to regard themselves as 'planetary citizens' and what this would mean. Finding answers to these questions is going to become more urgent as the twenty-first century progresses.

Environmentalism, Politics of

Environmentalism is one of several 'new social movements' challenging institutionalized politics. That movement strives to protect the natural environment, both for its own sake and ours, from unsustainable exploitation and degradation through pollution, overpopulation, maldistribution, technological excess, and resource extraction. Politically, greens adopt a decentralized and participatory style of protest politics which is often orthogonal to the workings of formal political institutions. Internationally, various environmental protection regimes have been created by intergovernmental agreements and energized by nongovernmental organization activism.

1. Environmentalist Concerns

Although their concerns sometimes extend to the 'built' or 'social' environment, self-styled environmentalists generally seek to protect the 'natural' environment. Natural environments are rarely pure, of course, and few places are literally untouched by human hands. Heather dominates the Scottish moors because of past agricultural practices, for example, and eucalyptus the Australian bush because of Aboriginal 'firestick' land management. Many sites and species owe their social salience to the resonance they have with human history and heritage, symbolisms, and meanings. Thus, it is apt to say (more anthropocentrically than some 'deep ecologists' would prefer) that political concern is indeed with 'our' environment (Goodin 1992, Chap. 2).

Some of the interests which environmentalists have in view are similarly anthropocentric. Overpopulation (Ehrlich 1968), maldistribution (Brandt 1980), and resource depletion threaten to starve us: Malthus' (1803) old prophecy has acquired new urgency through modern computer modeling (Meadows et al. 1972, Council on Environmental Quality and the Department of State. 1980). Pollution threatens to poison us and technology to overwhelm us (Commoner 1971). Greenhouse gases threaten global warming, melting the polar ice caps, and CFCs threaten the ozone layer that protects us from the sun's ultraviolet rays (McKibben 1989). To nuclear power greens say, 'No thanks!', in part because they see it as unnecessary (like 'cutting butter with a chain saw'), in part because of risks of radioactive leaks from operating plants (such as at Chernobyl) or waste storage facilities, and in part because of fears of diversion of nuclear materials to bomb-building (Goodin 1982, Chap. 10, Lovins et al. 1980).

Anthropocentric concerns merge with biocentric ones, insofar as what is bad for humans is bad for other species and ecosystems as well. One of the cornerstones of the modern environmental movement —Rachael Carson's *Silent Spring* (1962)—took the effect of DDT on birds as a harbinger of the dangers of chemical pollution to human health. The interconnectedness of all life is an ecological theme echoed repeatedly in the titles of major international reports, such as the report of the World Commission on Environment and Development, *Our Common Future* (1987), and the manifesto of the 1972 Stockholm Conference, *Only One Earth: The Care and Maintenance of a Small Planet* (Ward and Dubois 1972).

Environmentalists are also concerned with the well-being of animals, species or ecologies for their *own* sake, rather than because of the fate they share with humans. Environmentalists campaign to 'Save the Whales' from extinction, not because they want to eat them, but because they think that those noble and intelligent creatures have as much right to live as people do. Environmentalist concern sometime extends beyond the animal kingdom to inanimate creation. Biodiversity is just as valuable among plants as animals. Natural landscapes, wild rivers, and majestic canyons have a value which is not reducible just to the value of the birds and fish that live in them.

Environmentalist concern also extends widely in both time and space. Environmentalists are concerned with the legacies that current activities might be leaving for distant future generations, and with the impact that they might have on distant locales which none of them personally ever expect to visit. The wrongness of the harms we are inflicting on those distant peoples and places, environmentalists say, is in no way mitigated by the sheer fact of their distance, either in time or space. Neither is it mitigated by the inevitable uncertainty attaching to action at such a distance. Whereas economic calculations ordinarily discount uncertain effects, greens urge a 'precautionary principle' which in the face of uncertainty assumes the worst and strives to protect against it (Goodin 1982, Chap. 9, Weale 1992, UN 1992, Principle 15).

Many environmentalists are thus keen advocates of 'environmental justice,' internationally as well as domestically. The maldistribution of resources is seen as a key cause of environmental degradation, and remedying the one as a key step in remedying the other (UN 1992). Various schemes for 'sustainable devel-

opment' and 'ecological modernization' suggest ways to 'develop without damage' (Dryzek 1997, Chaps. 7–9, Dobson 1998). Ecofeminists, however, suppose that man's dominance of nature is of a cloth with men's dominance of women, and problems of environmental degradation cannot be resolved without resolving problems of gender subordination (Plumwood 1993).

2. *Movement Politics*

Politically, the key environmental slogan is: 'Think globally, act locally.' Although the scope of their concerns is global, many environmentalists suppose that the most effective way of pursuing them is through decentralized structures and local action (Goldsmith et al. 1972). For greens, 'small' is indeed 'beautiful' (Schumacher 1973).

Much of environmentalist action takes the form of protest politics, ranging from street marches and publicity stunts to eco-sabotage. An example of the latter is the radical US group, 'Earth First,' which advocates 'monkey-wrenching' modern technology, including everything from cutting down power lines to driving spikes into trees in old-growth forests to provide them with a means of 'natural self-defence' against anyone who tries cutting into them with a chainsaw (Dryzek 1997, Chap. 9, Goodin 1992, pp. 133–5). Less radical groups such as Greenpeace engage in direct but nonviolent action, such as stationing their ship *Rainbow Warrior* squarely within the exclusion zone surrounding the French nuclear test site in the South Pacific.

Those techniques of direct action and nonviolent mass protest are relatively standard across the other 'new social movements' with which environmentalists often make common cause, among them the peace movement, the feminist, gay, and lesbian rights movements, and various other human rights movements. Most of those share the same broad concern (and many of the same specific concerns) with the socioeconomic institutions of contemporary capitalism and the acquisitive, materialist values underlying them. Many organize themselves as loose networks rather than formal membership organizations. Many pursue their political objectives substantially through nonconventional means, outside the ordinary channels of established parties and legislative assemblies (Offe 1985).

Movement politics do sometimes take an institutional form, when environmentalists organize themselves into explicitly 'green parties' and interest groups (see *Green Parties*). The most famous among them, *Die Grünen* in Germany, entered the *Bundestag* in 1983 and joined the governing coalition led by Social Democrat Gerhard Schröder in 1998. Green parties were characterized, initially at least, by the same egalitarian, nonhierarchical ethos as the 'new social movements' from which they sprang (Douglas and Wildavsky 1982, Spretnak and Carpa 1986, Dobson 1990, Chap. 4, Goodin 1992, Chap. 4). They have decentralized organizational structures, characterized by grassroots democracy and rotating leadership. For some greens (such as the German *Fundi* faction), that political style is valued in itself, even if it costs them any real political power; but for others (the *Realos*, who won the German factional fight), the whole point of a political party is to seize power to do good, and internal party structures ought be aimed toward those ends (Goodin 1992, pp. 109–11, Dryzek 1997, pp. 173–5).

3. *Environmental Policy*

Many accomplishments of the environmentalist movement have come at the local or national rather than international level, and through the efforts of mainstream political parties rather than greens themselves. Examples range from the 1970 National Environmental Policy Act (NEPA) and the Environmental Protection Agency (EPA) in the USA to the 1989 Dutch National Environmental Policy Plan. The latter sort of regulatory regime is praised as more flexible and consultative and, because of that, more capable of altering pollution-generating practices. The US EPA is criticized for its inflexible 'command-and-control' approach and a fixation with 'end of the pipe' solutions, stopping pollutants from being released into the environment at the very end of the process rather than preventing them from being created in the first place (Dryzek 1997, Chap. 8, Weale 1992). Economists urge the replacement of regulatory policies with economic incentives, tradeable pollution permits, and the like (Pearce et al. 1989). It turns out, though, that even relatively toothless reporting requirements, such as the Environmental Impact Statements required by the US NEPA, can be surprisingly effective at 'making bureaucracies think' about the environmental consequences of their proposed actions (Taylor 1974).

Many environmental problems transcend national boundaries, however. Coordinated international action is then required, but that need not necessarily be universal in form. Early in these debates, George Kennan (1970) pointed out that most threats to the global environment come from the 'rich men's club,' and coordinated action among a majority of rich countries would go a very long way toward reducing those threats, whether or not others decline to join. Some of the most promising international agreements —notably, the 1987 Montreal Protocol restricting emission of ozone-destroying chlorofluorocarbons (CFCs)—are structured in precisely this way.

Institutionally, the 1972 Stockholm Convention led to the creation of a formal United National Environmental Program, based in Nairobi. Much of the impetus for international environmental protection has, however, come through the loosely coordinated actions of nongovernmental organizations (NGOs). Some of those are coalitions of environmental activist organizations, while others represent coalitions of

scientists in an 'epistemic community' driving the development of policies such as those embodied in the 1987 Montreal Protocol (Haas et al. 1993).

Environmentalism: Preservation and Conservation

Environmentalism represents one of the most influential and enduring social movements of our time. Bursting onto the American scene in the late 1960s, the modern environmental movement has not only taken root in the USA but has spread across the globe. The environmental movement is widely considered to be one of the most successful social movements of the late twentieth and early twenty-first centuries, especially in terms of gaining widespread societal acceptance of its goals (Dunlap 2000), and it is likely that it will continue to play an important role in regional, national, and global politics. This article traces the growth and diversification of modern environmentalism in the USA, briefly reviews the growth of environmentalism worldwide, and then examines the major stages of contemporary environmental activism—conservationism, environmentalism, and ecologism.

1. The Emergence and Growth of the US Environmental Movement

The organizational and ideological roots of contemporary environmentalism are commonly traced to the progressive conservation movement that emerged in the late nineteenth century in reaction to reckless

exploitation of the United States' natural resources. The progressive conservation movement is typically divided into two broad camps: utilitarian conservationists and romantic preservationists. While conservationists were interested primarily in the wise use and management of natural resources, preservationists were interested primarily in protecting natural areas from the encroachment of industrialization (Hays 1959, Nash 1982). Although the conservation movement faded from attention with World War I, it left a legacy of organizations (e.g., the Sierra Club and National Audubon Society) and government agencies (e.g., the National Park Service and the Forest Service). Additionally, the movement's concerns were continued throughout the early to mid-twentieth century by projects such as the Tennessee Valley Authority and the Civilian Conservation Corps, and by environmental luminaries such as Bob Marshall and Aldo Leopold.

More recent explorations of the historical origins of environmentalism have begun to highlight additional, yet often neglected, precursors to the modern environmental movement (Taylor 1998). From the mid-1800s to the mid-1900s, middle- and working-class whites developed an environmental agenda that focused on the creation of urban parks and the protection of public and industrial worker health and safety. This urban agenda, was, however, not strongly identifiable as a cohesive social movement. Unlike the conservation movement, it lacked a strong infrastructure and membership base, had few ties to powerful business and government interests, and lacked the strong symbolism and charismatic leaders that were the hallmarks of the conservation movement. Similarly, despite the existence of activism by and for people of color during this time, such activities have been eclipsed, not only by traditional historical accounts of environmentalism, but also by the public's greater acknowledgement of conservationists and preservationists, both currently and historically.

The shift from its historical precursors to the modern environmental movement is typically marked by two events: the publication of Rachel Carson's *Silent Spring* in 1962 and the April 22, 1970 Earth Day celebration that drew millions of participants. The modern environmental movement emerged during an era of widespread political activism and reform, and quickly achieved high levels of support from the public, activists, and even elites—all of whom found environmental issues to be relatively appealing and consensual compared to the civil rights and anti-Vietnam protests.

The growth of scientific evidence on environmental degradation, eloquently documented in *Silent Spring*, coupled with media-enhanced disasters like the Santa Barbara oil spill of 1969, generated widespread concern. Post-World War II affluence enabled larger numbers of people to spend leisure time in the outdoors, heightening their commitment to preserving areas of natural beauty. Affluence, combined with increased urbanization and education, also stimulated changes in social values, lessening concern with materialism and generating interest in the quality of life, including environmental quality (Hays 1987).

At the same time, traditional conservation/preservation organizations, such as the Sierra Club and the Wilderness Society, were aggressively battling threats to natural areas, and broadening their agendas to incorporate a variety of issues, including those espoused by the earlier generation of urban/industrial activists (e.g., pollution and public health). Legal changes enabled organizations to fight battles on several fronts, from congressional offices to courtrooms, where legal standing was becoming easier to achieve. Furthermore, new organizations, such as the Environmental Defense Fund and the Natural Resources Defense Council, began to emerge, typically aided by foundation funding (Mitchell et al. 1992).

While the environmental movement is composed of numerous local and regional organizations, it is the large environmental organizations, such as those previously mentioned, that form the most visible face of contemporary environmentalism in the USA. Large environmental organizations have combined memberships numbering in the millions; they solicit and control multimillion-dollar budgets; and they employ large professional staffs of lobbyists, lawyers, and scientists. A core group of these organizations form what is known as the national 'environmental lobby,' a relatively influential, bureaucratic, and professionalized group of organizations headquartered in Washington, DC (Brulle 2000).

Despite predictions of movement demise and evidence of a decline in public support after the initial Earth Day, the movement remained strong throughout the 1970s, maintaining relatively high public support and continuing to gain in organizational membership. Ironically, the Reagan administration generated renewed support for environmentalism in the 1980s, as its anti-environmental agenda stimulated increased public support for environmental organizations (Dunlap 1995). The twentieth anniversary of Earth Day in 1990 witnessed the extensive involvement of Hollywood, politicians, and corporations. Although much of this reflected superficial commitment, the event was successful in stimulating major membership growth spurts in many environmental organizations (Mitchell et al. 1992). While growth in these organizations subsided somewhat in the 1990s, the thirtieth anniversary of Earth Day in 2000 yet again revealed the staying power of environmentalism. Environmental issues remain important to the public, the environment has become a significant factor in many political campaigns, and recycling programs and 'ecologically correct' products have become increasingly popular.

The environmental movement, like any social movement, is far from monolithic. Indeed, much of the

success garnered by the 'mainstream' organizations (i.e., the environmental lobby) has engendered criticism that such organizations have become ossified, overly bureaucratic, and co-opted by the political and business interests of the status quo. Such criticism has fueled the development of a 'radical fringe,' a group of organizations and activists that advocate direct action (e.g., spiking trees, destroying bulldozers) and espouse 'deep ecology,' a philosophy grounded in self-identification with nature (Devall 1992). With the larger organizations ostensibly focusing more on their 'bottom line' (memberships and budgets) and safely maintaining their ties to powerful interests, radical groups argue that the mainstream environmental movement has become too willing to compromise in its efforts to protect the environment.

While radical groups argue that the mainstream movement has lost sight of nature, other environmentalists believe that the mainstream has lost sight of people. Grassroots groups fighting locally unwanted land uses (LULUs), such as toxic waste dumps or hazardous waste incinerators, have argued that the large organizations ignore their concerns in favor of more fashionable national and global issues (e.g., rainforest destruction or loss of biodiversity). Environmental justice activists have argued that the mainstream organizations have ignored issues of social justice (Bullard 1993). Mainstream organizations are not only dominated by middle- and upper-class whites, but such organizations, it is argued, have ignored environmental issues faced by members of the working class and people of color. Because these grassroots and environmental justice groups focus heavily on public health issues that have a great impact on families and communities, women have played a more significant leadership role in them than has been true of the mainstream environmental movement.

As can be expected with any successful social movement, the environmental movement has generated opposition. Opposition to environmentalism comes from an incredibly diverse set of groups and activists, including well-organized industry groups, conservative think tanks, grassroots groups, and militant anti-environmentalists (Switzer 1997). Although industry groups have existed since the movement's beginnings, it is the grassroots groups that have recently become more numerous as well as more organized. Whereas grassroots opposition was typically confined to the rural west (the Sagebrush Rebellion being the key antecedent in the 1970s and early 1980s), it has increasingly become a nationwide phenomenon. While some grassroots anti-environmental activism is funded by industry, much of it nonetheless stems from genuine local concern over the loss of control over management and use of land and other natural resources. The constituents of these grassroots groups include farmers, ranchers, miners, motorized recreationists, militia supporters, landowners—virtually anyone who feels negatively affected by governmental attempts to protect natural resources. Despite the growing activism of opposition groups, however, it remains to be seen whether they can succeed at significantly thwarting the publicly accepted environmental agenda in the USA.

2. *Environmentalism Around the Globe*

Environmentalism has clearly become a significant force in the USA. However, the USA is not unique in this regard, nor has environmentalism been confined to the 'richer' countries of the world. Not only is public support for environmental protection found around the globe (Dunlap and Mertig 1995), but activism on behalf of environmental protection has emerged in many nations, both industrialized and nonindustrialized.

Like the USA, other industrial nations have relatively well-organized and successful national-level environmental movements. The countries of Western Europe, in particular, have not only developed their own professionalized and institutionalized environmental organizations (with a corresponding growth in radical groups critical of the large organizations), but many have also established relatively successful Green parties that attempt to advance social as well as ecological concerns (Dalton 1994, Rootes 1997). The European Union's emphasis on environmental protection is probably one sign that the environmental movement(s) within Europe have been quite successful in promoting their concerns.

In many countries, activism on behalf of environmental issues has a long history, even though it has typically not been labeled as environmentalism until relatively recently. This is perhaps most true of the poorer countries of the world, where colonization and imperialism have historically threatened not only the natural resource base but the very survival and livelihood of local peoples. For many people in poorer nations, such historical threats have not disappeared. Thus, it is no surprise to see activists in countries as varied as Malaysia, India, Thailand, Brazil, Nigeria, and Kenya fighting against international corporations to protect their forests and rivers, to promote sustainable development, and to safeguard biodiversity from the onslaught of transnational seed companies and other forces of globalization. Paralleling the movement for environmental justice in the USA, these activists are motivated by more than a concern for environmental protection; central among their concerns are those of social justice, the protection of livelihood, and the survival and well-being of family and community (Guha and Martinez-Alier 1997). This 'environmentalism of the poor' also counts women among its strongest leaders, for they are the ones who are most likely to see the devastating impact that resource shortages and environmental degradation can have on families.

Around the world, as in the USA, environmental activists and groups have also faced increasingly organized and sometimes violent opposition. From the bombing of a Greenpeace ship in New Zealand and the use of Strategic Lawsuits Against Public Participation (SLAPP) against anti-road activists in Britain, to the detention of anti-dam activists in Malaysia and the violent—occasionally murderous—attacks upon activists in Mexico, Costa Rica, Nigeria, and Brazil, there have been numerous instances of a growing global 'backlash' against environmentalism (Rowell 1996). While these events are certainly sobering for those involved in the environmental movement, most observers recognize that backlash reflects fear of a social movement's success. As environmentalism gains strength around the world, it will undoubtedly generate growing opposition.

3. *The Trajectory of Environmental Activism in the USA*

Despite the historical presence of other forms of environmental activism, especially those focused on early urban and industrial concerns, the progressive conservation movement is widely recognized as being the principal ancestor of modern environmentalism. Although modern environmentalism continues to encompass the concerns and tactics of the progressive conservation movement, it goes beyond them in substantial ways. Because the environmental movement is so qualitatively different from the progressive conservation movement, including both its preservationist and utilitarian branches, some scholars treat them as two separate movements, others as distinct stages of one broad movement. The predominant characteristics of what we identify as the three main stages of environmentalism in the USA—'conservationism,' 'environmentalism,' and the recently emerged 'ecologism'—are juxtaposed below. In this discussion, the three stages are treated as parts of one broad and continuously evolving movement aimed at protecting environmental quality.

Rather than divorcing itself from its predecessors, each stage in this broad trajectory incorporates the concerns and tactics it inherited from earlier stages into its own, expanded agenda. For instance, ecologism does not ignore issues of resource management, the hallmark of conservationism, nor does it reject tactics such as political lobbying. In fact, the evolution of the movement has been marked by a gradual broadening of issues and growth in the diversity of groups dealing with such issues (Brulle 2000). While diversity exists in most mature social movements, and has been present in conservationism/environmentalism since the early split between Gifford Pinchot's utilitarian conservationists and John Muir's preservationists, the modern movement encompasses an extraordinary diversity of organizations, goals, ideologies, and tactics. The scheme used here attempts to display the predominant characteristics of each stage, but it should be emphasized that substantial diversity exists at each stage, especially the third.

In Table 1, major characteristics of each stage of environmental activism are noted, starting with the approximate beginnings of each one. Conservationism dates to the late nineteenth century, when the progressive conservation movement emerged; environmentalism includes the bulk of the modern environmental movement that arose in the 1960s; and ecologism, it is argued, emerged in the last two decades of the twentieth century—partly in response to perceived weaknesses within mainstream environmentalism.

Social movement scholars distinguish movements (here, stages of one long-term movement) by their interrelated set of goals, ideologies, and world views. Movement goals are the primary focus of action for activists; ideology is a broad statement of what the movement considers to be an 'ideal' state of affairs; and world view is the lens through which activists perceive the world, in this case the natural world that they are attempting to protect. Of special relevance is the distinction between an anthropocentric world view, where humans are the center of concern, and an ecocentric (or biocentric) world view, where ecosystems, other species, and all life on Earth are deemed important.

Despite the efforts of preservationists such as John Muir, conservationism was predominantly anthropocentric because it emphasized the wise use of resources for human benefit. Similarly, environmentalism has also been largely anthropocentric in its emphasis on environmental quality as crucial for a high quality of *human* life. Concerns for human health, outdoor recreational opportunities, and an esthetically pleasing natural world were all motivated by an underlying concern with the welfare of humans—even though the natural environment often derived benefit from these concerns.

The recent emergence of ecologism, however, has broadened earlier concerns by incorporating an ecocentric world view stemming largely from two noteworthy branches of the modern movement: deep ecology and radical environmentalism (Devall 1992). Adherents of ecologism believe that nature has a right to exist in and of itself, apart from human desires. Although this position existed in the conservation movement via John Muir and his followers, and was given new impetus by Aldo Leopold's 'land ethic' in the mid-1900s, only recently has it become a potent voice in the evolving movement. Advocates of ecologism hold as their primary goal the maintenance of ecological sustainability, for the entire earth and all of its inhabitants (Thiele 1999).

Social movements are further distinguished by the types of problems or issues that they address (their 'grievances'). The issues addressed by environmental

Table 1
Three stages of environmental activism

	Conservationism	Environmentalism	Ecologism
Approximate beginnings	Late nineteenth century	Middle twentieth century	Late twentieth century
Primary goals	Conservation of natural resources	Protection of environmental quality	Maintenance of ecological sustainability
Dominant ideology	Natural resources should be used efficiently for the good of all society	Environmental quality should be protected for a high quality of life	Ecosystems should be protected for the benefit of all species
Worldview	Anthropocentric	Anthropocentric	Ecocentric
Nature of issues	Geographically bounded (typically rural), specific, unambiguous	Geographically dispersed (often urban); delayed, subtle and indirect effects; potentially harmful to human health	Extremely diverse; systemic and synergistic effects; potentially irreversible and harmful to all life on Earth
Example	Over-logging of a specific forest area	Urban air and water pollution	Global environmental change
Cost of solution	Relatively small, localized	Often substantial	Potentially infinite
Tactics	Lobbying	Lobbying, litigation, citizen participation	Lobbying, litigation, electoral action, direct action, lifestyle change
Opposition/ culprits	Natural resource industries; local economic interests (loggers, hunters)	Corporations, economic growth, modern lifestyles	Status quo; excess human production, consumption, and population

activists have expanded over time, as environmental problems and society's awareness of them have grown. Not only has each stage seen new issues incorporated into a growing environmental agenda, but the issues themselves have been perceived quite differently over time. As modern technology and lifestyles have become more complex, the environmental problems they create have likewise increased in scale and complexity. Costs of solving environmental problems have also grown, reflecting a rapid change in the magnitude of the problems and our perceptions of them.

Conservationism typically dealt with specific and unambiguous issues, such as the protection of particular forestlands from logging. Compare this to air and water pollution, a typical concern of environmentalism. Pollution can diffuse over a broad area, its sources are often ambiguous, and its effects may be delayed and difficult to identify. In short, pollution is more subtle than logging, and controlling or stopping it is typically more difficult and costly.

Ecologism incorporates an even wider range of issues, as well as a significantly different perception of these issues. Especially notable is a greater emphasis on both micro and macro concerns. At the micro level, grassroots groups around the country are mobilizing NIMBY ('Not-In-My-Backyard') protests against garbage incinerators and hazardous waste sites. Minorities in particular are mobilizing against 'environmental racism,' the practice of locating environmentally noxious facilities in their communities. At the macro level, ecologism is concerned with issues of international import, such as global warming, ozone destruction, and the loss of rainforests. In addition, the growing radical wing of the movement, mentioned earlier, promotes an ecocentric world view and an emphasis on global ecological sustainability. In fact, radical groups such as Earth First!, as well as many of the grassroots groups, have developed explicitly in reaction to what they refer to as the 'reform' environmentalism and 'shallow' ecology embodied by the mainstream national environmental organizations.

These relatively new wings of the movement, while having some antecedents, reflect a qualitatively different approach to environmental issues. In fact, the major difference between ecologism and its forerunners is not so much in the types of issues it looks at, but rather in *how* it looks at them. Ecologism focuses on a bigger picture than either environmentalism or conservationism. Older issues such as concern for human health, and even the welfare of future generations, are important, but ecologism is marked by concern for overall ecological sustainability and recognition of the inherent interdependence of all life systems (Thiele 1999). Even NIMBYites are becoming concerned with the sustainability of current production systems, as witnessed by the growing NIABY ('Not-In-Anyone's-Backyard') attitude. Ecologism thus broadens environmental concern in various ways, fighting on a greater number of fronts—from local to global—and viewing other species and ecosystems as

having rights to exist independent of human interests. Concern for equity between species parallels a growth in concern for equity within the human race and across generations, as advocates of sustainable development attempt to rectify social injustice and poverty as well as environmental devastation throughout the world.

Ecologism entails an expanded critique of the status quo, based on a systemic and large-scale view of human impact on the natural environment. The pivotal concerns of ecologism are typically those that involve long-term, irreversible, synergistic, and often unpredictable consequences of human actions. Global warming and loss of biodiversity, for instance, are not only long-term and irreversible results of human actions, but they stem from an incredibly complex interplay of factors. While environmentalism has often addressed these issues, it has looked at them in a piecemeal fashion. Ecologism, on the other hand, views them in the context of the larger ecological–evolutionary global system. Advocates of ecologism talk about the end of nature, mass extinction, and the halt of evolution—unless human practices are altered, and soon. The purported causes and consequences, as well as the costs needed to remedy them, are therefore truly colossal.

A key aspect of social movements is the type of tactics they utilize. Just as the issues have broadened, so have the tactics employed by environmental activists. Tactically, conservationists relied heavily and successfully on lobbying government officials (epitomized by Pinchot's influence with Teddy Roosevelt). The solution to resource problems, they felt, came with governmental and scientific management of resources. In addition to traditional lobbying, environmentalists added litigation, research, and citizen participation to their repertoire, through the development of research- and legal-oriented groups as well as via letter-writing campaigns and mass protests (Mitchell et al. 1992).

Ecologism builds upon this tactical legacy—grassroots activists march and petition government officials, organizations engage in litigation and lobbying—but it increasingly employs more aggressive tactics such as consumer boycotts and various forms of 'direct action.' The growing radical wing of the movement is especially likely to engage in sit-ins, 'monkey-wrenching' of equipment, and other forms of 'ecotage' (from pouring quick rice in the radiator of a bulldozer to ramming a drift-net ship on the high seas) that are disavowed by mainstream environmentalists intent on 'working within the system' in order to reform it.

Recent years have also seen a rapid growth in other forms of activism, such as electoral action. More and more organizations are becoming active in political campaigns, not only publicizing candidates' records but publicly supporting selected candidates. In addition, advocates of ecologism, like their predecessors, promote lifestyle change, ranging from recycling and purchasing 'green' products, to reduced consumption and dietary changes. The tactics have clearly broadened and it is likely that they will continue to do so.

Finally, social movements can be distinguished by their opposition and the source of their grievances. Usually these are related, for those who benefit from environmentally harmful practices are most likely to oppose attempts to halt those practices. As our understanding of ecological problems has progressed, so has recognition of their embeddedness in the status quo. No longer are just a few 'robber barons' to blame for our problems; rather, as Pogo said: 'We have met the enemy, and he is us.'

Conservationism laid the blame for resource depletion at the feet of a relatively small group of people, and thereby stimulated limited opposition. Environmentalism, in contrast, blamed entire industries, modern lifestyles, and 'growthmania' in general, and in the process engendered broader opposition. Ecologism issues a critique that leaves few unscathed, for our entire species and the status quo (at least within industrialized nations) are to blame, albeit some aspects more so than others. Simply reforming current practices via legislation is therefore unlikely to suffice. As a simple example, rather than favoring installation of scrubbers on factory smokestacks to reduce pollutants, advocates of ecologism argue for alternative production techniques or giving up the product completely. Because the economic and social costs of halting human-induced environmental change could prove enormous, and leave little of modern life untouched, ecologism has the potential to stimulate enormous opposition.

4. *The Future*

The recent emergence of ecologism reflects the persistent evolution of societal concern over the impact of humans on the Earth. Based on the staying power of environmentalism over the past few decades, it is likely that the current wave of ecologism will continue to be a vital force. A major reason for this optimism is the great diversity of ecologism. Just as biodiversity is vital to the stability of ecosystems, tactical and ideological diversity may be among ecologism's greatest strengths. Still, given that ecologism has arisen out of frustration over the failure of environmentalism to halt ecological degradation, and given the immensity of the tasks (and opposition) it faces, the future for this latest phase of human efforts to protect the environment is uncertain. Ultimately, the true test of a social movement is its success in achieving its goals, not simply in maintaining its own survival.

Environments for Education

It is agreed generally that students' learning will be enhanced when family and school environments are supportive of education and in harmony with each other. In this article studies are examined that have investigated relationships between family and school educational environments and measures of students' school-related outcomes. Studies are organized into four general categories that are labeled as social-arithmetic environmental research, family and school structural characteristics, environmental press of families and schools, and interpretive analyses.

1. Social-arithmetic Environmental Research

One of the most significant sociological traditions in studies of education relates to attempts to describe empirically the social and educational conditions of society. Typically, the method that has been labeled as political arithmetic is used to explore associations between social and educational inequalities with the intention of possible educational reform by political means. A recent variant of political arithmetic has been developed in which statistical approaches such as structural equation modeling, logistic regression, and multilevel analyses are used to examine individual, social, and school influences on students' eventual educational and occupational attainments. Much of the research has lost, however, the political emphasis of earlier investigations. It might be more appropriate to classify the research as reflecting social rather than political arithmetic.

Social-arithmetic studies have often used adaptations of what has become known as the 'Wisconsin' model of status attainment. Typically, the research has shown that relationships between family background and young adults' status attainment are mediated by perceptions of parental and peer influences and by adolescents' aspirations. In addition, children's ability is related to successive measures of academic performance, independent of the effects of family social status.

A particularly interesting set of social-arithmetic studies has examined the longitudinal influences of children's early experiences on the educational outcomes of a group of US children in Baltimore. The investigations have shown that the quality of interactions with parents and teachers in early elementary school years is associated with children's reading and mathematics achievement 4 to 9 years later. In an attempt to disentangle the impact of family and school educational environments on outcomes, the Baltimore research has examined the differences between winter and summer learning. Winter learning refers to children's outcomes while school is in session and it reflects the influences of both home and school. In

contrast, summer learning that occurs during the long vacation is assumed to be related primarily to family influences. The research shows that for mathematics achievement there are consistent losses for poorer children during the summer vacation. It is suggested that schools are most beneficial for those children who need them most. The longitudinal investigations conclude that while families guide children's development throughout schooling, the quality of experiences in early school grades have a profound and continuing impact on children's eventual educational careers (Alexander et al. 1997).

The development of multilevel statistical models that recognize that students are members of classes, classes are nested within schools, and that schools are part of wider social structures such as neighborhoods, states, and countries, has allowed social-arithmetic research to examine the effectiveness of schools. A meta-analysis, using data from many countries, has shown that classroom conditions have a greater association with outcomes than do school organizational characteristics. In addition, the analysis indicates that across countries, students' family environment has a much stronger impact on academic outcomes than do the malleable features of schooling (Scheerens and Bosker 1997).

School effectiveness research in Britain has tended to show that it is possible to discriminate significantly between schools only when extremely successful and extremely unsuccessful schools are compared. From the British experience it is claimed that because of the limitations associated with present statistical modeling techniques, caution should be expressed when output league tables are used by governments and others to rank schools, and that parents need to be informed of the limitations of the research that generated the league tables (Goldstein and Spiegelhalter 1996). Similarly, an Australian study that combined multilevel analyses and structural equation modeling in a two-stage process concluded that because of modeling limitations, claims about educational effectiveness are at best tentative and at most spurious. It is suggested that future school effectiveness research should go into classrooms and examine those factors which optimize the quality of teacher–student interactions (Rowe and Hill 1998).

Although there have been substantial advances in the sophistication of statistical modeling in social-arithmetic research, there are concerns that such developments have not been matched by similar advances in the quality of the data that are being collected and in the elegance of theorizing. A summary of social-arithmetic research concludes that two melancholy propositions have been supported with increasing certainty:

(a) That class inequality is stubbornly resistant to social change when properly conceived in terms of relative rather than absolute improvements and equalization of life chances, and

(b) That educational reform, including reform of secondary schooling... has similarly failed to modify relative class chances though there may have been significant improvements in some countries with respect to the relative chances of women and some ethnic groups (Halsey 1994, p. 443).

2. *Family and School Structural Characteristics*

Family and school educational environments may be considered to consist of sets of structural constraints that provide opportunities for many children while limiting the choices of other children. In this section some of the structural characteristics that define children's educational environments are examined.

2.1 *Sibling Structure Variables*

Sibling variables such as sibship size (the number of children in families) and the birth order of children within families have often been used as indicators of children's family educational environments. Typically, these family structural characteristics are shown to have modest inverse associations with children's cognitive performance, especially verbal measures of achievement. A number of conceptual orientations have been presented to explain these relationships including the resource dilution hypothesis and the confluence model.

The resource dilution hypothesis indicates that sibling variables are related inversely to the cultural and material resources that parents are able to provide for their children. It is then proposed that such variations in the amount of family educational resources provided for different siblings are related to differences in children's educational outcomes. The confluence model proposes that children's cognitive development is related to the intellectual quality of family environments where quality is determined by influences such as sibship size, the age spacing among siblings, and whether individuals are only or last-born children (Zajone 1976). In the model, family intellectual environment is related to the average intellectual ability of all family members, including the child who is being studied. A family's intellectual environment is never stable, with changes being produced by alterations in family structure. The confluence model has generated vigorous controversy. It has been suggested, for example, that it may be a theory which is attempting to explain a social phenomenon that does not really exist (Retherford and Sewell 1991).

Much recent sibling structure research has examined whether the associations between sibling variables and educational outcomes are causal or attributable to other correlated factors such as socioeconomic status (Downey et al. 1999). In an analysis using change

models, for example, it has been shown that sibship size effects on cognitive performance disappear when family educational environments are taken into account (Guo and Van Wey 1999).

2.2 Single-parent Families

A number of theoretical orientations have been proposed to explain why the educational outcomes of children in single-parent households appear to be less favorable than the outcomes of children in two-parent families. The no-impact hypothesis suggests that the association between changing family structures and school outcomes can be attributed to a combination of other social contexts such as socioeconomic status, family ethnicity/race, and changing family economic circumstances. In the family socialization orientation it is suggested that the absence of a parent decreases the total amount of parental involvement in children's education that is related to poorer school outcomes. An instability, change, and stress perspective indicates that if children have to cope with the stress and instability that may accompany divorce, separation, or the death of a parent, then their school performance is likely to be affected negatively.

Although the findings from investigations that have examined the educational outcomes of children from single-parent families remain equivocal, the research is beginning to address a number of limitations of earlier studies. Investigations, for example, are beginning to (a) discriminate among different types of single-parent families such as divorced, separated, widowed, or never married, (b) include various social status measures as moderating variables, (c) examine the influence of changing family income as a background and a mediating variable, (d) separate the socioeconomic and ethnicity/race of families, and (e) differentiate between the effects on children's outcomes of families that are headed by fathers or mothers.

2.3 Ability Grouping in Schools

Perhaps the school structural characteristic that has been examined most widely has been ability grouping and whether tracking or streaming is related to students' academic outcomes. Some investigations have supported the divergence hypothesis of grouping which states that relative to what would have occurred if students had not been placed in ability groups, those students in high-ability groups gain in performance while those in low-ability groups lose in performance. However, findings from the research on ability grouping remain inconclusive. It is suggested that one reason for the inconsistent results might relate to how instructional resources are distributed within schools. If decisions about the allocation of teaching resources are associated with student placement, then the impact of ability grouping on outcomes might be primarily a function of the distribution of the quality of instruction. In addition, research has indicated that better educated parents can influence the tracks into which their children are placed, often independent of children's actual performance. The equivocal nature of the research suggests the need for further investigations of how ability groups are formed and how instructional resources are assigned to those groups; how families influence the assignment of children to ability groups; what the effects of ability grouping are on educational productivity and inequality; and what the effects of the alternatives to ability grouping are on learning outcomes.

3. Environmental Press of Families and Schools

In the development of a theory of personality, Murray (1938) suggests that to understand individuals' behavior it is necessary to define environments by the kinds of benefits and harms that they provide. The directional tendency implied in Murray's framework is designated as the press of the environment. An alpha press is defined as the benefit or harm that actually exists, as far as research can assess it, while a beta press is an individual's perception of the environment. In the following section the press of family and school educational environments are considered.

3.1 The Press of Family Environments

It was not until Bloom (1964) and a number of his students examined the environmental correlates of children's affective and cognitive outcomes that a 'school' of research emerged to assess the alpha press of families. Bloom defined environments as the conditions, forces, and external stimuli that surround, engulf, and impinge on individuals. These environmental characteristics may be physical and social as well as intellectual. It is proposed that such press variables form subenvironments with each subenvironment being related to the development of a particular human characteristic. A number of alterable alpha press variables have been identified as being consistently associated with school outcomes. These variables include family work habits, parents' academic guidance and support, language environment in the home, family stimulation to explore and discuss ideas and events, and parents' aspirations for their children (Marjoribanks 1994).

While alpha press studies have typically examined between-family environmental factors, there is a need to explore with greater sensitivity possible within-family influences. These latter family factors are often not shared by siblings such as the differential aspirations that parents have for their children or the experiences a child has with a chronic illness. The critical question becomes, why are children in the same

family often so different from one another? To answer this question perhaps interpretive analyses of families need to be undertaken in conjunction with alpha press investigations.

3.2 The Press of School Environments

There is now a large body of research that has defined classroom environments as the shared perceptions of students and sometimes of teachers. The schedules that have been constructed to assess the beta press of classroom and school environments are often referred to as high-inference measures. In contrast, low-inference techniques measure specific explicit phenomena such as the number of questions asked by students in a certain section of a lesson. Typically, perceptual measures are related to moderate amounts of variance in learning outcomes, often beyond the variance that can be attributed to student characteristics such as pretest performance or general ability. The practical implication of the research is that student outcomes might be improved by establishing classrooms that match those educational environments which have been shown to be associated with students' learning.

A limitation of most classroom learning environment instruments is that they measure an individual student's perceptions of a whole class, as distinct from students' perceptions of their own roles in the classroom. There is a distinction between the private beta press or idiosyncratic perception that each person has of an environment and the consensual beta press that the members of a group share about that environment (Fraser 1998). It is likely that future classroom and school environment research will be enhanced if personal as well as group forms of beta press schedules are adopted.

Many educators would argue that school learning environments need to be examined with a greater sensitivity than can be generated from perception measures. Researchers using such perceptual scales generally suggest themselves that the measures provide one portrayal of educational environments that is likely to be enriched by adopting other measurement measures. In the following section interpretive approaches to the investigation of educational environments are examined.

4. Interpretive Analyses

Increasingly in research related to family and school educational environments, concepts, and methodologies are being adopted from a number of theoretical orientations such as social phenomenology, ethnomethodology, symbolic interactionism, and critical discourse analysis. In educational environments, research of these interpretive perspectives has emphasized the need to examine the processes used by members of families and schools to define and manage their everyday lives. Investigations typically use variations of ethnographic methods to obtain accounts of why parents, teachers, and children perform certain acts and what social meanings they give to the actions of themselves and of others.

In an intensive study of parents' involvement with their third grade children, for example, Lareau and Horvat (1999) examined how inequality is perpetuated in school settings. They were concerned that previous research has not investigated adequately how family, cultural, and social resources are converted into educational advantages. From indepth interviews with the parents of 24 children, with staff in the children's school, and with members of the wider community, the study concluded that while a child's racial and social class are associated with social reproduction they do not determine it. In addition, the study indicates that those parents who have the capacity to activate intellectual capital are likely to have a substantial impact on their children's eventual status attainment. In an even more intensive ethnographic study, Goldenberg (1989) investigated the relationships among parental involvement, ability group placement, and the reading achievement of three first-graders. The findings indicated that teachers' perceptions of children's behaviors were related to the placement of children into academic groups. As a result, parents were able to affect group placement by influencing their child's classroom behavior.

Such interpretive analyses provide valuable insights into the relationships among family and school educational environments and children's school outcomes.

5. Future Research Directions

The complexity of the relationships among family and school educational environments and students' school outcomes indicates the difficult task that confronts parents and teachers when they attempt to design and implement programs to improve educational outcomes. Parents and teachers may create what they consider to be supportive and harmonious educational environments but children's perceptions and the meanings they impute to those environments may be influenced greatly by the social, cultural, and economic constraints that surround them. Investigations are required that integrate the most recent advances in the research orientations that have been considered in this article to examine how the cultural, economic, and social capital of families and schools are associated with the educational outcomes of boys and girls from different social status and ethnic/race groups. Unless such inclusive studies are undertaken it is unlikely that there will be significant advances in understanding how families and schools interact to influence students' learning.

Environments for Learning

The term 'learning environment' expresses that learning is dependent on various environmental factors, which are created to various degrees by external factors. A learning environment is made up of an arrangement of teaching strategies and methods, learning materials, and media. The learning environment represents the current temporal, spatial, and social learning situation and also includes the relevant cultural context. The basis for concrete measures to create learning environments provides a fundamental concept for teaching and learning. In the following, two central (purist) concepts are compared with each other and are then confronted with a pragmatic concept. In this manner, a framework for orientation is provided with regard to the design and assessment of learning environments.

1. The Cognitivist-based Concept: The Design of Object-oriented Learning Environments

1.1 Basic Assumptions

In a cognitivist position on teaching and learning, all efforts are devoted to instruction and to the question, how teaching and learning are planned, organized, and guided. In this way, the learners understand and internalize the contents of knowledge according to their system and succeed in learning based on predefined teaching and learning goals. In the design of learning environments, one concentrates on the object of teaching and learning, which as a rule is interpreted as a 'pre-fabricated knowledge system.' The teaching/learning process is therefore viewed as a type of 'knowledge transfer.' The teacher's function is to present and explain the contents of knowledge and also to guide the learner and to ensure that advances in learning are made. The learner remains in more of a passive position (Lowyck 1991). Under these conditions learning is to a large degree a receptive process. In object-oriented learning environments, great emphasis is placed on the assessment of how successful learning is. Norm-oriented and/or learning goal-oriented tests evaluate to which learning results the instructional methods have led. Instruction and evaluation are, in this case, viewed as two separate units.

1.2 Problems of the Cognitivist-based Teaching and Learning Concept

There is still a lack of empirical findings that justify a rational structuring of the learning and teaching processes, as it is postulated in the cognitively oriented teaching and learning models and in the discipline of ID. Especially lacking is the evidence that the effects of single instructional measures are replicable. Theoretically problematic is the instruction's analytical process of separating entireties into elementary parts that are transferred separately. This reductionist procedure ignores the fact that understanding is dependent on the

entire knowledge structure and not on its isolated parts. Contestable also is the instructional methods assumption that the effect of different methods can be exactly predicted (Duffy and Jonassen 1991). Most apparent, however, are the practical problems of the cognitivist view with its uneven role separation between teachers and learners, which results in many cases in receptive behavior from the learner. The resulting shortage of self-initiative and self-responsibility for the learning process and its success increases the possibility that the learners find themselves in a passive position and feel demotivated, or at best extrinsically motivated (Deci and Ryan 1993). In addition, systematized and logically prepared knowledge has little to do with the complex and unstructured demands of everyday situations (Resnick 1987). In this way cognitive-oriented instruction often produces 'tacit knowledge,' which has been gained but which cannot be used in real situations.

2. *The Constructive-oriented View: Design of Situational Learning Environments*

2.1 *Basic Assumptions*

Constructivism has been discussed intensively again in educational psychology since the 1980s, and specifically constructivism as a scientific and cognition theory and also as a paradigm in sociology, cognition science, and psychology ('new' constructivism) (see Gerstenmaier and Mandl 1995). In questions of teaching and learning the 'new' constructivism becomes especially relevant: in contrast to radical constructivism, the new constructivism is more concerned with the thinking and acting subject. Central to this is the assumption that knowledge is not a copy of reality, but rather a human construction (Knuth and Cunningham 1993). While teaching and learning methods in the tradition of the cognitive view hold the instruction at the center of their efforts, the views of the constructivists distinguish themselves by placing the learner and the learning process at the center. The question of how knowledge is constructed and the connection between knowledge and action is more important than how knowledge is transferred (Gerstenmaier and Mandl 1995). The learner finds him/herself in an active position, while the teacher has the task of providing problem situations and the tools to solve them and, if necessary, is available to react to the needs of the learner. In the constructivist position, learning is viewed as an active constructing process, which is situated in a definite context. Evaluation is an integral part of the constructivist view, in which processes are more important than results; however, there are no predefined evaluation methods, which are theoretically derived and empirically 'secured.'

2.2 *The Situated Cognition Movement*

From a constructivist perspective, the learning environment must provide the learner with situations in which their own constructive achievements, social interactions, and participation processes are possible, which is why these are referred to as 'situated learning environments.' It is the goal of situated learning environments that the learner understands the new contents and is able to use the gained knowledge and skills in a flexible manner. In addition, the learner should be able to develop problem-solving skills and other cognitive strategies. Above all, it is due to the situated cognition movement that the ideas of context and social participation in authentic situations have found widespread use in the learning process. The term situated cognition, in a similar fashion to the term constructivism, is not clearly defined and there are several theoretical variations. Common to both is the view that thinking, acting, and learning take place situally and that knowledge is on the one hand constructed by the perceiving subject and on the other hand is shared amongst a community (Resnick 1991). Concepts within the situated cognition movement stem from various influences, which range from cognitive anthropology (Lave 1991) to ecological psychology (Greeno 1989) to socio-cognitive schools of thought. Since the end of the 1980s various approaches have been developed in instructional psychology which are related to the Situated Cognition movement, for example approaches like Anchored Instruction (CTGV 1997), Cognitive Flexibility (Jacobson and Spiro 1992) or Cognitive Apprenticeship (Collins et al. 1989). The commonality exists in the fact that the learning processes are embedded within solving authentic problems and that learning is not restricted to the aspect of knowledge acquisition, but rather is viewed under the perspective of enculturation.

2.3 *Problems in Constructivist-oriented Teaching and Learning Concepts*

The constructivist view runs into difficulties when the question is raised regarding the empirical underpinning of the postulated effects of situated learning environments. Although the number of studies has recently increased, the findings are far from sufficient. In addition, several findings of transfer research contradict the constructivist postulate that knowledge is bound to context (Anderson et al. 1996). There is the problem that the promotion of learning processes through constructivist principles has led in subsequent knowledge tests to poorer results. The meaning of these findings is first qualified, when these results are compared to the results of later applied tests of the learner, which show a positive influence of

situated learning. Problems of the theoretical kind arise when a more radical constructivist perspective is taken, which states that there is no objective reality those teachers can pass along to their students. Many supporters of situated learning environments, however, take a less extreme view and assume that, aside from the individual construction capacities of the learner, it is possible to stimulate learning processes externally (Lowyck 1991). Even in the framework of this moderate constructivist position, teachers are given such large degrees of freedom that they have problems in making the right choice. It must also be mentioned that central concepts such as activity and situation are conceptually vague and used in a heterogeneous manner (Renkl et al. 1999). The supporters of the constructivist view must also accept the practical criticism that their approach for both teachers and learners may be very time-consuming and may result in a poor cost-benefit relationship (Anderson et al. 1996). The lack of direction and support for the learner in situational learning environments can also lead to undesirable results; one example could be that the demands placed on the students are too high. This is especially the case with learners who have disadvantageous learning conditions, so that the danger of a 'scissor effect' arises: as a rule, more competitive (motivated) learners profit from situated learning environments than less competitive learners. The goal of situated learning, namely the enculturation and acquisition of expertise, cannot be sought after in many contexts. For example where orientation and a lower achievement level are sufficient, proven cognitivist ways are practicable and from time to time more economical (Winn 1996).

3. *The Attempt at a Pragmatic View: Structure of Problem-oriented Learning Environments*

3.1 *Basic Assumptions*

The use of theoretical teaching and learning models in practice is difficult in many respects, regardless of whether they are models for creating object-oriented or situated learning environments. The practical problems of both the cognitivist and the constructivist position have made it clear that theoretical one-sidedness is problematic when applied to practice. The lack of clear empirical finds from which action-guiding rules for or against a definite form of teaching and learning makes the situation even more confusing. Against this background the attempt is increasingly being made to take a middle position between the cognitivist and the constructivist views and to find a balance between the primacy of instruction in object-oriented learning environments and the primacy of construction in situational learning environments. To a large degree, consensus has been reached supporting a relative constructivist conception of learning as an active, self-guided, constructive, situative, and social process (Reinmann-Rothmeier and Mandl 1997). Knowledge-based constructivism is also currently under discussion, in which learning is based on the personal construction of meaning from the perspective of the learner, but also presupposes sufficient knowledge, whose acquisition is barely possible without instructional guidance and support (Resnick and Williams Hall 1998).

3.2 *Problem-oriented Learning Environments*

A moderate constructivist view of learning does not in any way exclude guidance and support from teachers. It is neither possible nor sensible to solely rely on the constructive ability of learners. One cannot constantly transfer prefabricated knowledge systems to learners according to fixed rules. In various attempts to integrate object-oriented and situated learning environments and thereby to utilize the characteristics of both approaches, problem-oriented learning environments are often postulated. With a desideratum of characteristics, which especially the Anchored Instruction view, the Cognitive-Flexibility theory, and the Cognitive Apprenticeship view have in common, some guidelines from problem-oriented structuring of learning environments can be formulated, which also can be combined with instructional measures of cognitivist character. (e.g., CTGV 1997, Reinmann-Rothmeier and Mandl 1997):

(a) *Learning in a situated manner with authentic problems*: The starting point of learning processes should be authentic problems—problems which due to their relationship to reality and their relevance motivate the learner to develop new knowledge or new skills. Problem-oriented learning environments are therefore designed in such a manner that they make possible and encourage dealings with realistic problems and authentic situations.

(b) *Learning in multiple contexts*: To ensure that newly gained knowledge or concepts do not remain fixed to a certain situation, the same contents should be learned in different contexts. Problem-oriented learning environments are therefore designed in such a manner that the learned material can also be applied to and utilized in the analysis of other problems.

(c) *Learning using multiple perspectives*: In learning it should be considered that single contents or problems could be examined from different perspectives or aspects. Problem-oriented learning environments are therefore designed in such a manner that knowledge and concepts can be learned and applied using multiple perspectives.

(d) *Learning in a social context*: Learning must not be done as an individual process, but rather group learning and group tasks should be used in as many

learning phases as possible in the framework of situated problem analysis. Problem-oriented learning environments are therefore designed in such a manner that they make it possible to have cooperative learning and problem solving in groups.

(e) *Learning with instructional support*: Learning without any instructional support is ineffective and causes excessive demands on the learners. Teachers cannot limit themselves to giving opportunities to learn; they must also guide learners whenever necessary and especially give specific guidance for problem solving. Problem-oriented learning environments are therefore structured in a manner that provides both diverse possibilities for learning in complex situations and the knowledge necessary to work on problem solving.

It is also important to explicitly consider motivational factors that are generally lacking in the structuring of cogvitivist learning environments. Motivational factors are implicitly used in situational learning environments but conceptually receive rather little attention (Stark et al. 1998).

3.3 Empirical Arguments for Problem-oriented Learning Environments

Considerations of the compatibility of instruction and construction show a certain relation to the so-called 'adaptive teaching,' which strives towards an optimal fit between the internal need for the support of the learner and the external offer of support. The classic ATI (Aptitude Treatment Interaction) research (Cronbach and Snow 1977) shows an interaction between individual learning conditions and the teaching methods employed. It showed in numerous cases that learners with less advantageous learning conditions profited from a highly structured learning situation, but learners in advantageous learning conditions did not. Teacher-centered forms of instruction in the sense of the cognitivist view are more effective in disadvantageous learning conditions (i.e., little previous knowledge, lower intelligence, high level of anxiety). Situated learning environments, which place high demands on the capability of the learner to construct knowledge, appear to be more effective for learners with advantageous learning conditions. The strongest predictor for subsequent learning results has, in recent studies, proven to be the domain-specific preknowledge. The call for the combination of instructional principles from cognitivist and constructivist teaching and learning approaches has also gained empirical support from other fields. In initial business school education, for example, the combination of multiple perspectives (in the form of multiple examples and instructional support (in the form of requests for self-explanation)) has proven effective. A further example is case-oriented computer learning programs in medicine, which support learning in authentic problem situations with directions and expert commentaries as support (Gräsel 1997). In addition, there have been further developments in the Anchored Instruction approach, in which narrative anchors have been enhanced with teacher-supported learning cycles (CTGV 1997). Positive results have also been shown in attempts to implement problem-oriented teaching and learning forms within conventionally structured (mass-) universities and in this way to combine them in a logical way with new, constructivist-inspired models of teaching and learning.

Epidemiology, Social

Epidemiology is the basic science of public health: it focuses on the distribution of disease in the population and on the factors that explain that distribution. Social epidemiology is a subfield of epidemiology that concentrates on social factors as explanatory variables. There is increasing interest in the importance of social factors both for understanding the determinants of disease in the population and for the development of programs to prevent disease and promote health.

1. *Rationale for a Social Epidemiologic Approach to Disease Prevention*

1.1 *Magnitude of the Disease Problem*

Consideration of social factors in efforts to prevent disease is suggested by the sheer magnitude of many diseases (including coronary heart disease, cancer of various sites, arthritis, mental illness, diabetes, and stroke). While a one-to-one approach to diseases of great prevalence clearly is of value to patients, families, and friends, it does little to alter the distribution of disease in the population because new people develop disease even as sick people are treated and cured. Thus, an individual approach exhausts substantial medical care resources but does little to address those social and environmental factors that have initiated the problem. In this circumstance, an environmental approach to prevention is clearly more efficient.

1.2 *The Patterning of Disease Rates*

The continual swell of new 'at-risk' people in the population leads to the second reason for considering social factors in disease prevention research and programs: groups often have a characteristic pattern of disease over time even though individuals come and go from these groups. This pattern indicates that there may be something about groups that either promotes or discourages disease among individuals in those groups. One example of patterning of disease rates is provided by the case of coronary heart disease (CHD). CHD rates are far higher in the US than in Japan.Yet when men from Japan immigrate to the US, their CHD rates are five times higher compared to those in their country of origin. This increase in rate is observed even after account is taken of such CHD risk factors as blood pressure, cigarette smoking, diet, and serum cholesterol levels. It seems reasonable to suggest that something about the environment of the US causes people who settle here to slowly adopt the endemic rates of disease in the US (Marmot and Syme 1976). This example of patterned consistency of disease rates across geography, social, and cultural groups emphasizes the potential importance of environmental factors in the study of disease etiology. In consequence, a considerable amount of research has been done in hopes of identifying social and environmental factors so that interventions might be developed to prevent or control disease.

1.3 *Difficulties in Changing Behavior*

A third reason for the consideration of social factors in disease prevention is that the prevention of many diseases requires that people change their behavior. To prevent these diseases, people are increasingly asked to begin to do things they have not done previously, to stop doing things they have been doing for years, and to do more of some things and less of others. This behavioral approach to disease prevention contrasts with programs that attempt to do something 'to' people. While some diseases and conditions can be treated best by injection, surgery, or other nonbehavioral manipulations, most diseases of concern today cannot. Diseases such as cancer, diseases of the cardiovascular system, cirrhosis, and some respiratory diseases to a greater or lesser degree are associated with particular behaviors and hopefully can be prevented or treated by behavior change (Ferguson 1998,

Canada Department of Health and National Welfare 1974).

It is one thing to identify a risk behavior and another thing to insure that people will actually change that behavior. While there certainly are examples of successful programs to change behavior, the evidence suggests that behavior change is a very difficult and complex challenge (Syme 1986). While many different factors need to be considered in helping people change their behavior, one factor rarely considered is that of the environment. It is difficult to expect that people will change their behavior easily when many forces in the social, cultural, and physical environment conspire against such change (Leventhal and Cleary 1980). If successful behavior-modification programs are to be developed to prevent diseases, more attention will need to be given not only to the behavior and risk profiles of individuals, but also to the social environment within which people live.

2. *Social Factors and the Incidence of Disease*

2.1 *Personal Dispositions*

Since about 1970, research evidence has accumulated regarding the role of many social factors in disease etiology. While most of this work has been done in reference to coronary heart disease, other diseases also have been studied. Early studies emphasized the role of mobility and Type A behavior pattern as risk factors for disease, but subsequent research did not uniformly confirm these findings. A new generation of research has emerged from this early work that focuses on particular components of the behavior pattern such as antagonism, resentment, time urgency, anger, need for control, self-involvement, self-esteem, and hardiness (Syme 1992). The most impressive and consistent findings from this body of research have been on the concept of hostility which has been shown to be related to coronary heart disease in a wide variety of studies (Miller et al. 1996). Other research noted below has a limited sense of control to health, with other dispositions such as optimism and negative affect receiving increased attention.

2.2 *Social Support and Social Connection*

Historically, one of the earliest areas of interest in the social patterning of disease has been the beneficial effect of marital status on health. While this research area has yielded interesting results, it also has branched out to new research areas on social support and social connection.

It has been known for many years that people who are not married—whether single, separated, widowed, or divorced—have higher mortality rates than married people. Not only is having a spouse beneficial to health, but loss of spouse to death is particularly detrimental. Common to marital status research are the themes of social support and social connection. In an influential article Cassel (1976) pointed out that lack of social connection, such as disruption of marriage or moving to a new social setting, was associated with a wide range of disease outcomes. According to Cassel's hypothesis, the essential element in these situations was lack of social connection or support. In the absence of social connections a person becomes generally susceptible to illness, the specific type of which was determined by that person's particular risk situation. The concept of social support subsequently was studied in a large community sample in Alameda County, California (Berkman and Syme 1979), in Tecumseh, Michigan (House et al. 1982), and in eastern Finland (Kaplan et al. 1988). In these studies, a strong association between networks and mortality has been observed for all causes of death for men, but only sometimes for women. These findings persisted even after account was taken of a broad range of other risk factors such as age, obesity, smoking, physical activity, health practices, education, and family history.

Several reviews (Broadhead et al. 1983, House et al. 1988, Berkman and Glass 2000) have critically assessed this literature and have concluded that something of importance is going on but that the precise elements of this 'something' are not yet clear. One possible explanation for the inconsistent pattern of findings may be that a few simple questions about relationships (e.g., about marriage, clubs, and number of friends) may be enough to separate those with ties from those without ties in large, urban areas like Alameda County, but that these questions are not precise enough in smaller, more rural communities, or for women. Further work will be necessary to better define the importance of various dimensions of social networks and social support for health and wellbeing.

2.3 *Socioeconomic Status*

Socioeconomic status has the effect of grouping individuals and of nesting them within geographic, social, and occupational environments. Obviously, not all environments are equal. They are more or less desirable places to live or work for a variety of reasons: more or fewer public and private resources; better or poorer housing and infrastructure; higher or lower levels of social capital; and more or less evenly distributed wealth. These environmental differences are patterned by socioeconomic status. Yet, as noted above, socioeconomic status is often treated as if it was a characteristic of individuals. Poverty, richness, and social status are qualities of environments as well as of people.

Evidence that area socioeconomic status has an independent relationship with mortality, over and above individuals, has emerged in the 1990s. Haan and

colleagues showed that residents in a federally designated poverty area experienced elevated age, race, and sex-adjusted mortality over a follow-up period compared to residents of a nonpoverty area (Haan et al. 1987). In this study, the heightened risk of death persisted after adjustment for a wide range of demographic, behavioral, social, psychological, and health characteristics. These researchers concluded that the social environment contributed to the association between low socioeconomic status and excess mortality, independent of individual factors. Recently, other analyses have supported these results on a nationwide scale (Anderson et al. 1997).

Further support for this observation comes from England, where Blaxter (1990) investigated a wide variety of health outcomes in manual and nonmanual workers living in different types of areas. The interaction between social class of area of residence and individual social class characteristics was also reported by Yen and Kaplan (Yen and Kaplan 1996), and Shouls and colleagues (Shouls et al. 1996). Both studies found that poverty area of residence, together with individual characteristics, affect illness and adoption of risk behaviors.

Another approach to the study of area quality, one that focuses on economic patterns, involves attention to equality of income distribution, a concept which has no equivalent measure at the individual level. In recent years, evidence has accumulated to suggest that within populations of developed countries, it is the relative socioeconomic position as well as the absolute level of income that is associated with health (Wilkinson 1992). Wilkinson has shown that, in a sample of industrialized countries, life expectancy increases as the distribution of income in the country becomes more egalitarian. Data from the Luxembourg Income Study revealed a correlation of 0.86 between life expectancy and the proportion of the total net income received by the least well-off 70 percent of the population. In addition, when changes in income distribution and life expectancy were compared over time, increases in equality of income distribution were associated with greater increases in life expectancy.

Two other recent studies have explored the association between income distribution and mortality and morbidity within the United States. Although these studies used different measures of income distribution, they report similar results: as the equality of the income distribution increases, the age-adjusted rates of all-cause mortality decreases. In one of these studies (Kennedy et al. 1996), similar relationships are seen between state income equality and mortality from heart disease, malignant neoplasms, cerebrovascular disease, and homicide. In the second study (Kaplan et al. 1996), strong, significant correlations are observed between greater income equality and lower rates of all-cause and age-specific mortality, other health indicators (including rates of low birth weight, violent crimes, disability, per capita expenditures on protection, sedentary behavior, and current smoking), other social indicators (proportions of people who are unemployed, proportion receiving Aid to Families with Dependant Children, and proportion without health insurance). There is considerable debate as to the interpretation of these findings regarding income inequality. Some argue that income inequality at the population level simply represents individual differences within that population and that these individual characteristics cause disease (Gravelle 1998). Others suggest that income inequality affects health because it causes individuals with low income to experience relative deprivation with resultant feelings of distrust, shame, and hostility (Kawachi et al. 1997). A third view is that income equality is a reflection of political and economic forces in the community that generate inequality and that impact the distribution of such resources as schooling, medical care, social welfare, and working conditions (Lynch et al. 2000) which, in turn, affects health and wellbeing.

Social class differences are important determinants of health. Further research to better understand the meaning of social class gradients and of income inequality is important to help in the development of appropriate and effective interventions to improve health.

One of the most persistent disease patterns observed in public health research is that people in the lowest socioeconomic groups have the highest rates of morbidity and mortality. In a comprehensive review of 30 studies on this topic, Antonovsky noted the consistency of this finding dating from the twelfth century (Antonovsky 1967). Further, this differential has been observed throughout the world, regardless of whether the dominant diseases of death and disability were attributed to infectious or noninfectious causes and regardless of the specific methods used to assess socioeconomic status (Syme and Berkman 1976, Feinstein 1993).

In a massive nationwide survey of mortality in the United States, Kitagawa and Hauser (Kitagawa and Hauser 1973) found that mortality rates varied dramatically among socioeconomic groups for both men and women, whether socioeconomic status was studie in relation to education, income, or occupation: the lower the socioeconomic level, the higher the death rate. In addition, Kitagawa and Hauser found that those in lower socioeconomic groups had higher death rates for every cause of death except, among women, cancer of the breast and motor vehicle accidents. Higher rates of morbidity also have been observed among those in lower socioeconomic groups. These higher morbidity rates include virtually every disease as well as mental illnesses and conditions such as schizophrenia, depression, unhappiness, worry, anxiety, and hopelessness (Syme and Berkman 1976, Haan et al. 1989).

One problem with this observation is to identify those components of socioeconomic status that are

potentially amenable to intervention. Research done by Marmot and his colleagues (Marmot et al. 1978) on British civil servants provides an opportunity to identify some of these components. These investigators have demonstrated that British civil servants in the highest grade (administrators) had the lowest rate of coronary heart disease while those in the lowest grade (mainly unskilled manual workers) had rates four times as high. After account had been taken of such coronary heart disease risk factors as serum cholesterol, cigarette smoking, blood pressure, physical activity, glucose intolerance, and social support, the differences in rate between those at the top and bottom of the graded hierarchy was reduced to three times. However, about 60 percent of the difference in coronary heart disease rates among civil service grades remained unexplained after this adjustment. More interesting is the fact that workers in professional and executive jobs (grade 2) and in clerical jobs (grade 3) have coronary heart disease rates 2 and 3.2 times as high as administrators.

Although the relation of socioeconomic position to health is not linear in the general population, since the largest differences are usually seen at the broad lower end of the distribution, the finding of Marmot and colleagues poses a challenge. While it is reasonably simple to come up with possible explanations for the fact that those at the bottom have higher rates than those at the top, these explanations do not account for the fact that those close to the top have higher rates of disease than those at the top. Factors such as inadequate medical care, unemployment, low income, racial factors, poor nutrition, poor housing, and poor education may account for higher rates of disease among those in grade 5 but they seem unlikely to explain why professionals and executives in the British civil service have rates twice as high as administrators.

These socioeconomic differences in disease are not unique to British civil servants. They have been observed in a wide variety of populations in many different countries, and are not confined to a single age group or disease entity, having been observed for many body systems—including the digestive, genitourinary, respiratory, circulatory, nervous, blood, and endocrine systems (Haan et al. 1989, Marmot et al. 1978, Susser et al. 1985)—and diseases (e.g., most malignancies, congenital anomalies, infectious and parasitic diseases, accidents, poisoning and violence, perinatal mortality, diabetes, and musculoskeletal impairments) as well as for early stages of and progression to carotid atherosclerosis (Lynch et al. 1995, Lynch et al. 1997).

A number of approaches have been taken to explain the link between socioeconomic status and disease. One possible explanation is the concept of 'control of destiny.' It could be postulated, for example, that the lower down one is in the socioeconomic status hierarchy, the less control one has over the factors that affect life and living circumstance. This hypothesis is very general, and it does not specify whether control involves money, power, information, prestige, experience, or something else. Over the years, many social scientists have studied different concepts related to the idea of 'control of destiny': mastery, self-efficacy, locus of control, learned helplessness, controllability, predictability, desire for control, sense of control, powerlessness, hardiness, competence, and so on (Syme 1989).

Research on job stress provides an example of the feasibility of intervening on 'control.' For many years, researchers have explored the relationship between 'job stress' and disease. It was only after Karasek (Karasek et al. 1981), Theorell (Theorell et al. 1984), and their associates added the idea of job latitude and discretion to that of job stress that such a link was observed. These investigators have shown in several studies that occupational stressors have consequences for health especially when workers do not have sufficient latitude and discretion for coping with these stressors. When workers have little control over work pace and methods, higher rates of catacholamines are seen as well as higher rates of mental strain, coronary heart disease, and other health problems. The implications for prevention are perhaps clearer when one is able to focus on such concepts as worker discretion, latitude, and involvement rather than broader concepts such as socioeconomic status. This focus also directs attention to the work environment and not simply to the individual worker.

2.4 *Race and Ethnicity*

Another pervasive and persistent patterned regularity in the study of health and disease is seen between race and ethnic groups. For example, young and middle-aged Black Americans have disproportionately high morbidity and mortality rates (Lillie-Blanton et al. 1996). McCord and Freeman (1990) have estimated that Black men living in Harlem in 1980 had less chance of surviving to the age of 65 than men in Bangladesh, and recent data from a nationwide study by Geronimus (1992) show that this situation was even worse in 1990. Geronimus and colleagues indicate that about half of the higher mortality rate in Blacks is due to poverty. Other possible explanations for the differences in mortality rate and life expectancy might include discrimination, lifestyle factors, use of medical care, and biologic differences. Exploration of the relative importance of these factors is complicated by the fact that 'race' is such an imprecise term. Biologically, race is an indicator of the distribution of gene frequencies across populations, but, as Susser et al. (1985) point out, this distribution of genes is deeply conflated with geographic, social class, and cultural distinctions. Many physical anthropologists prefer to dispense with the term altogether because it is so vague.

Nevertheless, race clearly has social meaning. Race has impact on life choices and opportunities, on education and employment. Race influences the social environmental conditions in which people live. And race influences how people interact with each other and this may have health consequences. In an innovative and pioneering study, Krieger and Sidney (1996) studied the consequences of racial discrimination on blood pressure in 5,115 young adults in four US cities: Birmingham, Chicago, Minneapolis, and Oakland. Eighty percent of Black men and women reported experiences of racial discrimination in seven basic life situations. Racial discrimination and internalized responses to the discrimination were associated with elevations of blood pressure. Working-class Black adults who reported no experiences of discrimination, yet said they typically accept unfair treatment as a fact of life, had systolic blood pressure 7 mm Hg higher than white adults, and had higher blood pressure than Black adults who typically challenged and reported discrimination.

Racial categories are clearly associated with differences in life expectancy, disability, cirrhosis, infant mortality, birthweight, arthritis, diabetes, hypertension, anemia, and virtually every cause of death among adults. These are important and complex issues that deserve a high priority in our research agenda. Recent research on race, especially that focusing on Black–White differences, is providing important new findings (Geiger 1996, Fang et al. 1996, Laveist 1993). It is clear that this issue deserves serious and continued attention directed to a wider range of racial and ethnic groups.

3. Conclusion

The importance of social factors in the etiology of many diseases is becoming increasingly clear. The evidence for some factors remains tentative or unclear. Nevertheless, it is impressive that an increasingly large body of consistent findings is being generated in spite of these major methodologic problems. It may be premature to use the data emerging from this research in public health programs, but it is clear that they will be needed soon. The reason for this is that most serious diseases today are importantly influenced by the social environment. For these reasons, interventions in the social environment clearly will be necessary, and continued research on social factors therefore must become an important priority in both public health planning and program development.

Epigenetic Inheritance

'Epigenetic inheritance' is a term used to describe the transmission from one generation to the next of structural and functional variations that do not depend on genetic differences. In its broadest sense, the term includes the transmission of nongenetic variations in behavior, but its use is usually restricted to the inheritance in cell lineages of variations that are not based on changes in the genetic information carried in DNA. Such heritable epigenetic changes are part of normal development but there is increasing evidence that they can also be transmitted from one generation of organisms to the next. Epigenetic inheritance therefore has practical implications for medicine and agriculture, and theoretical implications for ideas about heredity and evolution.

1. *Definitions and Historical Background*

'Epigenetics,' 'epigenetic,' and 'epigenetic inheritance' are relatively new terms, derived from the much older term 'epigenesis.' According to the ancient and influential theory of epigenesis, development involves qualitative changes in organization, with the parts of the adult animal forming gradually and sequentially from an ovum that is amorphous and unorganized. In the rival theory of preformation, which was popular in the late seventeenth and eighteenth centuries, development was assumed to entail the growth or

unfolding of parts that already exist in miniature in the egg (Pinto-Correia 1997). Since the beginning of the nineteenth century, it has been accepted generally that development is through epigenesis, although a subtle form of preformation was introduced towards the end of the nineteenth century, when it was recognized that although developmental changes are qualitative, they are controlled by preformed determinants whose transmission and effects ensure hereditary continuity. For several decades after the rediscovery of Mendel's laws in 1900, the new science of genetics was concerned with the way these determinants, the genes, are transmitted from one generation to the next; their role in development received little attention until the second half of the twentieth century.

The introduction of the term 'epigenetics' by the British embryologist Conrad Waddington in 1947 (see Waddington 1975), reflected a growing interest in the relationship between genes and development, an interest which increased as the molecular nature of the gene was unraveled. Waddington coined the term epigenetics for the study of the causal mechanisms of development; the adjective 'epigenetic' is applied to the processes through which the genetic information in a fertilized egg is expressed and used in the production of the adult form, the visible phenotype. As the study of genetics and development progressed, it became clear that different cell types usually have identical genotypes, but express different sets of genes. (One important exception proved to be the cells of the immune system, where epigenetic changes involve alterations in DNA sequences.) Finding out which genes are expressed and what controls when and where they are expressed became the key to understanding the functional and structural specialization of cells and tissues during development. It also became clear that once a cell is committed to a particular form or function, that state is often transmitted to daughter cells, even though the stimulus that originally induced its development is no longer present. Thus, once a cell is committed to becoming a liver cell, it breeds true and by division gives rise to a lineage of liver cells; similarly, skin cells will give rise to skin cells, and kidney cells to kidney cells. This stable transmission of the alternative phenotypes of cells with the same genotype became known as 'cellular heredity,' 'cell heredity,' or 'epigenetic inheritance.'

Interest in the transmission of cellular states began to grow during the mid-1970s, as the molecular mechanisms and systems that underlie the control of gene expression started to be unraveled (Holliday 1990). Gradually, it was recognized that epigenetic information is transmitted not only between generations of cells in the cell lineages within an individual, but also between generations of individuals. The concept of epigenetic inheritance was therefore extended and now has both a narrow and a broad meaning. The narrow meaning limits it to cell memory in lineages within an organism, whereas the broad meaning includes the transmission of epigenetic information between any reproducing entities—cells, individuals, and even groups of individuals. This article focuses first on epigenetic inheritance in cell lines, and then discusses the consequences of the transmission of epigenetic variations between generations of individuals.

2. *Mechanisms of Transmission*

The systems that underlie epigenetic inheritance and enable the phenotypic expression of the genetic information in a cell to be transmitted to the next generation have been called epigenetic inheritance systems (EISs). Three broad types have been characterized (Jablonka and Lamb 1995): steady-state systems, structural systems, and chromatin-marking systems.

2.1 *Steady-state Systems*

These systems lead to patterns of gene activity persisting in cell lineages through the operation of regulatory feedback loops. The simplest example is that of a gene that controls its own transcription through positive feedback. When the activity of such a gene is induced by an external stimulus, some of the gene's product bind to its own control region. This binding leads to the continued activity of the gene. In this way, gene activity that initially depended on the presence of an external inducer is maintained by self-regulation—by the continuous induction of the gene by its own product. If the concentration of the gene-product is high enough and cell division is more or less equal, the gene's active state will be inherited, because the regulatory gene-product will be transmitted to daughter cells as an automatic consequence of cell division. This type of self-regulation means that cells with the same DNA sequence can have different but stable patterns of cell-heritable activities, which reflect their developmental history. Many examples of such self-perpetuating regulatory loops have been found in a variety of animals and plants. In most cases the systems are more complicated than the one described, with several genes and gene products involved in the feedback loop, but the principle is the same.

2.2 *Structural Inheritance Systems*

Cells contain many complex three-dimensional structures whose assembly seems to depend on the presence of existing similar structures. In ways that are not understood, old structures are used as templates for the production of the new structures that are required for cell growth and multiplication. The best-known examples of this type of inheritance come from the

study of single-celled organisms, such as the ciliated protozoan *Paramecium*. Genetically identical paramecia can show heritable differences in the patterns of ciliary rows on their cell surface, and experimentally altered patterns can be transmitted to daughter cells for hundreds of cell generations (Grimes and Aufderheide 1991). Although this type of inheritance is particularly conspicuous and stable in ciliated protozoa, structural inheritance is probably universal, since all cells rely on pre-existing structures when they produce new ones. The self-templating properties of some three-dimensional protein complexes is believed to underlie the transmission of diseases such as mad cow disease (BSE—bovine spongiform encephalopathy), where aberrant prion proteins seem to induce function-affecting changes in the conformation of normal prion proteins (Prusiner 1998).

2.3 Chromatin-marking Systems

Chromatin-marking systems are currently the best-understood EISs. Chromatin is the complex of DNA, proteins, and other macromolecules that make up chromosomes, and chromatin marks are the binding proteins or chemical groups that influence the activity of the DNA to which they are attached (Jablonka and Lamb 1995). The epigenetic information contained in chromatin marks is carried from one cell generation to the next with DNA. A good example of an inherited chromatin mark is a gene's methylation pattern. In many plants and animals, some of the cytosines in DNA are methylated. Although cytosine (C) is one of the four bases whose sequence encodes genetic information, the presence of a methyl group (C^m) does not affect its coding properties. However, cytosine methylation within or around a gene often determines whether or not the gene is active, and how easy it is to activate: usually low levels of methylation are associated with potential activity, while high levels are associated with inactivity.

Changes in methylation patterns occur during growth and development, so the same DNA sequence can have several different methylation patterns, each reflecting a different functional state, and each inherited stably through many cell divisions. The mechanism of transmission in this case is well understood, and depends on the way a cytosine in one strand of the DNA double helix is always paired with a guanine base (G) in the other. Methylation occurs symmetrically on the two strands, usually in CG doublets in which C^mG is paired with GC^m. Following DNA replication, in which the two parental DNA strands separate and are used as templates for building complementary daughter strands, the previously methylated sites remain methylated on the parental strand, but are unmethylated on the newly synthesized daughter strand. However, special enzymes recognize the asymmetrical, half-methylated sites, and preferentially methylate the cytosines of the new strand (Holliday 1990, Jablonka and Lamb 1995). Thus, because of the mirror symmetry of CG sites and the semiconservative nature of DNA replication, the specific pattern of methylation of a region of DNA is reproduced at every cell division.

Methylation patterns are not the only type of heritable chromatin marks. Chromatin marks involving DNA-associated proteins that affect the maintenance of gene activity can also be transmitted in cell lineages. The way these protein marks are replicated is beginning to be understood, and plausible models for the reproduction of nucleoprotein complexes which ensure that daughter cells inherit the state of activity of parental cells have been proposed (Lyko and Paro 1999).

3. Genetic and Epigenetic Inheritance Compared

The properties of the genetic and epigenetic inheritance systems overlap, but certain features are more characteristic of one than the other. Most stem from the fact that epigenetic systems are concurrently inheritance systems and response systems, whereas, with a few exceptions, information transmitted by the genetic system is not altered in response to external factors. The response function of the epigenetic system means that, unlike genetic variations, the origin of heritable epigenetic variations is not random—they are often induced by specific developmental or environmental changes. Frequently induced epigenetic variations are adaptive, although they need not be so. Whereas changes in the DNA sequence of a gene are rare, and reversion to the original sequence is even rarer, the response function of EISs means that, under some circumstances, the rate of change between epigenetic variants is very high and there may be coordinated changes in the epigenetic marks of several genes. However, although some inherited epigenetic changes differ from typical genetic changes in being nonrandom, frequent, reversible and adaptive, others resemble genetic mutations in that they are rare, random, nonadaptive, and unlikely to revert. No single criterion or set of criteria can be used to distinguish between the properties of the genetic and epigenetic systems.

4. Transgenerational Epigenetic Inheritance

Studies of the mechanisms of epigenetic inheritance were initially focused on cells in the cell lineages of multicellular organisms, but subsequently it was found that single-celled organisms such as bacteria and yeasts also transmit epigenetic variations to their descendants (Grandjean et al. 1998, Klar 1998). It was also realized that multicellular organisms sometimes transmit epigenetic variations between generations. Transgenerational transmission was recognized in two ways: either as genomic imprinting, in which a gene's

expression is influenced by the sex of the parent that transmitted it, or as the long-term inheritance of acquired variations over several generations.

4.1 Genomic Imprinting

During the formation of sperm and eggs, chromatin is modified. The way that it is modified in the male and female germ lines differs, so, at the beginning of embryonic development, the genes transmitted by the two parents are in different epigenetic states. If these differences persist during development and have phenotypic effects, the genes are said to be 'imprinted.' Imprints may involve differences in methylation patterns or in other types of chromatin marks. The effect of genomic imprinting is that the expression of some genes depends on the sex of the parent from which they were inherited. Normally imprints are erased and replaced in the germ line, so when a gene that was inherited from one sex is transmitted to the next generation through the opposite sex, the imprints are reversed. Imprinting seems to be widespread in both plants and animals, but currently it is being studied most intensively in mammals. It is known to be necessary for normal development and to affect the severity of expression of some genetic diseases, such as Prader-Willi and Angelman syndromes (Reik and Surani 1997).

4.2 Long-term Transmission

Most cases of the long-term transmission of epigenetic variations have been found in plants, which often have vegetative as well as sexual reproduction, but it has also been found in a variety of animals (Jablonka and Lamb 1995, 1998). Remarkably, the first morphological flower-mutant ever to be characterized, a peloric form of toadflax described by Linnaeus over 250 years ago, has turned out to be an epimutation, not a mutation; the difference between the normal and peloric forms is due to a difference in the gene's state of methylation, not in its DNA sequence (Cubas et al. 1999). Similarly, a well-studied case of variation in the coat color of the mouse has been shown to be the result of heritable epigenetic modifications, rather than of genetic or environmental effects (Morgan et al. 1999). Findings like these suggest that the long-term transmission of epigenetic variations may be far more common than was at one time thought likely.

5. Implications

Recognizing the ubiquity and importance of epigenetic inheritance has major implications for medicine and agriculture, as well as for the way that we think about heredity and evolution. Since the practical implications were the first to be generally recognized, they will be considered first.

5.1 Practical Implications

In recent years it has become clear that the variations transmitted through EISs can affect health and disease. First, many cancers involve cell-heritable epigenetic modifications, such as alterations in methylation patterns and other aspects of chromatin organization (Zingg and Jones 1997). Second, some hereditary diseases are caused by mutated imprinted genes, which show peculiar but characteristic patterns of inheritance (Reik and Surani 1997). In some cases the inherited conditions may not be caused by mutations, but by epimutations. Third, prionic diseases such as BSE and kuru seem to be the consequence of transmissible infectious protein complexes and the mechanism of reproduction and reconstruction of the infectious agents seems to involve structural, three-dimensional templating (Prusiner 1998). Fourth, some environmentally induced diseases, such as those caused by starvation or by taking thalidomide, seem to have long-term transgenerational effects (Holliday 1998). Epidemiological research programs and medical practice will have to accommodate information like this, and develop ways of recognizing, avoiding, and curing the diseases caused by heritable epigenetic changes.

In agriculture, the importance of epigenetic inheritance is already acknowledged widely, because it has caused many problems in genetic engineering aimed at crop improvement. Commonly, newly inserted foreign genes are heritably silenced through extensive DNA methylation, so ways of circumventing this problem have had to be developed. On the positive side, since some epigenetic variations can be induced by environmental changes, it may be possible to develop agricultural practices that exploit these inducing effects and thus develop epigenetically 'engineered' improved crops.

5.2 A Broader Concept of Inheritance and Evolution

Including EISs and other non-DNA inheritance systems (such as the transmission of information through behavior or language) produces a much richer and more general concept of heredity. Heredity does not depend solely on genes, and not only genotypes are inherited. Even at the strictly cellular level, the production and transmission of inherited variations involves several different mechanisms. With some of these, such as those underlying structural inheritance and steady-state systems, there is no real equivalent of the phenotype–genotype distinction, because the re-

construction of the phenotype is an integral part of the transmission mechanism.

With all EISs, the inheritance of acquired (induced) variation is common. Consequently, there is a 'Lamarckian' component in evolution, with the environment being both an inducer and a selector of epigenetic variations. The gradual broadening of the concept of heredity, and recognition that natural selection acts on several different types of heritable variation, which began in the last decades of the twentieth century, has challenged the widely accepted gene-centered neo-Darwinian version of Darwinism. A more comprehensive and more powerful Darwinian evolutionary theory is now being constructed, one that incorporates multiple and interacting inheritance systems.

Epilepsy

Epilepsy is a common disorder of the central nervous system (CNS) characterized by recurrent seizures. Seizures come in a variety of forms—some primarily motor and some affecting consciousness; some restricted to a local brain region and some involving the entire brain; some so dramatic as to be frightening and some so subtle as to be easily missed by the casual observer (Engel 1989, Engel and Pedley 1998). Current estimates are that approximately 1 percent of the population has a seizure disorder. Epilepsy respects no national, racial, or ethnic boundaries. Thirty to fifty percent of epilepsies in the U.S. (and other medically 'sophisticated' countries) are inadequately controlled by medication; that percentage is much higher in underdeveloped nations. Better understanding of the bases of seizure disorders is critical if we are to develop more effective treatments—and cures. This article provides a brief overview of our current insights into the cellular and molecular causes of epilepsy, and identifies the challenges for epilepsy research.

1. Definition of Terms

Although the term 'epilepsy' is usually used in the singular, 'epilepsy' (like 'cancer') refers to a diverse set of abnormalities, with different causes and different clinical expressions. The epilepsies are defined as chronic seizure conditions, and categorized by clinicians on the basis of the characteristic behavior and associated pattern of brain electrical discharge (the electroencephalogram, or EEG). This categorization scheme (Commission on Classification and Terminology of the International League Against Epilepsy 1981, 1989) has resulted in a useful—although complex—system for diagnosis and treatment, but generally ignores the underlying bases (molecular and cellular) for the seizures. A seizure can be viewed as a paroxysmal and synchronous discharge of a large population of neurons. Occurrence of an isolated, single seizure does not necessarily reflect brain pathology. Indeed, seizures can occur in the normal brain, and reflect normal responses to stress or injury.

Repetitive seizures, however, signal some chronic pathological condition of the CNS. Understanding that abnormality has been particularly difficult because the symptom—the seizure—is (for most epilepsies) episodic and unpredictable. Further, during the time between seizures (which may be months, or even years), the brain functions in an apparently normal fashion. Indeed, it is the unpredictability of seizures—as well as the loss of voluntary controls during these 'ictal' (i.e., seizure) episodes—that constitute major contributors to the morbidity associated with epilepsy.

2. *Categorization of Epilepsy Syndromes*

With advances in our understanding of underlying mechanisms of seizures, and of the processes by which a chronic seizure state is acquired (i.e., 'epileptogenesis'), it is now possible to categorize many epileptic disorders on the basis of the neurobiological cause rather than simply on the basis of the seizure behavior and EEG pattern. A general classification scheme, that covers most epilepsies, includes the following (overlapping) three categories: genetic disorders; developmental disorders; and acquired epilepsies (Fig. 1).

2.1 *Genetic Disorders*

A number of epilepsies have now been traced to single gene mutations. Many of the implicated genes code for ion channels (e.g., for sodium, potassium, or calcium) or for neurotransmitter receptor proteins (e.g., for acetylcholine or gamma-aminobutyric acid) (Berkovic and Scheffer 1999). Abnormalities in these proteins make at least some intuitive 'sense' in trying to understand seizure discharge, for much is known about how ion flux and neurotransmitters affect brain excitability. Other 'epilepsy genes' have been associated with structural brain abnormalities, such as seen in lissencephaly or tuberous sclerosis (Spreafico et al. 1999); abnormalities in these gene products result in developmental disorders generated through molecular signaling aberrations that we are just beginning to understand. Some of the implicated genes have functions yet to be elucidated. While single gene epilepsies are relatively rare, it is clear than some of the more common epilepsies (for example, childhood absence epilepsy—CAE, or juvenile myoclonic epilepsy—JME) are inherited in a more complex fashion, suggesting that multiple genes play roles in these disorders. Genetics also appears to play a significant role in determining seizure susceptibility, even in the normal population. Thus, major challenges for the field include characterizing and identifying the genes involved in multigenic seizure disorders, and gaining a better understanding of which genes are important in determining seizure predisposition. In addition, it is critical to understand the cellular pathways through which these genic abnormalities lead to neurophysiologic dysfunction. Identifying 'epilepsy genes' is not enough to solve the mystery of aberrant function. It is, however, a critical start—especially useful in developing new drugs (or other treatments) with specific molecular targets.

2.2 *Developmental Disorders*

The process of brain development is marvelously complex. Developmental neuroscience research has provided a rich background regarding the genetic and molecular signals involved in constructing a normal mammalian brain (Sanes et al. 2000). Abnormalities in these processes—in cell proliferation, migration, differentiation, and establishment of connections—may all lead to neurological disorders, including epilepsy (Schwartzkroin et al. 1995). Given the potential for developmental mistakes, it is actually quite remarkable that the incidence of neurological dysfunction is as low as it is. It should come as little surprise that seizure occurrence is higher among children (estimated at approximately 4 percent) than in the adult population—partly as a result of abnormalities in brain development (Spreafico et al. 1999), and partly because the properties of the immature brain render it particularly seizure-prone (Nehlig et al. 1999). The epilepsy incidence in children with other developmental disorders—cerebral palsy, mental retardation, autism, fragile X syndrome, etc.—is perhaps 10 times that in otherwise normal children, undoubtedly reflecting a general underlying brain pathology (Dodson and Pellock 2000). Since seizure incidence is so high among the young, since epilepsies may reflect abnormalities of genetics and/or brain development, and since the brain is so vulnerable to perinatal trauma (e.g., hypoxia, head trauma, infection), many epileptologists consider epilepsy to be primarily a set of disorders of childhood (Schwartzkroin and Moshe 2000). Why is it that these early insults are so likely to induce an epileptic state? Why do developmental brain abnormalities, such as seen in tuberous sclerosis or various forms of lissencephaly, correlate so highly with early seizure syndromes? We are just beginning to get a glimpse of the answers to these questions—and the general theme seems to revolve around the highly 'plastic' nature of the immature CNS. While in the adult, brain trauma often leads to cell death and loss of function, the immature brain is more resilient. Immature neurons appear to be less sensitive to injurious stimuli. The immature brain is capable of producing new neurons to a much greater extent than is the adult CNS. Immature nerve cells more readily make new connections when normal organization of the system is disrupted. While this 'plasticity'

Figure 1
Diagrammatic representation of conditions that underlie epileptic disorders; potential points of intervention (open arrows) in the epileptogenic process (solid arrows); and strategies for prevention, treatment and/or cure

preserves a significant amount of behavioral function, it may come at a cost—for the new circuits established by injured neural elements may not be entirely normal. Marginal injury and inappropriate connections appear to be two major contributors to the development of abnormal electrical activity—i.e., seizures.

2.3 Acquired Epilepsies

Many epilepsies can be associated with a particular traumatic stimulus (e.g., head injury) or medical condition (e.g., a tumor or an infection), and thus are designated 'acquired.' The implication of this designation is that the brain is (was) otherwise normal, and that the identified insult is the sole cause for the epilepsy. This assumption allows us to examine the variables associated with the epileptic condition, and thus to better understand what mechanisms are responsible for development of the epileptic state. As suggested above, many of our current hypotheses revolve around the new connections made by the injured brain, and the loss of critical elements that control the electrical excitability of the system. However, while it may well be the case that a given traumatic stimulus is the critical 'trigger' for epileptogenesis, it remains something of a mystery why such injury in one individual will lead to an epileptic state but the same injury to another individual will not. This situation has led to the concept of 'predisposition' with respect to epileptogenesis (Fig. 1). That is, there may be subtle factors—gene-based differences in seizure susceptibility, subclinical injury, or developmental abnormalities—that provide a background upon which a brain insult plays out. A subtle, preexisting injury may make it more likely that an individual with head trauma develops epilepsy at a later time. This concept also implicates another important possibility that is often discussed, especially within the context of pediatric epilepsies—that epilepsy is a 'progressive' disorder (Heinemann et al. 1996, Engel et al. 2000), which develops as a result of active neuronal processes. Thus, an initial subtle and benign insult may 'kindle' into a more significant and clinically troubling condition over months, or even years.

3. Basic Neuronal Mechanisms Underlying Seizure Discharge

In general, it is thought that seizures arise as a result of an imbalance between the processes responsible for excitation and inhibition in the brain (Fig. 2). This

Figure 2
Basic mechanisms underlying seizure discharge and epileptogenesis—contributors to altered balance between excitation and inhibition, and increased neuronal synchrony

imbalance leads not only to a state of 'hyperexcitability' but also to a condition of 'hypersynchrony'; that is, the neurons discharge at a higher rate than normally, and discharge in a characteristically synchronous pattern that overrides the normal patterns of neuronal activity. There are a host of processes to consider in trying to understand these changes (Fig. 2) (Delgado-Escueta et al. 1996). Most research has focused on the mechanism through which nerve cells generate electrical activity (i.e., the ionic balance and ion-selective channels that are the basis for neuronal signaling) and the neurochemical communication systems through which neurons excite or inhibit each other. These are the basic neurophysiological 'building-blocks' of brain function, critical to any consideration of neural activity, in the normal brain as well as in the brain exhibiting a neurological disorder. Indeed, investigations to understand the basic mechanisms of the epilepsies have contributed greatly to our understanding of normal brain function, and to dysfunction in other neurological pathologies.

The excitation–inhibition balance in normal brain is delicately regulated—perhaps to allow for the maximum degree of 'plasticity'. While excitatory discharge is a sign by which we recognize neuronal electrical activity, it is the *inhibition* that sculpts the patterns of interaction that make up normal information processing. Thus, much of epilepsy research has focused on key inhibitory mechanisms, and many theories regarding underlying epileptic processes involve changes in the quantity—or quality—of inhibitory mechanisms. A key to much of this analysis is the critical role played by the predominant inhibitory neurochemical in the forebrain, gamma-aminobutyric acid (GABA). Reduction of GABA synthesis, loss or reorganization of neurons that use GABA for their neurotransmission, and/or alterations in the receptors sensitive to this molecule have all been proposed as mechanisms of epilepsy. Also noteworthy is the fact that many of the antiepileptic drugs currently in use exert their actions, at least in part, through GABA receptors. It is clear that even small changes in this inhibitory system can have serious consequences. For example, blocking only 15–20 percent of GABA receptors can, in experimental preparations, produce seizures. Thus, in elucidating underlying seizure mechanisms, we are faced not only with identifying the salient processes, but also understanding the significance of mechanistic disruption in *quantitative* terms.

Basic epilepsy research since the 1960s has focused on the cellular and molecular mechanisms responsible for *seizure activity*. We have still to approach the bigger question of how a *chronic seizure state* is established. Research into the basic mechanisms of epileptogenesis is now a priority in many laboratories, in large measure because investigators see an opportunity to 'cure'

epilepsy before it starts (Fig. 1). An important goal is to identify/diagnose 'at risk' patients, and treat them so as to disrupt the underlying processes of epilepsy development. Much of this research is driven by the idea that epilepsy development 'recapitulates'—at least in some important processes—early developmental processes. Thus, there is much interest in the signaling molecules that guide the development of neuronal connections and of mature electrophysiological properties. Indeed, it is the plasticity of these processes, even in the adult brain, that have become primary targets in research and in treatment development.

4. *Epilepsy and Brain Plasticity*

What are the 'plastic' processes that give rise to epileptic conditions? As suggested above, many investigators believe that they are the same processes that we have identified as the basis for higher brain functions, such as learning and memory. We can define 'plasticity' as the ability of the brain to respond (structurally and/or functionally) to new stimuli, with adaptive behavior. Such plasticity is one of the primary functions of the highly developed cortical regions of the mammalian brain, where we believe that learning takes place—and where (perhaps not coincidentally) most seizures are generated. Investigators have elucidated many processes that are involved in such complex neural function, including: *long-term potentiation* (and depression) of synaptic interactions; *sprouting* of new connections; changes in the number and *subunit composition* of receptors and channels; *proliferation* and/or *death* of neural and glial elements; and (of course) the up- (or down-) *regulation of the genes* that code for protein products involved in these changes (Fig. 2) (Engel et al. 2000). These are all normal brain mechanisms. They are all implicated in genesis of epileptic conditions. The epileptic state is characterized by a loss of regulation or control of these plasticities. A little plasticity is critical for higher brain function, but too much plasticity leads to pathology.

Episodic and Autobiographical Memory: Psychological and Neural Aspects

Episodic memory is the type of memory that makes possible the recollection of personally experienced events. During an act of retrieval from episodic memory, an individual is said to be remembering the past. The term is closely related, but not identical, to autobiographical memory, which refers to memory for and about a person's own life.

The relation between episodic and autobiographical memory can be illustrated through the case study of a man, known as K.C., who became profoundly amnesic in 1981 following a serious closed head injury (Tulving et al.1991). As a result of the injury, K.C. suffered a complete loss of episodic memory, as he cannot recollect a single thing that has ever happened to him. Despite extensive questioning, he cannot remember even things that should be highly memorable, such as the accidental death of a brother to whom he was close. It follows that K.C. has a

drastically reduced ability to recount his autobiography. Yet he can report autobiographical facts, such as his date of birth, the names of many of the schools he attended, the make and color of a car he once owned, and the fact that he has spent many summers at his parents' cottage. K.C. is unable to *remember* any aspects of his life, although he *knows* many important facts about his past. In healthy individuals, autobiographical memory encompasses both what can be recollected episodically, and self-relevant knowledge that can be expressed through semantic memory.

1. A Psychological History

Psychological writing on the topic of episodic memory began with William James in his classic *Principles of Psychology* (James 1890). To James, the concept of *memory* was equivalent to what is now called episodic memory. The defining characteristic of memory was the conscious recollection that accompanied the retrieval of personally experienced events. 'Memory requires more than the mere dating of a fact in the past. It must be dated in *my* past… I must think that I directly experienced its occurrence.' (p. 612). Thus James distinguished between acts of episodic memory and other manifestations of learning and memory (semantic memory, classical and emotional conditioning), which do not involve conscious recollection of the personal past. Later philosophers and psychologists emphasized the role of such personal memories in defining an individual's personal identity and autobiography (Shoemaker 1959).

Although James provided a strong foundation, there was very little research directed at memory for personally experienced events for the next several decades. Psychological research became dominated by the idea that observable behavior, and not conscious experience, was the appropriate subject matter for the field. The study of learned responses was not compatible with the study of the remembering of experiences.

Contemporary investigations began when Tulving (1972) proposed the distinction between episodic and semantic memory. This distinction can be characterized in two different ways, and it is important for these meanings to be differentiated and the meaning used in a particular context to be made clear. One distinction has to do with a particular kind of memory task or memory performance, while the other concerns different neurocognitive memory systems in the human brain. Episodic memory was originally defined as the variety of memory that receives and stores information about temporally dated episodes or single events, and the temporal–spatial relations among them, while semantic memory comprised organized knowledge about the world, including information about words, objects, and events. The episodic/semantic distinction introduced the possibility that the remembering of single, personal events should be studied separately from factual knowledge. For many years, the study of memory for single events was classified as episodic memory research and it proceeded largely independently of research on semantic memory. Even today, the prototypical laboratory list-learning task in which participants are exposed to study material and then tested for what they have learned is often classified as an episodic memory task.

Over the intervening years, it became clear that the 1972 definition of episodic memory was no longer satisfactory. Performance of a so-called episodic memory task, such as free recall, can depend not only upon the type of conscious recollection that was described by William James, but also on general knowledge about single events from the past. Episodic memory now refers to a neurocognitive system that renders possible the conscious recollection of events as they were previously experienced. The defining characteristic of episodic memory is its dependence on a special kind of conscious awareness called *autonoetic awareness*. An individual with autonoetic (or 'self-knowing') awareness is capable of roaming at will in subjective time, by recollecting aspects of past experiences, or imagining future experiences through anticipations and daydreams. Semantic memory is defined as a neurocognitive system that makes possible the acquisition, retention, and use of factual information. The retrieval of semantic information is accompanied by *noetic awareness*, which is experienced when one thinks about something one knows. Noetic awareness does not involve any feeling of reliving the personal past; it represents knowledge about some aspect of the world.

While episodic remembering is necessarily autobiographical, a person's autobiography can be expressed through systems of memory that are not episodic. The final criterion is the individual's phenomenal feeling, not the contents, or veridicality, or age, or confidence of what is retrieved. Therefore, it is possible for individuals to recall autobiographical aspects of their lives, even single events in the recent past, via noetic awareness only.

2. Neural Bases

Research in cognitive neuroscience has made significant progress in identifying the brain structures that support episodic and autobiographical memory. Most of the relevant knowledge about the relation between neuroanatomy and memory has been gleaned from the study of patients with circumscribed brain injuries. Especially important has been the identification of patients with selective losses of episodic or autobiographical memory, with a relative sparing of other varieties of memory, such as semantic memory. The

integrity of two brain regions, the medial temporal lobes and the prefrontal cortex, are critical for the normal operations of episodic memory. The former area is necessary for the establishment of episodic and autobiographical memories, and also participates in their retrieval for a limited time following encoding. The latter area underlies the ability to become autonoetically aware of the personal past and future.

2.1 Medial Temporal Cortex and Episodic Memory

It is now well established that several structures in the medial temporal cortex have a critical role in both the encoding and retrieval of episodic memory. This region, often referred to as the *medial temporal lobe system*, comprises a number of anatomically connected and functionally interrelated structures, including the hippocampi, entorhinal, perirhinal, and parahippocampal cortices. Midline diencephalic structures, such as the medial thalamus and the fornix, are also included in this system.

The importance of the medial temporal cortex in episodic memory was established in one of the classic case studies in cognitive neuroscience (Scoville and Milner 1957). In an experimental surgery, a patient known as H.M. underwent bilateral hippocampal excision with the goal of curing his severe epileptic seizures. While the surgery was effective in the prevention of seizures, it had the unintentional side-effect of rendering the patient amnesic for all postsurgical events. To this day, H.M. cannot remember anything that has happened to him since the surgery, a condition known as *anterograde amnesia*. Over the intervening years, many other patients with damage limited to the medial temporal lobe system have reinforced the relation between this brain region and anterograde amnesia for episodic and autobiographical memories.

The medial temporal lobes receive highly preprocessed inputs from multiple, diverse cortical and subcortical brain regions. This makes the hippocampal system well-placed anatomically to bind or conjoin the inputs, and combine them into a single complex event or episode that could subsequently be stored and remembered (Cohen and Eichenbaum 1993). When the hippocampi and related structures are damaged, affected patients are unable to form a 'memory trace' from the various aspects of an ongoing event; it follows that the event cannot be subsequently remembered.

The hippocampal system participates in the retrieval of episodic memories for a limited time after encoding. Patients with anterograde amnesia typically are unable to remember events that occurred just before they became amnesic. The extent of this *retrograde amnesia* varies between patients yet there is typically a temporal gradient in which memory for recent episodes is affected more than that for remote episodes. As time passes after encoding, episodic and autobiographical memories gradually become reorganized, or consolidated. Over a period of several weeks or months, recollection becomes mediated by distributed areas in the neocortex.

Structures in the medial temporal lobes are critical for the encoding and retrieval of both episodic and semantic memory. The majority of patients with amnesic syndromes have an equivalent or roughly equivalent impairment in their ability to autonoetically recollect their past (episodic memory) as well as noetically know about the past (semantic memory). Yet some recent reports have described a group of amnesic patients with profound losses of episodic memory, with little or no deficit in semantic memory (Vargha-Khadem et al.1997). Two distinctive features of the pathology were that: (a) it was confined solely to the hippocampus itself, while sparing the surrounding cortex, and (b) it was sustained very early in life, before the patients had the opportunity to build a base of autobiographical memories. While the patients are unable to remember any of their ongoing experiences, they have made satisfactory progress through school, and assembled a large body of semantic knowledge. The patients have some autobiographical knowledge, as they *know* many facts about their lives, although they cannot *remember* anything that has happened to them. An increasing body of knowledge suggests that episodic memory processes depend upon the hippocampus proper, while semantic memory is mediated largely by the perirhinal cortex in the temporal lobes (Aggleton and Brown 1999), although a definitive resolution of this proposal remains elusive.

2.2 Prefrontal Cortex and Autonoetic Awareness

The operations of episodic memory are dependent upon a sophisticated variety of conscious awareness, one that arguably does not exist in nonhuman animals. Autonoetic awareness refers to the ability to consider one's subjective experiences in the past, present, and future. It is the human prefrontal cortex, defined as those aspects of the frontal lobes anterior to motor and premotor areas, which subserves the capacity for autonoetic awareness.

An extensive literature in clinical neuropsychology indicates that patients who have suffered injuries restricted to the prefrontal cortex often suffer from impoverished awareness of their own mental life. Though patients are fully awake, alert, and have full command of intelligence and language capabilities, they often appear either unwilling or unable to engage in self-reflection or introspection (Luria 1973). Reflection upon the personal past defines episodic memory. Multiple lines of research converge to show that the integrity of the prefrontal cortex is necessary for successful episodic recollection of past experiences. Although patients with large prefrontal lesions are not amnesic— they can learn from experiences and update their knowledge—recalled information does not have the subjective, personal quality that comprises epi-

sodic recollection. Similarly, as patients report about autobiographical experiences, they often discuss their own lives as if they are casual observers (Wheeler et al.1997). The prefrontal cortex confers humans with the ability to recollect prior experiences in a personal, subjective way. It follows that, when patients with prefrontal lesions attempt to recount their autobiography, it is the episodic component which is compromised, much more than the semantic component.

Because of its reliance upon autonoetic awareness, episodic memory is related to other cognitive skills and behaviors that are not typically considered to be memory capabilities. Autonoetic awareness allows for self-reflection extending into both the past and future. Patients with large prefrontal lesions typically lack ambition, foresight, and initiative, and this brain area has been considered as important for 'memories of the future' (Ingvar 1985). As such, episodic memory shows a close family resemblance to some sophisticated mental achievements, like introspection, anticipation, and daydreaming, which require individuals to reflect upon personal experiences, past or present, that are not part of the immediate perceptual environment.

Equality and Inequality: Legal Aspects

Law's role in the pursuit of equality remains a focal point of attention and controversy in both theory and practice. That inequality persists in many significant domains—employment, housing, education, wealth—is uncontroversial. However, the explanations and solutions for this continuing inequality have become more complex and elusive. Legal approaches developed to address first generation types of inequality—deliberate exclusionary treatment based on race, gender, or other identity classifications—are inadequate to address more complex, interactive, and structural forms of inequality. As the experiences and causes of inequality become more subtle and multifaceted, consensus over the role of law in addressing inequality has also fractured.

Many of the recurring disagreements in case law, commentary, and politics proceed from the clash between theories of equality. These theories in turn reflect differences in the assumptions about the causes of inequality, the appropriate balance between inequality and competing values, and the proper role of courts in addressing social problems. This essay lays out four conceptual and legal approaches to equality, focusing on the employment context as a case study. The employment context in the United States has become a proving ground for other areas of discrimination law and practice. It features a wide range of conceptual approaches to inequality. As such, it provides a useful vehicle for mapping the terrain of argumentation about legal approaches to inequality. (See *Discrimination*; *Affirmative Action: Comparative Policies and Controversies*; *Affirmative Action: Empirical Work on its Effectiveness*; *Injustice: Legal Aspects*.)

1. Formal Equality of Treatment

The dominant conception of equality in American antidiscrimination law is embodied in the concept of 'colorblindness.' The law pursues equality by eliminating race, gender, or other suspect classifications as a legitimate basis of making decisions. It focuses on the state of mind of the decision maker, and targets intentional reliance on race or gender as the violation of the equality norm. It is also process oriented, in the sense that it is the taking account of race or gender in the treatment of employees that constitutes both the harm and the wrongful conduct.

This paradigm mirrors the social and political context that led to the adoption of civil rights legislation. In the period preceding the enactment of Title VII, deliberate exclusion of women and people of color from private employment was lawful and even, for some, morally acceptable. Many companies had employment policies that segregated or excluded workers based on race and gender (Abrams 1989, Fiss

1976, Crenshaw 1988). Supervisors and co-workers displayed open hostility or bias to workers based on their sex or race, and fired, refused to hire, or segregated workers based on those attitudes.

The formal equality model, and its implementing principle of antidiscrimination, is closely linked to these factual and moral conditions. Within that paradigm, discrimination occurs when an actor with formal power over subordinates in the workplace hierarchy deliberately uses that power against a particular subordinate because of attitudes, motivations, or desires relating to sex or race.

This model defines the wrongful conduct as intentional, unequal treatment based on race, gender, or some other class-based characteristic that is viewed as arbitrary. For inequality to count as legally relevant under this theory, it must be demonstrably caused by this form of deliberate, class-based exclusion. The premise of this model is that these class characteristics are irrelevant to the underlying decision, and that taking class membership into account is thus arbitrary and unfair (Fiss 1971, Fallon 1984). This premise embraces the idea that employers may, and usually do, properly differentiate among employees based on qualifications relevant to effective job performance. By taking race or gender into account, employers unjustifiably depart from merit-based decision making. This violates basic notions of fairness, because people deserve to be treated 'on the merits,' based on an individualized assessment of their capacities (Fallon 1984, Gutmann 1996). Exclusion based upon characteristics that are beyond the control of the affected individual are viewed as particularly morally problematic (Fiss, Brest 1976). Decisions based on class membership thus offend dignitary values, in addition to undermining instrumental values of efficiency.

The goal of the formal equality model is 'colorblindness': employment decisions should be made without regard to employees' race or gender. Race, gender, and other categories of status operate as fixed, universal, and static categories based on membership in a set, unchanging group identified by predetermined, and often physical, characteristics such as skin color. The assumption is that group status is, by definition, irrelevant to decisions about capacity to do the job, that considering class status is by nature arbitrary, denigrating, and unfair, that decision makers can make decisions without noticing or taking account of racial and gender characteristics, and that equality can be achieved by a rule that prohibits employers from considering race or gender in making employment decisions.

This theory of equality provides remedies to individuals who have been subjected to a process tainted by racial or gender considerations. It is decidedly ahistorical and individualistic in its focus, and compensatory in its explicit remedial approach. Many who embrace a formal equality approach believe current racial inequality results from factors unrelated to racial discrimination. They question the legitimacy and efficacy of legal norms to address this form of inequality. (Browne 1993, Rabkin 1998, Sowell 1984). Perhaps the most vehement expression of this view in the US can be found in Justice Scalia's concurring opinion invalidating voluntary affirmative action in government contracting based upon its inconsistency with the principle of color blindness: 'To pursue the concept of racial entitlement—even for the most admirable and benign of purposes—is to reinforce and preserve for future mischief the way of thinking that produced race slavery, race privilege, and race hatred. In the eyes of government, we are just one race here. It is American' (*Adarand Constructors vs. Pena* 115 S. Ct. 2097 [1995]). (See *Affirmative Action: Comparative Policies and Controversies*; *Affirmative Action: Empirical Work on its Effectiveness*)

1.1 Critiques of Formal Equality

The dominance of formal equality in American antidiscrimination law has produced a wide array of criticism. One set of critiques questions the colorblindness prohibition on grounds of autonomy and freedom of association, a view expressed by Richard Epstein (1992). Other criticism proceeds from the view that colorblindness is an inadequate response to continuing inequality. Most fundamentally, critics point out that a formal equality theory leaves in tact a legacy of state-produced inequality and subordination. It ignores the role that group status continues to play in shaping the life expectancies, opportunities, and experiences of group members. It locks in the continued effects of past formal exclusion, imposing the consequences of that continued exclusion on the excluded groups themselves. By defining equality solely in terms of the conduct of the perpetrator, a formal equality approach normalizes conditions of marginalization and exclusion, and the group dimensions of these material conditions. It does not begin to address the perspective of those who experience exclusion, marginalization, and unequal enjoyment of resources and status (Freeman 1990, Crenshaw 1988, Gotanda 1991). At the same time, 'It conceals the distributive consequences of group-salient practices in a semantic code that defines instrumental rationality as race-neutral' (Siegel 2000). A moral theory that might be suitable for a just society, i.e., one that does not systematically disadvantage people based on their race, loses its moral premise for a society that is unjust in those ways (Gutmann, 1996, Sunstein 1994).

On a conceptual level, David Strauss has pointed out the logical inconsistencies of colorblindness as an antidiscrimination principle. To protect a designated group against treatment targeting that group, the state must pay attention to and indeed specially protect the interest of that group. Thus, colorblindness is contra-

dictory. Strauss also points out that the metaphor of colorblindness really doesn't fit its use in the non-discrimination context. Colorblindness in the literal sense prevents an individual from seeing color; colorblindness as an equality model prevents an individual from acting on what he or she sees. This approach presumes that individuals can see race but keep it from influencing their perceptions, conduct, and decisions (Strauss 1986).

Recent work in the social sciences challenges the assumption (which underlies the formal equality model) that conscious decision making adequately describes the current dynamics of exclusion and unequal treatment. Bias is produced not only as a result of motivation but also as a product of racial or gender schemata, multiracial group interactions, and patterns of conflict resolution or avoidance (Krieger 1995, Lawrence 1987, Sturm 1998). Bias or exclusion often results from interactive patterns of non-inclusion, as much as from exclusion motivated by bias (Donnelon and Kolb 1994, Wilkins and Gulati 1996). Members of nondominant groups may well be treated differently based on their race, notwithstanding the decision maker's lack of intention to do so.

Historians have also challenged the theory of formal equality for its ahistoricism. Colorblindness ignores historically constituted patterns of group inequalities that are 'socially pervasive (articulated across social domains), and socially persistent (articulated over time)' (Siegel 2000). Examining race and gender inequality from a historical standpoint reveals relations of group inequality embedded in the social organization of work, reproduction, and sexuality. 'In short, when considered from a historical standpoint, discrimination has no transcontextual or fixed form' (Siegel 2000).

Robert Post applies this structural account of the dynamics of bias to the law itself. Using what he calls a sociological account of the field, he contends that law does not and cannot cause employers to make judgments about qualifications in a way that is totally race and sex blind. Legal actors are themselves engaged in a social practice of shaping the norms and conventions by which sex and race are given social meaning. 'Antidiscrimination laws always begins and ends in history, which means that it must participate in the very practices that its seeks to alter and regulate' (Post 2000). To pretend otherwise is to allow courts to rely on unarticulated assumptions and premises that legitimate some racial or gender meanings and challenge others.

2. *Functional Equality of Treatment*

A modified approach to equal treatment attempts to take account of the more structural, interactive, cognitive, and unconscious character of bias in the second generation of discrimination. This theory provides a framework that continues to account for inequality as a result of unintentional as well as intentional biased treatment. Functional equality focuses on whether differences in treatment based on group membership produce unequal outcomes, regardless of whether a policy or specific intention explains that unequal treatment. It broadens the focus of analysis from formal and deliberate decisions to the social context and practices that produce decisions. Differences in treatment between majority and minority group members that are arbitrary, in the sense that they are not justified by criteria of economic rationality, violate this principle of equality. These differences in treatment are morally problematic because they are unfair. Fair opportunity requires that 'equal consideration should be given to all qualified candidates so that candidates are chosen on the basis of their qualifications, where qualifications are set that are relevant to the legitimate social purposes of the position in question' (Gutmann 1996). If differences in treatment are attributed to stereotyping, cognitive bias, or differential access to the networks that structure advancement, they violate this fairness principle, even if the decision maker did not consciously intend that result. The harm is not only the stigma or loss of dignity that results from substituting group characteristics for individual assessment. It is also the difference in access that results from patterns of exclusion that emerge from social interaction or cognitive bias (Krieger 1995, Sturm 1998).

This form of inequality is often difficult to identify at the level of individual decisions. For this reason, functional equality of treatment approaches often focus on patterns of unequal treatment affecting groups of similarly situated individuals. Unexplained disparities in treatment of similarly situated members of majority and minority groups are problematic under this approach (*Teamsters vs. United States*, 431 US 324 [1977]). Fault, in the sense of conscious intent to exclude based on irrelevant and suspect classifications, is not necessarily a criterion for discrimination. Thus, functional equality theories depart from morality-based conceptions of discrimination and move to a focus on remediation.

2.1 *Critiques of Functional Equality*

The move away from fault-based notions of discrimination and formal notions of equality involves the courts in more subtle, complex, and interactive forms of bias. Critics of this move have questioned whether this is an appropriate role for the law in general and for courts in particular. If cognitive bias is widespread, indeed, ubiquitous, is it appropriate to rely on the law to change embedded patterns of interaction (Krieger 1995)? Others have questioned

the viability of a model of discrimination that, by its nature, can only be detected by looking at patterns involving groups over time (Browne 1993, Rabkin 1998). Do courts, and employers for that matter, have the capacity to prevent and redress bias at the level of cognition and group interaction? However, theories of proof and remediation have developed that operate effectively at the group and structural level. These theories shade into a third conceptual approach to inequality: equal achievement.

3. *Equal Achievement or Equal Outcome*

This concept of equality focuses on differences in the material conditions of members of particular groups. It is rooted in social reality, and looks at the distribution of jobs, income, and status of members of groups that have previously been subjected to systematic exclusion and subordination (Fiss 1976, Fallon 1984, Freeman 1990). The focus of this theory is the group, rather than the individual who has been excluded as a result of group status. Groups continue to matter because they define the opportunity structures affecting their members. For these theorists, group status must be directly addressed because it is the level at which inequality operates. For some, groups also have independent normative value, reflected in the patterns of cultural and political meaning that emerge among individuals who identify as a group (Gotanda 1991). These theorists justify the focus on groups not only in instrumental terms, but also as an independent value.

The empirical premise of equal outcome or equal achievement is that current inequality continues to be the result of systematic and legally sanctioned subordination. Legal intervention is justified to remedy persistent and arbitrary differences in resources, social status, and opportunity based on group membership. The current system for allocating opportunities continues to reflect biased criteria that systematically disadvantage non-dominant groups. Thus, group-based remediation compensates for departures from merit-based decision making (Fiss 1971, Harris and Narayan 1994). The goal of this approach to equality is outcome oriented: disparities in group status should be reduced or eliminated.

The normative justifications for the equal achievement theory are largely compensatory and remedial. Past group-based subordination justifies current group-based remediation. This theory rests on the premise that the group continues to have social meaning. The group continues to experience harm that is a consequence of the history of group-based exclusion, and members of the group experience the current manifestations of that harm. For this reason, matching harm to individual injury is thus both unnecessary and counterproductive (Crenshaw 1988). Moreover, group-based remediation is necessary to overcome barriers to participation that are perpetuated through individual, neutral processes that do not compensate for the effects of past discrimination (Siegel 2000, Abrams 1989).

Other justifications for the achievement theory of discrimination are more pragmatic: bias is difficult to prove and process rules are easy to evade. Outcome measures serve as an adequate proxy for bias that continues to affect access to fair process and opportunity. If a process is fair and race or gender neutral, it will produce a result that more or less mirrors the composition of the pool. Outcome measures that strive for a workforce that mirrors the racial or gender composition of the pool simply accomplish directly what may be more difficult to achieve through reforming the decision-making process. These measures also provide an easy-to-implement remedy that responds to concerns about judicial capacity to detect and correct patterns of bias (Fiss 1971, Gutmann 1996).

3.1 *Critiques of Outcome Theories of Equality*

Adherents of formal equality criticize outcome-based theories as inconsistent with the principle of race neutrality. Some critics take the view that any approach that treats race or gender as a salient category, even for remediation, reinforces the continued significance of those categories and is thus discriminatory. They also question the appropriateness of remedial strategies that focus on groups. This skepticism proceeds in part from an increasing willingness to question the empirical assumption that current inequality is the result of past legal subordination. Since the 1970s, some scholars have developed alternative explanations for persistent inequality that emphasize characteristics of the racial or gender group, rather than patterns of exclusion or marginalization (Glazer and Moynihan 1975, Sowell 1984). Once the causal link between current economic or social inequality and legal exclusion or subordination is questioned, that skepticism undercuts the perceived legitimacy of group-based remedies. Indeed, some critics of outcome theories of equality question whether racial or gender status continues to have any meaning at the level of the group. Some conservative critics thus suggest that group-based remediation is just another form of racial or gender-based decision-making, and is thus illegitimate (Belz 1991, Abram 1986). Finally, they treat outcome-based equality theories as inconsistent with principles of merit-based decision-making and thus contrary to both efficiency and dignitary values (Browne 1993).

Outcome theories have also been criticized by progressives as an inadequate framework to define equality policy because they rest so heavily on pragmatic considerations and lack an adequate normative foundation. Outcome theorists typically view their strategies as contingent and temporary. They do not generally defend group-based redistribution as an end

in and of itself, but rather as a means to an end. Nor do they reveal what it was about current practice that is objectionable, other than the result. The absence of a clearly articulated normative justification invites challenges to the legitimacy of any efforts to address racial or gender bias. Outcome approaches, if used as the exclusive theory justifying equality initiatives, may thus stunt the refinement, rearticulation, and reformation of the normative meaning of racial and gender participation and exclusion. They may also reinforce the perception that equality and efficiency are competing goals (Sturm 2001, Sturm and Guinier 1996).

4. *Equal Access*

Equal access theories focus on inequalities that result from unfair criteria and structures of interaction. They target decision-making that is formally fair but functionally biased in favor of members of a particular group. The central question is whether the structure, process, or criteria of decision-making arbitrarily favors members of one group over another for reasons unrelated to the articulated goals underlying the decision (Sturm 2001).

The most widely articulated conception of equal access theory accepts the moral legitimacy of differentiating among applicants based on meaningful differences in their qualifications to carry out the functions of a position. Reasonable disagreements exist, however, concerning the social purposes relevant to a particular job, the relative importance of multiple purposes, and the best way to assess which applicants meet those qualifications. 'Those members of society who currently have the power to set qualifications may tend to value those qualifications that favor people similar to themselves' (Gutmann 2000). Moreover, these power differentials shape the structures for assessing individuals' qualifications and opportunities for advancement. These standards and structures are no more likely to produce valued social outcomes than others that do not exclude members of non-dominant groups. As such, these exclusionary standards and practices are unfair, and thus discriminatory (Strauss 1998).

The classic case of *Griggs vs. Duke Power Co.* (401 US 424 [1971]) lays out this theory through a fable: 'Congress has now provided that tests or criteria for employment or promotion may not provide equality of opportunity merely in the sense of the fabled offer of the milk to the stork and the fox.' If the goal of the employer is to find out who can drink milk, it is arbitrary and unfair to make that determination by evaluating all animals' capacity to drink milk from a saucer. Discrimination thus occurs when an employer relies upon conditions, criteria, or practices that favor members of a particular group, if that advantage is arbitrary in the sense that it does not advance the articulated goals of the employer.

This theory defines discrimination as conduct that deprives individuals or groups of meaningful access to employment opportunities through the use of standards, criteria, or structures that fail to minimize the expression of bias, or that arbitrarily advantage one group over the other (Friedman 1986). It builds on the practical insight that discrimination and inequality often result from arbitrary, unstructured, and unaccountable decision-making. It uses outcome measures not to define the harm, but to signal the likelihood that an employment process is biased, and thus to trigger scrutiny of the adequacy and fairness of the criteria and their application. The beneficiaries of this theory are both individuals, who are denied the opportunity to compete based on unbiased selection processes, and groups, which are systematically disadvantaged in their access to jobs.

Equal access theory has thus emerged as an integrative approach to discrimination that accepts the inevitability, if not the legitimacy, of merit-based distinctions but introduces structural and group notions of fairness to the question of how to define and implement merit-based decision making.

4.1 *Critiques of Equal Access Theory*

Equal access theory has been called both over- and under-inclusive. Its potential for radically restructuring employment decision-making prompts challenges based on the intrusiveness of such a theory into the autonomy of employers. This criticism often proceeds from the view that courts should not engage in the process of institutional restructuring and act illegitimately if they move beyond the role of dispute resolution and compensation for discrete individual harms. The under-inclusiveness critique challenges the acceptance of merit or market criteria as a morally defensible basis for distinguishing between the opportunities of potential employees. The weaker version of this critique, preferred by outcome theorists, argues that the continued pervasiveness of a caste system so infects the distribution of opportunities as to delegitimate a system of merit that produces racially identifiable results (Freeman 1990, Strauss 1998). The stronger version of this critique challenges the moral legitimacy of differentiating access to social goods based on any arbitrarily distributed characteristics, including talents and motivation. 'There is no more reason to permit the distribution of income and wealth to be settled by the distribution of natural assets than by historical and social fortune … . From a moral standpoint the two seem equally arbitrary' (Rawls 1974).

The differences in approach to equality summarized in this essay recur in and help to explain deep fractures in employment discrimination doctrine, legislative policy making, and public discourse about equality. Current debates often pose formal equality of treat-

ment and equal outcome as the only two available conceptions of equality, and force a choice between them. The increasing complexity of the dynamics of bias, along with the decreasing political and judicial viability of outcome theories of equality, have increased the attention to and importance of access theories of equality. These theories are, however, the least normatively and empirically developed. Emerging scholarship in the area of employment discrimination has begun to fill this crucial gap. It remains to be seen whether the law will respond dynamically to these new understandings of the dynamics and meaning of workplace inequality.

Equality of Opportunity

Equality of opportunity is a concept that has been used frequently in the sociology of education, and in particular in discussions of social class differences in education, although the key ideas are applicable in many other fields. In the sociology of education the focus has been on whether there are equal opportuni-

ties for children with the same measured ability, or from different social class backgrounds in gaining access to higher or more privileged institutions such as grammar schools or universities. The concept could be applied equally well, however, to the unequal opportunities faced by boys and girls, or by members of different ethnic minorities, and it could be applied to questions of access to other institutions, such as the professions or the legislature. There are two main versions of the concept: a narrower sense of *equal treatment* in the competition for access for people with the same relevant abilities, and a broader sense of *equal rates of access* for people with different ascribed characteristics.

The narrower version of the concept has strong normative connotations. Equality of opportunity has frequently been taken to be a normative ideal in education and in liberal-democratic societies generally. A motion submitted to the British Trade Union Congress in 1896, for example, urged that 'our education system should be completely remodeled on such a basis as to secure the democratic principle of equality of opportunity' (quoted in Silver 1973, p. 11). Equality of opportunity has often been contrasted with other possible conceptions of social justice, such as equality of outcome, which would typically be associated with a socialist rather than a liberal-democratic social order.

As a normative ideal, equality of opportunity can be seen as a special case of the notion of fairness—that people with the same relevant traits or competencies should be treated in the same way. In the particular context of education, equality of opportunity frequently has been taken to mean that people with equal academic aptitude or ability should be given equal access to advantaged sectors of education. This was the dominant interpretation in the first half of the twentieth century, exemplified by the work of Gray and Moshinsky (1938) in Britain. Similarly in America, Lloyd Warner and his colleagues wrote 'we might speak of equality of educational opportunity if all children and young people exceeding a given level of intellectual ability were enabled to attend schools and colleges up to some specified level. This is the only practicable kind of equality of educational opportunity' (Warner et al. 1946).

Historically, the term was used frequently in the context of access to grammar-school education in Britain: the fact that affluent parents were able to secure fee-paying places at the prestigious grammar schools, places that were denied to equally able children of less affluent parents, was taken to be manifestly inequality of opportunity. More generally, one can think of any discriminatory procedure for regulating access to advantaged institutions as constituting inequality of opportunity.

In this respect, inequality of opportunity also becomes an explanatory concept as well as a normative ideal. Thus, fee-paying becomes one possible explanation for the observed class differences in access to grammar schools. The inability to afford fees is a possible mechanism that might explain why children of equal ability had unequal rates of access. (In practice, however, the abolition of fee-paying after World War II did not lead to a reduction in class inequalities, suggesting that fee-paying may not have had the explanatory role assumed by pre-war scholars; see Halsey et al. 1980.)

This explanatory sense of equality of opportunity implies a voluntaristic model of action where individuals are confronted with opportunities that they may choose whether or not to exercise. Inequality of educational opportunity implies that there are barriers, such as fee-paying or discriminatory selection procedures, which prevent some appropriately qualified individuals who wish to gain access from actually doing so. This interpretation lends itself to a rational choice account of educational decision-making, as in the work of Boudon (1974), and Erikson and Jonsson (1996).

However, in the post-war sociological literature, inequality of opportunity was used frequently as a synonym for, rather than an explanation of, class differences in access to privileged institutions. Thus, for example, the term 'inequality of opportunity' has been applied to any class difference in educational attainment regardless of the explanatory mechanism that might have generated that inequality. This approach has thus moved away from the earlier conception of equal opportunities for those with equal abilities, which would be consistent with some observed class differences in access, to a broader definition that ignores the unequal class distribution of measured ability.

The broadening of the concept in this way probably reflected a growing sociological distrust of the concept of IQ or measured ability. The broader interpretation could be justified on the grounds that the class distributions of ability and of preferences for education are themselves socially conditioned. This can therefore be thought of as a sociologically deterministic model.

More generally, the broader conception was congruent with the distinction between ascribed and achieved characteristics that became a focus of a great deal of post-war sociological research and theory. Discussions of inequality of opportunity could thus be integrated with mainstream sociological enquiry. Social class origin is an ascribed characteristic, and inequality of educational opportunity could be redefined as the persistence of ascribed characteristics in influencing educational outcomes. While much broader than the earlier conceptions, this interpretation was still distinct from that of equality of outcome in that it was consistent with inequalities between individuals.

Whether this broader conception serves much useful purpose, however, is unclear. Once the focus on

unequal treatment is removed, both the normative and the explanatory roles of the concept can be questioned. Moreover, since there is already an established distinction between ascribed and achieved characteristics, it is doubtful whether much is to be gained by broadening the concept so that it merely duplicates the notion of ascription. It may be better to preserve the original emphasis on equal treatment and to retain the concept as an explanatory rather than a purely descriptive one.

Equality: Philosophical Aspects

The ideal of equality is that everyone shall have the same. Different versions of the ideal require that people have the same rights, or status, or opportunity, or condition, or whatever it is deemed important to equalize. Since being equal in one respect can force inequality in other respects, different conceptions of equality are rivals. Currently ideals of equality are many and various, and also controversial.

1. Lockean Equality: Equality as Nondomination

Locke (1690) affirms that all men are 'naturally in' a '*state of perfect freedom* to order their actions, and dispose of their possessions and persons, as they think fit.' Locke adds that this natural state is 'also one of *equality*, wherein all the power and jurisdiction is reciprocal, no one having more than another.' Being of the same 'species and rank,' men should be 'equal one amongst another without subordination or subjection.' Call this equality as nondomination. According to this Lockean ideal, all adult humans have equal natural rights to live as they choose so long as they do not wrongfully harm others. This implies that no person ought to find herself placed without her consent in a relationship in which she is subject to the will of another and forced to obey the other's commands. Much ink has been spilled puzzling over what might be meant by stating as Locke does that men are 'naturally in' a state of equal freedom. The puzzles dissolve if one construes the natural right to equal freedom as a moral right that each person possesses independently of institutional arrangements or customary beliefs in the society the person inhabits. The institutional arrangements in a particular society may include slavery, and customary beliefs may presume that slavery is perfectly justified, but nonetheless one may hold that each person has a moral right to equal freedom which implies that others are duty bound not to enslave her.

The Lockean claim of human equality conflicts with views that people may legitimately be born to a state of subjection to others as occurs in a feudal or caste society. This claim also seems to conflict with the view that at least if one is born and raised in a tolerably just society one is legitimately subject to the authority of its government in the absence of any consent one has given to this just authority. The claim also seems to conflict with the view that there are forms of subjection that are not morally legitimate and that should be viewed as violating the Lockean right of equality properly construed even if they secure the voluntary consent of all parties to the relationship. This is to claim that some right of equal freedom is inalienable (nontransferable) and nonwaivable (the right-bearer cannot release those bound by the duty to comply).

2. Democratic Equality

The Lockean idea that all adult persons have equal rights to liberty and property opposes the idea that by birth some persons legitimately acquire authority and power over others. But as stated the Lockean ideal does not require equality of political status, and is compatible with (for example) an hereditary monarchy, so long as the king respects everyone's Lockean rights. A further and independent requirement of equality is equality of democratic citizenship—that the coercive political order of government should be subject to popular control, with each qualified adult having an equal right to stand for political office and to vote in free and fair elections. Rousseau (1968) argues for democratic equality on the ground that only

in an ideal form of democracy can individuals submit to political authority while being autonomous in the sense of obeying only laws they give themselves and avoiding subjection to the will of another person.

Democratic equality can be interpreted more expansively. In this broad sense, democratic equality prevails in a society to the degree that each adult person has equal power to influence the outcome of political processes, or alternatively, to the degree that all adult persons with equal personal ability to influence others' opinions have equal power to influence political outcomes.

3. *Equality of Opportunity*

In a caste society, accidents of birth and social connections strongly influenced by birth tend to determine who enjoys positions of special privilege and above-average advantages. Desirable niches in the hierarchical social structure may be reserved for men rather than women, for those of noble lineage rather than commoners, for those who are members of a favored religion, clan, tribe, or skin color grouping.

3.1 *Formal Equality of Opportunity*

The ideal of formal equality of opportunity or careers open to talents challenges the legitimacy of caste privilege. Applied to places in educational institutions, formal equality of opportunity requires that such places be open to any applicants, and that applications be judged on their merits, with criteria of merit being selected so they are predictive of applicants' ability and ambition to succeed at the course of study to be undertaken. (It is consistent with formal equality of opportunity that schools charge tuition and fees and that among applicants selected on the basis of merit, only those sponsored by someone willing and able to pay tuition and fees are actually admitted to school.) The formal equality of opportunity ideal can be adapted to apply to competitions for desired positions in business enterprises and state bureaucracies and to bank loans made available to would-be entrepreneurs.

Formal equality of opportunity constrains the freedom of property owners to do whatever they might choose with property they legitimately own. At least, if formal equality of opportunity is enforced by coercive legal rules or social norms backed by informal sanctions, the freedom of property owners is to that extent limited. The ideal of formal equality of opportunity is compatible with any degree of inequality in the extent to which individuals have the opportunity to develop their native talents into skills that would render them qualified in meritocratic competitions. Hence, it could happen that in a society regulated by equality of opportunity all good jobs go to the children of the wealthy and well educated.

3.2 *Fair Equality of Opportunity*

A public school system funded by general taxes exhibits a commitment that goes beyond formal equality of opportunity in the direction of assuring to all individuals at least some minimally adequate opportunity to become trained and to acquire skills that will render them qualified for meritocratic competitive posts. The ideal implicit in the idea of education funded by the public, pressed to its limit, becomes substantive or fair equality of opportunity. This norm is satisfied when all have equal opportunity to develop their native talents into the skills needed for meritocratic success. If better-off parents provide special education and socialization for their children so that they have special opportunities to become qualified, these advantages are somehow exactly offset, in the society of fair equality of opportunity.

Rawls (1999) espouses fair equality of opportunity and specifies that in the society that satisfies this norm any two individuals drawn at random from the population who have the same ambition and the same native talent will have the same prospects of competitive success for posts that confer advantages. Ambition here is a desire to attain some class of advantageous positions coupled with the willingness to work hard to become qualified for meritocratic competition. Having the same native talent as another is having the same disposition to develop skill given an identical environment. This latter idea is inherently fuzzy, as one sees by noting that one person might develop greater skill than another under educational regimen A and lesser skill than the other under educational regimen B. The notion of ambition embedded in the idea of fair equality might also provoke unease, as when it is noted that a society in which all girls develop the ambition to be homemakers and all boys develop the ambition to have satisfying and lucrative employment could satisfy fair equality even though all meritocratic competitions are won by men. But the general intent of the Rawlsian norm is clear. One might regard the norm of fair equality of opportunity as the ideal of a classless society, in which being born of privileged parents does not affect in the slightest an individual's prospects for acquiring a privileged position in adult life except via the mechanism of inheritance of genes and via parental and other social effects on the development of ambition. Evidently the norm is intended to be at best very roughly approximated, because precisely measuring the degree to which a society deviates from fair equality as defined here is not possible even in principle.

4. *Equality of Condition*

In a democratic society with fair equality of opportunity prevailing, some people could end up leading grim, unenviable lives while some are extra-

ordinarily prosperous, and some of the prosperous may lead wonderful, enviable lives. This could occur whether the economy consists of state-owned or privately-owned firms. The discussion to follow focuses on a competitive market economy with private ownership.

Some would hold that equality of democratic citizenship along with equality of opportunity is equality enough, and that inequalities in life prospects that emerge in a market economy over time are not morally troublesome. Others disagree. Seminal works exploring this issue include Rawls (1999) and Nozick (1974).

4.1 Pure and Impure Egalitarianism; Equality vs. Priority

Call someone who claims that it would be morally desirable if the material condition of people were to become more nearly equal an egalitarian. This view takes many forms. One important distinction is between those who regard material equality as contributing to an ideal that is morally desirable but morally optional and those who hold on one or another ground that closer approximation to material equality is morally required. This distinction cross-cuts another, between those who believe that it is morally appropriate for the state to enact coercive social policy aimed at equality of condition and those who deny that such use of state power can be morally permissible. One might be an egalitarian either because one believes (a) that equality is instrumental to attaining some further moral goal or partially constitutive of some further moral goal or because one believes (b) that equality of some sort is *per se* morally desirable. The impure egalitarian has a reason of type (a) for affirming equality, the pure egalitarian a reason of type (b).

One should also take note of a position that may be confused with egalitarianism but is in fact distinct from it. The egalitarian holds that it is better if all have the same level of benefit. The prioritarian on the other hand holds that it is morally better to bring about a gain in benefit for someone, the lower that person's lifetime benefit level would be absent the particular gain in question. In short, the prioritarian gives priority to helping the worse off. Everyone's having the same, or closer to the same, is not a goal for the prioritarian (see Parfit 1995, Temkin 1993).

An egalitarian advocate, whether pure or impure, is better regarded as proposing a component of fundamental moral principle, not an immediate guideline for laws and public policies. Public policies should be set in terms that are operationalizable, feasible to administer. A society would presumably do better by its fundamental values if it does not attempt to enact them as public policies but instead chooses policies that seek to achieve feasible goals that are reasonable proxies for the fundamental values.

Equality is in one respect a clear notion: given some way of measuring people's condition, their condition is equal when everyone's is the same according to this measure. But when people's condition is unequal, the notion of equality itself does not provide a measure that ranks different possible distributions and specifies which are more or less equal than others and by what extent. Philosophers discussing equality in recent years have not paid much attention to this issue (but see Temkin 1993, and Sen 1992).

4.2 Equality among Whom?

The articulation of an ideal of equality requires a specification of the persons or entities whose condition should be rendered equal. One aspect of this issue is whether the relevant units to be equalized are individuals or social groups. Some might hold that equality of condition should hold across ethnic, supposed racial, or religious groups, or across groups living in different regions of a society. The discussion to follow simply assumes that individual human persons are the relevant units for an ideal of equality of condition.

Equality of condition might be deemed desirable to sustain either (a) among the inhabitants of each political society taken one at a time or (b) among all human persons alive anywhere. Those who favor equality within each political society but not across political societies are sometimes labeled 'patriotic egalitarians' and those who favor equality across political societies are labeled 'cosmopolitan egalitarians.' A further dimension of the 'equality among whom?' specification is time. An egalitarian might give priority to attaining a closer approximation to equality among persons alive now or among persons who shall live now and in the future. (Policies that affect population growth and economic growth will affect the degree of inequality obtaining among persons living at different times.)

Another aspect of 'Equality among whom?' is whether equality is supposed to obtain in the condition of persons at each moment of time, or in the lifetime overall condition of persons, or perhaps among age groups at each moment of time. Notice that inequality between young and old is consistent with equality among all persons over the life course.

4.3 Equality of What?

Under this heading theorists debate how to measure people's condition for purposes of determining who qualifies as better off and who worse off when policies to enhance the extent to which equality is achieved are being considered or applied. (But it is evident that this issue of the basis of interpersonal comparison must be addressed by a wide class of theories of distributive

justice, not just those that affirm equality of condition. Anyone who espouses the notion that government should redistribute from better off to worse off persons needs some metric for deciding who is better off and worse off, and the metric had better make sense or else the ethic of redistribution will be unpalatable.)

Perhaps the most obvious candidate measure is equality of money or, more broadly, equality of material resources. On the simplifying assumption that material resources can be divided into homogeneous lots, one implements this ideal by dividing all such resources into N identical lots, one for each of the N persons in the group whose members are to be made equal.

Equality of material resources might be thought problematic on at least two grounds. The first difficulty is that this ideal leaves intact and unremediated the inequalities in the talents and useful personal traits possessed by individuals. If equality of material resources obtains between two persons, otherwise similar except that one is born legless and armless, the handicapped individual must devote a large portion of her resource allotment to compensate for the lack of abilities that normal legs and arms provide. One's resources for achieving one's ends include personal resources as well as material resources. Excluding the former may seem an arbitrary limitation.

A second difficulty is that equality across individuals' holdings of material resources over their entire lives might be thought to leave too little role for personal responsibility in the proper determination of each person's holdings. One might seek an interpretation of the ideal of equality of condition that does not require society continuously to offset in the name of equality the foreseeable impact of the risky and conservative, wise and foolish, careless and prudent choices made by individuals as they pursue their individual life plans.

This concern about responsibility might regard it as instrumentally valuable (holding people responsible for their choices is a useful means to attain other goals) or as intrinsically morally desirable (it is better in itself if benefits go to the responsible and deserving rather than to the irresponsible and undeserving).

Responding to these difficulties, Dworkin (2000) has proposed that people should be made equal in the level of uncourted disadvantage they suffer in their lives. The idea is that people should be made equal in their unchosen circumstances so far as is feasible, but they should not be compensated for differences among them that stem from their different ambitions and preferences and their choices of action to achieve their individual aims in life. Accordingly, equality of resources is expanded to encompass personal resources and adjusted to integrate a notion of individual responsibility for how one's life goes.

The family of views that interprets the ideal of equality of condition as equality of resources of some sort is united in rejecting the family of doctrines that prizes equality of utility, or well-being, or welfare across persons. This welfarist family of views supposes that when one person's condition is assessed as better or worse than another's for purposes of distributive justice the relevant measure is how well the person's life is going, the goodness of the life for the person who is living it. The goodness of a life in this sense is different from the sense in which the life of a person who sacrifices herself for others might well be deemed noble or admirable or good. Such a life is good (admirable), but not by virtue of that fact good for the person whose life it is. Good in the welfarist sense is what a person aims at when she is being rationally prudent.

Resourcist theories of distributive justice take it to be an important principle that society should not seek to make people equal in their personal well-being. Two considerations support this principle. One is that reasonable people will persist in disagreeing about what is ultimately valuable or worthwhile in human life. What people owe to each other by way of equal justice cannot depend on agreement on some conception of human good, because no such agreement can be forthcoming. Hence individual well-being cannot serve as a standard for determining whether someone is better off or worse off. The second consideration is that there should be a division of responsibility between society and the individual, such that if each individual is allotted equal resources according to the appropriate conception, then what individuals do with their equal resources is their business, not society's.

The ideal of equality of welfare varies in content as it is filled in with different conceptions of welfare or well-being. On subjective conceptions, whether something is good for a person and to what degree depends on her attitudes and opinions regarding it. A subjective conception might identify individual welfare with desire satisfaction or life aim fulfillment or enjoyment. On objective conceptions, whether something is good for a person and to what degree is fixed independently of her subjective attitudes and opinions regarding it. One might identify individual welfare with entries on an objective list, such that the greater the extent to which the person gains items on the list, rated by their relative importance, the better her life is going. To give a welfarist conception the best run for its money, the most plausible conception of welfare must be used to fill in its content.

The welfarist responds to the claim that reasonable people cannot agree about what renders a life intrinsically valuable for the one who is living it partly by insisting that the claim greatly underestimates the degree of consensus on the nature of the human good that does exist among reasonable people and partly by allowing that to the extent that there is genuinely reasonable disagreement about the human good, to that extent there is only limited commensurability in this domain.

The responsibility objection against the ideal of equality of welfare has prompted the reply that the welfarist egalitarianism can accommodate a sensible norm of personal responsibility (Cohen 1989). But when one tries to work out the details it becomes clear that integrating an appropriate norm of personal responsibility into any ideal of equality of condition is so far an unsolved problem.

Consider this revision of equality of welfare: Society is responsible for bringing about an arrangement that induces equality of opportunity for welfare among individuals. Roughly, the level of opportunity for welfare provided by one's circumstances is the level of welfare one would reach if one conducted oneself as prudently as can reasonably be expected over the course of one's life. A prudent individual acts efficiently to advance his or her own welfare within the limits of legal and moral constraints. One determines whether a person has acted as prudently as can reasonably be expected by relativizing the requirement of prudence to that individual by taking account of the person's unchosen deficits in choice-making and choice-executing talent.

Equality of resources could be revised to become equal opportunity for resources, an ideal that is satisfied among a group of persons just in case all would have the same resources (or alternatively, the same expected level of resources) if all behaved as prudently as can be expected. As stated, both equal opportunity views may seem too unforgiving in the way they incorporate personal responsibility into an egalitarian ideal. If one fails to meet the specified standard of prudent conduct by even a tiny amount, there is no constraint on the extent to which one's fortunes may plummet without triggering egalitarian concern.

Another approach to interpreting distributive equality supposes that what people owe to each other by way of providing all opportunities for a choice-worthy life is a set of freedoms (Sen 1992, Nussbaum 1999). Freedom might seem just another way of referring to opportunity, but identifying these two approaches would be a mistake. For one thing, since an individual's opportunity for welfare provided by her circumstances is the welfare level she would reach if she behaved as prudently as could reasonably be expected, with less freedom the individual who has difficulty being prudent could have more opportunity for welfare.

The freedom metric for distributive justice is calibrated in terms of effective not merely formal freedom. The distinction is that one is formally free to do *X* if no law forbids the doing of *X* and no one wrongfully interferes with one's attempts to do *X*. One is effectively free to do *X* provided that if one chooses to do *X*, and genuinely tries to do *X*, one will do *X*.

The ideal of equality of effective freedom is indeterminate pending some specification of significant or valuable freedoms, the ones that should be equally secured for persons. To fix the content of the ideal, it is necessary to identify valuable modes of action or ways of being such as being well nourished, having adequate shelter, having relationships of friendship and love, sustaining close family ties, attaining significant work achievement, experiencing enjoyment in one's activities and avoiding useless pain, participating in the political life of one's community, gaining understanding of the world, and so on. Call these various doings and beings 'functionings,' and identify equality of freedom with the effective freedom or capability to function in these valuable ways.

Since individuals differ in their traits, they will require different packages of education and resources in order to get (close to) equal effective freedom to function. For the effective freedom approach, what is morally important is not the level of resources that one has access to *per se* but what one is enabled to do and be by means of these resources.

The equality of freedom approach limits the responsibility of society to provision of real freedom for individuals. The level of actual functionings reached is a 'don't care' from this standpoint. For example, society provides conditions in which each can exercise religious liberty, but whether and how religious freedom is exercised and the resultant spiritual life that people experience is a matter of culture, not justice as equality.

Equality of effective freedom or capability to function as stated does not adopt a stance on personal responsibility. Suppose that an individual has an initial effective freedom to function in some significant way, but squanders the resources that assured the freedom, and when equivalent resources that are supplied again, squanders them again. At some point in this cycle one might suppose that equality of effective freedom should not be sustained further.

However, how to integrate a sensible account of personal responsibility into an egalitarian distributive ethic is far from settled. No account asserted in current discussions has attracted a consensus of support.

4.4 Doubts about Whether Equality of Condition Is Morally Desirable

The question arises, why should everyone have the same? What makes equality of condition morally desirable? Some theorists suspect the answers are that nothing renders equality of condition *per se* desirable.

One seed of doubt about the intrinsic value of equality is planted by noting that if one can achieve equality or a closer approximation to it by worsening the condition of those who are better off without improving anyone's condition, from the standpoint of equality one must hold that this leveling down is desirable. This implication of equality is expressed in the slogan, 'Equality itself is as well pleased by graveyards as by vineyards.' But a change from the status quo that worsens someone's condition without

making anyone's condition better in any respect cannot be a change for the better in any respect, some think. This thought rejects the idea that equality of condition is per se desirable.

Asserting the intrinsic moral significance of equality of condition, theorists sometimes note that the wealthy in a prosperous world control enormous amounts of resources while the impoverished of the world lead grim lives in horrible conditions. But a plausible rejoinder (Frankfurt 1987) is that it is evidently not the gap between rich and poor *per se* that is morally troublesome but rather the sheer badness of the lives that the poorest people on the earth lead. For if the gap between rich and poor were *per se* significantly objectionable then the same-sized gap between super-rich and merely rich should be equally objectionable. But if the latter gap does not seem especially morally problematic, then the relative position of rich and poor cannot be regarded as *per se* especially morally problematic either.

5. *A Puzzle about Basic Equality Status*

An egalitarian holds that people should be made equal in some aspect of their condition on some moral ground. What justifies equality among persons on any conception? It is often supposed that nonhuman animals, even if their interests should be considered in determinations of action and policy, do not count for as much as humans. This discounting of animals strikes many as plausible, but what underlies it? The usual suggestion is that normal adult humans have cognitive capacities that render them intrinsically better than animals, so their interests and welfare should count for more. The puzzle then is that normal humans differ significantly in their possession of the cognitive capacities that are supposed to render all humans fundamentally equal in their basic moral status. If an ordinary gorilla has a lesser moral status than an ordinary human because the latter is smarter, why does not the ordinary human have lesser moral status than another human who is much smarter? It might be urged that what makes all persons equal and superior to other animals is that all normal humans have cognitive capacities at some threshold. Having cognitive capacities above the threshold does not confer superior moral status. But why and how this is so is not yet clear.

Equity

Equity is usually defined as fairness, impartiality; justness. Consequently, Equity in Law is said to exist when justice administered between parties appears as based upon natural reason or ethical judgement—whether or not it is in conformity with written (State) law. Indeed, equity can be considered either as a

concept immanent to the law or as a set of principles outside the law, the function of which is to allow the judge to give soft interpretations in concrete cases in order to reach not too unmerciful solutions. Hence, equity is working at large in legal systems where the judge plays an important role, like common law or other systems where state law has a reduced role, whilst the official use of it is very insignificant in other legal systems, such as positivist continental laws. Equity in Law can be examined under two main headings. Equity in Law has always been considered (a) *ethically* as an opportunity to refer to equity against positive (State) Law, and (b) *politically* as the way to open law to necessities borne from economic developments.

1. Equity as a Common Expedient

In this sense, equity is positioned between law and ethics. In the Western legal tradition, equity was even culturally perceived as the only foundation of law. Equity and justice go hand in hand in Western legal philosophy. But the Roman root *aequus* was translated by two words which acquired two very distinct meanings through the ages: 'equity' on the one hand, and 'equality' on the other. The distinction led to opposing political theories on law and justice.

Roman Law defined legal work as skillfulness in settling what is good and fair: *Ars boni et aequi* (Celsius and Ulp, *Dig*. I, 1, 1, pr.). Among traditional legal principles, we find also the rule according to which equity must be expected in everything, but above all in Law (Paul, *Dig*., 50, 17, 90). As Pretorian law, a great part of everyday Roman legal regulation was progressively built upon equity in order to complete positive law. The Roman distinction between *ius honorarium* and *ius civile* has been seen by some authors as a forerunner of what would later exist in England as a distinction between common law and equity: a 'body of rules existing alongside the original civil law, founded on distinct principles, and claiming incidentally to supersede civil law in virtue of a superior sanctity inherent in these principles' (Maine 1861, p. 25).

Equity is used to replace legal rules drawn from statute or common law when these rules are considered too inadequate or unyielding for the expectation of justice in a specific case. Hence, equity was always considered as a common expedient against legal (state) justice where this latter appeared too distant from ethics, moral or customs. This route to justice was historically employed to such a degree that the gambit was embodied in many legal traditions, re-emerging from time to time according to need.

In opposition to legal unfairness, equity is regarded as either a refuge (equity prompts legal rules to law givers) or a recourse (equity is the alternative source of a redress or remedy to those provided by established law).

From ancient times, equity was considered to be an efficient means to establish justice in law. Without equity, law would be unjust (*Summum ius*, *summa injuria*). Within legal anthropology, Henri Sumner Maine showed in his work *Ancient Law* (1861) that equity is considered an instrument to bring harmony to progressive societies. According to this author, equity is one of the three agencies by which primitive law has been adapted to the requirements of a developing society and an improving morality.

Equity was also considered in Western legal tradition as a complement or a corrective to positive law. There are a number of aphorisms on this topic, such as *Hæc æquitas suggerit*, *etsi deficiamur jure* or *Æquitas nihil aliud est quam jus quam lex scripto prætermisit*, i.e., equity must be followed where there is no legal norm to reach a solution. But when the man in the street talks of 'equity,' he is thinking of ideal justice which may even be contrary to the law. Here lies that faith in the fairness of a claim to some natural law existing above positive laws or statutes. Equity focuses on the imperfections of law and can even be preferred to a legal norm where it provides a useful corrective to legal institutional justice by improving an equitable outcome: *Placuit in omnibus rebus præcipuam esse justitiæ æquitatisque quam stricti juris rationem*. Equity is better than a solution drawn from a strict interpretation of law. Such a theory, elaborated from Aristotle onwards, runs through the western legal tradition through Roman Law, subsequent Canon Law (Grossi 1998) and right through continental legal regimes before the French revolution.

That law can be brought into harmony with society through equity is currently demonstrated by legal sociologists, whose research illustrates specific circumstances in which societies make appeals to alternative procedures where equity plays an important role. This is particularly clear when it is not ingrained within a culture to instinctively call on the law for help as the main way to resolve conflicts, such as in traditional Chinese or Japanese cultures. Moreover, equity is often grasped as an opportunity for a workable alternative to state law, where it is not envisaged by a written legal norm. In the last decades of the twentieth century, for instance, equity was cited in alternative movements by both Italian and Brazilian judges (*Alternative Use of Law* and *Alternative Justice*, in Arnaud 1993).

2. Equity as a Means of Adapting Legal Regulation to Political Prerequisites for the Development of an Economy

All through the building of the occidental legal tradition, whilst laws were considered a means to protect communities and insure their reproduction following a specific pattern, equity also appeared as

the way to open up law to necessities born from the development of trade. Here, equity appears (a) as an earlier technique to create a society for merchants, and (b) in the last decades of the twentieth century, as a means to implement a global legal order.

2.1 Equity as a Foundation of Trading Societies

At the end of the Middle Ages, the opposing pressures of the wish of kings to concentrate absolute powers in their hands, the opening up of everyday life to trade and merchants, as well as the emergence of a *bourgeoisie*, led the various national laws to adapt themselves to the development of landed and propertied interests. Western laws gradually expanded into opposing systems: the common law and equity tradition on the one hand and continental legal positivism on the other.

After centuries of legal rationalization, equity was definitively taken up from the discourse of ethics and located as one of the foundations of law, appealing to natural law and reason, even as against positive law and statutes (Hugo Grotius, Samuel Pufendorf, Christian Wolff and their disciples in Northern Europe; Jean Domat in France).

As to the continental romano-canonic tradition, equity was quickly made subservient to state law. Despite the influence of Domat's work on French jurisprudence, equity was forbidden in France by the *Ordonnance civile* of 1667. The French Revolution of 1789 was partially directed against the discretionary power of judges. A project to reintroduce equity as a tool in judicial interpretation in the French Civil Code was drastically cut down by Bonaparte. Finally, the judge was considered merely to be the mouthpiece of state law. It is true that we can find counterexamples in nineteenth-century France, such as judicial decisions by the 'Bon Juge Magnaud' who used equity to avoid enforcing the law against the poor. But this use of equity was a rarity and almost all such decisions were reversed by the court of appeal.

We can also identify some slight remains of equity in Civil Law, even in the French Civil Code (articles 565, 1135, 1854). The strongest examples are, however, drawn from the Swiss Civil Code, articles 1 and 4: 'The law must be applied in all cases which come within the letter or the spirit of any of its provisions. Where no provision applies, the judge shall decide according to the existing customary law, and, failing which, according to the rules which he would lay down if he had himself to act as legislator. Herein he must be guided by approved legal doctrine and case-law … Where the law expressly leaves a point to the discretion of the judge, or directs him to take circumstances into consideration, or to consider whether a ground alleged is material, he must base his decision on principles of justice and equity' (see Lloyd and Freeman, p. 1231).

At the same time, in the common law countries, legal developments went in the opposite direction. There, indeed, equity refers to that part of the law of England which is derived not from the custom of the realm nor the enactments of Parliament, but from the decisions of the old Court of Chancery, consolidated in 1873, along with the other superior courts in the supreme court of judicature. Such equity pertains to a right recognized by a court of equity through a specific procedure. Here, we are faced with procedural equity and not 'natural justice.' Jurisdiction in equity is one of the three clearly marked divisions into which the jurisdiction of the court falls, together with a miscellaneous jurisdiction and a common law jurisdiction. The equitable jurisdiction of the court originated in the power which the chancellor assumed in the Middle Ages to modify a strict and formal legal system on moral grounds.

There are a number of principles used as guidelines when it is necessary to make appeal to this notion of equity; equity acts *in personam*; equity will not suffer a wrong to be without a remedy; equity follows the law; equity looks to the intent rather than the form; equity imputes an intent to fulfil an obligation; equitable remedies are discretionary; delay defeats equities; he who comes into equity must come with clean hands; equity takes into account the balance of convenience; where there are equal equities, the law prevails and the first in time prevails; equity, like nature, does nothing in vain; equity never wants a trustee; equity aids the vigilant; equality is equity; equity will not assist a volunteer; equity will not permit a statute to be a cloak for fraud.

In England, because the remedies which the common law courts could give were initially limited by the forms of writs available, men turned to the Chancellor for equity for assistance. The two systems came to be administered by wholly independent tribunals whose decisions were frequently in conflict. The early jurisdiction of the Court of Chancery was in its nature extremely vague. From the beginning of the seventeenth century, it is possible to discern certain general principles in the exercise of the court's jurisdiction. The early seventeenth century was the principal turning point in the history of the court, for the common law lawyers were seeking to prohibit the Chancery from interfering with common law rights. King James I resolved the conflict between the two jurisdictions in favor of Chancery. From this time onward, although the conflict did not die down until the end of that century, the court gradually developed jurisdiction co-ordinate with that of the common law courts and on settled principles. In the eighteenth and nineteenth centuries, it came to follow precedent as strictly as they.

The principal distinction between the two systems was that, whereas the rules of common law were supposed to have been established since time immemorial, those of equity could in almost every case

be traced to the Chancellor who invented them. In the nineteenth century the jurisdiction of Chancery, now clearly defined, was frequently classified according to its relationship to the common law as being exclusive, concurrent or auxiliary. By the middle of the twentieth century, the Chancery division consisted of the Lord Chancellor and judges divided into groups which were respectively assigned matters within the peculiar jurisdiction of the division.

In the USA, equity was developed with relative consistency during the nineteenth century. The expansion of the equity system was subject to statutory grants bestowed to each state, which constitutes a specific feature of American legal history. During the Civil War, the equitable jurisdiction was generally attributed to courts of double jurisdiction. Since 1848, many states excluded the distinction between law and equity in favor of one 'civil action.' At last, there was a complete fusion of law and equity by the adoption, in 1938, of the federal rules of civil procedure, promulgated by the US Supreme Court under authority of an Act of Congress.

2.2 Equity as a Referent in the Framework of Contemporary Political Theory

Recently, the use of equity was proposed by neoliberal legal philosophers as a way to put into common practice some fundamental legal principles. Hence, equity has become a referent in the framework of globalization, re-emerging in many new areas of legal work, e.g., private, regional and international judicial assemblies, and directly in relation to global governance. The importance of the recourse to equity in contemporary neoliberal legal and political philosophy is due to (a) the predominance of the Anglo-American legal tradition in international legal relations, (b) the special focus given to the above-mentioned principle according to which 'equality is equity,' and finally (c) the claim for a minimal state.

After much controversy surrounding the Aristotelian idea of 'corrective justice,' equity was reintroduced as the legal principle of equal treatment of people in the allocation of legal benefits and obligations. John Rawls designates as *'equality of fair opportunity'* the equity of opportunities which cannot be reduced to a merely hypothetical right (Rawls 1971, pp. 14, 46). Here arises a paradox: the more the State intervenes in establishing equality of opportunities, the more it stands apart from the ideal of contractualism which characterizes the minimal state. Consequently, there could be no coherent basis for imposing common global lawful and unique interpretations (for example, of human rights). This means that it would not be possible to universally expect the same behavior through all institutions, whether national, local, or international.

Popper's claim for the importance of tradition, a tradition which offers the moral structure of a society, is grounded in the idea that herein lies the social meaning of justice and equity. On the one hand, tradition reveals the degree of moral feeling which each society attains; on the other, should there be conflict between opposing interests, tradition is the moral framework which allows us to find fair or equitable compromises (Popper 1963, Chap. 17, paragraph 3). Institutions alone give a society its legal structure appropriate to this moral background.

According to Friedrich Hayek, society is developing upon a set of individual interests pursued, although not always fully recognized, in the framework of the 'open society' or 'great society'—the global society. A free society is a pluralist society without a common hierarchy of peculiar achievements. The market supposes a discipline, a system of rules of behavior. The market is a game able to create wealth. Indeed, it gives each player adequate information in order to allow him/her to answer to needs of which he/she is not able to be directly aware. Thanks to this game, opportunities increase for each player since nobody is treated unequally. And there is no inequality when the result of the game is different for different people: on the contrary, the market mechanism itself produces impersonal flags, signs which show the players when and how they have to modify their actions to adapt to events of which they are only indirectly aware.

States from time to time wish to introduce social justice through legal regulation. But equity cannot be considered as a means of establishing social justice. Social justice, Hayek writes (Hayek 1973), destroys the spontaneous feature of the market, proscribes the possibility of a great society, and is incompatible with liberty. In other words, equality of treatment before the law—even in the name of charity—leads to arbitrary outcomes. There are requests and revolts against the abstraction of the rules which must be observed within the framework of the Great Society. Indeed, there is always a predilection for concrete human circumstances. But such feedback would only reveal a lack of intellectual and moral maturity faced with the necessities of an impersonal global order of humankind.

Globalization supposes an interdependence within all humankind as we move towards the realization of an open society in which people must accept risk. Consequently, globalization produces inequalities. Peace will result only from the observance of rules of fair behavior. Equity will be realized provided that everybody is treated equally according to these abstract rules of fair behavior. Equality of opportunities cannot be implemented beyond equal treatment before the law.

The State must not involve itself in a process of social justice with the purpose of giving to a group of

citizens what belongs to others. Success or failure must depend only upon each person's action and cannot flow from the knowledge and power held by public authorities. Authoritarian intervention generates disorder and cannot be equitable. To speak of concrete common goals is specific to small closed societies in which people were protected by community at the price of their freedom. In contrast, a great society of free people can exist only if everybody submits to 'equal' abstract rules.

In this context, it is easy to understand that the state must play a minimal role. The 'entitlement theory' (Nozick 1974) based upon a discussion of Hart's 'principle of fairness' (Hart 1961) challenges the claims for State action aimed at implementing equality among people.

Where the State is striking space, the judge becomes a masterpiece in the framework of the legal structure. The judge enjoys extended powers in such a society. He has to correct permanently the disturbances within an order which is spontaneous, not artificial, and which tells people what they have to do. Such a judge must decide in 'equity' in the sense that he has to decide if people's behavior is appropriate to what can normally be expected in comparison with the common conduct of the members of the same group.

The law of the judges is a translation of what people have learned from their actions. Judges' function is to maintain a permanent and efficient order in people's behavior. The judge contributes to improving a given order, an order which must not be upset by changes within relationships between citizens.

Such contemporary theoretical views on equity are particularly significant. Globalization is promoting neoliberal views on law, justice and equity. Indeed, equity has already become a common referent for regional and international Courts of Justice. This leads in turn to many ambiguities, for instance in the implementation of the European Union's *Equal Treatment Directive* against sex discrimination. This last rule is based upon a general feeling of equity … but supposes some affirmative action through Community (state) intervention (see the *European Law Journal* 1998, and Posner 1993, pp. 404–5). The same ambiguity can be found in the report by the Commission on Global Governance entitled *Our Global Neighborhood* (Commission on Global Governance 1995). In this report, written at the request of the United Nations, we read that 'Justice and equity are essential human values. Respect for them is indispensable for peace and progress … Where large numbers of citizens are treated unfairly or denied their due … discontent is inevitable and conflict likely.' However, 'a concern for equity is not tantamount to an insistence on equality.' Therefore, equity 'does call for deliberate efforts to reduce gross inequalities, to deal with factors that cause or perpetuate them, and to promote a fairer sharing of resources' (Commission on Global Governance 1995, p. 51). This is good as political principle, but what practical legal rule can flow from such abstract, inconsistent, and equivocal discourse?

Nevertheless, and despite of the lack of general agreement on its relationship with equality, equity appears as a newly contemporary and significant notion which promises great possibilities for redesigning law-making, the administration of justice, and the process of judicial decision-making.

A.-J. Arnaud

Ergonomics, Cognitive Psychology of

The term 'ergonomics' and the ideas behind it were introduced by the Polish scientist Jastrzebowski as early as 1857. However, only at the beginning of the twentieth century did growing concern about the health of the workforce develop which gave rise to the foundation of dedicated research institutes in a number of countries. Although at that time ergonomic problems were addressed, the rise of ergonomics as an organized field had to wait until World War II and thereafter. It was only in the 1950s that the Ergonomics Research Society in the UK and the Human Factors Society in the USA were founded.

Several subdisciplines of psychology address issues related to human work. To some degree ergonomics can be seen as a blend of engineering and of experimental psychology. It is not only the application of knowledge from experimental psychology to engineering, the fertilization is bidirectional. Among the influences which triggered and shaped the rise of cognitive psychology were developments in engineering such as information theory, control theory, and computer science. A core characteristic of these developments was the abstract nature of major concepts; they were functional and not linked to physical implementations of the functions. Hence they were also suited for the analysis of human performance. Among those who established the close relation between ergonomics and cognitive psychology which developed as human work became more and more 'mind-work' rather than 'body-work' were Paul Fitts in the USA and Donald Broadbent in the UK. Both of them contributed to the key issues of what is sometimes called 'cognitive ergonomics' or 'psychological ergonomics.' Three of these key issues will be briefly addressed.

1. Human–Machine Systems

Humans interact with machines to achieve certain goals at work. In some way human–machine systems are basic units of ergonomic analysis. They can differ vastly in terms of complexity, depending on the kind of machine involved. The term 'machine' in this context is to be understood broadly, ranging from simple tools such as hammers and screwdrivers to vehicles and computers and finally to largely automated technical systems such as can be found in power plants and in the chemical industry. Issues that arise from the study of complex human–machine systems are addressed in a number of other places in this encyclopedia (see *Expert Systems in Cognitive Science*; *Human–Computer Interaction*; *User Interface Design*).

1.1 Manual Control

A basic characteristic of a machine is its transformation of human movements into machine output, e.g., of movements of a computer mouse into movements of the cursor on the screen, or of rotations of steering wheels into changes in the direction of vehicles. In spite of the tremendous differences in terms of complexity, there are commonalities among many human–machine systems. Formally skilled operation of a machine requires the solution of a control problem, that is, a solution of the problem to find an appropriate input to achieve a desired output.

There are different types of solutions to a control problem. Two basically different ways are a closed-loop solution and an open-loop solution, which can be combined. In both cases the transformation implemented by the machine is (approximately) inverted and applied to the desired output. With closed-loop control the approximate inversion is an emergent characteristic of the closed-loop structure, whereas open-loop control requires an internal model of the transformation by the machine.

Manual-control tasks are typically studied by means of tracking setups which have the basic structure of a closed-loop system. The development of an internal model mostly implies the learning of an intermodal relation, specifically of the relation between visually perceived output of the machine and proprioceptively sensed self-produced movements. When such a relation follows a power law (which includes proportionality), it is easy to learn, and internal models of the transformation can be fairly precise. This becomes

apparent when the machine has to be operated in an open-loop fashion, with the feedback loop being interrupted. However, when the transformation involves other nonlinear relations, an inversion (e.g., move the mouse to the right for a cursor movement to the left), or dynamic components (such as an integration in the case of driving a vehicle), internal models tend to become less precise and the dependence on closed-loop control more pronounced.

Perhaps the most extensively studied variation of visuo-motor relations is called stimulus–response compatibility. For example, when a cursor moves to the right upon a mouse movement to the right, this would be a spatially compatible relation, and a directional reversal would produce an incompatible relation. More generally, the term 'compatibility' refers to the naturalness of a visuo-motor transformation, which is often fairly obvious to a user. Usually there are strong differences between compatible and incompatible relations when visual stimuli and responses share a common dimension (such as left–right). Whether or not a certain relation is compatible depends not only on the physical situation, but also on the mental representation of it. For example, when one has to respond to small and large numbers between 1 and 12 by pressing a right or left key, the assignment of small numbers to the left key and large numbers to the right key results in shorter reaction times (compatible relation) than the opposite assignment (incompatible relation); however, the normally incompatible relation becomes compatible when one imagines the numbers being arranged on the face of a clock.

1.2 Monitoring and Supervisory Control

Modern technology allows machines to become more and more complex, and manual-control tasks can mostly be automated. Modern airplanes are popular examples of this. There is a certain irony in such automation which should not be overlooked. On the one hand automation serves to avoid human errors and to reduce mental load, but on the other hand there are emergency situations in which the system changes from automatic to manual control. The irony is that a human operator who is deprived of the daily experience of controlling the machine in normal situations is required to master it in the difficult emergency cases. In the normal situation, the task of the operator in highly advanced transport and production systems becomes that of a supervisor. The task of the supervisor is no longer continuous control of the system output, but rather the monitoring of the system state, the discovery and diagnosis of abnormal states, and the taking of appropriate actions when abnormal states are discovered.

Monitoring can be a boring task: irregular system states are rare events, so there is little that happens. The classical problem which gave rise to the systematic study of maintained attention to displays which only rarely indicate critical events is that of the radar controller. In the course of a watch there is typically a fairly rapid decline of the probability of detecting a critical event, the so-called vigilance decrement. The same phenomenon can become a problem in industrial inspection tasks. In particular, the really rare events carry a risk of being overlooked. One of the factors which are likely to contribute to the vigilance decrement is temporary inactivation of the appropriate task set.

Monitoring can also be a task which places too high a burden on a human operator. There can be hundreds of state variables which have to be monitored, so the decision as to which state variable to inspect next can be difficult. In their inspection patterns operators adjust to the characteristics of the state variables. For example, state variables which change rapidly tend to be inspected more frequently than state variables which change only slowly. In addition, interdependences between state variables guide the inspection pattern. However, in the case of a failure the normal characteristics of the state variables may no longer be present, so that inspection patterns can be misguided.

The detection of abnormal system states can take minutes or hours, depending on a number of conditions. Among them is the rate of change of system states, which can be slow. Again, as does the pattern of inspection behavior, fault detection relies heavily on the operator's internal model of the system. Unfortunately the concept of an 'internal model' is somewhat elusive when it comes to a precise characterization. One of the reasons is that the internal model on which monitoring and supervisory control is based is not necessarily identical with the reportable knowledge of an operator. Both incidental observations and formal studies suggest that at least part of the knowledge on which the operators' monitoring and control actions are based is implicit in nature.

2. Workload and Multiple-task Performance

One of the classical and continuing problems is the assessment of workload. Its importance results from the notion that overload or underload can result in errors, accidents, and/or health risks. There are three types of measurements that are employed for workload assessments, physiological measurements (such as heart rate and heart-rate variability), subjective ratings, and behavioral data.

The assessment of workload by means of behavioral data is closely linked to the study of multiple-task performance. Everyday observations suggest that the mind can be more or less dedicated to the performance of a certain task. To bring this observation into the realm of scientific treatment, the concept of capacity

or of resources has been introduced: the more capacity is dedicated to the performance of a certain task, the higher is the performance in this task, and the less capacity is available for the performance of other concurrent tasks. From this general idea, it follows that there should be a tradeoff between performance levels in two concurrent tasks when performers vary their respective emphasis and, theoretically, the proportions of total capacity allocated to each of them. Performance tradeoffs indeed exist. For practical purposes, these simple concepts suggest that performance in a subsidiary task could be used to assess mental workload. However, so far all attempts to find a subsidiary task that could be used as a kind of yardstick in the assessment of mental load have failed.

The limits of multiple-task performance are important not only in the context of workload assessment, but also in the context of work design. For example, in supervisory control situations can arise which require different actions concurrently. Sometimes concurrent actions can be physically impossible, so that the problem becomes one of scheduling tasks according to priorities. Even when concurrent activities are physically possible, there is not only interference because of limited mental capacity, but also interference of a more specific kind, related, for example, to cross-talk within the perceptual or motor systems. A basic principle is that interference becomes more pronounced as the perceptual information for different tasks, the effectors involved, and the nature of the information (e.g., verbal vs. pictorial) become more similar.

3. *Skill Acquisition*

Human performance can be improved by practice, and the time needed for a certain action (such as the classical example of rolling a cigar) declines. Practice curves can be described by a power function for a great variety of skills; this fact is referred to as the 'power law of practice.' However, skilled performance has a number of additional characteristics. It tends to be less variable, and it tends to be associated with a reduced workload and less interference with the performance of concurrent tasks. The latter aspect of skill acquisition is called automatization. However, the reduction of dual-task interference is not a universal characteristic of skill acquisition, but there can also be certain secondary tasks for which dual-task interference increases.

In many cases the skills required to operate complex human–machine systems are acquired by means of special training devices, so that there are degrees of freedom in designing the training procedure. The design of training procedures can be a fairly complex process. Often it involves the identification of task elements which are practiced separately, special instructions, and special feedback. The training procedure shapes the internal model of the machine. Thus, a critical factor for the success of training procedures is the match of the practice situation and the final 'test' with the real system, in particular the match with respect to functional characteristics and with respect to the information available. Somewhat ironically, too much can be done to support the learner during training in terms of guidance and feedback; performance can become dependent on such additional guidance and feedback so that it will deteriorate as soon as it is no longer available.

Erikson, Erik Homburger (1902–94)

Erik Erikson was born on June 21,1902 in Frankfurt, Germany to a Danish Jewish mother, Karla Salomonsen. He was eventually given his stepfather's name (Homburger) and later christened himself, Erikson. He grew up in Germany, completed his gymnasium in Karlsruhe and in 1921 enrolled in art school. However, he soon left this and after a *Wanderschaft* period, he secured his first professional position in the late 1920s as a teacher, together with Peter Blos, in Vienna's Heitzing School founded by Eva Rosenfeld, Dorothy Burlingham, and Anna Freud. The latter became

Erikson's analyst and supervisor in play therapy with children. Erikson married a Canadian dancer, Joan Serson, in 1930. In 1933, now the father of two sons, he left his incompleted studies at the University of Vienna, was voted a full member of the Vienna Psychoanalytic Society and emigrated to the United States with his young family. He established a private practice in Boston and was made a member of the Boston Psychoanalytic Society despite that body's parochial policy of limiting membership to physicians. During the next 5 years, Erikson worked at the Judge Baker Center in Boston, the Murray Clinic at Harvard, secured a position at Yale with the Gesell clinic and Institute of Human Relations, and began an important professional relationship with the anthropologist, Margaret Mead.

In 1938, Erikson, whose surname until this time had been his stepfather's (Homburger), changed his name to Erikson, became a US citizen and moved to California to take a position at Macfarlane's Institute of Child Welfare in Berkeley and established a substantial private practice in San Francisco in 1942–3. While working with returning veterans at the Mount Zion Rehabilitation Clinic, he began a friendship with the Jungian analyst Joseph Wheelwright, who broadened Erikson's Freudian perspective. In 1949 he became a professor at Berkeley, in spite of lacking the usual academic credentials, but soon left after refusing to sign the McCarthy era loyalty oath—a 'Here I stand' gesture that may have prefigured his forthcoming book on Martin Luther. In 1950 he presented his and Joan's outline of the human life cycle to a White House Conference and saw his most influential book, *Childhood and Society*, published. He returned to the eastern US in 1951 to join the Austen Riggs Center in Stockbridge, Massachusetts as clinician and author. There he established important professional and personal relationships with ego psychoanalyst Robert Knight and David Rapaport and he completed his second major book, *Young Man Luther*, (1958). He published the monograph *Identity and the Life Cycle* in *Psychological Issues* (1959) expanding both on the life cycle outline and on ego identity, a concept, together with 'identity crisis' that was to become associated with his name in the mind of the public.

With help from David Riesman and Robert White, Erikson moved from Stockbridge to Boston and Harvard in 1960 and became a professor, but outside any particular academic department. In the midst of, and to some extent with reference to, the student unrest of the 1960s, Erikson began work on his second psychobiography, *Gandhi's Truth* (1969) and for which he received both the Pulitzer Prize and the National Book Award. In addition, *Insight and Responsibility* (1964), *Identity: Youth and Crisis* (1968), and a revision of *Childhood and Society* (1963/1985) were also completed during this period. These books reflected a growing shift in Erikson's thinking from the development of the individual, to the social context of individuals' development, to the moral and ethical implications of different forms of social organization for humankind. In this transition, the work of his friend, Paul Tillich, was influential. Clearly, Erikson had begun to move quite a distance from his orthodox psychoanalytic initiation by Anna Freud.

By the beginning of the 1970s Erikson had become one of the most respected and honored thinkers within the psychoanalytic developmental area, described by one reviewer as 'the most influential of living psychoanalysts.' He delivered two sets of honorary lectures: the Godkin at the John F. Kennedy School for Government at Harvard in 1972, and the Jefferson for the National Endowment for the Humanities in Washington, DC, in 1973. These eventuated in two more books, *Toys and Reasons* (1977) and *Dimensions of a New Identity* (1974). *Life History and The Historical Moment* (1975) occasioned significant criticism from both feminists and New Left sources who found Erikson still too politically and psychologically conservative. Erikson's most important final writings were on the last life cycle stage of *Integrity: Reflections on Dr. Borg's Life Cycle*, a commentary on Bergman's film, *Wild Strawberries*, *The Life Cycle Completed: A Review* (1982), and *Vital Involvement in Old Age* (1986) written with Joan Erikson and Helen Kivnick. Erikson continued to do clinical work until 1990. He died on May 12, 1994, in Harwich, Massachusetts.

Erikson lived through the world-shaping events of the twentieth century: World War I, the Great Depression, World War II, and the United States' coming-of-age in Vietnam. The national and ideological strands that the Eriksons gathered up and wove into his psychosocial developmental theory were numerous: Danish, German, North American, Jewish, Protestant, classical psychoanalytic, ego psychoanalytic, and even Jungian. His literary/theoretical excursions into a form of biography that he labeled 'psychohistory' further widened his intellectual scope to include Luther in Reformation Germany, Gandhi in pre-independence India, Hitler in pre-W.W.II Germany, Gorky in Bolshevik Russia, and Jesus Christ in biblical Palestine. Although only one of a number of psychoanalytic thinkers who left Europe for America in the 1930s, only Erikson integrated and transformed these disruptive experiences into a clinically, theoretically, and empirically useful outline of the stages of normal human development.

Erikson took a 'configurational' approach to children's play therapy, wherein he considered the spatial arrangement of items chosen by the child to be as important as the items themselves or the stories linking them. He carried this configurational approach over into his psychosocial developmental chart that portrays the human life cycle as consisting of eight central developmental crises, each having its more or less specific age-related time of ascendance. The first three stages: Trust vs. Mistrust (infancy), Autonomy

vs. Shame, Doubt (early childhood), and Initiative vs. Guilt (play age) parallel the Freudian psychosexual stages: oral, anal, and phallic. However, in contrast to Freudian libido theory, these stages of ego growth refer not just to erogenous body zones, but to modes of behavior and senses of oneself and of the world that are shaped by the child-rearing practices of particular parents embedded within their particular culture. The description of life cycle stages after childhood constitutes Erikson's unique contribution to psychoanalytic developmental theory. In these he outlines a sequence of ego development extending beyond childhood through the adult years: Industry vs. Inferiority (school age), Identity vs. Identity Confusion (adolescence), Intimacy vs. Isolation (young adulthood), Generativity vs. Stagnation (middle adulthood), Integrity vs. Despair (old age). Associated with each of these stages are social institutional 'rituals' (e.g., infancy: 'motherhood') as well as eventual 'virtues' (e.g., infancy: 'Hope').

The emergence of each of the eight stages in this sequence is governed by an epigenetic principle comprising a built-in developmental progression of individual physical and psychological change occurring with a social context of age-related 'average expectable' demands and provisions. Because Erikson located personality development firmly within the social context, he is to be credited with initiating psychosocial developmental theory. Optimal development in childhood consists of a balance between the opposite poles described above, tilted in favor of the more positive alternative. Beginning in adolescence, resolution of a developmental crisis incorporates both poles into a synthesis. For example, Identity development includes an element of Diffusion or Confusion; Generativity formation incorporates some Stagnation; and there is no Integrity without some accompanying Despair. The primarily positive resolution of each stage is considered to be crucial for the resolution of the next stage. However, consistent with Erikson's configurational approach, there is an aspect to the design of his developmental chart that allows for remediation of inadequately resolved issues or precocious resolution of 'future' developmental issues. Each stage is assumed to arise during every chronological period, although the nature of that stage is shaped by the dominant issue of the period. For example, a Basic Trust vs. Mistrust crisis re-occurring at Intimacy will take a form configured by the adult nature of relationships typical of early adulthood. Because they arise again at each succeeding chronological period, previously unresolved age-specific issues can be remediated through the provision of 'better-than-average expectable' conditions (e.g., counseling, psychotherapy, or enriched milieux).

In the broadest view, Erikson proposes that there are crucial periods ('crises') of development characterizing the human life cycle, and societies have developed institutions that, more or less, furnish a matrix within which these developmental crises are resolved. Ideally, societal rewards and demands mesh with individual needs and abilities at each of these stages. Whereas Freud furnished a view of personality from the 'inside out,' looking to the individual's unconscious in order to understand cultural products, Erikson, while accepting the essential Freudian dynamic principles, added a perspective from the 'outside in,' beginning at the level of the whole individual and describing a particular culture's impact on human growth. Also, in contrast to Freud, Erikson saw ego growth as continuous throughout the life cycle—from infancy to old age. Erikson has been criticized from a number of quarters. Orthodox psychoanalytic theorists (e.g., Jones, Eissler) saw Erikson's emphasis on social factors and the ego in the development of personality as paying insufficient attention to the causative role of early childhood experiences and the primacy of unconscious factors in determining later adult personality. In short, they found him insufficiently 'Freudian.' Early feminist critics (e.g., Weisstein, Millett) took Erikson to task for his assumption of a unique developmental trajectory for women based upon their biological differences from men—in other words, too 'Freudian.' Later feminists (e.g., Gilligan) criticized him for paying insufficient attention to women's differences from men in terms of their capacities for care and relationship. Object relations theorists (e.g., Fairbairn, Winnicott) and self theorists (Kohut) felt that Erikson was somewhat superficial in underemphasizing the importance of early mother–child interactions and discussing too much the importance of social factors in personality development. By contrast, some historians and sociologists (e.g., Kushner, Weinstein, and Platt) have found Erikson's theory too little concerned with underlying causative social factors and questioned the universality of his eight-stage model. Social critics from the left (e.g., Fromm, Kovel) thought Erikson too conservative in his apparent acceptance of the social status quo. And, finally, social scientists (e.g., J. McV. Hunt) found Erikson's writing too imprecise to allow for empirical research. Erikson, himself, was critical of attempts to validate his theory with experimental methods, preferring more clinical and social approaches.

Erikson's primary contribution, emerging from the smoke of all the controversy noted above, has been a comprehensive overview of the human life cycle that incorporates somatic, psychological, and social elements. The influence of his psychosocial approach has been pervasive throughout ego psychoanalytic theory, developmental psychological research, and educational counseling, although there is no 'Eriksonian' school of psychotherapy. Almost every psychology textbook on personality theory and developmental psychology of children, adolescents, and adults has a section devoted to Erikson. Although his descriptions of early developmental stages usually are covered, it is the identity issue at adolescence with which he is most

closely associated, followed by his descriptions of adult life cycle stages. Even political theory, especially the 'politics of identity,' has been influenced by his approach. Erikson has amended Freudian theory to make it more understandable, 'experience-near,' growth-focused, researchable, and socially useful. Although criticized by classical Freudians, Erikson's extension of psychoanalytic theory into the realm of normal, and optimal, human development, may have saved that theory from its excessive interiority and obscurantism. In addition, because of its essentially interpersonal nature, Erikson's theory has provided a valuable link between drive-based classical and ego psychoanalytic theory and relationship-based object relations theory. From a social–political perspective, the psychosocial developmental outline proposed by Erikson is sufficiently clear and putatively universal that it can provide a guide for social programs that focus on establishing optimal conditions for human development across the life cycle. This becomes increasingly practicable in view of the research (see Kroger 2000) that is accumulating supporting the validity of measures of the Eriksonian stages of Industry, Identity, Intimacy, Generativity, and Integrity.

Errors in Statistical Assumptions, Effects of

Each statistical procedure rests upon a collection of assumptions for its validity. For example, many statistical procedures assume that a data set consists of a collection of independent observations. A large number of these same procedures also assume that the observations all have the same distribution. Each of these assumptions, as well as any others that a procedure assumes, may or may not be reasonable in a given application. If one or more of the assumptions justifying a procedure fail to hold, the statistical properties of the procedure may be different than they would be if the assumptions hold. This article discusses ways to assess the sensitivity of a statistical procedure to violations of its assumptions.

1. Introduction

The development of almost every statistical procedure is accompanied by a list of properties possessed by the procedure under some specified statistical assumptions. For example, the t-test is a uniformly most powerful unbiased level α test if one assumes that the data $X_1,\ldots, X_n$ comprise a sample of independent random variables with common normal distribution. Of course, one can perform a t-test with data $X_1,\ldots, X_n$ regardless of whether one makes some or all of the

International Encyclopedia of the Social & Behavioral Sciences ISBN: 0-08-043076-7

assumptions. One cannot expect the associated properties to hold, however, if one does not believe the assumptions. If one has reason to believe (or fear) that one or more of the assumptions used to justify a statistical procedure fail to hold, then one should be concerned with how sensitive the properties are to the assumptions. For example, suppose that the observations $X_1,\ldots, X_n$ have some distribution other than normal. How much does that affect the probability of type I error when I use the level α t-test? How much does it affect the power of the test at important alternatives? This entry will not attempt to answer all of the questions of this sort. Rather, this entry describes general ways to assess the sensitivity of statistical procedures to specific violations of their assumptions. An excellent discussion of the role of assumptions in statistical models was initiated by Box (1980).

Related to the question of sensitivity is the question of diagnosis. That is, can one tell whether or not the data suggest that certain assumptions are indeed violated? There are several statistical methods that have been developed to diagnose violations of assumptions of the linear regression model. Some of these are discussed in *Linear Hypothesis: Regression (Graphics)*.

For a given statistical procedure, one first needs to be aware of what assumptions justify the procedure. Then one needs to decide which aspects of the procedure and which assumptions the sensitivity of which one wishes to assess. One needs to decide which violations of those assumptions one is willing to contemplate and finally how one wishes to measure the sensitivity. Each of these issues is examined in a detailed study of one statistical procedure in Sect. 2.

Theoretical results concerning sensitivity can be difficult to derive, even for the most elementary types of violations. Hotelling (1961) and Efron (1969) analyze the effects of some specific types of violations on the distribution of the t statistic. Box (1953) discusses the effects of violations of assumptions on tests concerning variances.

2. *The t-test*

Since the t-test is such a popular statistical procedure, let us first consider violations of its assumptions. The assumptions for the validity of the t-test are that the data comprise a sample of independent random variables, all with the same normal distribution. Specifically, there are three key assumptions:

(a) the observations are independent;

(b) the observations all have the same distribution; and

(c) each observation has a normal distribution.

There are many ways in which these assumptions can be violated. For example, the observations might be dependent. (See *Time Series: General* for discussion of one type of model of dependence between observations.) The observations might have different distributions. Alternatively, some or all the observations might have distributions other than normal. Finally, it is possible that more than one assumption is violated. For example, each observation could have its own distribution, none of which is normal, and they could be dependent.

The most crucial properties of a test procedure are its size and power. These can be measured from the distribution of the test statistic given a set of assumptions about the data. For example, consider a test of the null hypothesis that the mean μ of a sample of random variables is 0. If one were interested in measuring the sensitivity to the assumption that the data are normal, and if one contemplates the possibility that a linear function $a(X-b)$ of each observation X has a Cauchy distribution, then one must reinterpret μ to be something other than the mean (e.g., the median, b). The power of the test can then be written as a function of $a\mu$.

2.1 *Theoretical Results*

Clearly, it is not reasonable to expect to find theoretical results that handle every possible departure from the assumptions. For some violations, it is possible to determine analytically how sensitive a procedure will be. For example, suppose that the observations $X_1,\ldots, X_n$ have normal distribution with mean μ and common variance σ^2, but that they have common correlation ρ. And suppose that one wishes to perform a t-test of the null hypothesis that the mean of the distribution is μ_0. The t statistic has the form

$$T = \frac{\bar{X}-\mu_0}{\sqrt{S^2/n}} \tag{1}$$

where $\bar{X}$ is the sample average and

$$S^2 = \frac{1}{n-1}\sum_{i=1}^{n}(X_i-\bar{X})^2 \tag{2}$$

Under the usual assumptions for the t-test, if $\mu = \mu_0$, then T has a t distribution with $n-1$ degrees of freedom. In the case of common correlation, it is possible to show that the random variable $U = T/\sqrt{1+n\rho/(1-\rho)}$ has t distribution with $n-1$ degrees of freedom. If ρ is greater than 0, the distribution of T will be more spread out than the nominal t distribution if $\mu = \mu_0$. This will have the effect of making the size of the t-test larger than its nominal value. For example, if $\rho = 0.05$ and $n = 10$ and one uses a test with nominal size 0.05; the actual size is 0.10. If the null hypothesis is false and $\mu \neq \mu_0$, then U has noncentral t distribution with $n-1$ degrees of freedom and noncentrality

parameter $\mu\sqrt{n/[1+(n-1)\rho]}$. The effect of this on the power of the test is not so obvious, but it is not as dramatic as the effect on the size.

For other violations, one can attempt to reason qualitatively what the effect will be. For example, suppose that the observations $X_1,\ldots, X_n$ come from a distribution with heavier tails than a normal distribution (i.e., observations far from the median occur with high probability). And suppose that one wishes to perform a t-test of the null hypothesis that the median of the distribution is μ_0. Some theoretical results concerning this case have been derived by Benjamini (1983). A heavy-tailed distribution will produce a value $\bar{X}$ with more variability than a normal distribution will. That is, we would expect to see large values of $|\bar{X}-\mu_0|$ with higher probability from a heavy-tailed distribution than from a normal distribution. But the effect of heavy tails on $\sqrt{S^2/n}$ should be even greater than the effect on $\bar{X}$ because the squaring gives the large deviations $X_i-\bar{X}$ much more prominence. Hence, one expects $|T|$ to be smaller if the data have a distribution with heavy tails than if the data have normal distribution. Not all violations lend themselves to qualitative analysis of this sort, however. And, as Benjamini (1983) points out, an intuitive analysis like this might only hold in special cases, as will be noted later in this article.

When one wishes to focus on a specific collection of possible violations, then one can perform simulations to assess both qualitative and quantitative sensitivity. Simulation has advantages and disadvantages when compared to theoretical analysis. A simulation can be designed to assess the sensitivity of any statistical procedure to any specific collection of violations of its assumptions. However, each simulation analysis assesses only the specific violations for which it was designed and does not tell us how sensitive the procedure is to other, albeit similar, violations. Of course, simulations are generally quick and easy to perform, so one could perform many of them to cover a large number of specific violations. The remainder of this section illustrates the sorts of simulations that one might perform in order to assess the sensitivity of various aspects of t-test to some of the more easily understood violations of assumptions.

2.2 *Violations of Normality*

Suppose that one thinks that the observations are normal with mean μ and variance σ^2, and that one wishes to test the null hypothesis that $\mu = 0$. Suppose that most interest lies in a test with level 0.05 and with the power of the test when $\mu = \sigma$. However, suppose that one is willing to contemplate the possibility that the data come from a distribution that is not normal. If that distribution does not have a mean or does not have a variance, then one will need to reinterpret μ and/or σ. For distributions without a mean, let μ stand for the median. For all distributions, let σ stand for 0.741 times the interquartile range (which happens to be the standard deviation when the data have a normal distribution). Now, one can simulate samples of size n from every distribution that one wishes to consider and compute the probability that $|T| > c$, where c is the 0.975 quantile of the t distribution with $n-1$ degrees of freedom. For distributions with mean (or median) 0, this probability will be the size of the test. For distributions with mean $\mu = \sigma$, this probability will be the power of interest. Table 1 reports the results of several simulations. Each row of the table represents two million simulated samples of size $n = 10$ or $n = 20$ from a distribution that is not normal. The simulated data from the t distribution have three degrees of freedom. The simulated data from the gamma distribution have parameter 2. The σ in the last column is 0.741 times the interquartile range. The 'Normal' rows give the theoretical values under the normal distribution assumption. For each sample the statistic T was computed. The table reports the estimated probability that $|T| > c$ for c equal to the 0.975 quantile of the t distribution with $n-1$ degrees of freedom.

Table 1
Simulated sizes and powers of the t-test under violations of normality

Distribution	Sample size (n)	Prob. of $\|T\| > c$	
		$\mu = 0$	$\mu = \sigma$
Laplace	10	0.042	0.593
	20	0.046	0.862
Cauchy	10	0.019	0.295
	20	0.020	0.325
t (3 degrees of freedom)	10	0.040	0.619
	20	0.043	0.848
Uniform	10	0.054	0.971
	20	0.052	1.0
Exponential	10	0.099	0.786
	20	0.081	0.997
Gamma (2)	10	0.077	0.838
	20	0.066	0.999
Normal	10	0.05	0.803
	20	0.05	0.989

A quick look at the rows of Table 1 corresponding to heavy-tailed distributions (Laplace, Cauchy, t) indicates what we argued earlier. That is, the probability of $|T| > c$ is smaller for these heavy-tailed distributions than for the normal. However, as is common with simulations, one must be careful not to generalize too far. If one had considered level 0.20 tests instead of level 0.05 tests, the results would have been slightly different. For example, with the Laplace distribution, the estimated level is slightly higher than 0.2 with samples of both sizes 10 and 20. This is consistent with the theoretical results of Benjamini (1983).

Table 2
Simulated sizes and powers of the t-test under violations of common distribution

Ratio of standard deviations	Sample size	Proportion with larger standard deviation	Prob. of $\|T\| > c$	
			$\mu = 0$	$\mu = \sigma$
2	10	0.1	0.047	0.809
	10	0.5	0.046	0.804
	20	0.1	0.048	0.984
	20	0.5	0.048	0.985
5	10	0.1	0.030	0.831
	10	0.5	0.037	0.800
	20	0.1	0.033	0.959
	20	0.5	0.046	0.982
10	10	0.1	0.017	0.829
	10	0.5	0.033	0.799
	20	0.1	0.015	0.948
	20	0.5	0.045	0.981
1	10	0	0.05	0.803
	20	0	0.05	0.989

2.3 Violations of Common Distribution

For the assumption that the observations have the same distribution, there are many possible violations. The data might split into two (or a few) groups, each of which has a common distribution. Alternatively, each observation could have its own distribution. Or there might be just one (or a few) observation(s) with distribution different from the others. All of these are possible even if one believes that each of the individual distributions has a normal distribution.

Table 2 gives the results of several simulations. As before, each simulation is based on two million simulated samples of size $n = 10$ or $n = 20$. Each sample consists of n normal random variables with a common mean μ but with either 10 percent or 50 percent having a larger standard deviation than the rest. The larger standard deviation is either 2, 5 or 10 times as large as the smaller one. The value of σ in the last column is

$$\sigma = \sqrt{(1-p)\sigma_1^2 + p\sigma_2^2} \tag{3}$$

where σ_1 is the smaller standard deviation, σ_2 is the larger standard deviation, and p is the proportion of the sample with the larger standard deviation. The 'Ratio = 1' rows give the theoretical values under the assumption that the data have a common normal distribution. The table reports the estimated probability that $|T| > c$ for c equal to the 0.975 quantile of the t distribution with $n-1$ degrees of freedom. Note how the size of the test can be significantly lowered by the inclusions of 10 percent of the observations with a standard deviation 5 or 10 times as large as the rest. The power of the test at $\mu = \sigma$ is not much affected by this type of violation. However, the value of σ/σ_1 increases as the ratio of the two standard deviations increases. If one had calculated the power at a fixed alternative, there would have been a dramatic decrease in power as the ratio of standard deviations increased and as the proportion with the larger standard deviation increased.

2.4 Violations of Independence

Violations of the independence assumption are a bit more difficult to think about. There are simple violations such as equal correlation that is not 0. Indeed, this case is the one that lent itself to an analytic solution earlier in this entry. Another type of violation of independence is time-series dependence. This means that the amount of dependence between observations depends on the order in which they were observed. Many data sets are collected without recording when the observations were made. This would make it impossible to perform a traditional time series analysis. However, we can still assess the effect of time series dependence on the distribution of a statistic like T, even if one did not record the observation times. For example, suppose that observations arrive in the order $X_1, \ldots, X_n$, regardless of whether or not one knows this to be true. One might consider the possibility that $X_i = \rho X_{i-1} + \varepsilon_i$ for $i = 2, \ldots, n$. Here $\rho \in [-1,1]$ and $\varepsilon_2, \ldots, \varepsilon_n$ are assumed to be mutually independent with variance $(1-\rho^2)$ Var (X_1). This type of dependence is called autoregressive of order 1. (For more detail on

Table 3
Simulated sizes and powers of the t-test under violations of independence

Sample size (n)	Correlation (ρ)	Prob. of $\lvert T\rvert > c$	
		$\mu = 0$	$\mu = \sigma$
10	0	0.05	0.803
	0.1	0.072	0.792
	0.3	0.138	0.773
	0.5	0.245	0.759
	0.7	0.412	0.761
	0.9	0.672	0.824
20	0	0.05	0.989
	0.1	0.074	0.982
	0.3	0.145	0.962
	0.5	0.256	0.928
	0.7	0.422	0.883
	0.9	0.688	0.864

autoregressive dependence, see *Time Series: ARIMA Methods*.)

Table 3 presents the results of several simulations. Each simulated sample has autoregressive dependence of order 1 with a different correlation. Each number in the table is based on 2,000,000 simulated samples. The rows with '$\rho = 0$' give the theoretical values under the assumption that the data are independent. The table reports the estimated probability that $|T| > c$ for c equal to the 0.975 quantile of the t distribution with $n-1$ degrees of freedom. Even correlation as small as 0.1 has a noticeable effect on the size of the test.

3. *Linear Regression*

The assumptions which justify the standard inferences in linear regression are a bit more complicated than those which justify the t-test. In turn, the types of violations of these assumptions are also more complicated. To be specific, consider simple linear regression. The data comprise a set of pairs $(Y_1, x_1),\ldots,(Y_n, x_n)$, and the numbers $x_1,\ldots,x_n$ are considered fixed, known constants. Alternatively, the remainder of the probabilistic statements are to be understood conditional on these values. The assumptions are that

(a) the random variables $Y_1,\ldots,Y_n$ are independent,
(b) every Y_i has a normal distribution,
(c) Var (Y_i) is the same for all i, and
(d) there exist numbers β_0 and β_1 such that $\mathrm{E}(Y_i) = \beta_0 + \beta_1 x_i$.

This section will briefly discuss violations of these assumptions, but not in as much detail as it did for the one-sample t-test. Failures of independence can come in the same forms that they did for the one-sample t-test. However, there are additional varieties available as well. For example, one might consider the possibility that there is correlation between Y_i and Y_j that depends on how far apart x_i and x_j are. Each Y_i can have a distribution that depends on x_i through more than just its mean and/or variance. Indeed, there are standard methods in regression analysis for diagnosing and dealing with cases in which it appears that Var (Y_i) depends on x_i. The dependence of $\mathrm{E}(Y_i)$ and x_i can be very general. It might seem reasonable in some problems to assume that $E(Y_i)$ is a monotone function of x_i, but not always. For more discussion of regression methodology, including diagnosing violations of assumptions, see *Linear Hypothesis: Regression (Basics)* and *Linear Hypothesis: Regression (Graphics)*.

4. *Sensitivity of Bayesian Procedures*

Bayesian procedures (see *Bayesian Statistics*), being statistical procedures, are also based upon probabilistic assumptions, and are thereby sensitive to violations of their assumptions. Typically, a Bayesian procedure is based on the same types of assumptions as any other procedure plus additional assumptions about the distributions of any parameters (such as μ and σ^2 in the t-test) that might appear in the statistical model. These latter assumptions are generally part of what is called the prior distribution of the parameters. Sensitivity of Bayesian procedures to violations of all of these assumptions can be assessed in a manner similar to what was done earlier in this article. However, those who use Bayesian procedures to represent subjective beliefs conditional on the observed data (see *Probability: Interpretations*) would be more interested in assessing sensitivity in a different manner.

For example, suppose that one wants an interval estimate of a parameter μ, and one models data $X_1,\ldots,X_n$ as independent normal random variables with mean μ and variance σ^2. One would also specify a prior distribution for (μ, σ^2). After observing the data values $X_1 = x_1,\ldots,X_n = x_n$, one would then compute the appropriate interval estimate $[a,b]$. Then one could ask what interval would have been computed if one had modeled the data as having a different distribution. For example, suppose $(X_i - \mu)/(0.6745\sigma)$ are modeled as independent with Cauchy distribution. (The factor of 0.6745 makes the interquartile range of X_i the same as it would have been if the data were normal, namely 1.349σ.) Under this Cauchy assumption, a different interval $[a',b']$ would be computed using the same observed data values $x_1,\ldots,x_n$. The change from the interval $[a,b]$ to the interval $[a',b']$ measures the sensitivity of the process of forming an interval estimate to this change of the assumption about the distribution of the data. This type of sensitivity of the process of forming an inference differs somewhat from the type of sensitivity of a particular procedure that was described earlier. Sensitivity of process is not a uniquely Bayesian concern,

however, and it can also be measured for changes to assumptions in non-Bayesian inference.

There have been some successful attempts to take considerations of sensitivity to assumptions into account explicitly in the formulation of Bayesian models. Model uncertainty (see Draper 1995) and Bayesian model averaging (Hoeting et al. 1999) attempt to develop methodology for expressing directly in the modeling process the belief that more than one out of several competing statistical models might be appropriate for the data, and it may not be clear which one is best. For example, one might not be able to decide whether to model data as normal random variables or as Cauchy random variables. The methods of model uncertainty and model averaging provide ways to pursue both models (as well as others that might seem plausible) without having to pretend as if we really believed firmly in precisely one of them.

Finally, there have been some methods developed to deal with specific common violations of assumptions. The assumption that all observations in a sample have the same distribution has received attention particularly in order to be able to accommodate the occasional outlying observation. One can model data as coming from a mixture of two or more distributions. One of the distributions is the main component on which most interest is focussed. The others represent the types of data that might arise when something goes wrong with the data collection procedure. Each observation can be modeled as coming from one of the component distributions with a probability associated with each component. Indeed, using powerful simulation methods (see *Markov Chain Monte Carlo Methods*) one can even compute, for each observation, the conditional probability that it arose from each of the components given the observed data.

5. *Conclusion*

This article has discussed the need for carefully acknowledging the probabilistic assumptions made to justify a statistical procedure and some methods for assessing the sensitivity of the procedure to those assumptions. If one believes that there are violations of the assumptions that might reasonably arise in practice, and if the procedure is overly sensitive to violations of those assumptions, one might wish to select an alternative procedure.

There are two popular approaches to choosing alternatives to standard statistical procedures when one fears that assumptions are likely to be violated. One is to use robust procedures, and the other is to use nonparametric procedures. Robust procedures are designed to be less sensitive to violations of specific assumptions without sacrificing too much of the good performance of standard procedures when the standard assumptions hold. Nonparametric procedures are chosen so that their properties can be verified under fewer assumptions. For more details on these types of procedures see *Robustness in Statistics* and *Nonparametric Statistics: The Field*.

Estimation: Point and Interval

Introduction

When sampling is from a population described by a density or mass function $f(x \mid \theta)$, knowledge of θ yields knowledge of the entire population. Hence, it is natural to seek a method of finding a good estimator of the point θ, that is, a good point estimator. However, a point estimator alone is not enough for a complete inference, as a measure of uncertainty is also needed. For that, we use a set estimator in which the inference is the statement that $\theta \in C$ where $C \subset \Theta$ and $C = C(\mathbf{x})$ is a set determined by the value of the data $\mathbf{X} = \mathbf{x}$ observed. If θ is real-valued, then we usually prefer the set estimate C to be an interval. Our uncertainty is quantified by the size of the interval and its probability of covering the parameter.

1. *Point Estimators*

In many cases, there will be an obvious or natural candidate for a point estimator of a particular parameter. For example, the sample mean is a natural candidate for a point estimator of the population

International Encyclopedia of the Social & Behavioral Sciences ISBN: 0-08-043076-7

mean. However, when we leave a simple case like this, intuition may desert us so it is useful to have some techniques that will at least give us some reasonable candidates for consideration. Those that have stood the test of time include:

1.1 The Method of Moments

The method of moments (MOM) is, perhaps, the oldest method of finding point estimators, dating back at least to Karl Pearson in the late 1800s. One of the strengths of MOM estimators is that they are usually simple to use and almost always yield some sort of estimate. In many cases, unfortunately, this method yields estimators that may be improved upon.

Let $X_1,\ldots, X_n$ be a sample from a population with density or mass function $f(x|\theta_1,\ldots, \theta_k)$. MOM estimators are found by equating the first k sample moments to the corresponding k population moments. That is, we define the sample moments by $m_j = \Sigma_{i=1}^n X_i^j/n$ and the population moments by $\mu_j(\theta_1,\ldots, \theta_k) = \mathrm{E}X^j$ for $j = 1,\ldots, k$. We then set $m_j = \mu_j(\theta_1,\ldots, \theta_k)$ and solve for $\theta_1,\ldots, \theta_k$. This solution is the MOM estimator of $\theta_1,\ldots, \theta_k$.

1.2 Maximum Likelihood Estimators

For a sample $X_1,\ldots, X_n$ from $f(x\,|\,\theta_1,\ldots, \theta_k)$, the likelihood function is defined by

$$\begin{aligned} L(\theta\,|\,\mathbf{x}) &= L(\theta_1,\ldots, \theta_k\,|\,x_1,\ldots, x_n) \\ &= \Pi_{i=1}^n f(x_i\,|\,\theta_1,\ldots, \theta_k) \end{aligned} \tag{1}$$

The values of θ_i that maximize this function are those parameter values for which the observed sample is most likely, and are called the maximum likelihood estimators (MLE). If the likelihood function is differentiable (in θ_i), the MLEs can often be found by solving

$$\frac{\partial}{\partial\theta_i}\log L(\theta\,|\,\mathbf{x}) = 0, \quad i = 1,\ldots, k \tag{2}$$

where the vector with coordinates $\frac{\partial}{\partial\theta_i}\log L(\theta\,|\,\mathbf{x})$ is called the score function (see Schervish 1995, Sect. 2.3).

Example If $X_1,\ldots, X_n$ are i.i.d. Bernoulli (p), the likelihood function is

$$L(p\,|\,\mathbf{x}) = \prod_{i=1}^n p^{x_i}(1-p)^{1-x_i} \tag{3}$$

and differentiating log $L(p\,|\,\mathbf{x})$ and setting the result equal to zero gives the MLE $\hat{p} = \Sigma_i x_i/n$. This is also the method of moments estimator.

If we instead have samples $X_1,\ldots, X_n$ from a binomial (k, p) population where p is known and k is unknown, the likelihood function is

$$L(k\,|\,\mathbf{x}, p) = \prod_{i=1}^n \binom{k}{x_i} p^{x_i}(1-p)^{k-x_i} \tag{4}$$

and the MLE must be found by the numerical maximization. The method of moments will give the closed form solution.

$$\hat{k} = \frac{\bar{x}^2}{\bar{x}-(1/n)\Sigma_i(x_i-\bar{x})^2} \tag{5}$$

which can take on negative values. This illustrates a shortcoming of the method of moments, one not shared by the MLE. Another, perhaps more serious shortcoming of the MOM estimator is that it may not be based on a sufficient statistic (see *Statistical Sufficiency*), which means it could be inefficient in not using all of the available information in a sample. In contrast, both MLEs and Bayes estimators (see *Bayesian Statistics*) are based on sufficient statistics.

1.3 Bayes Estimators

In the Bayesian paradigm a random sample $X_1,\ldots, X_n$ is drawn from a population indexed by θ, where θ is considered to be a quantity whose variation can be described by a probability distribution (called the *prior distribution*). A sample is then taken from a population indexed by θ and the prior distribution is updated with this sample information. The updated prior is called the *posterior distribution*.

If we denote the prior distribution, by $\pi(\theta)$, and the sampling distribution by $f(\mathbf{x}\,|\,\theta)$, then the posterior distribution, the conditional distribution of θ given the sample, $\mathbf{x}$, is

$$\pi(\theta\,|\,\mathbf{x}) = f(\mathbf{x}\,|\,\theta)\pi(\theta)/m(\mathbf{x}) \tag{6}$$

where $m(\mathbf{x}) = \int f(\mathbf{x}\,|\,\theta)\pi(\theta)\,\mathrm{d}\theta$ is the marginal distribution of $\mathbf{x}$.

Example Let $X_1,\ldots, X_n$ be i.i.d. Bernoulli (p). Then $Y = \Sigma_i X_i$ is binomial (n, p). If p has a Beta (α, β) prior distribution, that is,

$$\pi(p) = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} p^{\alpha-1}(1-p)^{\beta-1} \tag{7}$$

the posterior distribution of p given y, is

$$\begin{aligned} f(p\,|\,y) &= \frac{f(y, p)}{f(y)} \\ &= \frac{\Gamma(n+\alpha+\beta)}{\Gamma(y+\alpha)\Gamma(n-y+\beta)} p^{y+\alpha-1}(1-p)^{n-y+\beta-1} \end{aligned} \tag{8}$$

which is a beta distribution with parameters $y+\alpha$ and $n-y+\beta$. The posterior mean, a Bayes estimator of p, is

$$\hat{p}_{\mathrm{B}} = \frac{y+\alpha}{\alpha+\beta+n} \tag{9}$$

2. Evaluating Point Estimators

There are many methods of deriving point estimators (robust methods, least squares, estimating equations, invariance) but the three in Sect. 1 are among the most popular. No matter what method is used to derive a point estimator, it is important to evaluate the estimator using some performance criterion.

One way of evaluating the performance of a point estimator W of a parameter θ is through its mean squared error (MSE), defined by $\mathrm{E}_\theta(W-\theta)^2$.

MSE measures the average squared difference between the estimator W and the parameter θ. Although any increasing function of the absolute distance $|W-\theta|$ would serve, there is a nice factorization

$$\begin{aligned}\mathrm{E}_\theta(W-\theta)^2 &= \mathrm{Var}_\theta W + (\mathrm{E}_\theta W-\theta)^2 \\ &= \mathrm{Var}_\theta W + (\mathrm{Bias}_\theta W)^2\end{aligned} \tag{10}$$

where we define the bias of a point estimator as $\mathrm{Bias}_\theta W = \mathrm{E}_\theta W-\theta$. An estimator whose bias is identically (in θ) equal to zero is called *unbiased*.

For an unbiased estimator we have $\mathrm{E}_\theta(W-\theta)^2 = \mathrm{Var}_\theta W$, and so, if an estimator is unbiased, its MSE is equal to its variance. If $X_1,\ldots, X_n$ are i.i.d. from a population with mean μ and variance σ^2, the sample mean is an unbiased estimator since $\mathrm{E}\bar{X} = \mu$, and has MSE

$$\mathrm{E}(\bar{X}-\mu)^2 = \mathrm{Var}\bar{X} = \frac{\sigma^2}{n} \tag{11}$$

Controlling bias does not guarantee that MSE is minimized. In particular, it is sometimes the case that a trade-off occurs between variance and bias. For example, in sampling from a normal population with variance σ^2, the usual unbiased estimator of the variance $S^2 = \frac{1}{n-1}\Sigma_{i=1}^n(X_i-\bar{X})^2$ has MSE $= 2\sigma^4/(n-1)$. An alternative estimator for σ^2 is the maximum likelihood estimator $\hat{\sigma}^2 = \frac{1}{n}\sum_{i=1}^n(X_i-\bar{X})^2 = \frac{n-1}{n}S^2$. This is a biased estimator of σ^2 with MSE

$$\begin{aligned}\mathrm{E}(\hat{\sigma}^2-\sigma^2)^2 &= \left(\frac{2n-1}{n^2}\right)\sigma^4 < \left(\frac{2}{n-1}\right)\sigma^4 \\ &= \mathrm{E}(S^2-\sigma^2)^2\end{aligned} \tag{12}$$

showing that $\hat{\sigma}^2$ has smaller MSE than S^2. Thus, by trading off variance for bias, the MSE is improved.

Measuring performance by the squared difference between the estimator and a parameter is a special case of a function called a *loss function*. The study of the performance, and the optimality, of estimators evaluated through loss functions is a branch of decision theory. In addition to MSE, based on squared error loss, another popular loss function is absolute error loss, $L(\theta, W) = |W-\theta|$. Both of these loss functions increase as the distance between θ and W increases, with minimum value $L(\theta, \theta) = 0$. That is, the loss is minimum if the estimator is correct.

In a decision theoretic analysis, the worth of an estimator is quantified in its risk function, that is, for an estimator W of θ, the risk function is $R(\theta, W) = \mathrm{E}_\theta L(\theta, W)$, so the risk function is the average loss. If the loss is squared error, the risk function is the MSE.

Using squared error loss, the risk function (MSE) of the binomial Bayes estimator of p is

$$\begin{aligned}\mathrm{E}_p(\hat{p}_{\mathrm{B}}-p)^2 &= \mathrm{Var}_p\hat{p}_{\mathrm{B}} + (\mathrm{Bias}_p\hat{p}_B)^2 \\ &= \frac{np(1-p)}{(\alpha+\beta+n)^2} + \left(\frac{np+\alpha}{\alpha+\beta+n}-p\right)^2\end{aligned} \tag{13}$$

In the absence of good prior information about p, we might try to choose α and β to make the risk function of $\hat{p}_{\mathrm{B}}$ constant (called an *equalizer* rule). The solution is to choose $\alpha = \beta = \sqrt{\mathrm{n}/4}$, yielding

$$\mathrm{E}(\hat{p}_{\mathrm{B}}-p)^2 = \frac{n}{4(n+\sqrt{\mathrm{n}})^2}$$

We can also use a Bayesian approach to the problem of loss function optimality, where we would use the prior distribution to compute an average risk $\int_\Theta R(\theta, W)\pi(\theta)\mathrm{d}\theta$, known as the *Bayes risk*. We then find the estimator that yields the smallest value of the Bayes risk. Such an estimator is called the Bayes rule with respect to a prior π.

To find the Bayes decision rule for a given prior π we write the Bayes risk as

$$\begin{aligned}&\int_\Theta R(\theta, W)\,\pi(\theta)\,\mathrm{d}\theta \\ &\quad = \int_\chi\left[\int_\Theta L(\theta, W(\mathbf{x}))\,\pi(\theta\,|\,\mathbf{x})\,\mathrm{d}\theta\right]m(\mathbf{x})\,\mathrm{d}\mathbf{x}\end{aligned} \tag{14}$$

where the quantity in square brackets is the expected value of the loss function with respect to the posterior distribution, called the *posterior expected loss*. It is a function only of $\mathbf{x}$, and not a function of θ. Thus, for each $\mathbf{x}$, if we choose the estimate $W(\mathbf{x})$ to minimize the posterior expected loss, we will minimize the Bayes risk.

For squared error loss, the posterior expected loss is minimized by the mean of the posterior distribution. For absolute error loss, the posterior expected loss is minimized by the median of the posterior distribution. If we have a sample $X_1,\ldots, X_n$ from a normal distribution with mean θ and variance σ^2, and the prior is $n(\mu, \tau^2)$, the posterior mean is

$$E(\theta \mid \bar{x}) = \frac{\tau^2}{\tau^2+(\sigma^2/n)}\bar{x}+\frac{\sigma^2/n}{\tau^2+(\sigma^2/n)}\mu \qquad (15)$$

Since the posterior distribution is normal, it is symmetric and the posterior mean is the Bayes rule for both squared error and absolute error loss. The posterior mean in our binomial/beta example, $\hat{p}_B = \frac{y+\alpha}{\alpha+\beta+n}$, is the Bayes estimator against squared error loss.

We can loosely group evaluation criteria into large sample or asymptotic methods, and small sample methods. Our calculations using MSE and risk functions illustrate small sample methods. In large samples, MLEs typically perform very well, being asymptotically normal and efficient, that is, attaining the smallest possible variance. Other types of estimators that are derived in a similar manner (for example, M-estimators—see *Robustness in Statistics*) also share good asymptotic properties. For a detailed discussion see Casella and Berger (2001), Lehmann (1998), Stuart et al. (1999) or Lehmann and Casella (1998, Chap. 6).

3 Interval Estimation

Reporting a point estimator of a parameter θ only provides part of the story. The story becomes more complete if an assessment of the error of estimation is also reported. Informally, this can be accomplished by giving an estimated standard error of the estimator and, more formally, this becomes the reporting of an interval estimate. If $\mathbf{X} = \mathbf{x}$ is observed, an *interval estimate* of a parameter θ is a pair of functions, $L(\mathbf{x})$ and $U(\mathbf{x})$ for which the inference $\theta \in [L(\mathbf{x}), U(\mathbf{x})]$ is made. The *coverage probability* of the random interval $[L(\mathbf{X}), U(\mathbf{X})]$ is the probability that $[L(\mathbf{X}), U(\mathbf{X})]$ covers the true parameter, θ, and is denoted by $P_\theta(\theta \in [L(\mathbf{X}), U(\mathbf{X})])$.

By definition, the coverage probability depends on the unknown θ, so it cannot be reported. What is typically reported is the confidence coefficient, the infimum of the coverage probabilities, $\inf_\theta P_\theta(\theta \in [L(\mathbf{X}), U(\mathbf{X})])$.

If $X_1,\ldots, X_n$ are i.i.d. with mean μ and variance σ^2, a common interval estimator for μ is

$$\mu \in \bar{x} \pm 2\frac{s}{\sqrt{n}} \qquad (16)$$

where $\bar{x}$ is the sample mean and s is the sample standard deviation. The validity of this interval can be justified from the Central Limit Theorem, because

$$\frac{\bar{X}-\mu}{S/\sqrt{n}} \to n(0, 1) \qquad (17)$$

the standard normal distribution. We then see that the coverage probability (and confidence coefficient) of Eqn. 16 is approximately 95 percent.

The above interval is a large sample interval since its justification is based on an asymptotic argument. There are many methods for constructing interval estimators that are valid in small samples, including these.

3.1 Inverting a Test Statistic

There is a correspondence between acceptance regions of tests (see *Hypothesis Testing in Statistics*) and confidence sets, summarized in the following theorem.

Theorem *For each $\theta_0 \in \Theta$, let $A(\theta_0)$ be the acceptance region of a level α test of H_0: $\theta = \theta_0$. For each $\mathbf{x} \in \chi$,* define a set $C(\mathbf{x})$ *in the parameter space by*

$$C(\mathbf{x}) = \{\theta_0 \colon \mathbf{x} \in A(\theta_0)\} \qquad (18)$$

Then the random set $C(\mathbf{X})$ is a $1-\alpha$ confidence set. Conversely, let $C(\mathbf{X})$ be a $1-\alpha$ confidence set. For any $\theta_0 \in \Theta$, define

$$A(\theta_0) = \{x \colon \theta_0 \in C(\mathbf{x})\} \qquad (19)$$

Then $A(\theta_0)$ is the acceptance region of a level α test of H_0: $\theta = \theta_0$.

Example If $X_1,\ldots, X_n$ are i.i.d. $n(\mu, \sigma^2)$, with σ^2 known, the test of H_0: $\mu = \mu_0$ vs. H_1: $\mu \neq \mu_0$ will accept the null hypothesis at level α if

$$\bar{x} - z_{\alpha/2}\frac{\sigma}{\sqrt{n}} \leqslant \mu_0 \leqslant \bar{x} + z_{\alpha/2}\frac{\sigma}{\sqrt{n}} \qquad (20)$$

The interval of μ values, $[\bar{x} - z_{\alpha/2}\sigma/\sqrt{n}, \bar{x} + z_{\alpha/2}\sigma\sqrt{n}]$, for which the null hypothesis will be accepted at level α, is a $1-\alpha$ confidence interval for μ.

3.2 Pivotal Inference

Perhaps one of the most elegant methods of constructing set estimators is the use of pivotal quantities (Barnard 1949). A random variable $Q(\mathbf{X}, \theta) = Q(X_1,\ldots, X_n, \theta)$, is a *pivotal quantity* (or pivot) if the distribution of $Q(\mathbf{X}, \theta)$ is independent of all parameters. If we find a set C such that $P(Q(\mathbf{X}, \theta) \in C) =$

$1-\alpha$, then the set $\{\theta: Q(\mathbf{X}, \theta) \in C\}$ has coverage probability $1-\alpha$.

In location and scale cases, once we calculate the sample mean $\bar{X}$ and the sample standard deviation S, we can construct the following pivots:

Form of pdf	Type of pdf	Pivotal quantity
$f(x-\mu)$	location	$\bar{X}-\mu$
$\frac{1}{\sigma} f\left(\frac{x}{\sigma}\right)$	scale	$\frac{\bar{X}}{\sigma}$
$\frac{1}{\sigma} f\left(\frac{x-\mu}{\sigma}\right)$	location-scale	$\frac{\bar{X}-\mu}{S}$

(21)

In general, differences are pivotal for location problems, while ratios (or products) are pivotal for scale problems. See also *Fiducial and Structural Statistical Inference*.

Example Suppose that $X_1, \ldots, X_n$ are i.i.d. exponential (λ). Then $T = \sum_i X_i$ is a sufficient statistic for λ and $T \sim$ gamma (n, λ). In the gamma pdf, t and λ appear together as t/λ and, in fact the gamma (n, λ) pdf $(\Gamma(n)\lambda^n)^{-1} t^{n-1} e^{-t/\lambda}$ is a scale family. Thus, if $Q(T, \lambda) = 2T/\lambda$, then

$$Q(T, \lambda) \sim \text{gamma}(n, \lambda(2/\lambda)) = \text{gamma}\,(n, 2)$$

which does not depend on λ. The quantity $Q(T, \lambda) = 2T/\lambda$ is a pivot with a gamma $(n, 2)$, or χ^2_{2n}, distribution, and a $1-\alpha$ pivotal interval is

$$\frac{2T}{\chi^2_{2n,\,\alpha/2}} \leqslant \lambda \leqslant \frac{2T}{\chi^2_{2n,\,1-\alpha/2}}$$

where $P(\chi^2_{2n} > \chi^2_{2n,\,a}) = a$.

3.3 Bayesian Intervals

If $\pi(\theta \mid \mathbf{x})$ is the posterior distribution of θ given $\mathbf{X} = \mathbf{x}$, then for any set $A \subset \Theta$ the posterior probability of A is

$$P(\theta \in A \mid \mathbf{x}) = \int_A \pi(\theta \mid \mathbf{x})\, \mathrm{d}\theta$$

If $A = A(\mathbf{x})$ is chosen so that this posterior probability is $1-\alpha$, then A is called a $1-\alpha$ *credible set* for θ. If $\pi(\theta \mid \mathbf{x})$ corresponds to a discrete distribution, we replace integrals with sums in the above expressions.

The interpretation of the Bayes interval estimator is different from the classical intervals. In the classical approach, to assert 95 percent coverage is to assert that in 95 percent of repeated experiments, the realized intervals will cover the true parameter. In the Bayesian approach, a 95 percent coverage means that the probability is 95 percent that the parameter is in the realized interval. In the classical approach the randomness comes from the repetition of experiments, while in the Bayesian approach the randomness comes from uncertainty about the value of the parameter (summarized in the prior distribution).

Example Let $X_1, \ldots, X_n$ be i.i.d. Poisson (λ) and assume that λ has a gamma prior, $\lambda \sim$ gamma (a, b), where a is an integer. The posterior distribution of λ is

$$\pi(\lambda \mid \textstyle\sum_i X_i = \sum_i x_i) = \text{gamma}(a + \sum_i x_i, [n + (1/b)]^{-1}) \tag{22}$$

Thus the posterior distribution of $2[n+(1/b)]\lambda$ is $\chi^2_{2(a+\Sigma x)}$, and a $1-\alpha$ Bayes credible interval for λ is

$$\left\{\lambda: \frac{\chi^2_{2(a+\Sigma x),\,1-\alpha/2}}{2[n+(1/b)]} \leqslant \lambda \leqslant \frac{\chi^2_{2(a+\Sigma x),\,\alpha/2}}{2[n+(1/b)]}\right\} \tag{23}$$

We can also form a Bayes credible set by taking the highest posterior density (HPD) region of the parameter space, by choosing c so that

$$1-\alpha = \int_{\{\lambda: \pi(\lambda \mid \Sigma x) \geqslant c\}} \pi(\lambda \mid \Sigma_i x_i)\, \mathrm{d}\lambda \tag{24}$$

Such a construction is optimal in the sense of giving the shortest interval for a given $1-\alpha$ (although if the posterior is multimodal the set may not be an interval).

4. Other Intervals

We have presented two-sided parametric intervals that are constructed to cover a parameter. Other types of intervals include (*a*) one-sided intervals, (*b*) distribution-free intervals, (*c*) prediction intervals, (*d*) tolerance intervals.

One-sided intervals are those in which only one endpoint is estimated, such as $\theta \in [L(\mathbf{X}), \infty)$. Distribution-free intervals are intervals whose probability guarantee holds with little (or no) assumption on the underlying distribution. The other two interval definitions, together with the usual confidence interval, provide us with a hierarchy of inferences, each more stringent than the previous.

If $X_1, \ldots, X_n$ are i.i.d. from a population with cdf $F(x \mid \theta)$, and $C(\mathbf{x}) = [L(\mathbf{x}), U(\mathbf{x})]$ is an interval, for a specified value $1-\alpha$ it is a:

(a) *confidence interval* if, for all θ, $P_\theta[L(\mathbf{X}) \leqslant \theta \leqslant U(\mathbf{X})] \geqslant 1-\alpha$;

(b) *prediction interval* if, for all θ, $P_\theta[L(\mathbf{X}) \leqslant X_{n+1} \leqslant U(\mathbf{X})] \geqslant 1-\alpha$;

(c) *tolerance interval* if, for all θ and for a specified value p, $P_\theta([F(U(\mathbf{X})\,|\,\theta) - F(L(\mathbf{X})\,|\,\theta) \geqslant p] \geqslant 1-\alpha$.

So a confidence interval covers a mean, a prediction interval covers a new random variable, and a tolerance interval covers a proportion of the population. Thus, each gives a different inference, with the appropriate one being dictated by the problem at hand. Vardeman (1992) argues that these 'other intervals' provide an inference that is different from that of a confidence interval and are as important as confidence intervals.

5. *Conclusions*

Point estimation is one of the cornerstones of statistical analysis, and the basic element on which many inferences are based. Inferences using point estimators gain statistical validity when they are accompanied by an interval estimate, providing an assessment of the uncertainty. We have mainly discussed parametric point and interval estimation, where we assume that the underlying model is correct. Such an assumption can be questioned, and considerations of nonparametric or robust alternatives can address this (see *Robustness in Statistics*). For more on these subjects see, for example, Hettmansberger and McKean (1998) or Staudte and Sheather (1990). Full treatments of parametric point and interval estimation can be found in Casella and Berger (2001), Stuart et al. (1999), or Schervish (1995).

Ethical Behavior, Evolution of

The distinction between good or bad and what we ought or ought not do constitutes the subject matter of ethics. Early students of the evolution of ethical behavior (EEB) and some sociobiologists attempted to direct the study of EEB into the domain of prescriptive ethics. Twenty-first century sociobiologists are not concerned with the nature of vice, virtue, or the rules of moral behavior, but with the question of the biological origin of ethical behavior. To disregard the distinction between the questions of ethics and the questions of the evolutionary causes and the bases of human ethical behavior is to misunderstand the discipline of EEB, which is not a branch of philosophy or of ethics, but a subdiscipline of sociobiology. No prescriptive code can be derived from the theory of evolution; therefore, the previously used term 'evolutionary ethics' is a misnomer that must be dropped from sociobiological usage. An excellent philosophical examination (Flew 1967) and a superior historical analysis (Richards 1987) on EEB are available.

The ideas on EEB will be exemplified by a review of arguments, first, of the originators of EEB; second, of ecologists, ethologists, geneticists, linguists, neurophysiologists, and cognitive scientists; and third, of sociobiologists and their supporters and opponents.

1. *The Originators of the Idea*

Charles Darwin, in *On the Origin of Species* (1859), established the homology between human and nonhuman primate morphology, but not between human and nonhuman behavior. In his revised edition of *The Descent of Man* (1885), he recognized that the moral sense or conscience differentiates humans from the other animals, and that 'The imperious word *ought* seems merely to imply the consciousness of the existence of a rule of conduct, however it may have originated.' He believed that the understanding of the EEB would be enlarged by studies of nonhuman behavior, and that nonhuman animals possessing parental and filial instinct would exhibit a kind of rudimentary intellectual and moral sense. He supported this by arguing that, first, social instincts lead animals to social groups and to perform 'social services'; second, as the mental faculties develop, images and feelings endure and are subject to recall; third, development of language facilitates communication; and last, acquisition of habits helps to guide the conduct of individuals within the community.

Humans, to Darwin, are social animals who have lost some early instincts but retain the protohuman instinctive love and sympathy for others. Some instincts are subject to group selection; the altruistic social behaviors of early humans were not for the good

of species or individuals, but for the welfare of the group. Humans ought to obey the instincts acquired and prescribed by the rule of conduct within society. These Darwinian views have been accepted, except that a small number of biologists finds the theory of group selection (that is, a natural selection operating on more than one member of a lineage group, in which the selection is beneficial for the group rather than for the individual) inadequate to explain altruism (behavior that increases the fitness of the other at cost to self).

There are three Darwinian contributions to EEB. First, the acceptance of morphology as a product of evolution repudiated creationism and thus, the divine source of morality, and at the same time implied that human behavior is also evolutionarily derived. Second, the rejection by Darwin of what John Dewey called 'the holy arc of permanence' meant that all human behavior, including ethics, evolved, is evolving, and will evolve. Third, EEB is concerned with the origin of ethical behavior, and not with the prescriptions of ethics.

Spencer asserted that ethical behavior began in nonhuman social animals, was developed by—and conforms to—the law of evolution, and reached its full expansion in cultural evolution. He argued that cooperation is beneficial to social units, is a cause of physiological and sociological divisions of labor, and it profits all members in a society, but only when social bargains are respected. Cooperation arose at the dawn of life when altruism was dependent on egoism, and egoism was dependent on altruism. Offspring are preserved and species maintained by altruistic acts. To Spencer, evolution was thus a progressive moral force operating within human society and leading to the ethical improvement of humankind.

Spencer replaced the Darwinian natural selection with the 'survival of the fittest,' and developed his concepts in economic terms that led to Social Darwinism. It is now realized that the nurturing of offspring in human and nonhuman families can only be explained in terms of the Spencerian concept of cooperation, which thus appears to be evolutionary. In social groups there must be selective pressure to encourage altruism and to discourage selfishness. By definition social life is altruistic. Spencer's ideas on cooperation were more fully developed by Kropotkin (1902).

T. H. Huxley (1894, reprinted in Nitecki and Nitecki 1993) supposed that protohuman morphology, human society, intellect, and morality are parts of nature, but that human behavior—unlike behavior in other animals—is not innate; therefore, there is a chasm between humans and other animals. Human character, by which he meant the moral and intellectual essence, is passed from generation to generation. He accepted the pessimistic view of human life as a continuous and uneven struggle against the cosmos, and assumed that competition is the exclusive element of the living world. Perhaps Huxley overstressed competition and selfishness as a natural instinct, and underrated cooperation and altruism as evolutionary factors. His panoramic view of life replaced the old body/soul dichotomy with the nature/culture dichotomy.

Although Huxley objected to Social Darwinism as expressed in the Spencerian 'survival of the fittest,' he nevertheless accepted the seventeenth-century perspective of natural selection as a 'struggle for existence.' It was this eternal struggle between humans and cosmos that colored his view of nature, and blinded him to the role of cooperation in evolution.

2. *The Unintended Developers of the Idea*

The conclusions of early psychological behaviorists were that behavior, with the exception of physiological actions, is purely a cultural phenomenon. Learning was also cultural. However, ecologists (Allee et al. 1949) and ethologists (Tinbergen 1951) established that behavior and learning are processes of the central nervous system, and are products of genetics *and* of social interactions. Thus behavior may be both innate and acquired. Animal social interactions are occasionally in a one-to-one relationship (cause and effect), but transmission from the stimulus to the response is mostly through a complex of neurological channels. Behavior is so complex that it does not allow itself to be controlled by a single gene.

The environment *and* the chemical releasers of animals control and influence behavior by acting upon endocrine glands and upon sense organs. If the cooperative human and nonhuman groups are units of selection, then survival is of *greater* importance to the group as a whole than to the individual.

Ecologists documented that mutualism occurs not only between organelles within cells and among individual organisms, but also in groups and even in kingdoms of organisms: herbivores cooperate with symbiotic algae, bacteria fix nitrogen within leguminous plants, and fungi with algae form lichens. Ecologists postulated that instincts are inborn nervous mechanisms that may be activated, and that instinct contributes to the fitness of both individuals and groups. Animals are social only when acting within the group of the same species.

In the reverse of anthropomorphism, ethologists applied the concepts derived from the studies of nonhuman behavior to humans, and established that both human and nonhuman physiology and behavior are constantly modified, changed, and influenced by the presence of other individuals. Without the presence of another individual, the terms 'good' or 'bad' behavior have no meaning.

Ethologists stressed the role of genes in human behavior, the role of information encoded in the genome, and also the role of development in forming the behavioral patterns. They argued that human nature is neither inherently good or bad, but is both, and therefore 'natural' cannot be equated with 'good' or 'bad.'

The geneticist Muller (1959) reasoned that altruistic acts foster the multiplication of altruistic genes, and that cooperation (or mutual aid) is a genetic factor of great value for the worldwide social organization. He agreed with Darwin that the protohuman group was the primary unit of selection in which altruism developed, but for altruism to become fixed in humans the group must remain isolated. Not only our morphology and our DNA, but also our behavior evolved.

Linguistic studies (Pinker 1997) proved that language capacity is already present in newly born humans. Ecologists had already pointed out that human behavior, including language, requires at least two individuals. Linguists added that this presence is necessary for language to develop. Therefore, the capacity for language is genetic, but it must be socially primed to be activated. Since human infants can do simple additions before they can talk, linguists reasoned that even arithmetic has an evolutionary basis. However, to many researchers the structural features of human language differentiate it from nonhuman communications. Others believed that the difference is of degree only.

Neurophysiological and cognitive studies recognized that all mental activities, including consciousness, are products of the physiological functions of the material brain. Mental activities are programmed by instinct and are controlled in recognized locations in the brain. Consciousness is innate in humans. These investigations shifted the argument from dualism to materialism. It is self-evident that the very long human infancy requires cooperation of parents and society. Infants recognize and learn altruism and love of mother, and how to reciprocate.

It follows, from the ecological to cognitive researches, that nonhuman and much human behavior have evolutionary bases. Biologists now agree that, at least in some nonhuman animals, complex behavior has more than simple genetic components, and that humans are *both* biological and cultural beings. These studies established the positive correlation between brain structure and mental activities, questioned the brain/mind dichotomy, and laid the foundations for the sociobiological analysis of EEB.

3. *Sociobiology*

Sociobiology is the systematic study of the biological basis of *all* social behavior in *all* organisms, including humans (Wilson 1975). Ecologists and neurophysiologists accepted the nonhuman and some human behavior and ability to learn as innate; sociobiologists concluded that altruism is also innate. Sociobiological emphasis on the analysis of altruism reinstated the almost dormant EEB. Originally sociobiologists alleged that, in human choices of ethical behavior, heredity plays a greater role than environment. They hypothesized that since men and women are sexually different, their behavior is also different, and the economic and political ranking of humans is natural.

Since sociobiologists contend that a straight line from nonhuman to human behavior exists, they presumed that the fusion of sociobiology with neurophysiology would explain the rules and properties of ethical behavior. Some sociobiologists proposed that ethics should be biologized and that the range of study of nonhuman behavior should be expanded into the domain of psychology. They assumed that ethical and moral concepts are guided by natural selection and by social forces, and that as long as some philosophers fail to accept the evolutionary bases of social behavior they will continue to reject EEB. Furthermore, the emerging sociobiology threatened the three popular existentialist dogmas: the uniqueness of the individual, the search for the meaning and purpose of human life, and belief in the freedom of choice of action. These assertions raised instant responses.

3.1 *Voices of Dissent*

Anthropologists (Sahlins 1976) immediately objected to the application of sociobiology to human behavior and morality. They claimed that culture cannot be reduced to biology because cultural environment controls the phenotype and behavior, and that human ethical behavior is fundamentally different from nonhuman. In this view sociobiology was mired in a Eurocentric patriarchal worldview.

Leftist and feminist critics (Caplan 1978) saw negative political consequences in genetic determinism and surmised that all social human behavior is exclusively environmental and without biological bases. They accused Wilson of Social Darwinism and sexism, that is, of the puritanical and moralistic defense of the old cultural interpretation of ethics, and of human behavior. They linked sociobiology to Nazism and racism. Those critics claimed not only that the science of sociobiology was wrong, but also that it was morally wrong, and their attack on sociobiology became, and continues to be, an attack on EEB.

The sociobiologists' injection of anthropomorphic terms for descriptions of nonhuman behavior was criticized for confusing homology with analogy and for introducing difficulties in analyzing behavior. Homology, when applied to morphology and behavior, requires common ancestry. Altruistic behavior is a function of the social group, but tendencies of organisms to form social aggregates do not appear homologous. Terms may imply homology, but, if altruism in nonhuman and human animals is not homologous, then the term altruism will incorrectly suggest that ethical principles have biological roots. However, terms usually have more than one meaning that is

decipherable only from the context of the sentence. If anthropomorphic terms are restricted to human actions and new terms are coined for nonhuman behavior, then the concept of EEB can be more clearly defined.

3.2 Soft Answers

The Christian tradition of the Fall, caused by original sin, held that humans are born evil, and Huxley claimed that cosmos is manifestly amoral. The struggle for existence, an intrinsically 'bad' property of all creation, did not need explication, but cooperation and altruism did, and all moral actions were judged in relation to the benefit of the group, however defined. Men sacrificing their lives in war were worshiped as heroes, and those dying for faith were beatified as martyrs. Cooperation and altruism have always been socially rewarded, while selfishness was condemned. It is this emphasis on virtue that the study of sociobiology introduced.

Thus altruism, the contrariant of the cold-hearted selfish power of the cosmos, demanded explanation. Because altruism was difficult to explain by natural selection, which acts only on individuals, Darwin proposed group selection. However, the term 'group selection' is too broadly used and includes population, community, and even species selection. For group selection to operate, all individuals must be related, altruistic, the group must be isolated and the gene flow restricted. Group living may be beneficial when it provides protection from predators (group size decreases predation), but it may also be harmful (it spreads diseases). Therefore, a surrogate model was proposed, that is, kin selection, a form of group selection, which was defined as the natural selection of genes in which the donor benefits its kin and thus favors the survival and reproduction of kin who possess the same genes. Although this process reduces the fitness of the donor, it increases the reproductive fitness of one or more kin and increases the frequency of genes of kin in the future generations.

Three other theories have been offered. First, inclusive fitness (Hamilton 1964) is not only the fitness of an individual and its offspring but also the fitness of *all* kin who share the same genetic constitution. This will insure the reproductive success of an individual, its offspring, and all relatives. Inclusive fitness and kin selection explain the genetic origin of cooperation and altruism.

Second, reciprocal altruism (Trivers 1971) is the genetic behavior causing cooperative behavior in expectation of return of altruistic acts. Reciprocity and most mutual aid are most common among relatives. It was assumed that human disoperation, aggression, reciprocity, kin-selected altruism, and general cooperation are not culturally controlled but are subject to natural selection. Thus, sociobiologists introduced a tit-for-tat concept to explain altruism, and they assumed that tit-for-tat is selected because there must be selection for altruistic acts.

The third theory argued that the unit of selection is a gene, not an individual, and the individual is only a carrier for the gene (Dawkins 1976). Selected genes are selfish and do not act for the survival of species, but only for the survival of the genes themselves. The value element of 'good' and 'bad' was thus replaced with altruism and selfishness as value-free properties. Since sociobiologists strongly adhere to the concept of natural selection, it follows that a struggle for existence, or even an 'arms race' should occur among genes. However, the role of genes in controlling human behavior and the contribution of human embryology to the ontology of behavior are still poorly understood.

Although genes responsible for such human behavior as altruism, homosexuality, and criminality have been claimed by sociobiologists to exist, it is doubtful whether they have been identified. It is also very difficult to differentiate what is genetically or environmentally fixed and what activates behavior, and it is too early to claim a detailed knowledge of the great complexity of behavior or of genes.

3.3 Voices of Assent

Zoology assumes that humans are animals; therefore, after Darwin, it became a proper approach to study the biological aspects of moral behavior, and to accept the comparisons of human with nonhuman social behavior. But, this produces nontrivial consequences. For if humans are animals, the definition 'animal' must include the properties that characterize humans. Thus, human ethical behavior becomes 'natural' and subject to natural selection. Many students of EEB recognize some dependence between evolution and ethics, and accept the role of natural selection in evolution, but are aware of the restrictions placed by natural selection on EEB. Natural selection is only a guiding force, and not the sole source of behavioral (and morphological) changes, and EEB in social groups is only one evolutionary component. The origin of ethical behavior in protohumans and its subsequent development are a subject matter of sociobiology, but the solution of prescriptive ethical problems, of what we ought or ought not do, is a concern of philosophy. While the study of evolution may explain EEB, it does not explain ethical values or goals.

Lumsden and Wilson (1983) emphasized that neither culture nor evolution is autonomous: 'culture is created and shaped by biological processes while the biological processes are simultaneously altered in response to cultural change.' Human ethics works because cultural forces alter the innate bases of

behavior. While genes may control the basic instincts, the behavioral responses to stimuli may be automatic; therefore, the response may not be always driven by natural selection.

The history of the idea of EEB circles around various theories of human nature, the interpretation of which is central to the entire gamut of dichotomies from nature/nurture to brain/mind. The evolutionary psychologist Cyrulnik (1993) called these dichotomies pseudoconcepts, because 'human behavior … is 100 percent innate and 100 percent acquired. Or, what amounts to the same thing, nothing is "innate" and nothing is "acquired." … the acquired can only be acquired by means of the innate, which in turn is always shaped by the acquired. Nature is nurtured!'

What EEB is asking is not prescription, but how we came to think about prescription. Although sociobiologists accept deep evolutionary bases of morality, few of them are comfortable with the concept of 'evolutionary ethics.' The use of this term has begun to disappear, not because all the questions on EEB have been answered, but because the term 'evolutionary ethics' unnecessarily confuses the ethical meanings of 'good' and 'ought' with the biological origin of altruistic behavior.

Ethical Codes, Professional: Business Codes

Business codes are formal or informal standards of behavior that give structure and direction to economic action and behavior. They codify the values of a corporation, an industry, or a whole sector, and thereby create accountability and certainty of expectation. Conceived of as self-binding acts, business codes provide constraints both to collective organizations (e.g., firms) and individual actors (e.g., management) within the economy. In Western economies, as well as in the emergence of a global economy, they play an important role as governance structures because of, and insofar as they make possible, the expansion of economical and societal cooperation.

1. History and Actuality

Voluntary standards of behavior in the economy as a means of self-binding and constraint can be found in early history. Their emergence is connected to the guilds of craftsmen and merchants in the Middle Ages, where they regulated behavior towards the other members of the guilds, customers, co-workers, and employees. In the beginning they were informal and derived from tradition, common rites, and the customs belonging to a trade. With the expansion of long-distance trading these standards were laid down and were adopted by traveling merchants. Thus they became increasingly formal which meant that they became enforceable by third parties. These early business codes served to ensure contracts concerning

future delivery and payment of goods and were enforceable by guild courts and the threat of ostracism (Mitchell 1969).

To the extent that national and international business laws were established and enforceable by government bodies during the nineteenth century, private standards of behavior based on the threat of ostracism and loss of reputation gradually started to lose their importance. But in the 1970s a renaissance of private standards of behavior emerged from two main sources. The first was the internationalization and globalization of markets and production networks, which were and still are unaccompanied by developments of political, juridical, and cultural institutions and their enforceability. Such business codes include maintaining human rights in cooperative relationships, for example with suppliers and partners, and they define common perspectives in areas where different values standards as well as cross-cultural values conflicts hinder the establishment of transcultural teams.

The second source was the organizational decentralization of corporations, which led to an increase in 'gray areas' and decreasing possibilities of utilizing direct monitoring and control mechanisms. Here business codes have to define a common set of values in order to give the company identity and a behavioral orientation. To reach this aim it needs to form vision, mission, and value statements, compliance standards, and rules for dealing with the company's stakeholders (customers, employees, suppliers, environment) (Weaver 1993). Such standards of behavior can be enforced by sanctions and incentives within the company. With regard to customers and suppliers the companies' reputation and brand names are important enforcing mechanisms.

2. *Minimum Standards, Problem Standards, and Corporate Standards*

Business codes are characterized by self-binding, possibilities of private enforcement, and the identity of the actors. Self-binding by voluntary constraints of action, certainty of expectation in contracts by forceability (sanctions, incentives, reputation), and the creation of corporate identity by means of codified and realized values in business routine make standards of behavior a functional equivalent to national regulations and laws. Whenever national or supernational regulations and their enforcement do not exist or are not feasible, regardless of the identity of an actor, private standards of behavior become a dominating issue of economic and societal governance. They are therefore known as 'soft laws' (Fatouros 1994). By creating certainty of expectation for economic action in societies which are characterized by division of labor, business codes directly influence the state of welfare in any given society. With these reliable and trustworthy rules more cooperation and more transactions are made possible than without them.

The distinction between minimum standards, problem standards, and corporate standards enables us to group modern business codes along with the kinds of cooperations and transactions that are steered by them.

2.1 *Minimum Standards*

Minimum standards are instruments serving the governance of global business transactions. There are, for example, 'Guidelines for Multinational Enterprises' and 'Corporate Governance Guidelines' (OECD 1991/1998), a 'Code of Conduct on Transnational Corporations' (UN 1994), and 'Guidelines on the Treatment of Foreign Direct Investment' (World Bank 1992), to name just a few. They define minimum requirements for such areas as working conditions, involvement of unions, safety at work, consumer protection, competition, technology transfer, investment in developing countries, corruption, and human rights.

Minimum standards emerge from bargaining processes between national governments, national and international organizations of employers and unions, and any nongovernmental organizations (NGOs) involved, directed by a recognized international organization (Fatouros 1994). Their status is precarious. These agreements are obligatory for the signing parties although they cannot be enforced by law. Whether it is possible to implement them therefore depends on the voluntary efforts of the contractors as well as on whether or not it is possible to take action against rule breakers or to damage their reputation in a cost-generating way. Their strength lies in the fact that they provide standards which possess some chance of realization while there is no suitable international law available or accessable. Their weak points are the difficulty of implementing and controlling them. Nevertheless, they are a significant component of economic globalization because they are a functional equivalent to the still underdeveloped international business law. Hence, they create a certain formal and political certainty within the world economy which is a crucial demand for worldwide prosperity.

2.2 *Problem Standards*

Problem standards define proposals of behavior that help to solve certain problems, and go far beyond the rules of the game asserted through the minimum standards. One example from the area of ecological sustainability is the 'responsible care' process of the chemical industry's international associations and companies. From the area of social responsibility the

efforts to abolish child labor and forced labor according to the Council on Economic Priorities' standard 'Social Accountability 8000' may be cited. Problem standards are highly ambitious compared to the potentialities and mentality of many companies. Hence they are accepted by only a few companies, mostly by those which have elaborated them, usually in cooperation with NGOs. This may happen in associations or chambers of commerce or in loose assemblies of those companies for whose business actions the problem in question is instantly relevant. Their strength lies in their model character and in the fact that they make practical experiences concerning these standards possible. Their weakness lies in mostly very difficult controlling and in possible competitive disadvantages for those companies that do not succeed in overcoming the costs of implementing and keeping the standards through prices.

2.3 Corporate Standards

Corporate standards codify the constitutive and action-directing values of a corporation. As codes of conduct or codes of ethics they are components of corporate governance, that is, of the leading, steering, and controlling mechanisms of an economic organization. They are also expressions of the distinct philosophy and policy of the corporation. The values of a corporation can be classified as performance values (e.g., profit, quality), cooperative values (e.g., loyalty, team spirit), communication values (e.g., respect, transparency), and moral values (e.g., integrity, fairness) (Wieland 2000). A firm gains identity and distinctiveness as soon as a specific values mix drawn from these four classes of values endows it with a particular profile. Particularity here means that it fits best with the promises of the company, with its tradition and history, and the aspired direction of future developments. As a rule, these business codes provide regulations for coping with suppliers and customers, shareholders and employees, as well as rules of law and of environment protection. They are part of an overall ethics management system by which the business codes are operated and pursued in corporate practice. Normally this is executed by means of internal and external communication, by training, by ethics officers, and by being incorporated in labor contracts, and the system is controlled by monitoring audits (Weaver et al. 1999).

The systems themselves can be divided into law-driven and value-driven ones (Paine 1994). While the first are compliance programs which focus on the observation of the rules of law and are organized by the legal department of a corporation, the latter as value management systems aim at a comprehensive development of the corporate culture specifically concerning relations with the totality of stakeholders. Codes of ethics therefore never make any statements about existing matters of fact, and they never stand in for the moral consensus of all parties that are interested in the company. It is just the other way around. They define the values of an organization against all stakeholders and declare them conditional for further interaction. As conditions of cooperation with and within an organization these values are shaped like commitments of performance. The company commits itself to these values and promises to continually work on the fulfillment of its commitment. This makes it obligatory for all stakeholders also to bind themselves to the values. In the last decade of the twentieth century, about 80 percent of the big US companies had such codes (Center for Business Ethics 1992). In Europe this must be estimated considerably lower, although there are no exact figures available.

Apart from those reasons for the renaissance of business ethics mentioned in the outset another important factor is legal developments. Because of the introduction in the USA of organizational liability in case of deviant behavior of employees, incentive systems have been installed which make it financially worthwhile to document before the court the implementation and communication of a code of ethics, so that in case of an individual breach of law, the organization cannot be held responsible for it (United States Sentencing Commission 1995). Legal developments similar to this can also be observed in Europe. In this context business codes aim to achieve a higher level of transparency and thereby enhance the means of control in the corporation. The strength of standards of behavior in corporations is that they are highly specific and integrate the involved actors in maintaining them by the implementation of incentives. However, they cause problems for any form of control and by the fact that they have to be introduced into the operative actions of the corporation in a relevant way.

3. Functions and Effect

Although all three kinds of business codes refer to different types of cooperation and transactions they are identical in respect of their functions and effectiveness. These can be differentiated as follows:

(a) Business codes are a functional equivalent to national deficits of regulation by way of directing companies to self-binding and self-control.

(b) Business codes determine and define the identity of those corporations that bind themselves to standards of behavior. These corporations are distinguished from other organizations in the public arena of realization and communication.

(c) Business codes are the basis, as well as a criterion of selection, for corporate decisions. Hence, they define the range of liability a company claims beyond existing law.

(d) Business codes internally and externally indicate the behavioral preferences of an organization and at

the same time communicate a challenge to all its stakeholders to bind themselves to them.

(e) Business codes provide certainty of expectation in business relations and make possible the building up of mutual trust by creating a check against informational uncertainty and opportunistic behavior.

(f) Their prevalence on the one hand relies on economic benefits which arise from the acceptance of standards of behavior. On the other hand one runs the risk of losing economic and social reputation in any case of violation of the legal and moral obligations committed to.

(g) The aspects mentioned—self-binding, identity, responsibility, certainty of expectation, building up trust, reputation—constitute a system of mutual effects which lead to an expansion of economic and societal cooperation and to accompanying gains from trade.

(h) These effects can only be reached by actually maintaining the standards of behavior within the business routine of the company. For that purpose they have to be implemented and integrated into the operative processes of the organization and its management. One of the most important instruments in this respect are ethics management systems.
